6. Drainage. Give consideration to providing subsurface drainage (underdrains) of raised curb medians. Earth or aggregate backfill in the medians may become saturated and bleed water through joints or cracks in the pavement.

34-3.03(d) Depressed Medians

Wherever practical, use a depressed median on rural freeways, expressways, and other designated arterials. Depressed medians have better drainage and snow storage characteristics and, therefore, are preferred on high-speed arterial highways. In addition, they provide the driver with a greater sense of comfort and freedom of operation. Where a depressed median is proposed, the designer should consider the following:

1. Widths. Depressed medians should be as wide as practical to allow for the addition of future travel lanes on the inside while maintaining a sufficient median width. In addition, the median should be sufficiently wide so that a median barrier will not be warranted. Chapters 44 through 48 provide the recommended minimum depressed median widths.

2. Longitudinal Gradeline. The recommended center longitudinal gradeline of a depressed median with an unpaved ditch is 0.5% with 0.3% considered as a minimum. However, on long approach roadways to major river or stream crossings, the design profile gradeline of the roadways may be 0% with the median ditch gradeline designed as a special ditch to provide proper drainage.

3. Drainage. Because water is allowed to flow into a depressed median, the designer needs to consider drainage when determining the appropriate depth of a depressed median. The usual depth is 3 ft (1.0 m). Chapter 40 of the *BDE Manual* and the *IDOT Drainage Manual* provide additional details on drainage design.

34-3.04 Median Selection

34-3.04(a) General

When selecting a median type, recognition must be given to urban/rural location, access needs, design speeds, availability of right-of-way, safety, capacity, intersection spacing, traffic signals, economics, environmental impacts, public acceptance, and functional classification. Note that higher functional classifications will warrant a greater effort in managing access to a street or highway and in retaining mobility.

Guidelines for median types through large “residential” areas are not provided. These areas typically are avoided in the location of arterial routes and should be treated as special cases. When selecting median types within urban fringe areas, urban outlying business districts, and throughout the entire suburban area (especially within the limits of “closed suburban”), special efforts will be necessary to coordinate the proposed median design with existing and planned zoning regulations. This will require contacting the responsible zoning boards and/or local officials to coordinate the planning and selection of a median type.

On certain projects, more than one median type may be necessary and/or desirable. The length of a project will be a major influence in this determination. On relatively short highway sections, the number of different median types should be limited to a select few. On longer highway projects, changes of median types should generally be made at the borders of natural cultural subdivisions.

For the selection of curb type for raised medians, see Section 34-2.04.

34-3.04(b) Urban Median Types

On streets in downtown areas or central business districts (CBD), abutting building development often prohibits space for off-street parking and entrance driveways for individual businesses. These conditions, plus the extensive use of one-way street systems in the CBD, generally lessen the need for medians and protective left-turn lanes. However, where a median may be required, a 12 ft (3.6 m) flush median delineated by paint and/or thermoplastic pavement markings is usually appropriate. Where intersections are closely spaced, the median generally will be delineated as an “S” shape to provide overlapping left-turn lanes. Figure 34-3.C provides an example of a typical median design in the CBD and typically widths.

In the urban fringe areas and outlying business districts, off-street parking and entrance driveways usually are quite numerous. Consequently, a raised-curb median generally is not appropriate in these areas because it deters access to abutting businesses and homes. In these areas, a 12 ft (3.6 m) to 14 ft (4.2 m) wide flush TWLTL median or a 16 ft (5.0 m) wide traversable TWLTL median generally is desirable. These median widths provide space for left-turn lanes at intersections and offer protection for the mid-block left-turning vehicles. Where traffic volumes and mid-block left turns are unusually high, the traversable TWLTL median with an M-2.12 (M-5.30) CC&G may be the most desirable design. Figure 34-3.D provides an example of a typical median design in fringe areas and outlying business districts. The design speeds are usually either 30 mph to 40 mph (50 km/h or 60 km/h).

Freeways and expressways in urban areas will generally require a flush median with concrete barrier due to the need to incorporate the necessary cross section within a restricted right-of-way. Desirably, this median width should be 22 ft (7.0 m), which allows for 10 ft (3.0 m) left shoulders and 2 ft (1.0 m) for the concrete barrier. Wider widths may be required; see Chapters

44 and 45. At a minimum, a 20 ft (6.0 m) width with a concrete barrier is considered acceptable under the reconstruction category with only two lanes in each direction.

34-3.04(c) Suburban Median Types

Suburban areas are divided into two subcategories—closed and open. These are discussed in Section 43-2. The appropriate medians for each of these area types are discussed below:

1. Closed Suburban. The following median types will apply:

   a. TWLTL Medians. This median type can consist of either a flush TWLTL median or a traversable TWLTL median and is typically used with curb and gutter along the outside edges of the traveled way. These median types are applicable where the existing predominant abutting development includes numerous and closely spaced commercial entrance driveways. It is particularly appropriate where there is strip development and no appreciable street network. Design speeds should not exceed 45 mph (70 km/h). Preferably, the maximum number of through lanes should not be greater than two in each direction. The traversable TWLTL median is occasionally used in metropolitan areas where traffic volumes and mid-block left turns are unusually high.

   b. Raised-Curb Medians. This median type is generally applicable where a design speed of 40 mph or 45 mph (60 km/h or 70 km/h) is desired and a street network exists to permit access to the predominant abutting development. On six-lane urban streets, the raised-curb median is the most appropriate design. Normally, right-of-way should be available to provide for either a 16 ft (5.0 m), 18 ft (5.5 m), or 22 ft (7.0 m) wide curbed median. These widths provide space for the initial and future installation of left-turn lanes at public street intersections and high-traffic generator locations. Access to any strip development or open-space segments usually can be provided by properly spaced median openings and service drives. This median type should be coordinated with the local officials because mid-block left turns are prohibited.

      Where managing access to the street is practical and desirable, consider using the 22 ft (7.0 m) wide median as the first design option. Where right-of-way is more restricted, or if most intersections will be signalized in the future, consider using the 18 ft (5.5 m) wide median. The use of the 16 ft (5.0 m) wide raised-curb median only should be considered in areas where right-of-way is highly restricted and the use of a wider curbed median is not feasible. If dual left-turn lanes are required, the median width at intersections should be a minimum of 30 ft (9.5 m) wide and desirably 36 ft (10.5 m) wide.

2. Open Suburban. The following median types will apply:

   a. TWLTL Medians. Selection of this median type is based on the same criteria as discussed in Item 1 above for a closed suburban area.

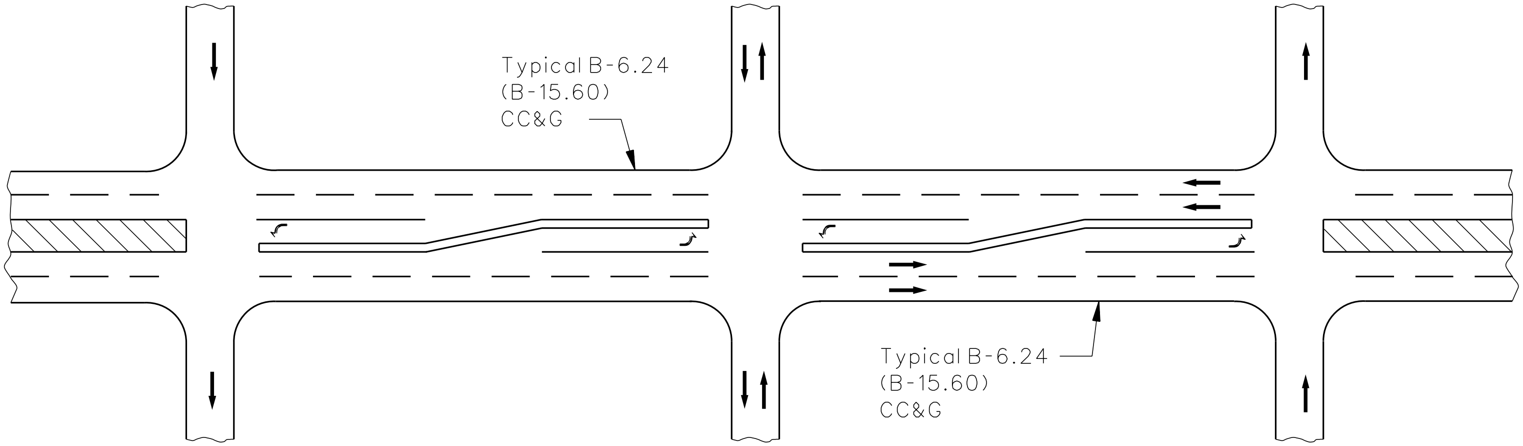
b. Raised-Curb Medians. This median type is applicable where a maximum 45 mph (70 km/h) design speed is desired and where managing access to the street is practical and desirable. Availability of right-of-way typically favors a median width narrower than 44 ft (13.2 m). For open suburban areas, raised-curb median widths of 18 ft (5.5 m) or 22 ft (7.0 m) generally are considered the most feasible widths. The 22 ft (7.0 m) width allows for U-turn movements and the storage of passenger vehicles in the median crossover at unsignalized intersections. Consider using the 18 ft (5.5 m) wide median where right-of-way is restricted.

In conjunction with these median widths, provide spacing of median openings at approximately 500 ft to 600 ft (150 m to 180 m) apart. Construct all necessary median openings initially allowing for slight adjustment of the spacing requirements to fit existing intersections, property limits, drainage ways, and terrain. The location of all possible future median openings should be shown in the approved Phase I report. Provide left-turn lanes at all median crossovers and at future median openings as they are constructed.

Existing and future developments abutting the highway should plan their traffic circulation according to the initial median openings or the proposed median openings as shown in the Phase I report. Accordingly, it should be emphasized in discussions with municipalities and developers, that private service drives and/or coordination of other traffic circulation facilities with adjacent property owners will be a necessary part of the land-use planning.

c. Depressed Medians. This median design in suburban locations is applicable for non-access controlled highways where a 50 mph (80 km/h) design and posted speed are preferred and where right-of-way reasonably can be acquired for inclusion of necessary safety features. The following will apply:

- Typical median widths are 44 ft (13.2 m) to 50 ft (15 m). These widths provide for 6 ft (1.8 m) to 8 ft (2.4 m) wide median shoulders, 1V:6H or 1V:5H median slopes, and a 2 ft (500 mm) wide median ditch.
- U-turns are afforded better protection with these median widths and can be permitted indefinitely even with left-turn lanes.
- As a minimum, access to abutting properties with this type median would be accommodated in the same manner as described above for raised-curb medians. Where practical, consider more restrictive access to the highway in a manner similar to expressway designs.

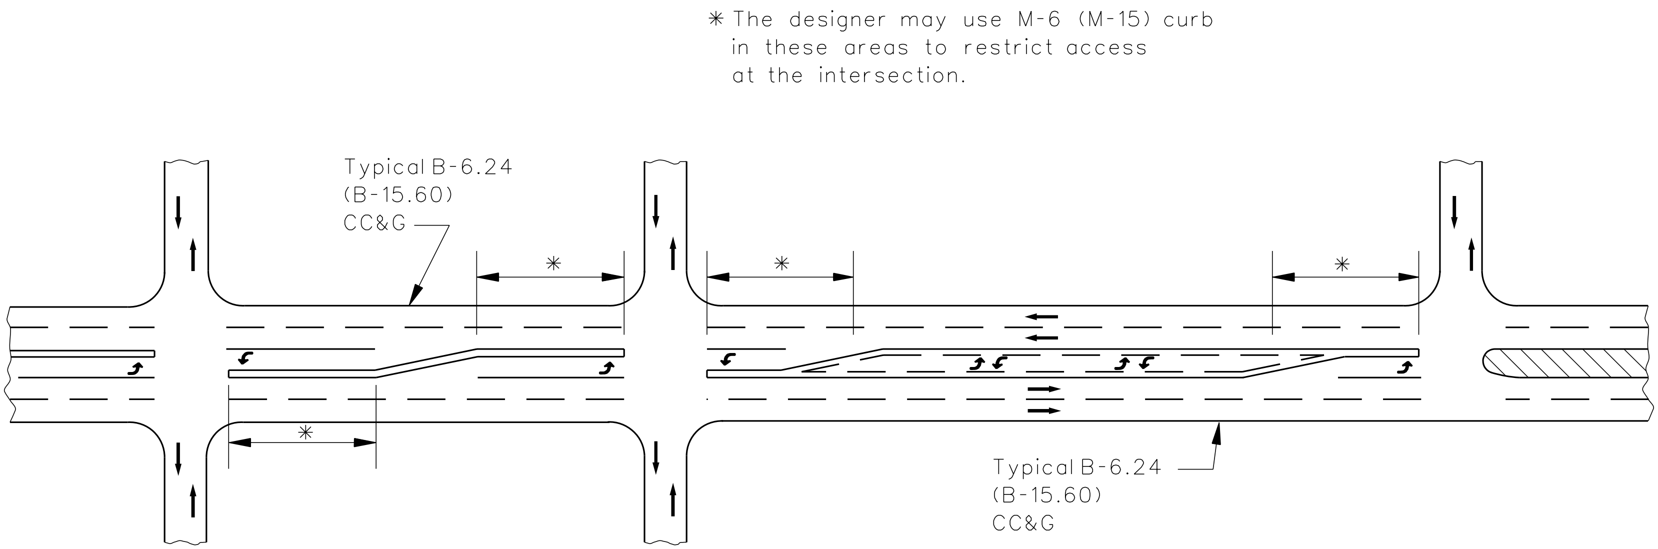


Notes:

- *Assumed design speed is 30 mph (50 km/h).*
- *Overlapping left-turn lanes in median are usually marked with paint or thermoplastic.*
- *Uniform width: 12 ft (3.6 m).*

TYPICAL MEDIAN DESIGN
(Central Business District)

Figure 34-3.C



FLUSH TYPE MEDIAN	TRAVERSABLE TYPE MEDIAN
Uniform Width: 12 ft -14 ft (3.6 m - 4.2 m)	Uniform Width: 16 ft (5.0 m)
Usually marked with paint or thermoplastic.	Median outlined with M-2.12 (M-5.30) CC&G.
Used as two-way, left-turn lane in mid-block locations.	Used as two-way, left-turn lane in mid-block locations.

TYPICAL MEDIAN DESIGNS
(Fringe and Outlying Business District)

Figure 34-3.D

34-3.04(d) Rural Median Types

In rural areas, medians are typically only provided on freeways, expressways, and other designated high-speed arterials. Also, median islands are provided at rural intersections for the inclusion of left-turn lanes and on crossroads through interchanges. In general, right-of-way is more available in rural areas. Typical median types in rural areas include depressed medians, flush medians with barriers, and short sections of raised-curb medians. The primary function of a median in rural areas is to increase operational safety of the highway by neutralizing the interference of opposing traffic. Selection of rural median types is based on the following:

1. Depressed Medians. This median design is applicable for both access controlled and non-access controlled highways and where right-of-way can be reasonably acquired. Depressed medians are mainly used on the following:

    a. Freeways. Depressed median widths for new freeways are either 56 ft (17 m) (four lanes) or 60 ft (18 m) (six lanes). These median widths provide for 8 ft (2.4 m) or 10 ft (3.0 m) wide left shoulders, 1V:6H median slopes, and a 4 ft (1.2 m) wide ditch. See Chapter 44 for typical sections of four-lane and six-lane freeways.

    b. Expressways and Four-Lane Minor Arterials. For new construction and reconstruction projects, the median width for these type highways is typically 50 ft (15 m). This median width will also accommodate 1V:6H median slopes and a 2 ft (600 mm) wide ditch based on the narrower median shoulders. See Chapter 45 for typical sections.

        On expressway-type highways, median widths wider than 50 ft (15.0 m) may be desirable at isolated intersection locations where a large number of tractor-trailer movements exist and where traffic signals will not be required. In this situation, it is recommended that the designer consider a 64 ft (19 M) wide median. These wider medians through the intersection will allow for median storage of the tractor-trailer unit.

        Where expressways are developed through reconstruction of existing two-lane highways, the addition of near-parallel lanes may cause extra-wide median widths at existing horizontal curves. Where the added roadway is on the outside of an existing curve, the alignment transition to a uniform median width generally should be constructed on one end of the proposed horizontal curve only (i.e., either upstream or downstream). Where the added roadway for the proposed expressway is located on the inside of an existing curve (allowed to remain in place), the proposed horizontal curve is designed to fit into back and forward tangents. This design then provides for a variable width median through the two adjacent horizontal curves. See Chapter 45 for median widths allowed to remain in place.

2. Flush Medians. Flush medians consist of two double yellow lines marked at the edge of the traveled way with transverse striping in the median area. This median type is mainly used at rural intersections where left-turn lanes are needed and as an alternative to raised-curb median islands at isolated intersections.

3. Raised-Curb Medians. On high speed (≥ 50 mph (80 km/h)) rural multilane highways, do not delineate medians with continuous curbing because it may constitute a safety hazard. However, median curbing may be used at isolated intersections (see Chapter 36) and through interchange crossroad locations where more positive control measures are needed to promote safer traffic operations or where required for proper drainage. In these situations, use an M-2 (M-10) curb along the crossroad median; see Figure 34-2.A.

34-4 ROADSIDE ELEMENTS

34-4.01 General

Earth slopes are required to provide roadside and median ditches adjacent to highway facilities and to provide a stable transition from the highway profile to adjacent terrain features. With maintenance operations, economy may be attained through the use of mechanized equipment which operates best on relatively flat earth slopes. Flat slopes also facilitate turf establishment and are often required for soil stability. In addition to aesthetic enhancement, flat and well-rounded side slopes, combined with proper roadway elevations above natural ground lines, minimize snow drifting problems. With proper elevations, cross winds sweep the snow from the roadway surface, thus facilitating snow removal operations.

Using broad flat slopes on roadside ditches, which are totally visible to the driver, lessens the feeling of restriction and add considerably to a driver's willingness to use the shoulder and earth slope area in emergencies. The use of flat side slopes for roadside ditches reduces both the depth and velocity of water, and thereby minimizes damage from erosion. See Chapter 38 for guidance on earth slopes and clear zones.

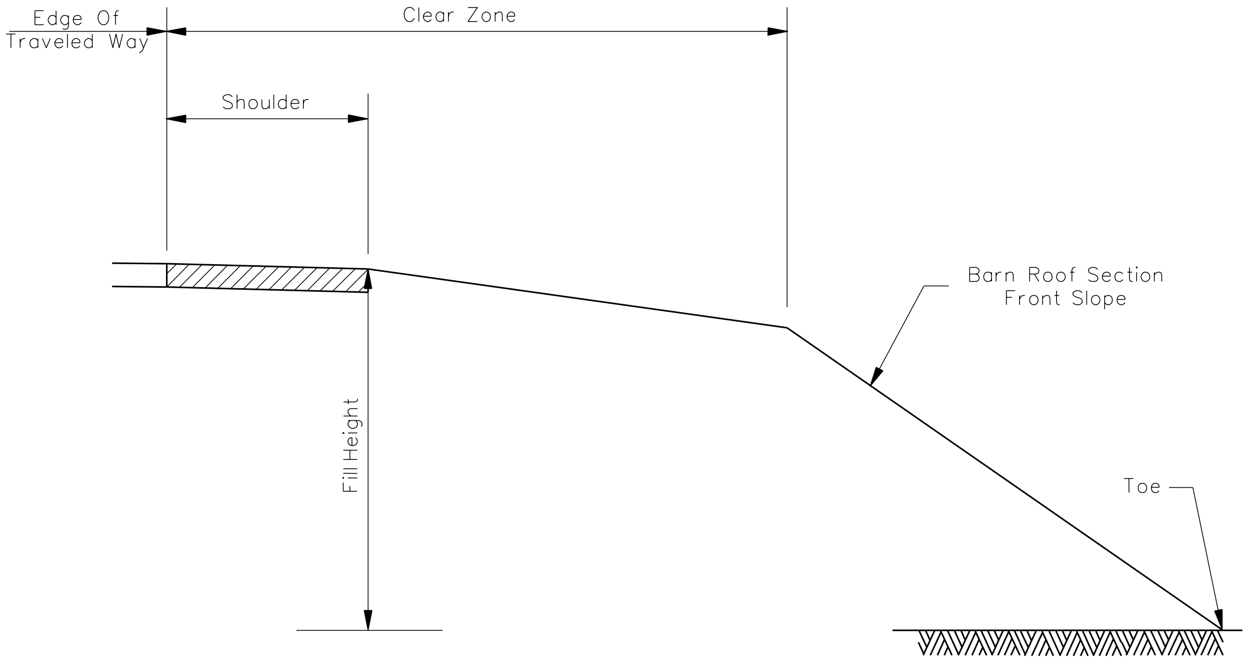
For urban facilities other than freeways and expressways, side slopes generally will be determined on a case-by-case basis considering the roadside development and right-of-way restrictions. For some urban projects, relatively steep side slopes and/or retaining walls may be required.

34-4.02 Fill Sections

Front slopes in fill sections are the slopes extending outward and downward from the hinge point to intersect the ditch bottom or natural ground line. The slope criteria depend upon the fill height, urban/rural location, project scope of work, and the presence of curbs. Figures 34-4.A and 34-4.B present the fill slope criteria. The designer should also consider the following:

1. Maximum Slope. As indicated in Figures 34-4.A and 34-4.B, the maximum front slope should be 1V:3H. A 1V:3H slope is a practical maximum when considering maintenance operations (e.g., mowing), erosion control, and roadside safety. Slopes steeper than 1V:3H should be used where fill heights are greater than 30 ft (9.0 m). Slopes steeper than 1V:3H will normally require a roadside barrier; see Figure 38-6.X for the location of the barrier where curbs are present.

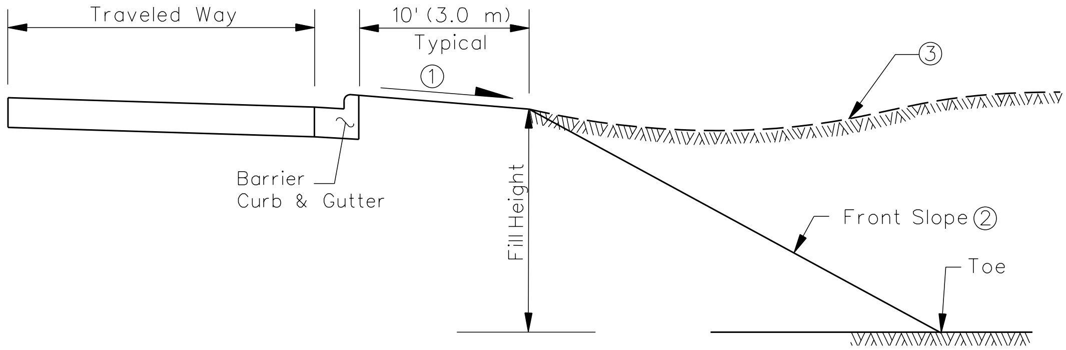
2. Shelf. For curbed sections, a 3 ft to 10 ft (900 mm to 3.0 m) shelf is provided beyond the curb. If sidewalks are present or anticipated, the shelf width should be 10 ft (3.0 m) and sloped away from the roadway at a rate of 2%. If no sidewalks are present or anticipated, slope the shelf away from the roadway at 5%.



Project Scope of Work	Fill Height	Front Slopes (V:H)
New Construction and Reconstruction	0 ft – 30 ft (0-9 m)	1:6 to clear zone edge 1:3 maximum to toe
	>30 ft (>9 m)	1:2 uniform slope with a roadside barrier
Existing to Remain (Reconstruction)	0 ft – 30 ft (0-9 m)	1:4 to clear zone edge 1:3 maximum to toe
	>30 ft (>9 m)	1:2 uniform slope with a roadside barrier

TYPICAL FILL SECTIONS
(Highways Without Curbs)

Figure 34-4.A



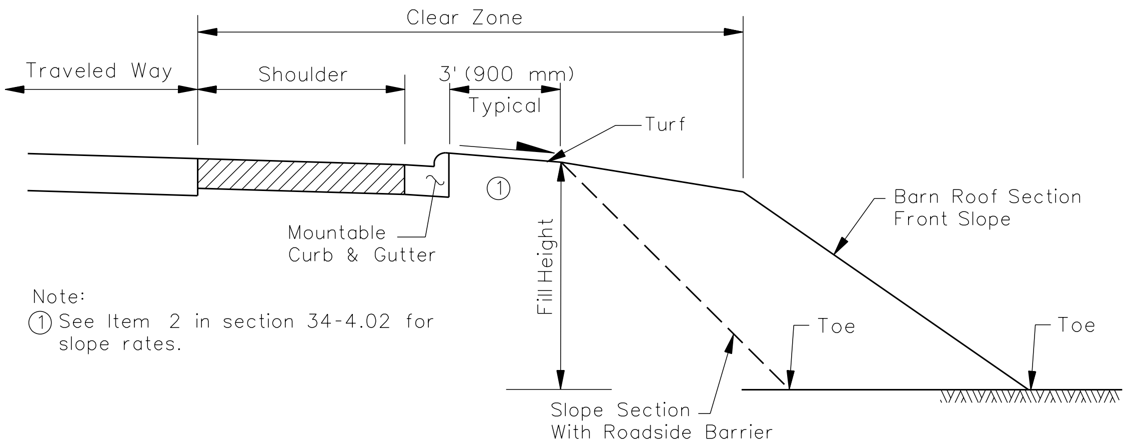
Notes:

① See Item 2 in Section 34-4.02 for slope rates.

② Desirable - 1V:4H; see Chapter 38.

③ For urban and suburban reconstruction projects, see Item 4 in Section 34-4.02.

(A) DESIGN SPEED ≤ 45 mph (70 km/h)



Note:
① See Item 2 in section 34-4.02 for slope rates.

(B) DESIGN SPEED ≥ 50 mph (80 km/h)

Project Scope of Work	Fill Height	Front Slopes (V:H)
New Construction and Reconstruction	0 ft – 30 ft (0-9 m)	1:6 to clear zone edge 1:3 maximum to toe
	> 30 ft (>9 m)	1:2 uniform slope with a roadside barrier
Existing to Remain (Reconstruction)	0 ft – 30 ft (0-9 m	1:4 to clear zone edge 1:3 maximum to toe
	> 30 ft (>9 m)	1:2 uniform slope with a roadside barrier

Note: For clear zones in curbed sections, see Section 38-3.

TYPICAL FILL SECTIONS
(Curbed Facilities)

Figure 34-4.B

3. Benching. Where the height of a fill exceeds 30 ft (9.0 m), consider benching of the slope to minimize erosion problems. Approximately halfway down the slope, provide a bench with a V-type ditch. On short sections, the bench can be graded to drain to one side. For longer sections, grade the bench to drain from both directions. For more guidance on benching designs, the designer should contact the district geotechnical engineer.

4. Reconstruction Projects. For some reconstruction projects in urban or suburban locations, the existing pavement may be slightly above the surrounding topography. If this occurs, provide a drainage swale behind the curb and gutter as illustrated in Figure 34-4.B.

5. Other Considerations. Although Figures 34-4.A and 34-4.B provide specific criteria for front slopes, also consider right-of-way restrictions, utility considerations, and roadside development when determining the appropriate front slope for the site conditions. If practical, consider using flatter front slopes than indicated.

34-4.03 Ditch Sections

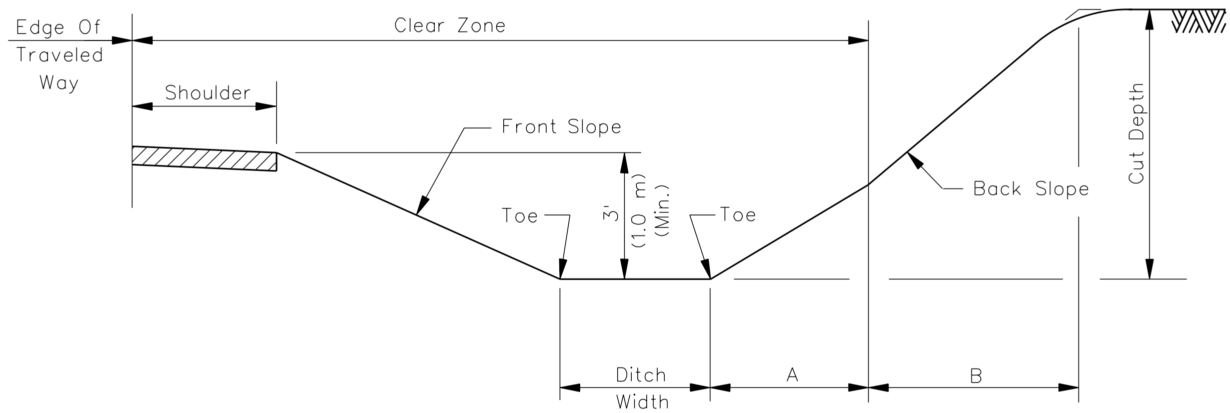
34-4.03(a) Typical Slope Rates

On facilities without curb and gutter, roadside ditches are provided adjacent to embankment locations and in cut sections to control drainage. Figure 34-4.C presents IDOT criteria for embankment locations and cut sections. As illustrated in Figure 34-4.C, the ditch section includes the front slope, ditch width and back slope for the type of highway. Where the cut height exceeds 10 ft (3.0 m) from the bottom of the ditch to the existing ground line, the designer may consider using a 1V:2H back slope beyond the clear zone to reduce excavation costs.

Where the height of a cut exceeds 30 ft (9.0 m), consider benching the back slope to minimize erosion problems. Approximately halfway down the slope, provide a bench with a V-type ditch. On short sections, the bench can be graded to drain to one side. For longer sections, grade the bench to drain from both directions. For additional guidance on benching designs, the designer should contact the district geotechnical engineer.

34-4.03(b) Material and Soils Conditions

The designer must ensure that permanent erosion control is considered in the design of ditches in cut slopes. The designer should contact the district landscape architect and the district geotechnical engineer, who will review the existing soil conditions to determine if additional measures may be required to control erosion (e.g., additional topsoil, special plantings, paving). It will be the designer’s responsibility to consider their recommendations for incorporation into the plans. As a general guide, longitudinal ditch slopes less than 1% can be seeded, slopes of 1% to 3% usually will require sodding or seeding with an erosion control blanket, and slopes greater than 3% will require riprap or other protective lining. Very flat longitudinal ditch slope



Project Scope of Work	Front Slope (V:H)	Minimum Ditch Bottom Width	Back Slopes (V:H)	
			A	B
New construction or reconstruction	1:6	4 ft (1.2 m) (1)	1:3	(2)
Reconstruction (allowed to remain in place) and 3R	1:4	2 ft (600 mm) (1)	1:3	(2)

Notes:

(1) A wider ditch may be used where detention storage of storm water is an important consideration.

(2) Where the height of cut exceeds 10 ft (3.0 m), consider using a 1V:2H back slope beyond the clear zone. See Section 38-3 for discussion on clear zones.

TYPICAL DITCH SECTIONS

Figure 34-4.C

(i.e., < 0.4%) may require a paved ditch so as to maintain the flow line over time. For more information on the design of ditch linings, the designer should review Chapter 40 in the *BDE Manual* and the *IDOT Drainage Manual*.

34-4.03(c) Hydraulic Design

Roadside and median ditches are to be designed according to the criteria presented in Chapter 40 and the *IDOT Drainage Manual*. The use of these criteria will ensure the proper drainage of the pavement subgrade and the adequate conveyance of surface flow without creating erosion of ditch sections.

34-4.04 Cut Sections With Curbs

On facilities with curbs, a shelf is provided with a back slope beyond the shelf. The shelf is usually sloped towards the roadway to eliminate the need for a separate drainage system behind the curb. Where sidewalks are present or anticipated in the future, provide a shelf width of 10 ft (3.0 m) with a cross slope of 2%. Where sidewalks are not present or anticipated in the future, the shelf cross slope should be 5% to provide for adequate drainage. This criteria is illustrated in Figure 34-4.D.

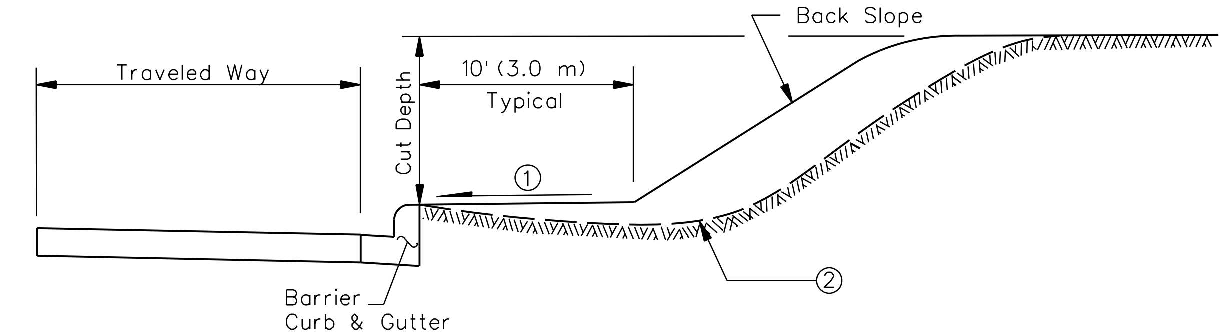
Where the height of a cut exceeds 30 ft (9.0 m), consider benching the back slope to minimize erosion problems. Approximately halfway down the slope, provide a bench with a V-type ditch. On short sections, the bench can be graded to drain to one side. For longer sections, grade the bench to drain from both directions. For additional guidance on benching designs, the designer should contact the district geotechnical engineer.

34-4.05 Rock Cuts (Back Slopes)

In rock cuts, the back slope generally is 1V:0.25H but could vary depending on the type of rock and field conditions; see Figure 34-4.E. For large cuts, benching of the back slope may be required. For guidance on benching designs in rock cuts, the designer should contact the district geotechnical engineer.

Conduct a cost-effective study to determine if a rock cut should encroach into the clear zone area or be located outside of the clear zone. If the rock face is located within the clear zone, provide a smooth rock cut or shield it with a roadside barrier. If the rock face and ditch to capture falling rock is outside of the clear zone, a roadside barrier typically will not be warranted.

In addition, conduct a hydraulic analysis to evaluate the need to control cascading water from the top of the cut and to determine the conveyance needs or roadside drainage at the toe of the cut.



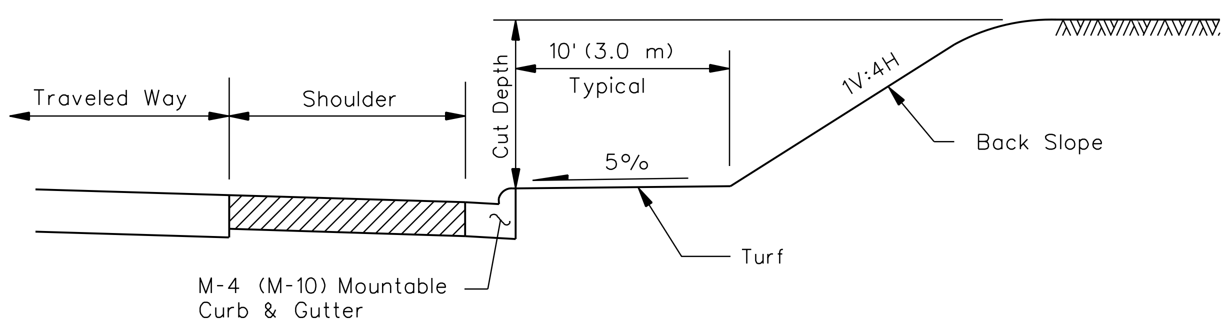
Notes:

① 2% If sidewalks are present or anticipated.
5% If sidewalks are not present or anticipated.

② Drainage swale may be needed to meet field conditions.

Facility	Back Slopes (V:H)
Urban Arterials	1:3
Urban Marked Route Collectors	1:2

(A) DESIGN SPEED $\leq$ 45 mph (70 km/h)



(B) DESIGN SPEED $\geq$ 50 mph (80 km/h)
(RESTRICTED RIGHT-OF-WAY)

Note: See Section 38-3 for clear zone discussion.

TYPICAL CUT SECTIONS
(Curbed Facilities)

Figure 34-4.D

(B) DESIGN SPEED ≥ 50 mph (80 km/h)

Notes:

① *Use 2% if sidewalks are presented or anticipated. Use 5% if sidewalks are not present or anticipated.*

② *Discuss with the district geotechnical engineer to determine extra width needed for falling rock.*

③ *Back slopes in rock may require benching. Contact the district geotechnical engineer.*

④ *See Section 38-3.04.4 for clear zone discussion on rock cuts.*

TYPICAL ROCK CUT SECTIONS

Figure 34-4.E

34-4.06 Roadside Safety

To safely accommodate a run-off-the-road vehicle, all slopes should be as flat as practical. Section 38-3 presents specific criteria to determine desirable front slope, ditch width, and back slope combinations. All hazards within the clear zone should be removed, relocated, made breakaway, or shielded.

34-4.07 Transverse Slopes

Common obstacles along roadsides are embankment (transverse) slopes created by median crossovers, driveways, or intersecting side roads. The criteria for designing transverse slopes are discussed in Section 38-4.

34-4.08 Geotechnical Features

During the Phase I development stage, the designer must ensure that the topography and geology of the selected alignment and profile are compatible with the proposed fill and cut slope sections. The use of earthwork computer programs will help to determine cross section limits. In addition, on new construction or reconstruction projects, the Phase I Geotechnical Report and any additional data must be analyzed during the preparation of the construction plans. This will help to ensure the stability of selected cut and fill slopes which are 1V:3H or steeper.

Major or unusual geotechnical features within the project limits will require special consideration. These features should be reviewed with the district geotechnical engineer. Usually, a meeting to discuss the geotechnical features will be warranted. The designer should discuss geotechnical features with the district geotechnical engineer, when the project includes the following:

1. Earthwork. Soil or rock cuts or fills where:
   - the maximum height of cut or fill exceeds 30 ft (9.0 m), or
   - the cuts or fills are located in topography and/or geologic areas with known stability problems.
2. Soil and Rock Instability Corrections. Cut, fill, or natural slopes which are presently or potentially unstable.
3. Retaining Walls. Where the maximum height at any point along the length of the retaining wall exceeds 10 ft (3.0 m), the Bureau of Bridges and Structures will be responsible for the retaining wall design and review. Geotechnical aspects may include bearing capacity, settlement, overturning, and sliding. When selecting the wall type, note that precast concrete block walls are not appropriate:

- in areas which will be exposed to salt or other de-icing chemicals;
- in wet areas which will keep them in a saturated condition, therefore allowing detrimental freezing to occur (e.g., a wall next to a pond, lake, or stream);
- for structurally critical applications (e.g., a wall to retain a road, support a bridge cone, support an abutment/pier);
- for tiered wall systems; and
- for walls higher than 5 ft (1.5 m), as measured from the top of the block elevation to the finished grade line at the wall face.

4. Difficult or Unusual Geotechnical Problems. These conditions may include embankment construction on weak and compressible foundation material (difficult) or fills constructed using degradable shales (unusual).
5. New or Complex Designs. This may include geotextile soil reinforcement, permanent ground anchors, wick drains, stone columns, etc.
6. Unusual Design Methods. This may include experimental retaining wall systems or pile foundations where dense soils exist.

34-4.09 Aesthetics

The designer should explore various options to improve the visual impact a roadway will have on the landscape. Varying the cross section elements will typically improve the aesthetics of the roadway. This may include:

- increasing or decreasing the side slopes to reduce the magnitude of exposed cut and fill slopes,
- reducing ditch widths or depths to reduce the amount of cut,
- using slope rounding to blend cuts and fills into the natural ground,
- warping side slopes to match the natural landscape,
- retaining existing vegetation,
- using a raised-curb or depressed median with plantings, and
- providing structures which match the natural landscape.

Section 33-6.03 provides additional guidance for improving highway aesthetics relative to its surroundings. Address aesthetic issues with the Stakeholders during the Context Sensitive Solutions (CSS) process.

34-5 RIGHT-OF-WAY

34-5.01 General

The purpose of acquiring highway rights-of-way is to provide sufficient room to construct the facility, to enable the safe operation of vehicles on the facility, and to permit the safe and efficient maintenance of the facility.

The Bureau of Program Development in Districts 2 through 9 and the Bureau of Programming in District 1 are responsible for plotting highway cross sections during Phase I studies. These cross sections aid in establishing the right-of-way width required for the construction and future maintenance of the highway. However, the exact final location of the right-of-way line will be the responsibility of the District Chief of Plats and Plans after all environmental commitments, construction, safety, and maintenance requirements have been met. The guidance used by the District Chief of Plats and Plans is contained in *IDOT Land Acquisition Policies and Procedures Manual*.

34-5.02 Definitions

The following definitions apply:

1. Permanent Right-of-Way. Right-of-way acquired for permanent ownership by the State for activities which are the responsibility of the State for an indefinite period of time. The State obtains the title to the property. Permanent right-of-way is typically acquired for roadways, roadsides, etc.

2. Temporary Construction Easement. Easements acquired for the legal right of usage by the State to serve a specific purpose for a limited period of time (e.g., construction, maintenance and protection of traffic during construction). Once the activity is completed, the State yields its legal right of usage.

3. Permanent Easements. Easements acquired with the perpetual right to construct and maintain a public highway and incidental facilities over and across the surface of lands. Types of permanent easements include:

   - highway easements,
   - utility easements,
   - storm sewer easements, and
   - areas of soil or ground water contamination.

4. Channel Easements. Easements acquired specifically for stream channel construction and maintenance, which provides the State with a permanent right of ingress and egress. The property owner relinquishes the right to modify the channel dimensions (e.g., slopes).

34-5.03 Establishment of Right-of-Way Lines

Proposed right-of-way lines will be dimensioned from a centerline or survey line. Centerlines may be the centerline of pavement to remain in place, proposed centerline of pavement, centerline of median, or centerline of platted streets. Survey lines may be a survey line of the proposed improvement or relocated survey line. Do not dimension the right-of-way line from a centerline of pavement in place, existing right-of-way line, or any other line that will be removed. Dimensions must be from a line that can be located in the field (e.g., monuments, physical objects, ties).

34-5.04 Right-of-Way Width

Width of the proposed right-of-way or break points in rural areas should be based on multiples of 5 ft (2.0 m) (e.g., 65 ft, 70 ft, 75 ft). Avoid widths of right-of-way or break points that are a decimal of a foot (meter) unless the proposed right-of-way line is along the property line. However, there may be cases where the proposed right-of-way or break points are rounded off to the nearest foot (300 mm) (e.g., existing development, near or at the back edge of the sidewalk). Right-of-way lines parallel or concentric with the existing centerline or survey line are the most desirable. On curves, it also may be advantageous to use a series of straight lines.

In general, for new facilities, the minimum right-of-way width will be the sum of the traveled way(s), outside shoulders, median width (if applicable), necessary width for fill and cut slopes, plus a maintenance border area beyond the construction limits. The total width will vary according to the functional classification and urban/rural environment.

In general, minimal additional right-of-way will be required for 3R projects. However, ditch cleaning and slope flattening may be desirable on these projects. Consequently, strips of minimum width of right-of-way or easements may be required.

Adequate right-of-way must also be attained around side road radius returns to accommodate the shoulder and ditch/drainage transition from the mainline to the side road. Culverts also require special attention particularly on extensions. Right-of-way may be required to match existing channels.

In addition to the border area beyond the construction limits, allowance may be necessary for the provision of frontage roads, special drainage facilities, roadside clear zones, and future expansion of the highway. These border areas are required for maintenance operations, the retention of natural growth for scenic and ecological purposes, erosion control and, in some cases, for accommodating public utilities; see Section 34-6. Border areas also serve as a buffer between the limits of construction and abutting private development.

34-5.05 Other Considerations

In addition to the minimum right-of-way widths, the designer should consider the following:

1. <u>Design of Right-of-Way Breaks</u>. Desirably, the right-of-way limits should be uniform and the number of breaks minimized. This will limit the number of right-of-way markers or corner fence posts. In addition, the designer should consider the following:

    a. <u>Break Points</u>. Identify each “break point” in the right-of-way line by a station and offset distance from the centerline or the survey line of construction.

    b. <u>Changes</u>. Avoid abrupt changes in the right-of-way lines. Where changes are required, the rate of change should be as flat as practical.

    c. <u>Breaks on Property Lines</u>. A change in the distance from the centerline to the right-of-way line should not occur on a property line if there is a taking from two adjacent properties. Right-of-way markers set on apparent property lines in the past are now considered by their owners as located on the property lines, which may or may not be correct.

    d. <u>Non-Stakeable Breaks</u>. Avoid right-of-way breaks where the break points cannot be staked. For example, avoid a right-of-way break point in a stream or in a driveway. Also, right-of-way breaks should be at least 20 ft (6.0 m) from the edge of any body of water (e.g., lakes, streams).

    e. <u>Small Parcels</u>. Additional right-of-way break points and short distances between breaks may be considered only where it will eliminate a taking (parcel) or will avoid leaving a small uneconomical remnant. In rural areas, small irregular and triangular-shaped remainders less than 50 ft (15 m) in width will be included as part of the right-of-way. To avoid relocating a building in urban areas, the right-of-way line may need to be adjusted.

2. <u>Acquiring Fee to Dedicated Right-of-Way</u>. Obtain the fee interest in right-of-way. When the owner has a fee interest to dedicated right-of-way which is adjacent to the property, the fee interest may be acquired for that portion of the right-of-way which lies between the existing right-of-way line and the property line. This would be in addition to any new right-of-way required. This procedure will eliminate the owner from having to pay taxes on the dedicated right-of-way and will make it easier for utility companies to obtain permits.

3. <u>Utility Adjustments</u>. Problems may occur with utility adjustments where the right-of-way lines are irregular and/or are placed too close to the outer limits of construction. For example, where a pole line is relocated on State right-of-way, the utility company may be faced with the following problems:

    - numerous guy wires,
    - poles or guy wires on private property that require easements and which may cause delays, and/or

- requesting cross sections from the State for the utility company to identify where it may or may not place power and/or communication poles.

Similar problems are encountered with relocated water and gas mains. Although these matters often do not cause direct and tangible cost to the Department, they may create unnecessary expense to the utility and indirectly may create delays to construction and increase user delays.

4. End Right-of-Way Taking (Terminal Parcel). Where a construction project ends within the limits of a particular property, it is desirable to continue the right-of-way across the property if additional right-of-way will be required for a future project. If the proposed project ends within the property, taper the proposed right-of-way line into the existing right-of-way line.

5. Variable Median. For variable width medians, describe the right-of-way from one survey line or centerline, wherever practical. For wide medians (200 ft (60 m) or more), it may be necessary to describe the right-of-way from two survey lines or centerlines.

6. Sidewalks. If a sidewalk will be constructed on a project, locate the right-of-way line a minimum of 1 ft (300 mm) from the back edge of the sidewalk, if practical. Grading for sidewalk construction, which lies outside of the existing or proposed right-of-way, Requires a temporary easement.

7. Intersection Sight Distance (Corner Cuts). Acquire adequate right-of-way to provide the applicable intersection sight distance as described in Chapters 36 and 49.

8. Fee Taking Versus Temporary Easement. Where it is necessary to work outside the existing right-of-way lines for grading of roadside ditches, channel changes, slope rounding, construction of temporary access roads at bridges, and/or other locations, the Department should acquire additional working area in fee interest in lieu of a temporary easement on construction projects. Additional width of right-of-way at bridges will allow for easier access for bridge maintenance and for work on channels (e.g., realignment, placement of riprap, jetties).

34-6 UTILITIES

34-6.01 Definition

A “utility” is defined as a privately, publicly, or cooperatively owned line, facility, or system for producing, transmitting, or distributing communications, cable television, power, electricity, light, heat, gas, oil, crude products, water, steam, waste, storm water not connected with highway drainage, or any other similar commodity. This includes any fire or police signal system or street lighting system, which directly or indirectly serves the public. The term “utility” will also apply to a utility company inclusive of any wholly owned or controlled subsidiary. The term “utility” includes those facilities used solely by the utility which are a part of its operating plant.

34-6.02 Location

In general, it will be the responsibility of the planner and designer to locate, identify and, to the maximum extent practical, avoid disturbance of all existing utilities and to determine, initially, the appropriate utility locations on new construction and reconstruction projects. The planner and/or designer should review Chapter 6 of the *BDE Manual* and the current edition of the *IDOT Accommodation of Utilities on Right-of-Way of the Illinois Highway System* for the latest utility accommodation criteria.

34-6.03 Design Considerations

The overall Department objective is to ensure completion of the required adjustment for all conflicting utility facilities in a mutually satisfactory manner in advance of the roadway construction. The district utility coordinator is responsible for working with the utility companies to develop the relocation design details for utility relocations or adjustments. This criteria is presented in the *IDOT Accommodation of Utilities on Right-of-Way of the Illinois State Highway System*. The designer should ensure that the proposed design is consistent with the proposed highway improvement.

1. Utility Locations. Utility installations should be located as follows:

   - Locate longitudinal utilities parallel and as near as practical to the right-of-way line but not more than 8 ft (2.4 m) from the right-of-way line.
   - Locate ground-mounted appurtenances for underground facilities within 1 ft (300 mm) or as near as practical to the right-of-way line.
   - No new above-ground longitudinal utilities, including any above-ground appurtenances for underground installations, will be placed within the clear zone.
   - No new longitudinal utility installations will be permitted under the paved portion of streets and highways under State jurisdiction.

- Utilities will not be permitted to cross under State highways in cattle passes, culverts, or other drainage facilities.

- New manholes will not be permitted in the traveled way or shoulders of State highways. Existing manholes may remain in place.

- Utility crossings should be approximately 90 degrees to the highway centerline as practical.

- No utility appurtenances (e.g., pumping stations, transformers) will be allowed within interchange right-of-way.

- Special restrictions may be placed on utility companies where visual quality is an important consideration. See *IDOT Accommodation of Utilities on Right-of-Way of the Illinois Highway System* for more information.

2. Cover. The following cover criteria, below the pavement surface, will be required for underground installations:

   a. Power. These installations will require a minimum cover of 30 in. (750 mm).

   b. Communication. Where these installation are installed by the plowed method, the minimum cover will be 2 ft (600 mm).

   c. Gas Pipelines. Gas installations must have a minimum cover of 30 in. (750 mm) at all locations within the highway right-of-way.

   d. Water Lines. To prevent freezing, place water lines below the frost line.

   e. Sewers and Drain Lines. Storm sewers, sanitary sewers, and drain lines must have a minimum clearance of 30 in. (750 mm) to the top of pipe to prevent freezing.

3. Aerial. The following will apply to power lines and/or communication lines:

   a. Guy Wires and Brace Posts. These devices will not be allowed on the State right-of-way.

   b. Overhead Clearances. For overhead power and communication lines crossing fully access-controlled facilities, the minimum vertical clearance is 20 ft (6.1 m) and for other facility types 18 ft (5.5 m).

   c. Location. In general, aerial utility poles should be located as close to the right-of-way line as practical. However, for urban areas the following will apply:

      - Curbed. For curbed sections, the minimum placement distance of poles behind the face of the curb is 18 in. (500 mm) to the closest face of the pole.

- Shoulder with Curb and Gutter at Shoulder Edge. The minimum pole placement is 4 ft (1.2 m) beyond the outside of the shoulder to the closest face of the pole. In addition, the clear zone distance must be checked.

4. Light Standards. Place light standards and power poles in accordance with the criteria presented in Chapter 56.

5. Detours. Awareness of potential utility conflicts is extremely important when constructing detours near the right-of-way line or on temporary right-of-way.

Chapter Thirty-five
ACCESS CONTROL/ACCESS MANAGEMENT

Chapter 35 discusses the general concepts of access management, describes common access management techniques, and presents detailed figures on providing access control for interchange crossroads and for crossroads intersecting expressways. Additional access control criteria and access management techniques are contained in the following chapters:

- Chapter 36, Section 36-7.01, provides general guidelines for designing the connections of proposed driveways and entrances to State highways in conjunction with new construction highway projects, and modifying the connections of existing driveways and entrances to State highways in conjunction with new construction, reconstruction, or 3R highway projects.
- Chapter 37 briefly describes access control criteria around interchanges.
- Chapter 44 presents access control drawings illustrating the mainline of rural and urban freeways.
- Chapter 45 discusses access control policies regarding expressways and includes illustrations of access control at frontage road/service drive intersections.
- Chapter 46 discusses access management techniques regarding Strategic Regional Arterials.

The IDOT Bureau of Operations handbook entitled, *Policy on Permits for Access Driveways to State Highways* (governed by the Illinois Highway Code sections 605 ILCS 5/4-209, 4-210, 4-211, and 4-212 and 92 Ill. Admin. Code 550) discusses procedures for obtaining access to non-access controlled State highways. It also describes the design requirements for driveways and entrances in conjunction with individual permits. Section 36-7.02 of this Manual also provides general information regarding the highway access permit process for new or revised individual entrances to a State highway.

35-1 GENERAL CONCEPTS

35-1.01 Definitions

1. Access Control. The condition where the public authority regulates the right of abutting owners to have access to and from a public highway by declaring the highway to be either fully or partially access controlled. This is accomplished through the purchase of access rights or right-of-way, driveway controls, turning restrictions, or geometric design (e.g., grade separations).

2. Access Management. The process of governing access to land development by a public agency where the agency considers the highway facility and its surrounding activities as part of an overall system. Individual parts of the system (e.g., zoning, land-use planning, site plan development, driveway permits, public transportation, roadway network) should be properly integrated and coordinated. Through proper application of access management, the objectives of providing safe and efficient traffic flow coupled with access to abutting properties can be achieved.

3. Controlled Access Highway. A highway where the right of abutting property owners or occupants of land to access, light, air rights, or view, in conjunction with a highway design, is controlled by a public authority (605 ILCS 5/8-101).

4. Full Control of Access. Highways which are designated to have full control of access are referred to as freeways. Priority is given to through traffic and access to the highway is only provided at interchanges with selected public roads. All other intersecting roads are either terminated at the right-of-way line, perpetuated with grade separations, or interconnected with other roads. Access is provided to properties abutting the freeway via frontage roads, service drives, or the existing public road system. Full control of access maximizes the capacity, safety, and vehicular speeds on the highway.

5. Partial Control of Access. An expressway design is the common term used for this type of facility. Priority is given to through traffic. Some intersections will be provided and private entrance connections will be allowed by permit. The proper selection and spacing of intersections and other connections provides a balance between the mobility and access functions of the highway.

   Partial access control is required on rural multilane highways designated as expressways. These highways generally are of significant length and connect major termini. In urban areas, an existing highway or street may be designated as an expressway design with partial access control. In addition, some suburban highways on the minor arterial system, which are planned for upgrading to a multilane highway, should be investigated and considered for partial access control.

   Access to expressways is provided by means of interchange facilities or by the following at-grade connections:

   - selected public crossroads,
   - frontage roads,
   - service drives, and
   - one point of direct access from an abutting property which is used solely for farming purposes and/or one point of access for a single family residence. Such points of access must meet the spacing requirements as stated in Chapter 45.

   Direct commercial access to an expressway is prohibited.

6. Managed Access. On highways with neither full nor partial control of access, the concepts of access management are applied to provide an optimum balance between mobility and access functions. Private development is not guaranteed direct access to State-marked highways. However, reasonable access is guaranteed.

7. Control by Regulation. All highways warrant some degree of access management. Control by regulation is exercised by the Department, county highway departments or municipalities to specify the location of private access to and from the public road system. Occasionally, statutory control is used on arterials to restrict access to only public roads and major traffic generators. Zoning may be used to effectively control development on adjacent property so that major generators do not hinder traffic operations. However, zoning restrictions are at the discretion of the local government. Driveway regulations and permits are used to control the geometric design of an entrance, driveway spacing, and driveway proximity to public road intersections.

8. Access Control Line. A line established by the Department that prohibits ingress to and egress from a highway facility. When an existing access controlled highway is reconstructed, the access control lines should be reviewed for possible revisions.

35-1.02 Authority

35-1.02(a) Freeways and Expressways

Chapter 605 ILCS 5 of the Illinois Compiled Statutes is commonly known as the *Illinois Highway Code*. Section 8-101 of the *Code* authorizes the Department, a county, or municipality to evaluate and establish an access controlled type highway which promotes the safety and convenience of highway traffic.

The governing agency also has the authority to control existing and future highway access to land abutting an access controlled highway (Section 8-107) and may extinguish the right of access by purchase or condemnation (Sections 8-102 and 8-103). The *Illinois Highway Code* further authorizes the relocation or termination of intersecting roads (Section 8-106) and the location of first access points on a side road or street (Section 8-101). BDE is responsible for the administration of access requirements for access-controlled highways. The details of access control around major intersections on expressways or along interchange crossroads are shown in figures contained in this Chapter.

35-1.02(b) Other State Highways

Chapter 605, Section 5/4-210, of the *Illinois Highway Code* authorizes the Department to adopt and amend reasonable and necessary rules, regulations, and specifications covering standard entrance or exit driveways that serve residential, farm, commercial, industrial, and roadside service establishments and other uses of property abutting upon highways. These regulations are contained in the *92 Ill. Admin. Code* 550, *Policy on Permits for Access Driveways to State Highways.* The central Bureau of Operations is responsible for administration of the Permit

Policy. In a general sense, Section 5/4-210 of the *Code* enables the Department to manage access to its network of non-access controlled State routes.

In addition, under Section 5/4-210, the Department may introduce controls such as conversion of streets or highways to one-way traffic operation, the prohibition of turning movements, the channelization of traffic by marked lanes, and the wide use of a variety of median types and median barriers.

35-2 ACCESS CONTROL CRITERIA

35-2.01 General

The extent of access control on any freeway or expressway is indicated by the access control line. During the development of location/design studies for a project, access control information is placed on aerial mosaics. The aerial mosaic exhibits are placed in an 11 in x 17 in format and are designated as an appendix to the Phase I report. See Section 35-5 for information on the preparation of access control plans. Access control lines are also placed on construction plans and right-of-way plats and plans.

The access control line is generally coincident with or parallel to the right-of-way line of the normal roadway section and is continuous throughout or intermittent, depending upon the degree of access control provided. The access control line, however, must assume various configurations at grade separation structures and bridges and also must be extended along intersecting highways. The extended distance along intersecting highways shall be sufficient to protect traffic movements near intersections or at interchange ramp terminals.

35-2.02 Access Control Along Interchange Crossroads

The development of the Interstate System and other access-controlled highways in Illinois has demonstrated the importance of minimizing congestion at freeway interchanges. This has been achieved by optimizing the relationship between the highway facilities and the use of land in interchange areas. Sound development of the area of influence around an interchange requires:

- proper land-use of the area adjacent to the interchange to maximize potential development, and
- proper highway design and length of access control along the crossroad.

Land-use planning in the interchange area is the responsibility of the local agency. One of their most valuable assets is undeveloped land. Unplanned development of this area can result in a substantial economic loss to the community and congestion on the adjacent highway system.

The design of the crossroad and the need for access control is a function of the design speed and projected traffic volumes. Also, operational maneuvers between the ramp terminal and the nearest access connection and adequate distance for advance guide signs have an important role in determining access control distances along the crossroad.

If private driveways, commercial entrances, and public streets are located too close to ramp terminals, they cause congested conditions due to conflicts between the ramp traffic, the through traffic on the crossroad, and the turning traffic at the first access connection. Substantial relief from these conditions can be obtained by the extension of access control a predetermined distance along the crossroads. This essential length of protected roadway will allow crossroad/ramp traffic to enter or leave the crossroad free of conflict with access connection traffic. Such a design will also result in safer and more efficient access to land around the interchange area.

To promote safe and efficient traffic operations in the proximity of interchange ramp terminals and to promote proper land-use planning, the Department has adopted several methods of establishing access control limits along crossroads. Figures 35-2.B through 35-2.J present the Department's access control criteria for interchange areas. These apply to various combinations of interchange type (diamond, parclo, or trumpet), mainline facility type (freeway or expressway), crossroad type (two-lane or multilane divided), ramp type (on, off, or slip), and type of control at ramp terminal intersections with the crossroad (controlled ramp or free-flow). Each figure includes narrative information specifically applicable to that figure. In addition, the following comments apply to all figures:

1. Dimension Values. Figure 35-2.A presents the values for distances (D), bay tapers (T), and lengths to first access condition (L) based on the design speed of the crossroad.

2. Application to Both Sides. The lengths of access control (A/C) as shown in the figures should be provided equally on both sides of the crossroad. This will preclude minor entrances from developing between the ramps and access connections creating closely spaced offset intersections.

3. Existing/Proposed Access Connections. The lengths as shown in the figures should be used for determining the location of access connections. However, where there are existing access connections on the crossroad, the exact termination points of access control may require a detailed study. The study may determine that certain access connections be closed and relocated to a new service drive or frontage road.

   For both existing and proposed connections, the specific design should also include consideration of the character of the area, cultural development, location of property lines, and skew angle of the intersection.

4. Extension of Access Control Beyond Minimums. At certain locations, it may be desirable to extend access control beyond the minimum limits to a nearby intersection or a major traffic generator. However, because the interchange area has marked potential for economic benefit to the community and for providing motorist services, discretion should be used in extending access control beyond the requirements. In all cases, an analysis should be made to determine if an extension of access control beyond the minimum requirements is a sound investment in the interest of highway safety and efficiency and consistent with abutting land use.

5. Controlled Ramp Terminal. A controlled ramp terminal is one through which traffic operations are normally regulated by either stop signs or traffic signals and entrance to or exit from such a terminal is through short-radius turns at a relatively slow speed. The establishment of minimum access control limits adjacent to a controlled ramp terminal is based on the need for auxiliary right- or left-turn lanes on the crossroad and for proper signing distance.

In evaluating operational maneuvers as a basis for establishing the extent of access control, the nearest access connection, whether existing, proposed, or future, is considered to be capable of generating traffic volumes of such magnitude as to require auxiliary turning lanes between the ramp terminal and access connection. Such consideration is necessary because the nature of such connections is readily susceptible to changes in development.

6. Free-Flow Ramp Terminals. A free-flow ramp terminal permits traffic to either enter or exit the crossroad at a relatively high speed without regulation of these maneuvers by either stop signs or traffic signals. The establishment of access control limits beyond free-flow ramp terminals, to the nearest access point, is based on the need for providing adequate space for critical operational maneuvers and to provide adequate geometric facilities for these maneuvers. Adequate distance for the placement of guide signs must also be provided.

USE TO DETERMINE MINIMUM "L" IN ACCESS CONTROL FIGURES			
Design Speed on Crossroad	**D**	**T**	**G + C**
US Customary			
30 mph	250 ft	150 ft	180 ft
40 mph	300 ft	175 ft	300 ft
45 mph	350 ft	200 ft	350 ft
50 mph	425 ft	225 ft	450 ft
55 mph	500 ft	250 ft	550 ft
60 mph	550 ft	275 ft	650 ft
70 mph	600 ft	300 ft	900 ft
Metric			
50 km/hr.	75 m	45 m	55 m
60 km/hr.	95 m	50 m	90 m
70 km/hr.	110 m	60 m	110 m
80 km/hr.	130 m	70 m	135 m
90 km/hr.	150 m	75 m	165 m
100 km/hr.	170 m	85m	190 m
110 km/hr.	185 m	90m	270 m

L = Length used to determine location of first access connection, ft (m)
T = Length of taper of left-or right-turn lanes, ft (m)
D* = Deceleration distance (which includes T) to a stop condition for left- and right-turn lanes, ft (m)
G = Distance a motorist travels while seeking a gap in the median lane after a free-flow entry, ft (m)
C = Distance traveled while changing lanes (assume 3 seconds of travel time), ft (m)
R_1 = Radius return (see Section 36-2), ft (m)
R_2 = Control radius (see Section 36-2), ft (m)

In some areas, the storage distance (S) may govern, and the length of the turn lane will be either D or S + T, whichever is larger. See Section 36-3 to determine S.

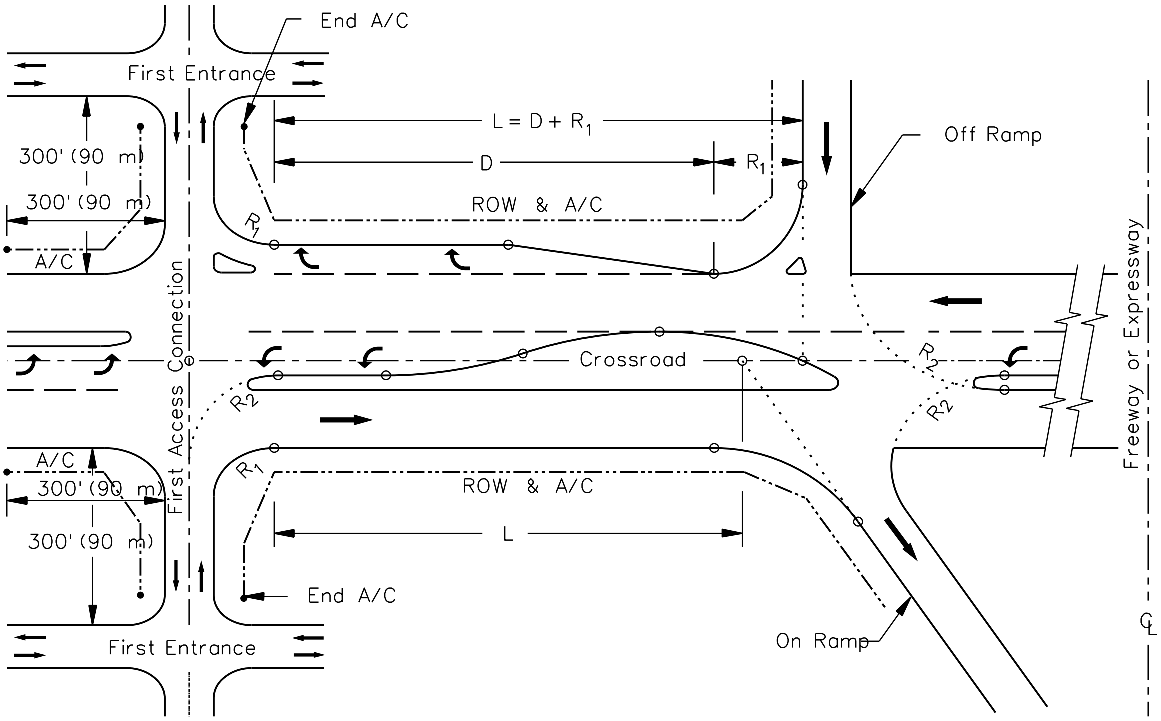
General Notes for Figures 35-2.B through 35-2.H

1. *Where the access connection is a marked route or potential high-volume generator, "L" should not be less than 700 ft (215 m) in rural areas and 500 ft (155 m) in urban areas. These distances will permit the proper placement of the M2-1 (Junction Marker) sign assembly or the placement of the D3 (street name) sign assembly for local roads and streets.*

2. *If the first access connection is a two-lane street or highway, the minimum distance to the first entrances on the access connection should be 300 ft (90 m). For multilane access connections, longer lengths must be considered to the first entrances to allow for the installation of left-turn lanes on the access connection. In all cases, access control is used in each of the four quadrants of the intersection of the first access connection with the crossroad.*

DIMENSIONS FOR ACCESS CONTROL FIGURES AND GENERAL NOTES

Figure 35-2.A



Notes:

1. *The critical length "L" between the off ramp and first access connection usually is governed by a need for a future right-turn lane into the access connection.*

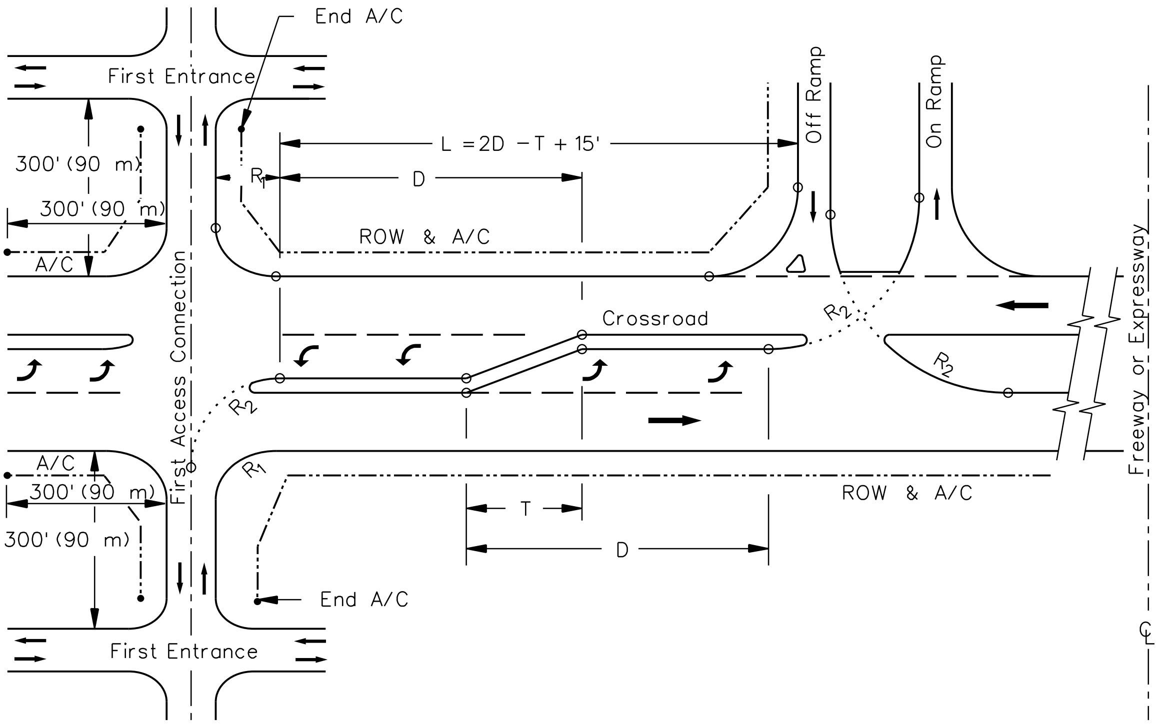
2. *In some cases, the length "L" on the same side of the crossroad as the on ramp may control the location of the first access connection. Check the length "L" on this side for sufficient signing distance. In rural areas, "L" should not be less than 600 ft (180 m). This distance will permit the proper placement of the Advance Route Turn assembly (Freeway) signs.*

3. *Also, refer to General Note 1 on Figure 35-2.A.*

4. *Refer to General Note 2 on Figure 35-2.A.*

ACCESS CONTROL ALONG CROSSROAD AT DIAMOND INTERCHANGE
(Two-Lane or Multilane Divided Crossroad)

Figure 35-2.B



Notes:

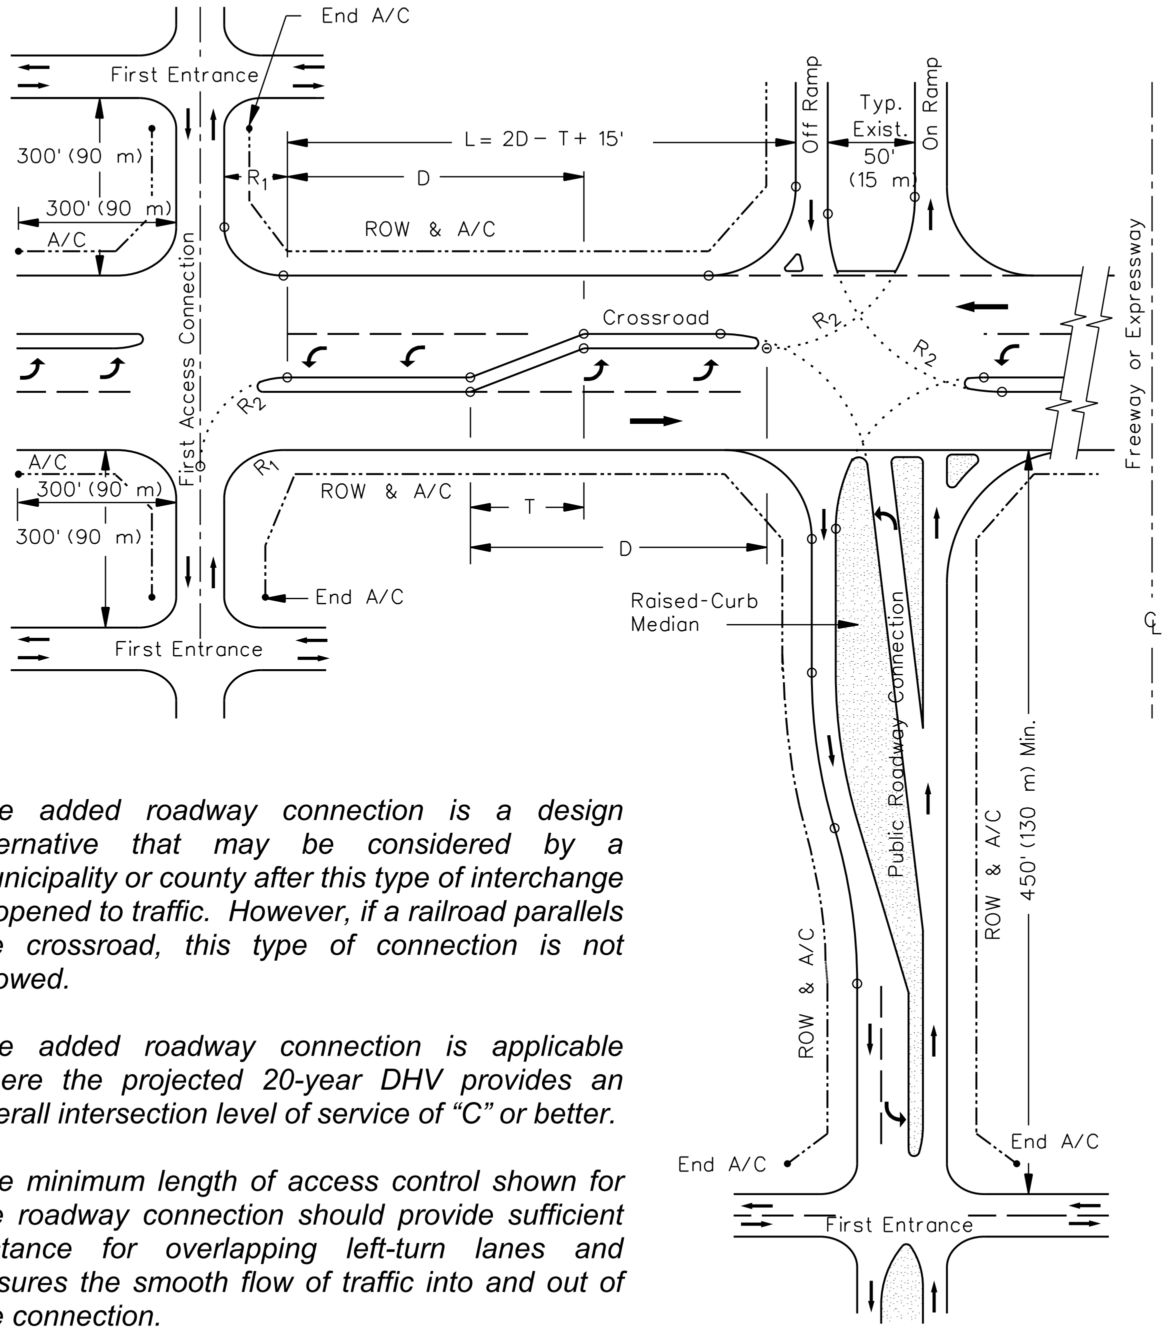
1. *The critical length "L" between the off ramp and first access connection is governed by the need for a left-turn lane into the access connection and the need for a left-turn lane into the on ramp. In addition, refer to General Note 1 on Figure 35-2.A.*

2. *On the opposite side of the crossroad from the off ramp, check the available distance to permit the proper placement of the Advance Route Turn assembly (Freeway) signs. In rural areas, this distance should not be less than 600 ft (180 m) from the access connection to the end of the left-turn lane on the crossroad.*

3. *Refer to General Note 2 on Figure 35-2.A.*

ACCESS CONTROL ALONG CROSSROAD FROM OFF RAMP AT TWO-QUADRANT PARCLO INTERCHANGE (Two-Lane or Multilane Divided Crossroad)

Figure 35-2.C



Notes:

1. *The added roadway connection is a design alternative that may be considered by a municipality or county after this type of interchange is opened to traffic. However, if a railroad parallels the crossroad, this type of connection is not allowed.*

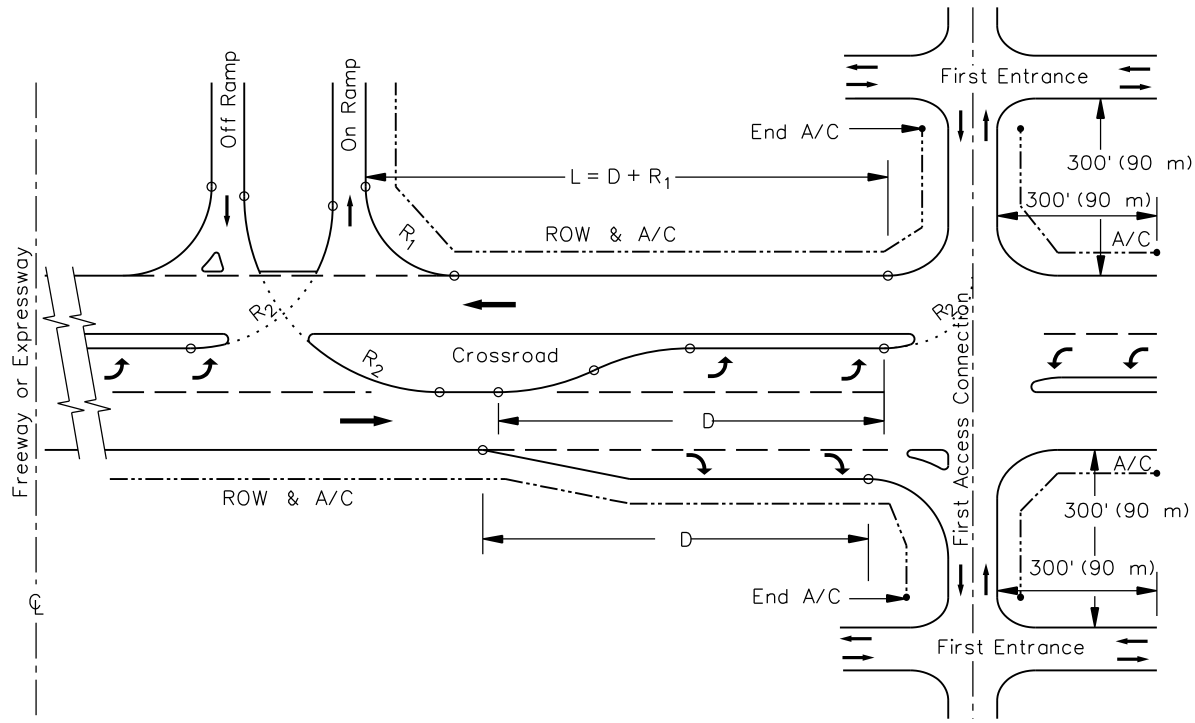
2. *The added roadway connection is applicable where the projected 20-year DHV provides an overall intersection level of service of "C" or better.*

3. *The minimum length of access control shown for the roadway connection should provide sufficient distance for overlapping left-turn lanes and ensures the smooth flow of traffic into and out of the connection.*

4. *Refer to General Note 2 on Figure 35-2.A for the proper design of access control for the first access connection on the crossroad.*

ACCESS CONTROL ALONG ADDED ROADWAY TO CROSSROAD ACROSS FROM OFF/ON RAMP AT TWO-QUADRANT PARCLO INTERCHANGE (Two-Lane or Multilane Divided Crossroad)

Figure 35-2.D



Notes:

1. *The critical length "L" between the first access connection and the on ramp usually is governed by the future need for a right-turn lane into the on ramp. In rural areas, "L" should not be less than 600 ft (180 m). This distance will permit the proper placement of the Advance Route Turn assembly (Freeway) sign.*

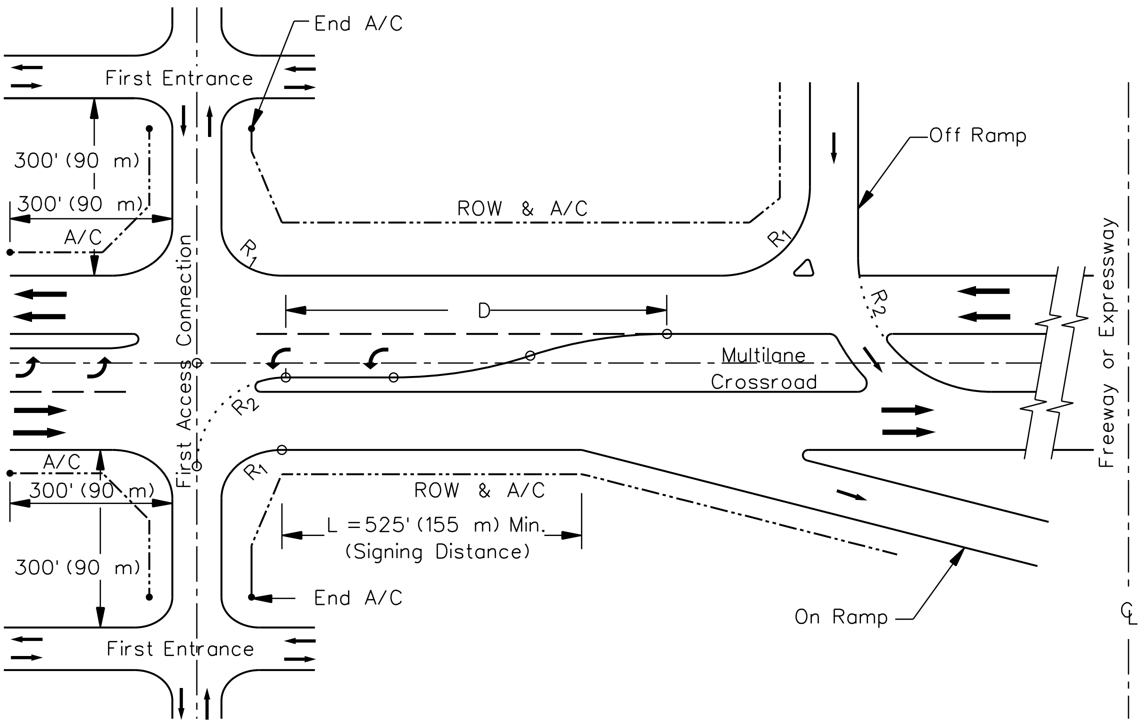
2. *In some cases, the future need of a right-turn lane into the access connection on the opposite side of the crossroad from the on ramp may control the location of the first access connection. Check the layout for the distance available to construct a right-turn deceleration lane.*

3. *Refer to General Note 1 on Figure 35-2.A.*

4. *Refer to General Note 2 on Figure 35-2.A.*

ACCESS CONTROL ALONG CROSSROAD FROM ON RAMP AT TWO-QUADRANT PARCLO INTERCHANGE (Two-Lane or Multilane Divided Crossroad)

Figure 35-2.E



Notes:

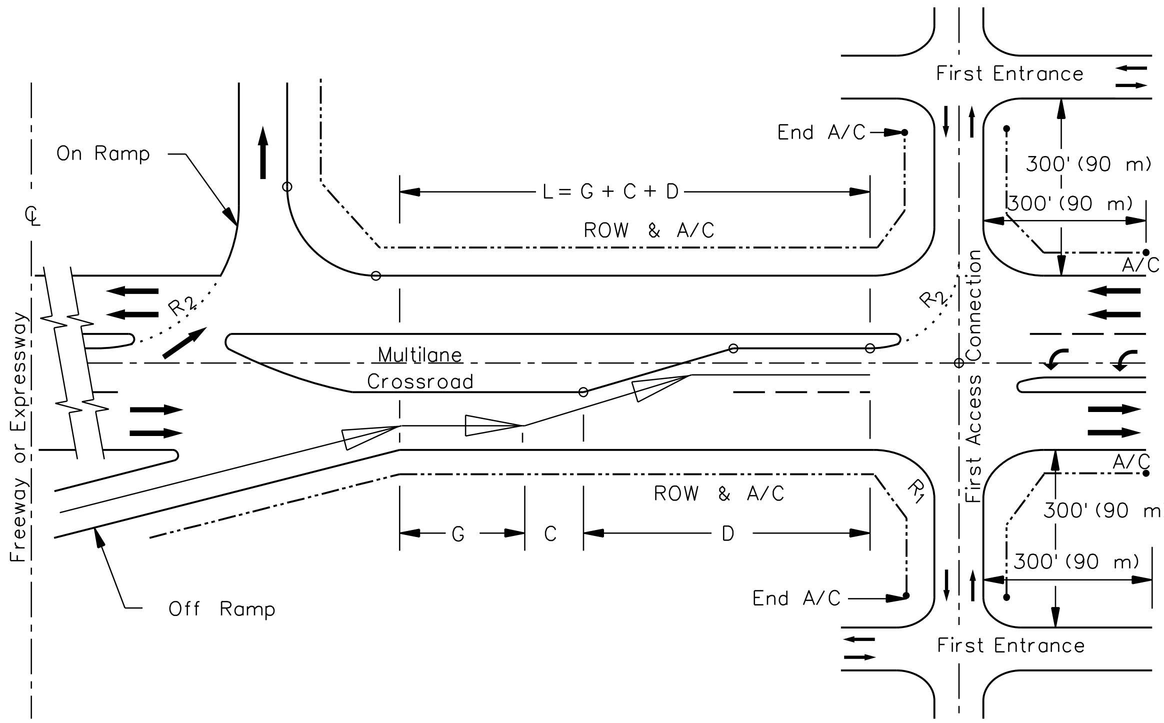
1. *The critical length "L" between the first access connection and the 1 ft (300 mm) stub of the free-flow on ramp is governed by the minimum advance signing distance. This minimum length will provide sufficient distance for the placement of the Advance Route Turn assembly (Freeway) signs.*

2. *Also, check the critical length "L" between the off ramp and the first access connection for adequate distance for a future right-turn lane into the access connection. In addition, refer to General Note 1 on Figure 35-2.A.*

3. *Refer to General Note 2 on Figure 35-2.A.*

ACCESS CONTROL ALONG CROSSROAD AT FOUR-QUADRANT PARCLO (Type A) INTERCHANGE (Free-Flow On Ramp)

Figure 35-2.F



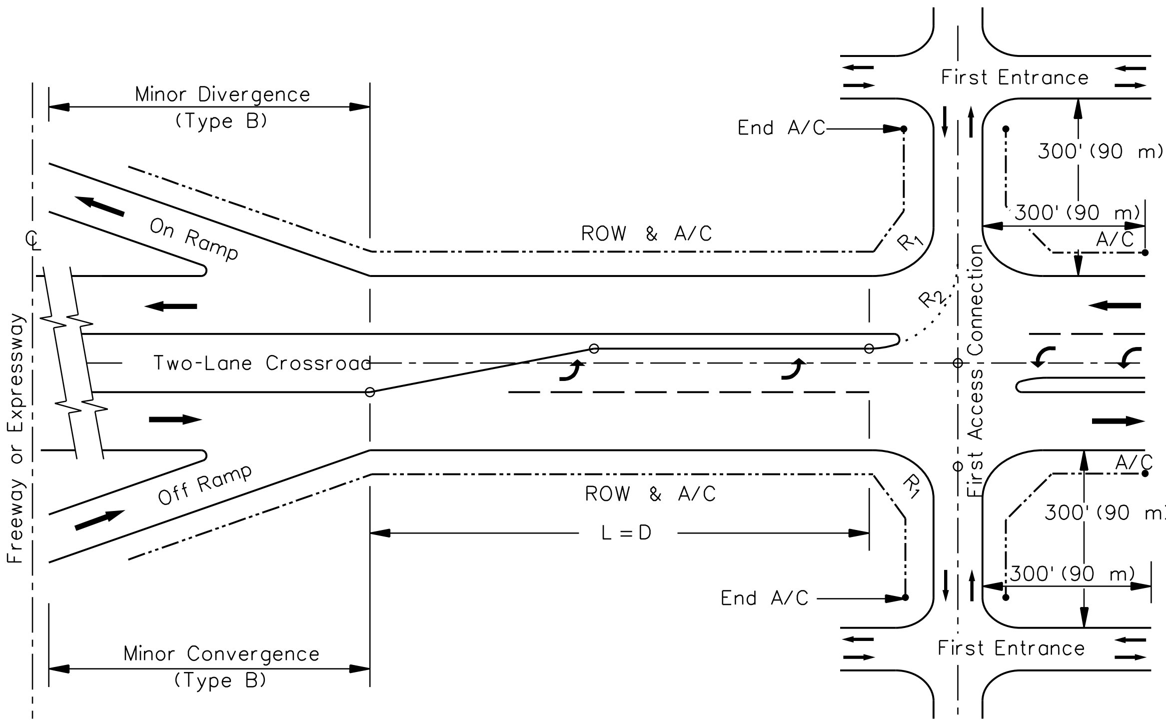
Notes:

1. *The critical length "L" is controlled by the free-flow off ramp maneuver. The minimum required distance to the first access connection is based on the design speed of the crossroad and is the combination of the operational maneuvers as shown schematically above. See the table in Figure 35-2.A for distances. Use the equation L = (n - 1) (G + C) + D, where n = 2 or 3 lanes, to determine the total required distances.*

2. *Refer to General Note 2 on Figure 35-2.A.*

ACCESS CONTROL ALONG CROSSROAD AT
FOUR-QUADRANT PARCLO (Type B) INTERCHANGE
(Free-Flow Off Ramp)

Figure 35-2.G



Notes:

1. *The critical length "L" between the ends of the Type B convergence and divergence on the crossroad to the first access connection usually is governed by the need for a left-turn lane into the access connection. Select a design speed and refer to the table in Figure 35-2.A.*

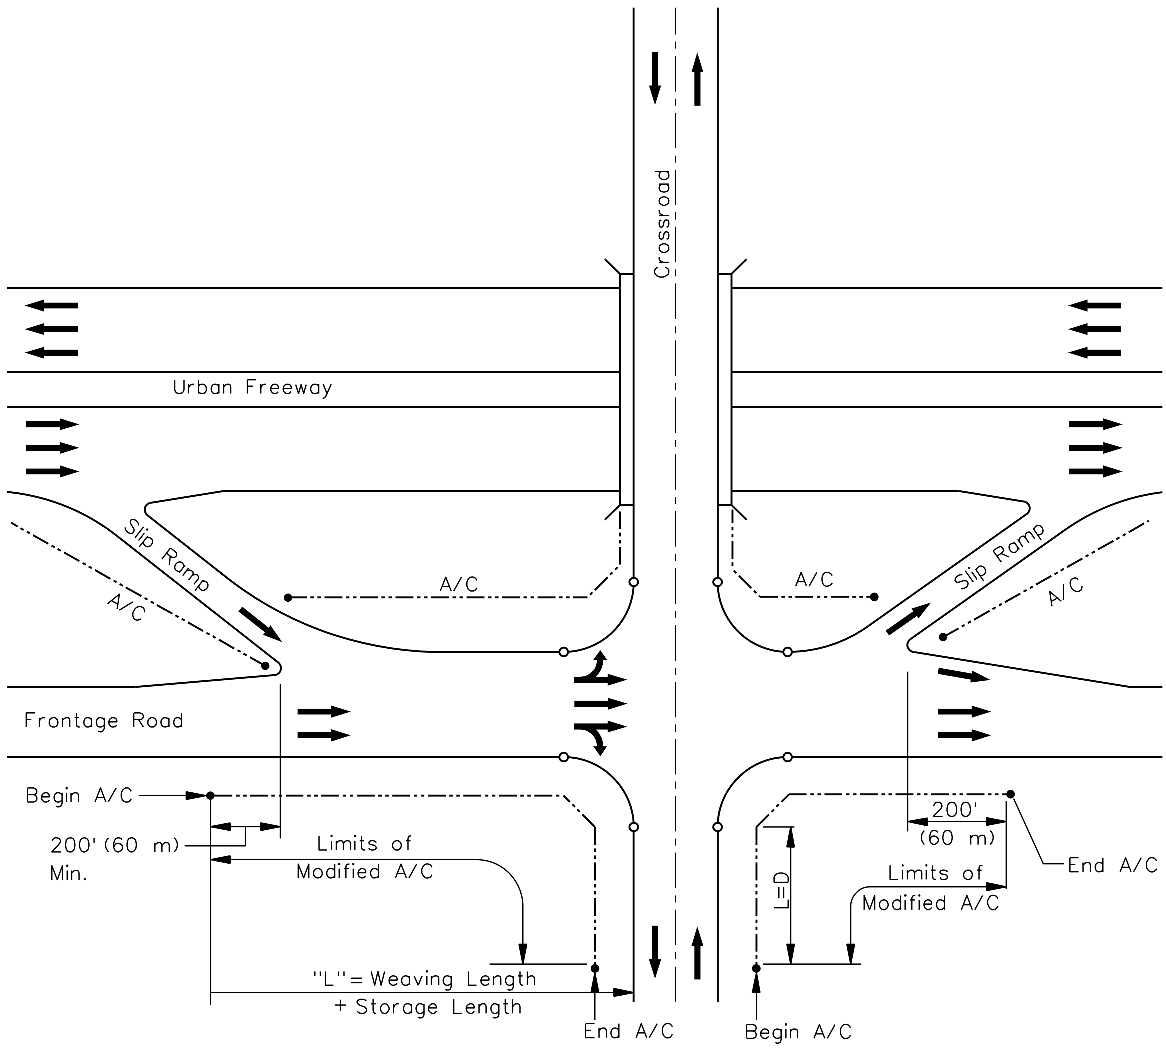
2. *In the case of a trumpet interchange stem which is designed as a multilane crossroad (Type A design), refer to Figure 35-2.G and use distances of "C" plus "D" to determine the critical length "L." Start at the end of the minor convergence.*

3. *Refer to General Note 1 on Figure 35-2.A.*

4. *Refer to General Note 2 on Figure 35-2.A.*

TRUMPET INTERCHANGE
(Two-Lane Divided Crossroad)

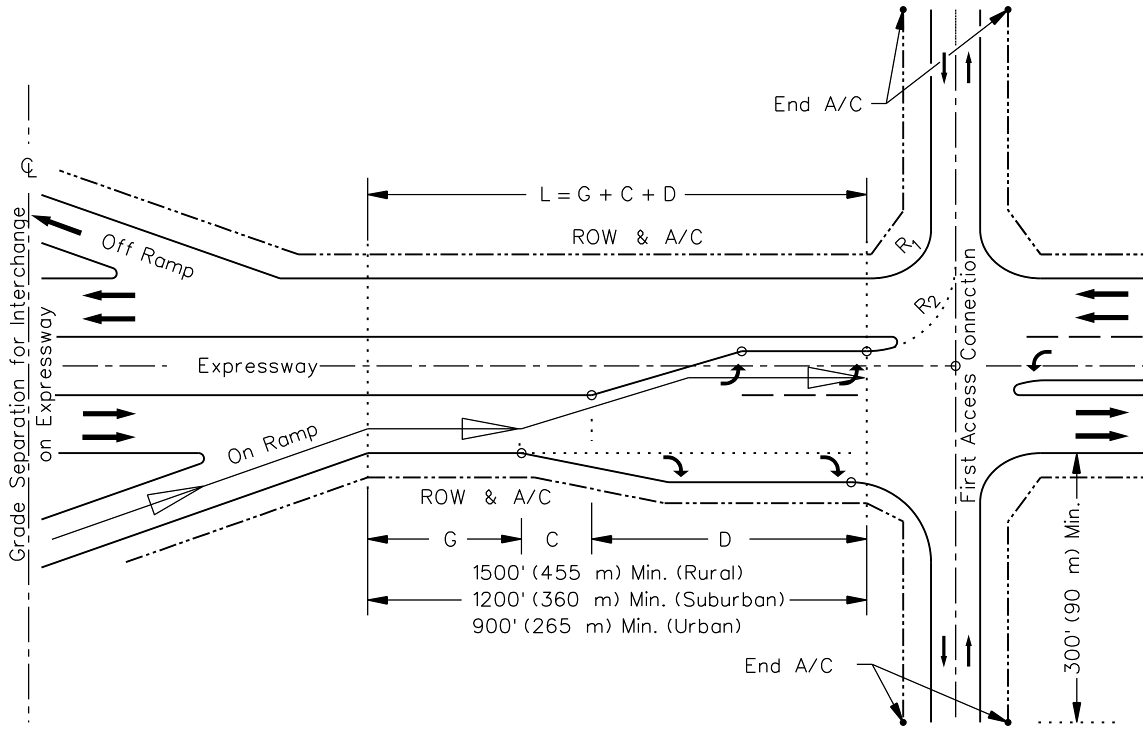
Figure 35-2.H



Note: The modified access control line is only used where single family residential entrances exist. For other types of development, full access control should be used along the frontage road and crossroad.

ACCESS CONTROL LIMITS NEAR URBAN FREEWAY SLIP RAMPS
(On And Off Of One-Way Frontage Road)

Figure 35-2.I



Notes:

1. *This figure illustrates the first access connection on an expressway type highway beyond the end of the entrance ramp terminal. The minimum required distance to the first access connection is based on the design speed of the expressway and is the combination of the operational maneuvers as shown schematically in the above figure. See the table in Figure 35-2.A for distances. Use the equation L = (n-1) (G+C) + D, where n = 2 or 3 lanes, to determine the total minimum required distance.*

2. *For details on the required length of access control on the first access connection, refer to Figures 35-2.K through 35-2.M.*

INTERCHANGE ON FOUR-LANE DIVIDED EXPRESSWAY
(Distance to First Access Connection on Expressway)

Figure 35-2.J

35-2.03 Expressways

35-2.03(a) Access Control at Crossroads

Where private driveways, commercial entrances, and access connections to public streets/highways are located too close to the expressway, they can cause hazardous and congested conditions due to conflicts between the expressway traffic, the through traffic on the crossroad, and the turning traffic at the access connections. Substantial relief from congested conditions can be obtained by the extension of access control a predetermined distance along the crossroad. This essential length of protected roadway will allow expressway traffic to enter or leave the crossroad free of conflict with access connection traffic.

The design criteria for access control on expressways are under the jurisdiction of BDE. Figures 35-2.K through 35-2.M illustrate examples of minimum access control requirements at expressway intersections with various crossroad configurations. At certain locations, it may be desirable to extend access control beyond minimum limits to a nearby intersection or a major traffic generator. Where future interchanges may be likely or are definitely planned at a crossroad, full control of access should be established along the crossroad to accommodate the actual type of future interchange or, if not known, at least 1000 ft to 1200 ft (300 m to 350 m) on each approach.

Figure 35-2.K illustrates an intersection of an expressway with a two-lane channelized crossroad. The use of left-turn lanes on both legs of the crossroad may be desirable from either a safety or operational perspective. If no access connections are existing or proposed and the 20-year DHV on the crossroad does not require more than two traffic lanes on the channelized approaches, terminate the access control along the crossroad near the ends of the mountable median strip or at a comparable point with flush channelization. The access connections shown in the figure indicate the minimum distance from the edge of the expressway where an existing or proposed public road or commercial access driveway may be connected.

Figure 35-2.L illustrates an intersection of an expressway with a multilane divided crossroad. Where a public road or commercial access connections are existing or proposed in the vicinity of the expressway intersection, terminate access control near the beginning of the radius returns as shown in the figure. Otherwise, terminate the length of access control along the crossroad opposite the theoretical nose location of a properly designed left-turn lane that will serve a future access connection. In determining the length of access control, assume that left-turn lanes will be required initially, for either safety or capacity, on both approaches of the crossroad intersection and for future turns into the access connections. The taper lengths for the left-turn lanes may be overlapped.

Figure 35-2.M shows an intersection of an expressway with an undivided crossroad (township road, county highway, or low-volume city street). Acquire access control along the crossroad for a minimum distance of 300 ft (90 m), as shown in the figure, which allows for the provision of constructing future overlapping left-turn lanes on the crossroad. The radius returns for existing, proposed, or future commercial access connections or public roads may begin near the point where the access control terminates.

With any of the three different crossroad designs, existing minor entrances may be permitted within the limits of access control under the following conditions:

- An existing private driveway for one single-family residence or one field entrance for farming purposes can be allowed to remain, by highway permit, as close as 100 ft (30 m) from the edge of the expressway traveled way.
- If it is determined that an existing commercial development will be significantly damaged, one low-volume entrance to such a development (on each side of the crossroad) can be allowed to remain by highway permit and access agreement as close as 200 ft (60 m) from the edge of the expressway traveled way. The decision to allow the existing commercial entrance to remain in operation must be carefully analyzed and a design exception must be requested in the Phase I report.

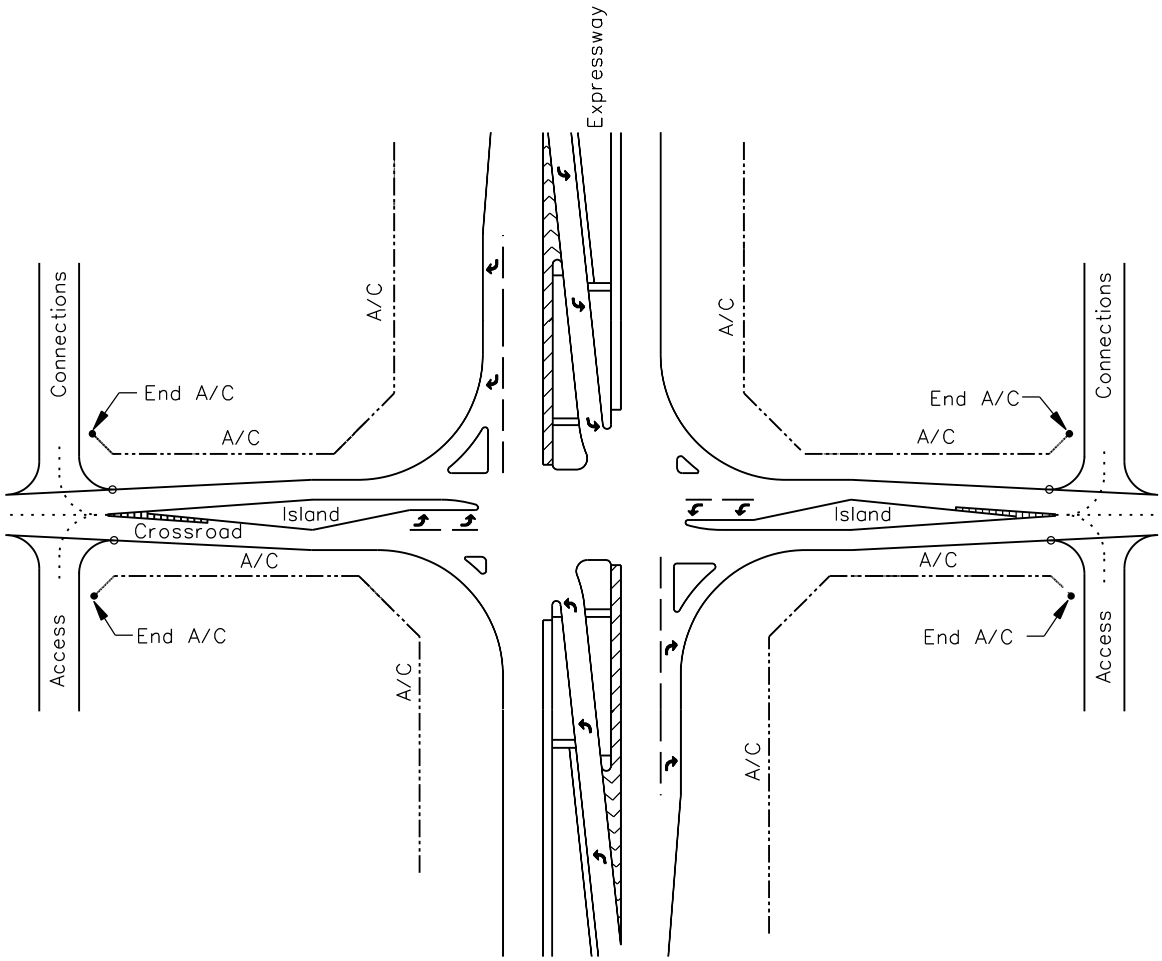
The design of access control as shown in Figures 35-2.K through 35-2.M will help to eliminate backups onto the expressway in the vicinity of the main intersection and thereby minimize any adverse operational effects on expressway traffic.

35-2.03(b) Access Control at Frontage Road or Service Drive Connections

Frontage road or service drive connections to expressways are in essence minor intersections and, therefore, require some measure of access control to ensure satisfactory operating conditions and safety. Frontage road connections should be designed to avoid storage deficiencies and operational difficulties in association with large traffic generators that may locate opposite or near the connection. Therefore, frontage road or service drive connections should be designed with access control provided as illustrated in Figures 45-2.H and 45-2.I. Access control is provided opposite the “T” to prevent future operational problems and could allow the connection of a public street in the future.

35-2.03(c) Elimination of Commercial Access

Direct access from commercial developments to the expressway is not permitted. Refer to Chapter 45 for a discussion on the design of commercial access points off of crossroads, frontage roads, and service drives.



Notes:

1. *The channelizing islands on the crossroad usually are constructed as a raised-curb median for optimum delineation.*

2. *Refer to text in Section 35-2.03(a) for further guidance*

UNDIVIDED CROSSROAD INTERSECTING EXPRESSWAY
(Limits of Access Control)

Figure 35-2.M

35-2.04 Access Restrictions Along Side Roads

Where a commercial entrance or street intersects a State highway, additional care should be taken to ensure future operational integrity of both routes, regardless of State highway cross section or current use of access control. This is typically completed by providing an access restriction along the side road for a sufficient distance beyond the nearest mainline edge of travel. See Section 36-7.02, item 4 for additional discussion. Additionally, Figure 36-7.D shows a typical design for a high-volume commercial entrance to a State highway utilizing an access restriction. This access restriction dimension is typically established at 300 feet (90 m) minimum, and can be increased based on proposed side road traffic. The district geometrics engineer will determine the proper distance for this dimension after analyzing traffic operations and performing a capacity analysis on the two closely spaced intersections. For existing locations without existing access control, or for locations where this length is proposed to be increased, coordination is required with the property owner, and purchase of access control rights will follow general land acquisition procedures and guidelines.

35-3 ESTABLISHING ACCESS CONTROLLED HIGHWAYS

35-3.01 Applicability

Highways are established as access controlled facilities where they comprise either a portion of a system of freeways (e.g., National System of Interstate and Defense Highways) or where a need to control access exists on the highway, such as on an expressway or on a portion of a highway (crossroads and side roads). Refer to the Illinois Compiled Statutes (605 ILCS 5/8-101).

35-3.02 Freeways or Expressways on New Location

An Access Control Plan is prepared as part of the location/design study. See Chapters 11 and 12 and Section 35-5 for details. After the detailed design for feasible alternatives is completed and after the Draft EIS is authorized for distribution, the district is required to conduct public involvement activities (usually an open house public hearing). Chapter 19 discusses the details of public involvement activities. The announcement for the public hearing should include a notice for road closures (see Chapter 11) and a statement on the implementation of corridor preservation. Guidelines for corridor preservation can be found in the *Land Acquisition Policy and Procedures Manual*.

After the public hearing is completed, the Design Report, Final EIS, disposition of comments received, and other documents (see Chapter 12) are submitted for approval by the Regional Engineer. For major new alignment projects or at the request of the Regional Engineer, submit the documents to BDE with a request for design approval. Once design approval is given and the Access Control Plan approved by the Regional Engineer/BDE, the district can then proceed to prepare and file a Route Location Decision and an Order Establishing a Freeway. These two documents are forwarded to BDE for execution. See Chapter 12 for examples of these two documents.

35-3.03 Freeways or Expressways on Existing Location

There are two types of access control scenarios in this category:

1. Where a highway is being studied as part of an overall system and a location/design study is initiated to examine whether the freeway or expressway should be located on new or existing locations, it will be necessary to complete the design study, the preparation of environmental documents, and public involvement before an existing alignment can be established as the preferred alternative.

   Assuming the preferred alternative is designated along the existing highway, the district then submits all reports to the Regional Engineer and requests design approval. After approval of the Design Report, which includes the Access Control Plan, the district can prepare and submit an Order Establishing a Freeway to BDE for execution. In addition, guidelines for implementing corridor preservation should be considered for the preferred alternative.

2. Where an existing segment of highway is already declared as an access controlled facility and the district wishes to extend the length of access control along the existing roadway or along a crossroad to provide for additional safety and mobility, it will not be necessary to prepare a design study on the proposed access extension. Instead, the following must be completed:

    - Discuss the proposal at a district coordination meeting.
    - Notify all existing property owners along the highway segment and discuss the proposed changes in access control with them. Document the results of each meeting. Single family residences and field entrances can be considered to remain in place by permit. No commercial entrances will be allowed.
    - Publish in the local newspaper an offer to hold a public informational meeting on the proposed changes in access control. Requests to hold a meeting must be submitted in writing to the district.
    - If the district decides to hold an informational meeting, summarize all comments received on the proposed changes in access control with proper documentation.
    - Submit a revised Access Control Plan and the disposition of any comments received on the proposed changes to BDE and request concurrence of the Plan. The revised Access Control Plan can be shown on an aerial mosaic, on revised plan sheets, or on an Intersection Design Study drawing as appropriate. FHWA must approve any changes in access control on the Interstate System.
    - Once the appropriate central office bureau has concurred with the revised Access Control Plan, the district can prepare a revised Order Establishing a Freeway and forward it to BDE for execution. The documents must include a copy of the previously approved Access Control Plan as an attachment.

A Route Location Decision is not required with either of the two scenarios described above.

35-3.04 Acquisition of Access Rights

The acquisition of access rights to property is a function of the Land Acquisition Office in each district. The *Land Acquisition Policies and Procedures Manual* includes a detailed discussion of the Department's policies and responsibilities in the acquisition of freeway (or expressway) rights-of-way and the provisions involved in purchasing access rights. To exercise full or partial control of access on an existing highway, the Department must acquire, by purchase or condemnation, the access rights of abutting property owners. However, the filing of an Order Establishing a Freeway on an existing highway (see Chapter 12) does not require the Department to immediately acquire all access rights but, whenever an access permit is requested on such a route, the Department has the option of either issuing a temporary permit or acquiring the access rights of the applicant.

When establishing an access controlled highway on a new location, a location not replacing an existing roadway to which an abutting owner formerly had access, the Department need not acquire nor pay for access rights because none exist.

35-4 REVISIONS TO EXISTING ACCESS CONTROL

Normally, changes in established access control are made only to allow additional or modified access to a local public road or designated street system as opposed to direct access to private property. However, revised access to private property is technically possible and legal although considerably more difficult to achieve.

When a release of access control is primarily intended to enhance transportation needs, it is referred to as "relinquishment of access control," and the *Bureau of Operations Policy and Procedures Manual* will govern the release. When the release of access control is primarily intended to serve a commercial development, the release is referred to as "disposal of access control," and the Bureau of Land Acquisition will determine the value of the previously acquired access rights, which will be credited to the Department's road fund.

The detailed discussion of these procedures is contained in Chapter 6 of the *Bureau of Operations Policies and Procedures Manual* and in Chapter 12 of this *Manual* (see Order Establishing a Freeway). Also for major revisions to existing access control on freeways and expressways, such as adding a new access point, see Section 37-1 for documenting and processing any requested changes.

35-5 ACCESS CONTROL PLANS

35-5.01 General

During the location study phase of an expressway or freeway design, an Access Control Plan is prepared by the district/consultant and included as an Appendix to the design or combined study for the project (see Chapter 12). Design approval of the project will constitute approval of the Access Control Plan. The Access Control Plan must be approved prior to the execution of an Order Establishing a Freeway.

35-5.02 Aerial Photography

Aerial photography is requested from the Surveys, Mapping and Modeling Section at the same time that mapping is ordered for the project. Once the photography is obtained, a mosaic is made of the photographic prints to alleviate some of the distortion between frames.

After the aerial mosaic is completed, it is re-photographed and made into half-tone positive exhibits. These base exhibits are then used to prepare the actual Access Control Plan. Original half-tone positive exhibits on mylar are never enlarged or reduced in size due to the distortion that would be created by such a procedure.

The half-tone positives should be made into one of the following scale ratios:

Urban Areas	Rural Areas
US Customary	
1:100 or 1:200	1:500 or 1:600
Metric	
1:1000 or 1:2500	1:5000 or 1:7500

The larger scale exhibit is requested where the designer wishes to show more detail on the Access Control Plan. The final Access Control Plan is developed into 11 x 17 in. sheets and assembled into a booklet format for ease of use by design and right-of-way personnel.

35-5.03 Fully Access Controlled Highways (Freeways)

The following data and information should be shown on the Access Control Plans for freeways:

- point of beginning and ending (stationing proceeds from west to east or south to north);
- North arrow;
- centerline distances, numbered to indicate every 100 ft (100 m) (urban) and every 1000 ft (300 m) (rural);

- property lines and ownership of land;
- major drainage courses with structure symbol;
- identity of all crossroads or streets by number and/or name;
- design traffic on the freeway between interchanges and on all crossroads to be separated or relocated;
- current ADT on all roads to be closed;
- existing and approximate proposed right-of-way lines;
- interchange locations with approved type and the ends of access control located on crossroad;
- frontage roads and proposed service drives (service drives may be revised as a result of ROW negotiations);
- data on intersecting railroads to include name, number and type of tracks, and number of trains per day; and
- any information that might be relevant to major environmental issues (wetlands, natural areas, etc.).

35-5.04 Partially Access Controlled Highways (Expressways)

The data and information described in Section 35-5.03 should be shown on the Access Control Plans for expressways. In addition, indicate the following information:

- all proposed or relocated field and private entrances to the expressway;
- proposed service drives and frontage roads and their direct connection to the expressway;
- proposed median crossovers;
- all existing entrances and median crossovers to be eliminated, where the expressway lies parallel and adjacent to an existing roadway; and
- limits of access control along each crossroad and at each direct connection.

35-5.05 Access Control Plan Symbols

To facilitate the preparation of Access Control Plans, Figure 35-5.A presents standard symbols for use. The symbols are drafted onto the half-tone positive exhibits. Attach a copy of the standard symbols to each Access Control Plan.

35-5.06 Construction and Right-of-Way Plans

Once the Access Control Plan has been approved through the design approval process, it is used as a guide in the preparation of construction plans and right-of-way plans. See Chapter 63 and the *Computer Aided Design, Drafting, Modeling and Deliverables Manual* for information on the preparation of plan sheets and CADD drafting guidelines.

35-6 ACCESS MANAGEMENT

35-6.01 Access vs. Mobility

35-6.01(a) Basic Conflicts

A functional highway system must provide both traffic service and land access. However, this dual need creates a fundamental conflict. Achieving maximum efficiency and safety in traffic operations requires restriction of access and, conversely, increased access may result in a degradation of safety and capacity.

The typical business development and highway improvement cycle illustrate the problem. When businesses request and are granted access to a highway facility, they generate more traffic and consequently more businesses are attracted to the area, thereby generating a need for yet more access. As the cycle continues, the originally efficient highway becomes more congested and safety may be compromised.

With further increased development resulting in increased property values, major improvements of the existing highway become impractical, and new service on a new location may be warranted. The access-mobility conflict could be repeated on the new facility. Implementing access management techniques can reduce such occurrences from disrupting the transportation system.

35-6.01(b) Relationship to Functional Classification

The fundamental differences in the need for access versus mobility have resulted in the current practice of functionally classifying highways. The functional classification system is discussed in Section 43-1. Ideally, the balanced highway system will provide high-mobility arterials with full or partial access control, collectors to provide an intermediate level of access and mobility, and local roads and streets with limited mobility and a higher level of access. The highway system, when viewed in aggregate, fulfills both the needs of mobility and access via the functional classification system and the application of access management.

Access management techniques are directed primarily at principal arterials (other than access controlled highways) and minor arterials where the potential for conflicts are most severe.

35-6.02 Objectives of Access Management

Improved traffic service is a primary objective of access management. From a highway engineering perspective, the objectives of access management are to optimize the balance between safe, efficient transportation (or mobility), and access. Section 35-7 presents access management techniques that accomplish these objectives.

35-6.03 Benefits of Access Management

When successfully implemented, the application of access management to arterial streets will yield several benefits, as discussed in the following:

1. Enhanced Mobility. Significant benefits may be derived by minimizing the number of traffic conflict points, separating conflict areas, removing traffic queues from the through lanes, and providing more space for acceleration-deceleration at access points. The result is increased traffic-carrying capacity of the highway and a higher level of service (e.g., higher operating speeds, fewer delays, increased convenience, less driver frustration, lower operating costs).

2. Improved Safety. Access management techniques that enhance mobility also improve safety. Smoother traffic flow, with lower speed differentials between through traffic and turning traffic and with the number of crossing opportunities reduced or eliminated, results in improved safety. Reducing traffic crashes has tangible economic benefits by reducing injuries, property damage, and delays.

3. Property Owner Benefits. Access management techniques typically improve access to abutting properties along the highway corridor. The convenience of smoother-flowing traffic with safer access attracts commercial development and business. Growth in traffic attracts businesses and will likely increase commercial property values even if access is restricted to a few strategic points.

4. Preservation of Highway Investment. By increasing the traffic-carrying capacity of a highway, access management techniques can extend the functional service life of a facility and postpone the need for major highway improvements. Highway widening or relocation frequently results in disruption and/or displacement of people and businesses. New highways are expensive and often involve significant impacts. Access management offers an alternative that can postpone or eliminate the impacts of new highway construction or reconstruction and associated problems of relocations and traffic delays.

35-6.04 Disadvantages of Access Management

Although access management techniques may be in the best overall public interest, individual road users and property owners may object to the inconvenience associated with the elimination or denial of a specific access point. A property owner or business customer, for example, may be required to drive a longer distance to reach the desired location.

When proposing an access management strategy, the advantages and disadvantages of various alternatives should be considered and the public must be involved in the final decisions. If implementation of access management techniques eliminates previously available access, then the property owner may be entitled to compensation.

35-6.05 Elements of an Access Management Program

35-6.05(a) Coordination

An effective access management program on a particular street must involve not only the engineering aspects of highway design and traffic operations but also the broader issues of land-use planning and zoning, public involvement, and enforcement powers. Most of these issues are addressed outside the highway agency; therefore, close coordination with other agencies and the public is needed to develop and implement an effective program.

Highway agencies have some authority to regulate access; however, local governments control land use and zoning. Unless there is coordination between the highway agency and land-use planners, attempts by the highway agency alone to manage access are not likely to succeed. A comprehensive and rational access management plan, developed in cooperation with local agencies in charge of planning and zoning, has a much greater chance of success.

The following administrative processes are usually included in individual access management programs:

- zoning regulations,
- subdivision approval (Plat Act),
- site plan development (Access Agreement),
- driveway permits, and
- roadway design and construction.

35-6.05(b) Enforcement

In coordination with public involvement, attaining and retaining access management may be implemented via the following:

1. Regulatory Authority. A public agency can manage access to streets through the use of its regulatory authority to control traffic movements. These powers can be used to manage access directly (e.g., through the use of driveway permits and regulations) or indirectly (e.g., through the use of raised-curb median and curbs along the edges of the street). Access management is effectively achieved when abutting property owners are required to comply with regulations necessary for the efficient flow of traffic. This presently occurs through the plat approval process, with access agreements for major developments and through approval of individual driveway permits.

2. Eminent Domain. By using "eminent domain," a highway agency can acquire private property when the action is deemed to be in the best interests of the public.

35-6.05(c) Engineering

The engineering component of an access management program consists of design criteria that control the number, location, and design of access points along the highway. The engineering components are grouped as follows:

1. Techniques. Access management includes the implementation of specific techniques that can be used individually or in aggregate to address an access problem. See Section 35-7.

2. Overall Design Criteria. Access management includes overall design criteria for the spacing between intersections, spacing between median openings, frequency of driveways, and the number of entrances and exits per property. These criteria are intended to provide the overall management of access along significant lengths of highway and, if the criteria are met, will help to ensure a continuous, high level of serviceability for the facility.

3. Detailed Design. All access elements must be properly designed to fulfill their intended function. For example, if a left-turn lane is installed, it must be sufficiently long to allow for vehicular storage. Driveway entrances should be designed for ease of entering and exiting considering their turning radii or flares, width, profile, etc.

Chapter 36 provides criteria and discusses details related to the spacing of intersections and design of median openings. The IDOT *Policy on Permits for Access Driveways to State Highways,* 92 *Ill. Admin. Code* 550 provides criteria and discusses details related to driveway location, spacing, and design.

35-7 ACCESS MANAGEMENT TECHNIQUES

In general, access management techniques are intended to minimize the frequency and severity of traffic conflicts, particularly at commercial driveway entrances. There are four major objectives for minimizing conflicts and increasing efficiency:

1. Category A — Limit the Number of Conflict Points. These techniques directly reduce the frequency of conflicts or reduce the area of conflict at some or all driveways on the highway by limiting or preventing certain maneuvers.

2. Category B — Separate Basic Conflict Areas. These techniques either reduce the number of driveways or increase the spacing between driveways or between driveways and intersections. They indirectly reduce the frequency of conflicts by separating turning vehicles at adjacent access points and by providing greater decision-making time for the through driver between successive conflicts with vehicles at driveways.

3. Category C — Reduce Deceleration Requirements. These techniques reduce the severity of conflicts by increasing driveway turning speeds or by improving sight distance.

4. Category D — Remove Turning Vehicles From Through Lanes. These techniques reduce both the frequency and severity of conflicts by providing separate lanes and adequate storage areas for turning vehicles.

With a decision to pursue access management on a particular street, many techniques are available from which to select an appropriate solution for a specific access problem. Figure 35-7.A summarizes 36 applicable techniques. Figures 35-7.B through 35-7.I provide sketches to illustrate some of the more common techniques.

Category A — Limit Number of Conflict Points
* A-1: Install raised curb median with left-turn deceleration lanes.
A-2: Install one-way operations on the highway.
A-3: Install traffic signal at high-volume driveways when warranted.
* A-4: Channelize median openings to prevent left-turn ingress and/or egress maneuvers.
A-5: Install physical barrier (curbs, ditches) to prevent uncontrolled access along property frontages.
A-6: Locate driveway opposite a three-leg intersection or driveway and install traffic signals where warranted.
* A-7: Install two two-way driveways with limited turns in lieu of one standard two-way driveway.
* A-8: Install driveway channelizing island to prevent outbound left-turn maneuvers.
A-9: Close certain median openings (raised curb-median used on the street).
* A-10: Provide barrier curb median adjacent to dual left turn lanes and the left turn taper.
Category B — Separate Basic Conflict Areas
B-1: Regulate minimum spacing of driveways.
B-2: Regulate minimum corner clearance.
B-3: Regulate minimum property clearance.
B-4: Regulate maximum number of driveways per property frontage.
* B-5: Consolidate access for adjacent properties.
B-6: Consolidate existing access wherever separate parcels are assembled under one purpose, plan, entity, or usage.
B-7: Encourage access onto a collector street (where available) in lieu of an additional driveway on main highway.

** See accompanying figure.*

ACCESS MANAGEMENT TECHNIQUES

Figure 35-7.A
(1 of 2)

Category C — Reduce Deceleration Requirements

C-1: Install traffic signals where warranted to meter traffic for larger gaps.
C-2: Time traffic signals to platoon traffic queues to create larger gaps.
C-3: Install visual cues (signing) at the driveway entrance.
C-4: Improve driveway sight distance.
C-5: Regulate minimum sight distance.
C-6: Optimize sight distance in the permit authorization stage.
C-7: Move sidewalk-driveway crossing laterally away from highway.

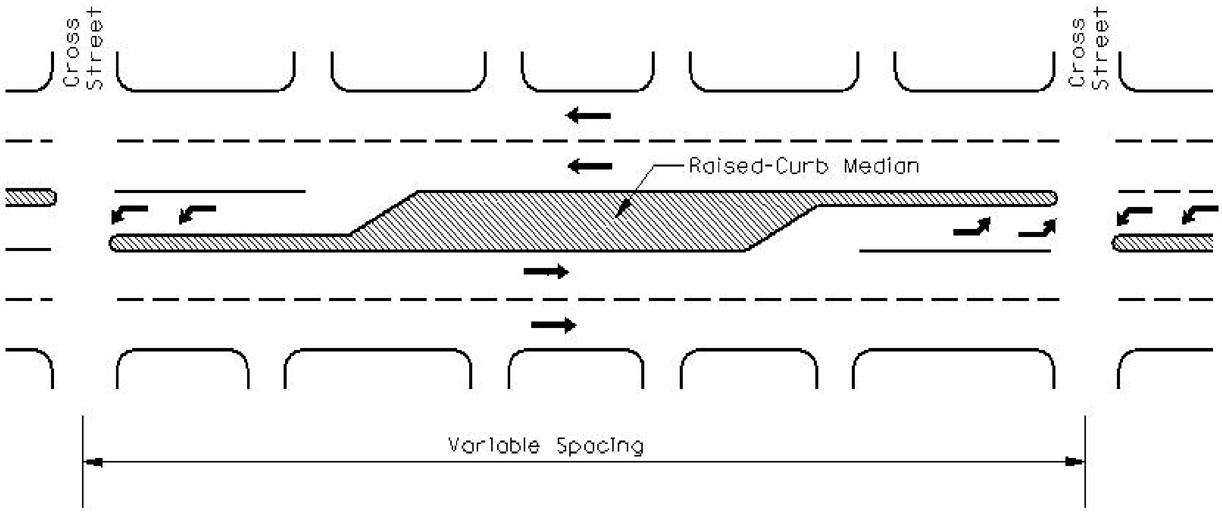
Category D — Remove Turning Vehicles From the Through Lanes

D-1: Install two-way left-turn lane.
* D-2: Install alternating left-turn lanes.
* D-3: Install left-turn deceleration lane in existing median.
D-4: Increase storage capacity of existing left-turn deceleration lane.
D-5: Install continuous right-turn lane.
D-6: Construct a local frontage road or service drive.
D-7: Install additional driveway when total driveway demand exceeds capacity.
D-8: Install right-turn deceleration lane.
D-9: Install additional exit lane on driveway.
D-10: Encourage connections between adjacent properties.
D-11: Encourage adequate internal design with circulation plan.
D-12: Provide a one-way frontage road.

* *See accompanying figure.*

ACCESS MANAGEMENT TECHNIQUES

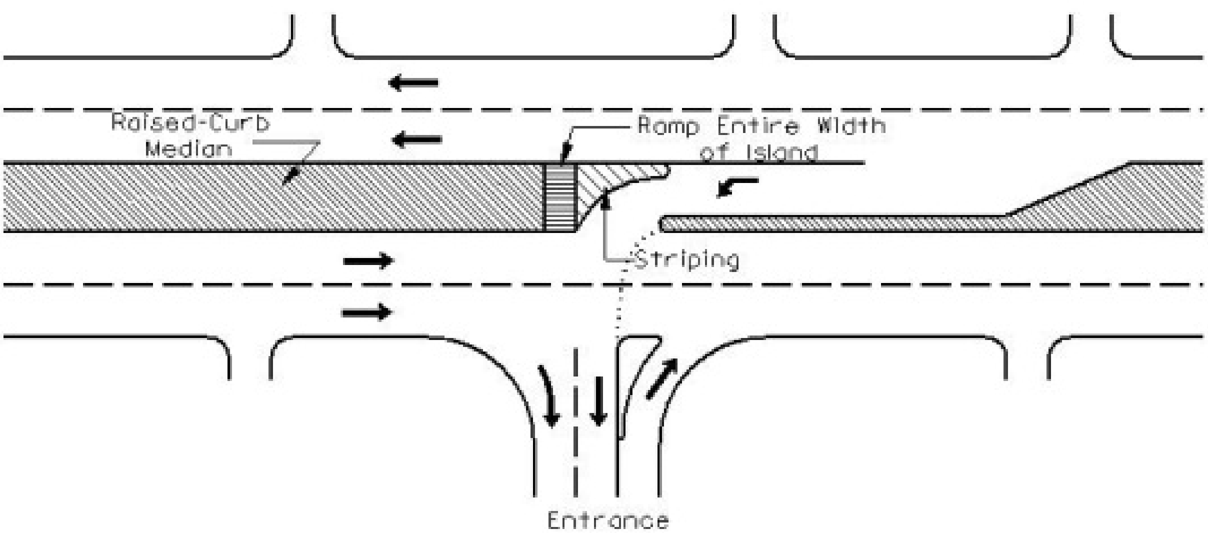
Figure 35-7.A
(2 of 2)



- Direct left turns prevented at all but major streets or major entrances.
- Desirable spacing between median openings is 660 ft (200 m) to 1320 ft (400 m)

A-1: INSTALL RAISED-CURB MEDIAN
(With Left-Turn Lanes)

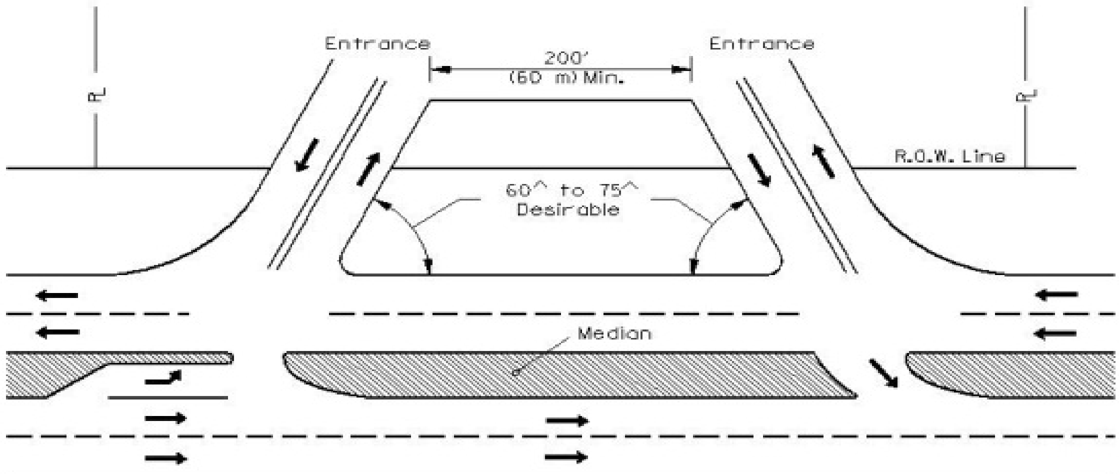
Figure 35-7.B



- Elimination of left-turn egress shown.
- Used on high-volume divided arterials where prevented left-turn volume from the entrance is relatively low.

A-4: CHANNELIZE MEDIAN OPENINGS

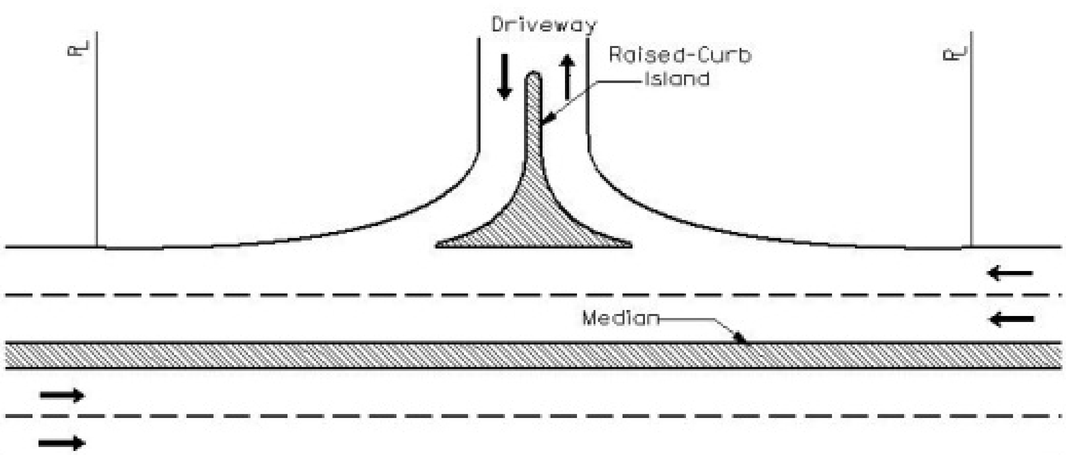
Figure 35-7.C



- Used where good internal circulation is available on property and frontage is relatively long.
- Reduces the frequency of conflicts at a single property.

A-7: INSTALL TWO TWO-WAY DRIVEWAYS
(With Limited Turns)

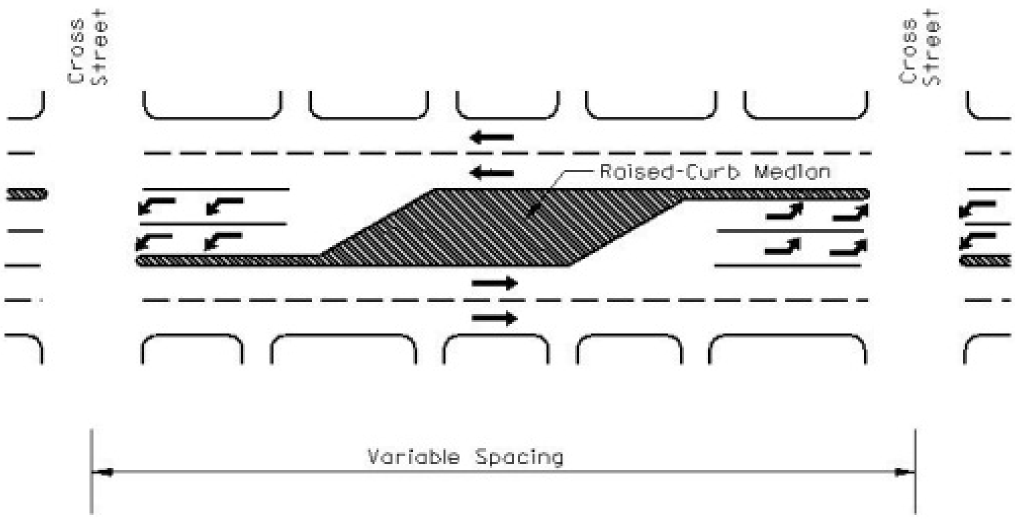
Figure 35-7.D



- Used on highway with medians in conjunction with major two-way driveways with low left-turn egress movements.
- Reduces conflict points from 9 to 2.

A-8: INSTALL DRIVEWAY CHANNELIZING ISLAND
(To Prevent Left-Turn Maneuvers)

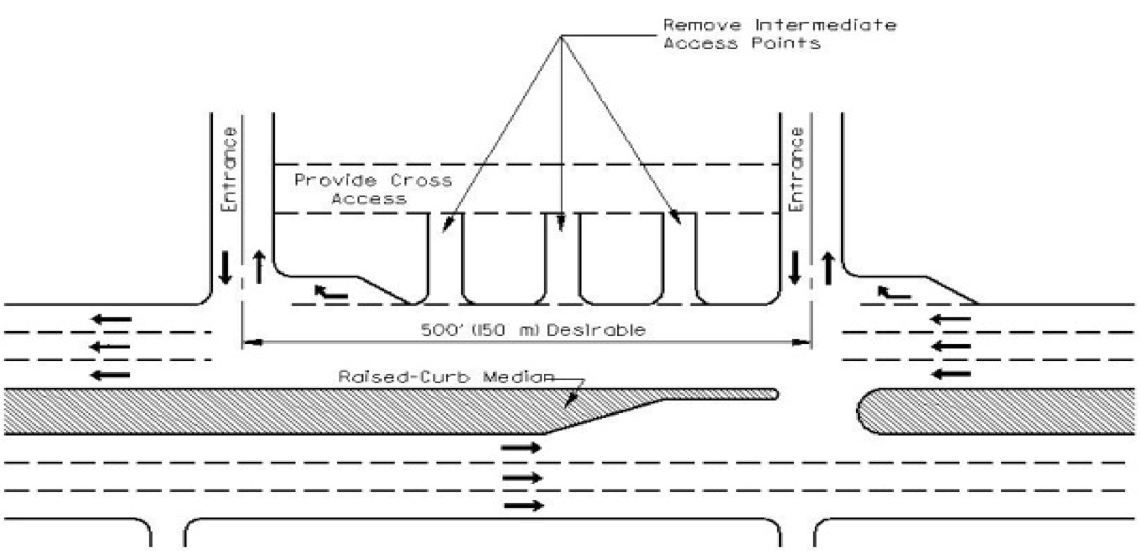
Figure 35-7.E



- Used to limit movements at access points near high-activity intersections

A-10: INSTALL BARRIER CURB MEDIAN
(With Dual Left-turn Lanes)

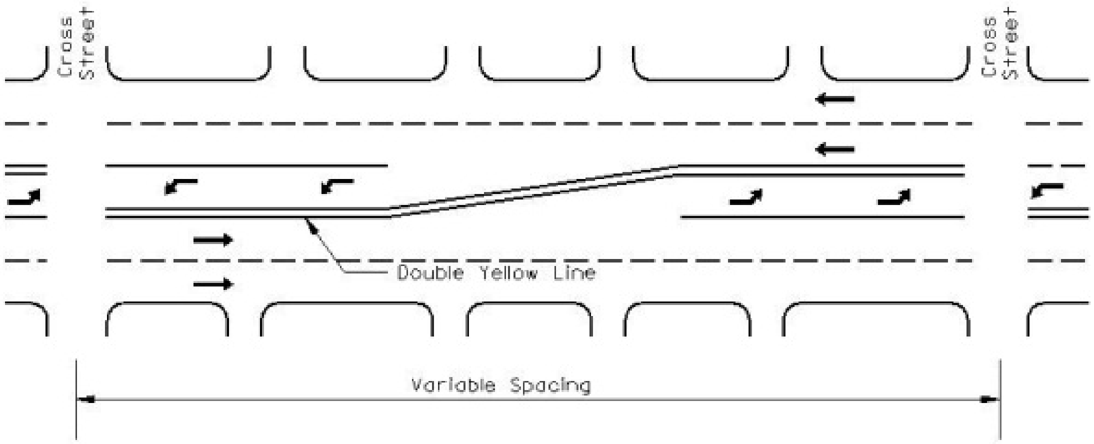
Figure 35-7.F



- Used where adjacent properties have continous parking lots.
- Used when separate parcels are assembled under one entity or usage.

B-5: CONSOLIDATE ACCESS FOR ADJACENT PROPERTIES

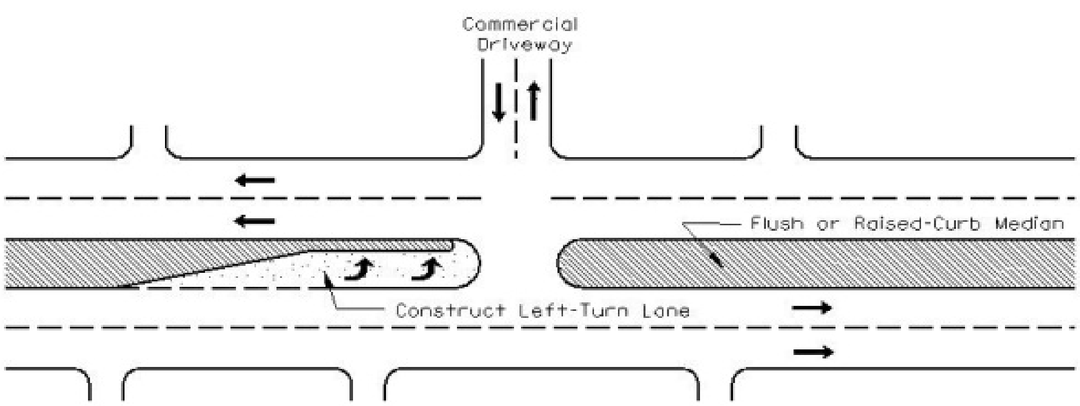
Figure 37-7.G



- Used in low-speed urbanized areas where right-of-way is restricted and left-turn demand into entrances is light.
- Usual spacing between cross streets is 450 ft (140m) to 650 ft (200m).

D-2: INSTALL ALTERNATING LEFT-TURN LANES

Figure 37-7.H



- Mainly used where median opening provides left-turn access into a commercial driveway.
- Reduces frequency of rear-end conflicts.

Chapter Thirty-six
INTERSECTIONS

Intersections are an important part of the highway system. The operational efficiency, capacity, safety, and cost of the overall system are largely dependent upon its design, especially in urban areas. The primary objective of intersection design is to provide for the convenience, ease, comfort, and safety of those traversing the intersection while reducing potential conflicts between vehicles, bicycles, and pedestrians. Chapter 36 provides guidance in the design of intersections including alignment, profile, design vehicles, turning radii, right-turning roadways, left- and right-turn lanes, intersection sight distance, channelized islands, and intersections near railroads. Information that is also applicable to intersections is included in the following Chapters:

- Guidelines for preparing and processing intersection design studies are discussed in Chapter 14.
- Application of bicycle and pedestrian accommodations through intersections is discussed in Chapter 17.
- The various curb types used for channelization, islands, and medians are discussed in Chapter 34.
- Selection of median widths at intersections is discussed in Chapter 34.
- Access management near intersections is discussed in Chapter 35.
- Guidance pertaining to intersections on Strategic Regional Arterials (SRA's) is discussed in Chapter 46.
- Two-way left-turn lanes are discussed in Chapter 48.
- Criteria for intersections on 3R projects are discussed in Chapter 49.
- The warrants and design criteria for intersection lighting are discussed in Chapter 56.
- Guidance on intersection traffic control devices, including striping, signing, and traffic signals is discussed in Chapter 57.
- Accessibility at intersections for persons with disabilities, including the design of compliant curb ramps, crosswalks, and roadway approach grades is discussed in Chapter 58.

36-1 GENERAL DESIGN CONTROLS

36-1.01 General Design Considerations

In every intersection design, there are many conflicting requirements that must be balanced against each other to produce a safe and efficient design. The five basic elements that must be taken into consideration include:

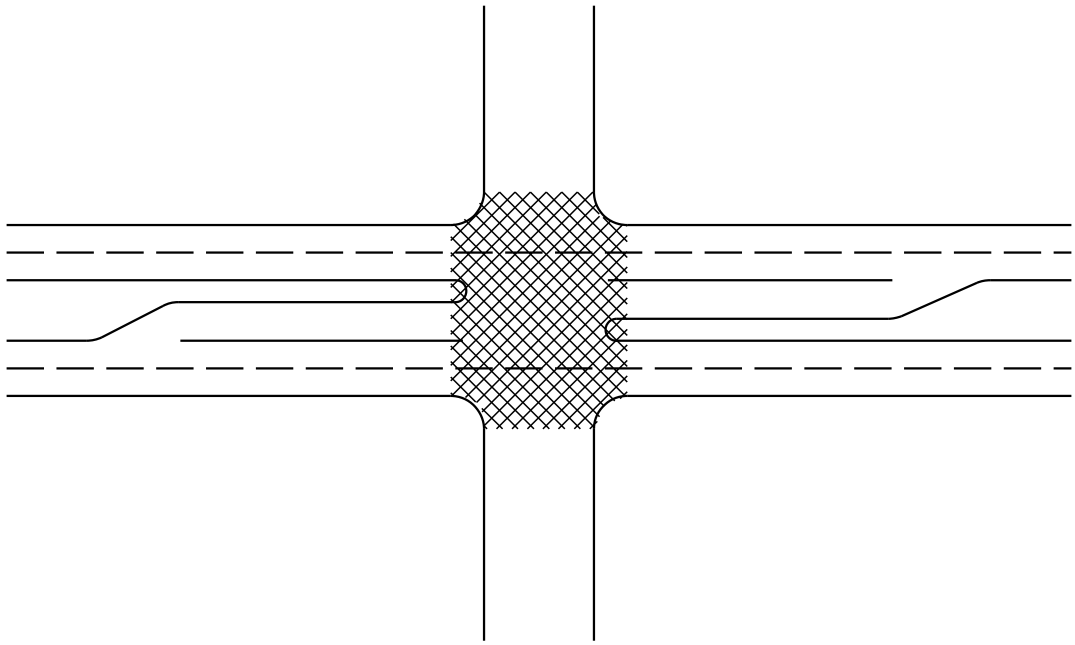
1. Human Factors. These include:
    - driving habits,
    - ability to make decisions,
    - driver expectancy,
    - decision and reaction time,
    - conformance to natural paths of movement, and
    - pedestrian use and habits.
2. Traffic Considerations. These include:
    - capacity,
    - DHV,
    - vehicular composition,
    - turning movements,
    - vehicular speeds (design and operating), and
    - safety.
3. Physical Elements. These include:
    - character and line of abutting property,
    - topography,
    - right-of-way,
    - horizontal alignment,
    - vertical alignment,
    - coordination of vertical profiles of the intersecting roads,
    - coordination of horizontal and vertical alignment for intersections on curves,
    - available sight distance,
    - intersection angle,
    - conflict area,
    - geometrics,
    - channelization,
    - traffic control devices,
    - lighting,
    - safety features,
    - bicycle traffic,
    - environmental impact, and
    - drainage requirements.

4. Economic Factors. These include:

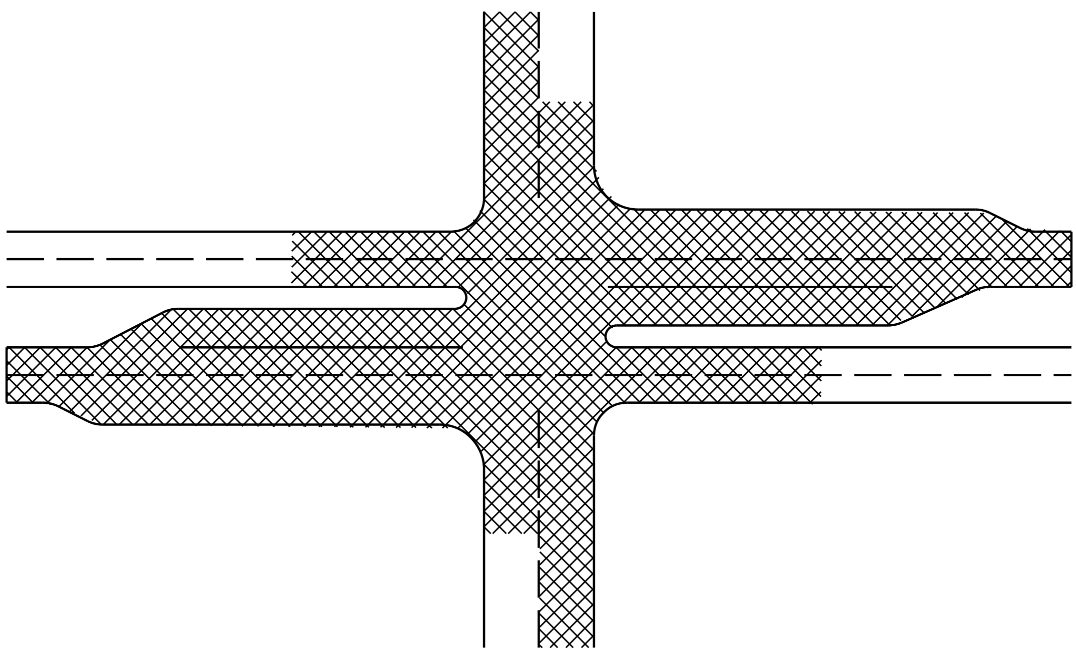
- cost of improvements;
- crash history;
- effects on adjacent property (e.g., access to businesses); and
- impact on energy.

5. Functional Intersection Area. An intersection can be defined by both functional and physical areas. These are illustrated in Figure 36-1.A. The functional area of the intersection extends both upstream and downstream from the physical intersection area and includes any auxiliary lanes and their associated channelization.

The essence of good intersection design requires that the physical elements be designed to minimize the potential conflicts among cars, trucks, buses, bicycles, and pedestrians. In addition, human factors of the drivers and pedestrians must be taken into account while keeping costs and impacts to a minimum.



PHYSICAL AREA



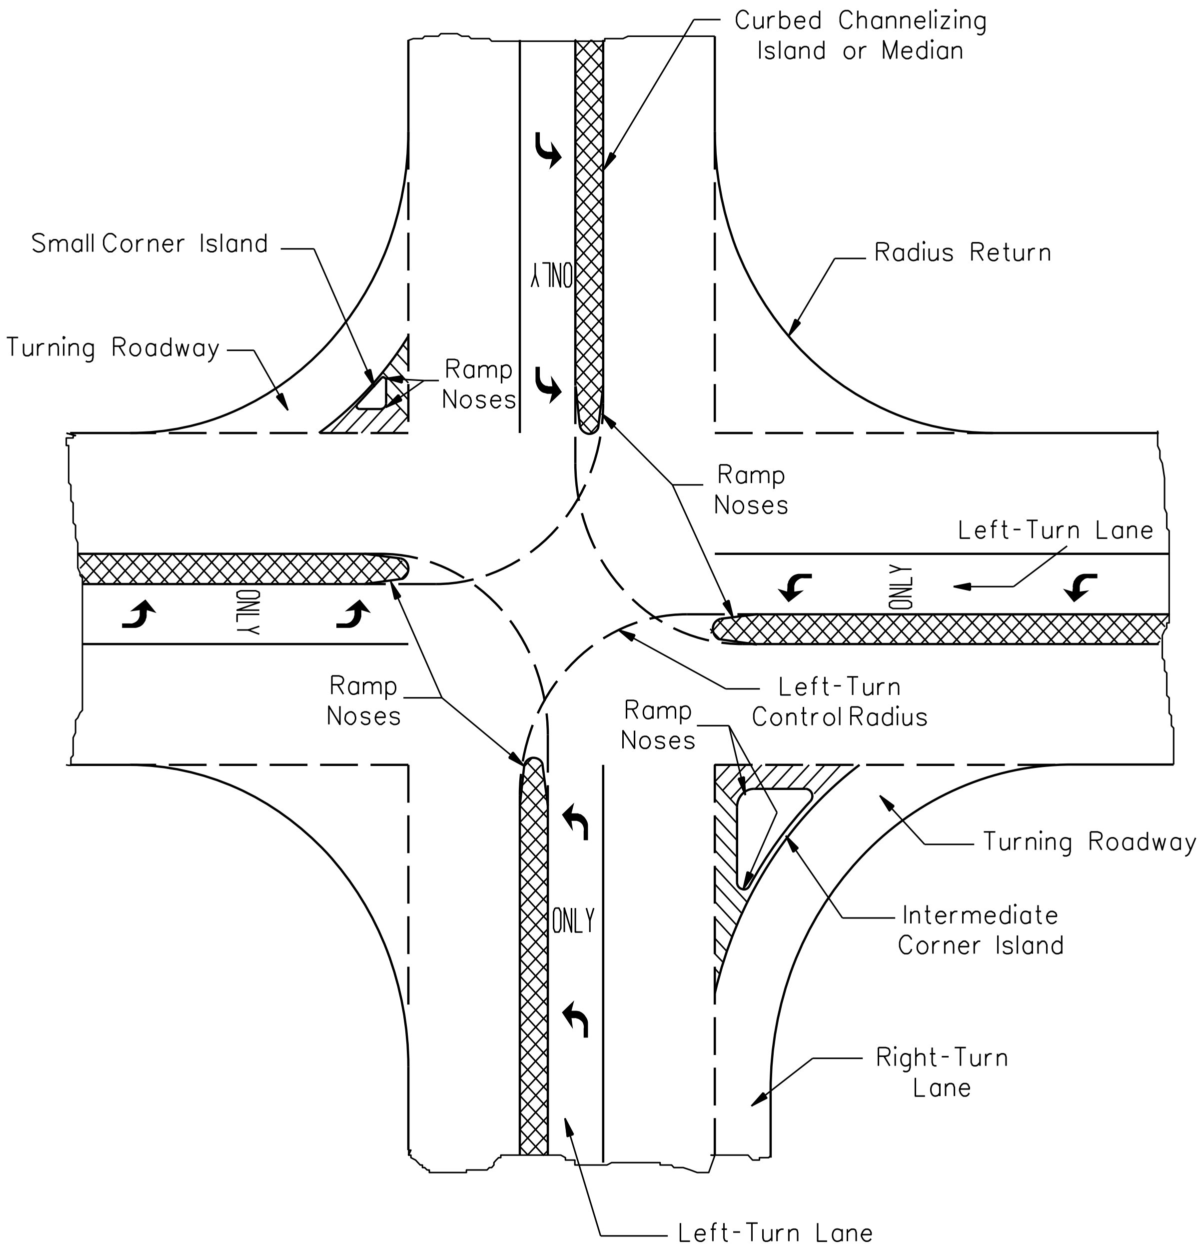
FUNCTIONAL INTERSECTION AREA

PHYSICAL AND FUNCTIONAL INTERSECTION AREA

Figure 36-1.A

36-1.02 Intersection Components

Figure 36-1.B illustrates several of the components that may be included in a typical intersection.



TYPICAL INTERSECTION COMPONENTS

Figure 36-1.B

36-1.03 Intersection Types

36-1.03(a) General

Intersections are usually a three-leg, four-leg, or multi-leg design. Individual intersections may vary in size and shape and may be channelized. The principal design factors that affect the selection of intersection type and its design characteristics are discussed in Section 36-1.01. Selection of the intersection type will be determined on a case-by-case basis.

Multi-leg intersections are those with five or more intersection legs. Where volumes are light and stop control is used, it may be satisfactory to have all intersection legs intersect at a common, all-paved area. At other than minor intersections, safety and efficiency are improved by rearrangements that remove some conflicting movements from the major intersection. This may be accomplished by realigning one or more of the intersecting legs and combining some traffic movements at adjacent subsidiary intersections or, in some cases, making one or more legs one-way departing from the intersection. Wherever practical, avoid using multi-leg intersections.

36-1.03(b) Alternative Intersection Designs

Some nontraditional designs may offer substantial advantages under certain conditions compared to corresponding conventional at-grade intersections or grade-separated diamond interchanges. The most commonly considered design options include:The FHWA publication entitled, *Alternative Intersections/Interchanges: Information Report (AIIR)*, which can be found on the FHWA website, addresses geometric design features, operational and safety issues, access management, costs, construction sequencing, environmental benefits, and applicability for alternative intersections. The *Report* provides guidance on the following alternative designs that may provide a unique solution to special situation

- displaced left-turn (DLT) intersection, also known as continuous flow intersection (CFI),
- median U-turn intersection (MUT),
- quadrant roadway intersection (QR),
- restricted crossing U-turn intersection (RCUT), also known as a J-turn or Superstreet,
- continuous green T intersection (CGT)
- double crossover diamond (DCD) interchange, also known as diverging diamond interchange (DDI), and
- displaced left-turn (DLT) interchange.

Section 36-9 provides planning guidance for alternative intersections. Intersection Control Evaluation (ICE) is a means to identify, evaluate, and document intersection alternatives to identify optimal geometric and control solutions.

Section 36-11 provides design guidance for RCUT, MUT, DLT and CGT intersections. Section 37-3.10 describes opportunities and design considerations for DDIs. Highway Capacity Software (HCS) now addresses the capacity of many of these alternative intersection types, in addition to more traditional intersection types; see Section 36-1.07.

Designers may also reference the FHWA publication entitled, *Alternative Intersections/Interchanges: Information Report (AIIR)*, which can be found on the FHWA website.

Some potentially useful information is presented on geometric design features, operational and safety issues, access management, costs, construction sequencing, and environmental benefits.

36-1.04 Intersection Spacing

Spacing for unsignalized intersections and driveways will depend on the available stopping sight distance, intersection sight distance, traffic volumes, turning volumes, the addition of turn lanes, turning speeds, access control, and local development. The actual spacing will be determined on a case-by-case basis.

When introducing a new intersection, the designer must ensure that there is sufficient distance between the new and adjacent intersections so that they form distinct intersections. Avoid short distances between intersections, if practical, because they may impede traffic operations. For example, if two intersections are close together, they must be considered as one intersection for signal phasing purposes. To operate safely, each leg of the intersection may require a separate green phase; however, this may reduce the capacity for both intersections.

The need to efficiently move high volumes of traffic, especially during peak periods, is a major consideration in the spacing of signalized intersections. It is important that the signals be synchronized to efficiently move traffic. Figure 36-1.C illustrates the relationship between speed of progression, cycle length, and signalized intersection spacing.

36-1.05 Intersection Alignment

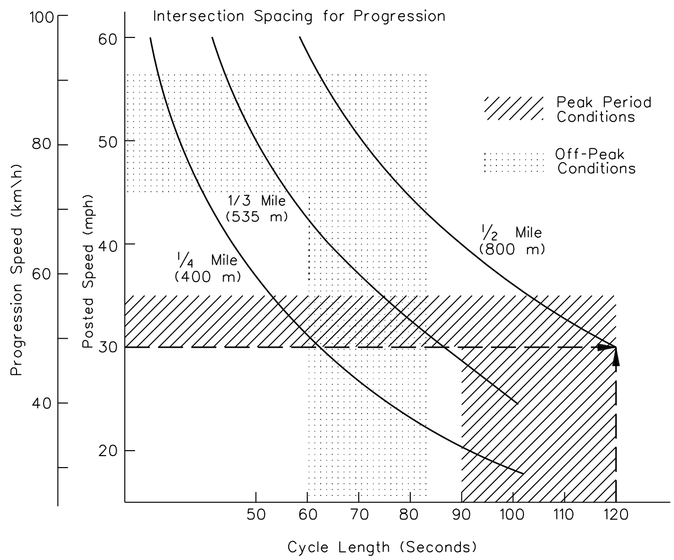
36-1.05(a) Angled Intersections

Highways should intersect at right angles. Intersections at acute angles are undesirable because they:

- restrict vehicular turning movements,
- require additional pavement and channelization for large trucks,
- increase the exposure time for vehicles and pedestrians crossing the main traffic flow, and
- restrict the crossroad sight distance.

Preferably, the angle of intersection should be within 15 degrees of perpendicular. This amount of skew can often be tolerated because the impact on sight lines and turning movements is not significant. Under restricted conditions where obtaining the right-of-way to straighten the angle of intersection would be impractical, an intersection angle up to 30 degrees from perpendicular may be retained for existing intersections, where historical crash data corroborates this decision. Where turning movements are significantly unbalanced, the intersections may be angled to favor the predominant movement. Intersection angles beyond these ranges may warrant more positive traffic control (e.g., all stop, traffic signals) or geometric improvements (e.g., realignment, greater corner sight distance).

Figure 36-1.D illustrates various angles of intersections and potential improvements to the alignment. Avoid using short-radius curves or unnatural travel paths near the intersection simply to reduce the intersection skew.



US Customary							
Cycle Length (sec)	Posted Speed (mph)						
	25	30	35	40	45	50	55
	Intersection Spacing for Progression (2)						
60	1,100 ft	1,320 ft	1,540 ft	1,760 ft	1,980 ft	2,200 ft	2,430 ft
70	1,280 ft	1,540 ft	1,800 ft	2,050 ft	2,310 ft	2,500 ft	2,640 ft
80	1,470 ft	1,760 ft	2,050 ft	2,350 ft	2,640 ft	2,640 ft	2,640 ft
90	1,630 ft	1,980 ft	2,310 ft	2,640 ft	2,640 ft	2,640 ft	2,640 ft
120	2,200 ft	2,640 ft	2,640 ft	2,640 ft	2,640 ft	2,640 ft	2,640 ft
150(1)	2,640 ft	2,640 ft	2,640 ft	2,640 ft	2,640 ft	2,640 ft	2,640 ft

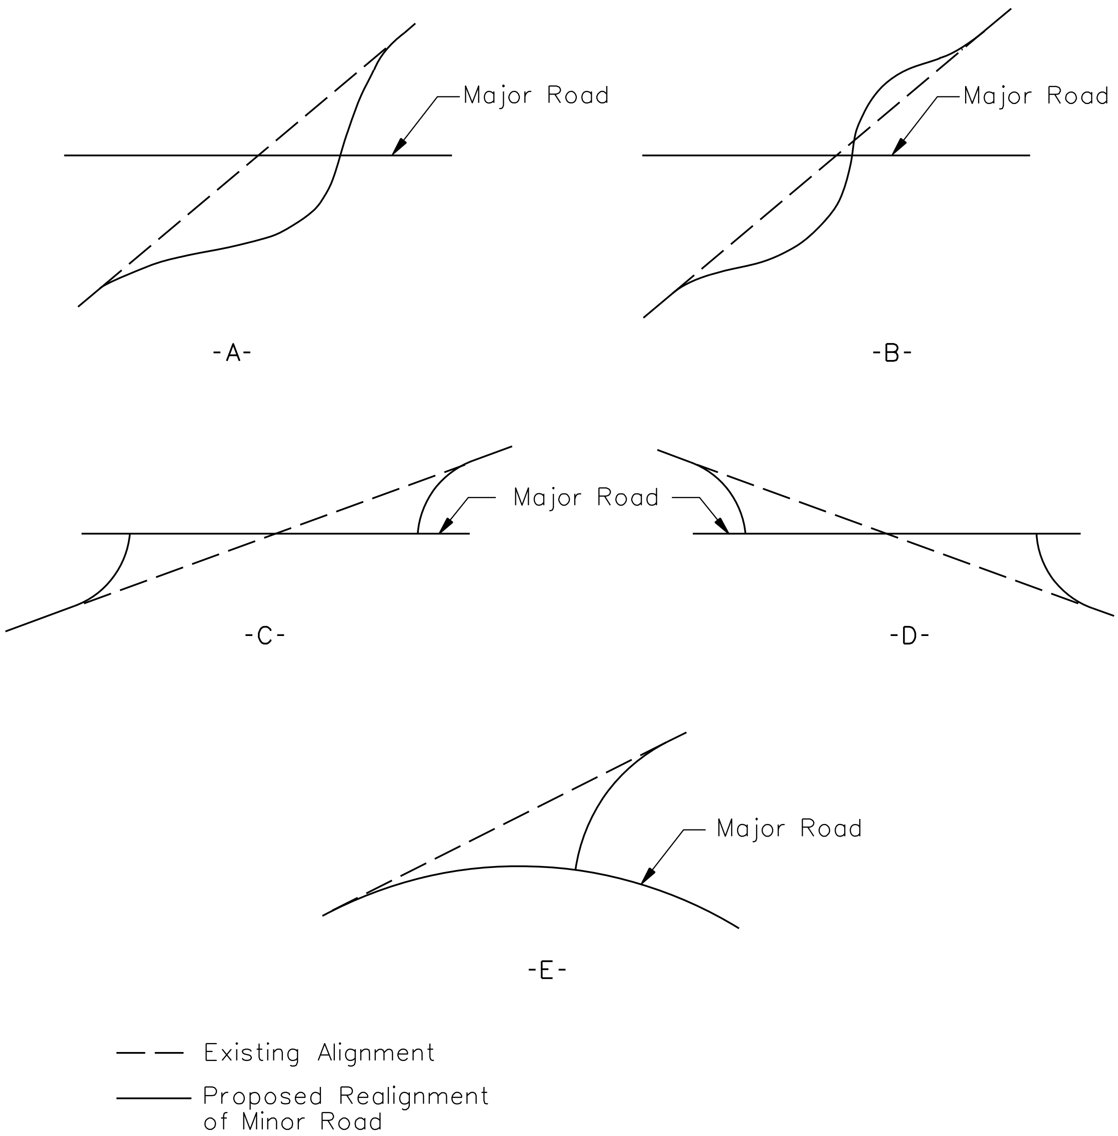
Metric							
Cycle Length (sec)	Posted Speed (mph)						
	25	30	35	40	45	50	55
	Intersection Spacing for Progression (2)						
60	335 m	400 m	470 m	535 m	605 m	670 m	730 m
70	390 m	470 m	550 m	625 m	705 m	760 m	800 m
80	450 m	535 m	625 m	715 m	800 m	800 m	800 m
90	495 m	605 m	705 m	800 m	800 m	800 m	800 m
120	670 m	800 m	800 m	800 m	800 m	800 m	800 m
150(1)	800 m	800 m	800 m	800 m	800 m	800 m	800 m

Notes:

1. *Represents maximum cycle length for actuated signal if all phases are used.*
2. *From a practical standpoint when considering progression, the distance between signalized intersections will usually be 2640 ft (800 m) or less. Therefore, the values in the table have been limited to 2640 ft (800 m)*

SIGNALIZED INTERSECTION SPACING GUIDELINES

FIGURE 36-1.C



Notes:

1. *Where there are high volumes of left turns from the major road, avoid using the offset intersection alignment illustrated in "C."*

2. *Revised alignments "C" and "D" are not desirable in agricultural areas with large numbers of farm vehicles crossing the major road.*

REALIGNMENT OF INTERSECTIONS

Figure 36-1.D

36-1.05(b) <u>Intersections on Curves</u>

Preferably, all legs of an intersection should be on a tangent section. Where a minor road intersects a major road on a horizontal curve, the geometric design of the intersection becomes significantly more complicated, particularly for sight distance, turning movements, channelization, and superelevation. The following guidelines address horizontal alignment at intersections:

1. <u>Realignment</u>. If relocation of the intersection is not practical, the designer may be able to realign the minor road to intersect the major road perpendicular to a tangent on the horizontal curve; see example "E" in Figure 36-1.D. Although an improvement, this arrangement may still result in difficult turning movements due to superelevation on the major road.

2. <u>Superelevated Mainline</u>. If the mainline is on a horizontal curve, the mainline superelevation rate must be minimized so that slowing or stopped vehicles do not slide across the pavement during wet or icy conditions. Figure 36-1.E provides the criteria for the maximum superelevation rate and rollover criteria that should be used where an important crossroad intersects a superelevated State highway. An important crossroad may be a marked highway, county highway, township road, or town street.

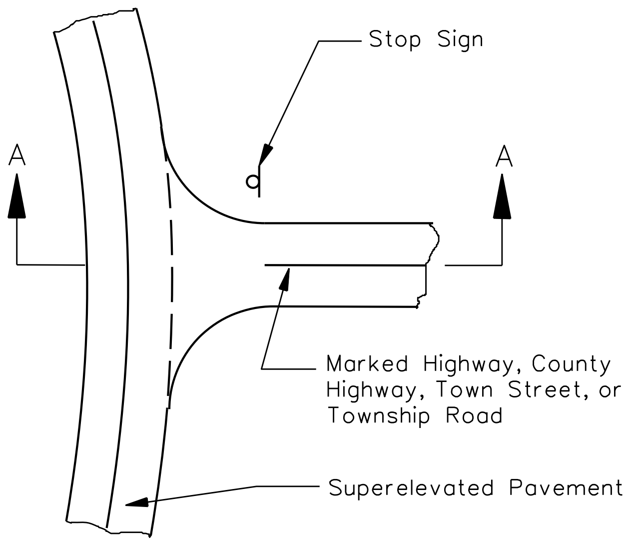
3. <u>Curved Approach</u>. Where a State highway or local road is on a curved alignment and is approaching a stop condition, special consideration is required in the design of the horizontal curvature prior to the intersection. This condition is illustrated in Figure 36-1.F. When designing this type of an approach, consider the following guidelines:

    - To design the horizontal curve, assume a design speed 20 mph (30 km/hr) less than the approach speed, but not less than 30 mph (50 km/hr) for design speeds less than or equal to 50 mph (80 km/hr).

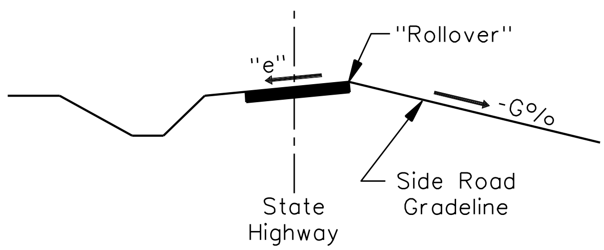
    - The superelevation rate on the approach curve to an intersection should be limited to a maximum superelevation rate of 5% or less. The objective is to use as flat an alignment as practical with lower superelevation. The preferred design is to maintain a normal crown section through the curve assuming Method 2 distribution of superelevation. The minimum radius should not be less than that permitted for the highway classification. For additional guidance on horizontal curve designs; see Chapter 32.

    - Provide a short tangent section prior to the intersection. This will allow for the superelevation runoff to be developed outside of the intersection radius returns.

    This procedure recognizes the need to accommodate a reasonable operating speed on a stop-controlled approach, while minimizing the potential for adverse operations on superelevated pavements during snow and ice conditions. Where the curved road is a local facility, design the curvature using the Bureau of Local Roads and Streets' criteria. With the local roads criteria, the design is dependent on ADT and, in many cases due to the low ADT, the local facility can be designed with a normal crown section.



PLAN VIEW

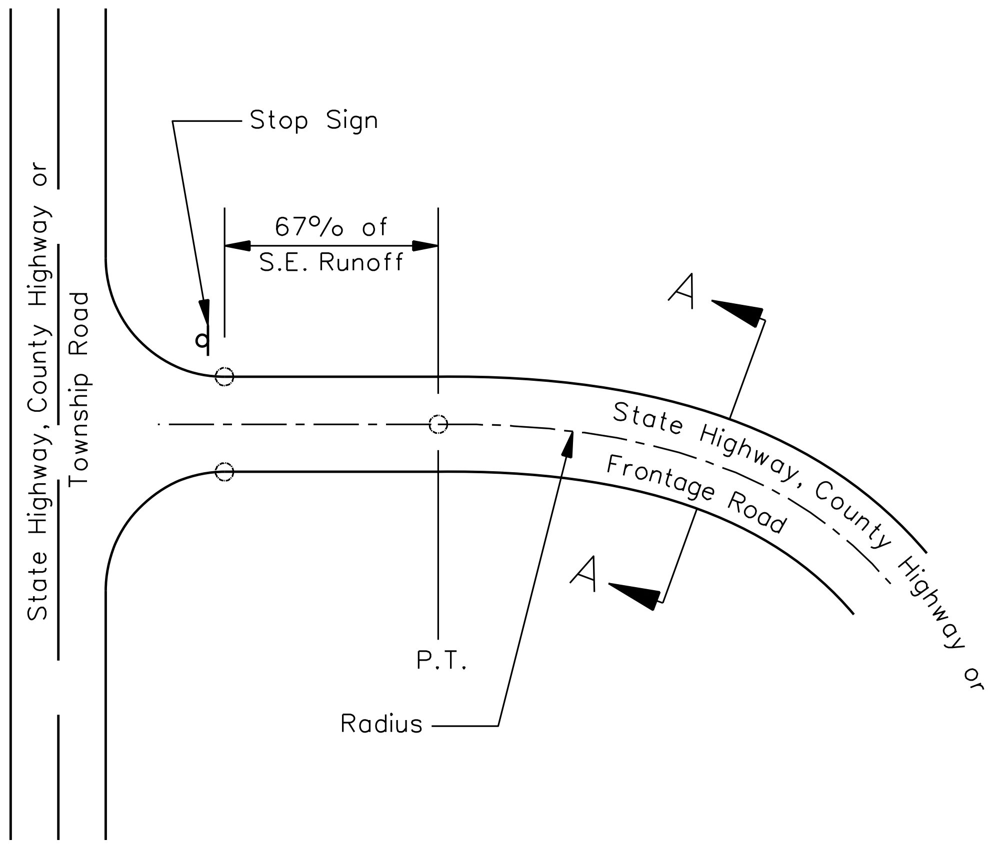


CROSS SECTION A-A

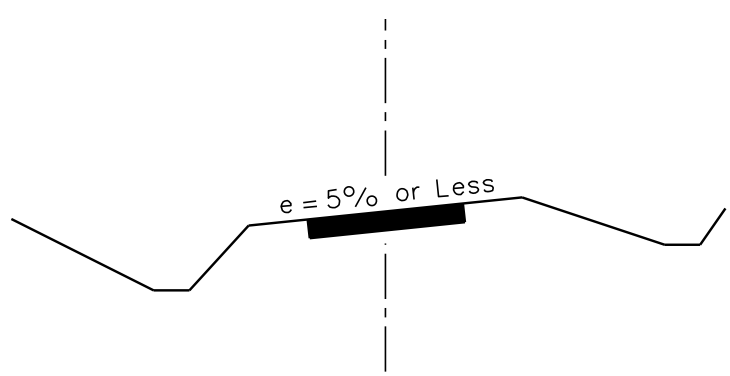
Type of Improvement Category	Maximum Superelevation Rate "e" for Intersections on Curve	Rollover Guidelines
"New Construction" at an important crossroad	4% Desirable Maximum	5% Desirable Maximum 6% Maximum
To remain in place with "Reconstruction" at an important crossroad	6% Maximum	7% Desirable Maximum 8% Maximum
To remain in place with "Reconstruction" at a minor crossroad	8% Maximum	9% Desirable Maximum 10% Maximum

INTERSECTION WITH SUPERELEVATED MAINLINE

Figure 36-1.E



PLAN VIEW



CROSS SECTION A-A

INTERSECTION WITH SUPERELEVATED SIDE ROAD

Figure 36-1.F

4. Frontage Road Approach. Where a stop-controlled frontage road approaches a grade separated crossroad, the typical curved alignment may be replaced with a “buttonhook” design to minimize impacts and land acquisition; see Figure 36-1.G. This layout is especially suited to those cases where turning traffic between the frontage road and crossroad is light compared to the through traffic on the frontage road.

36-1.05(c) Offset Intersections

In general, 4-leg intersections should be designed such that opposing approaches line up with each other (i.e., there is no offset between opposing approaches). However, this is not always practical. Figure 36-1.H presents a diagram of an intersection with an offset between opposing approaches. Because of possible conflicts with overlapping turning vehicles, offset intersections should only be allowed to remain on low-volume approaches. The following criteria will apply for offset intersection approaches:

1. Maximum Offset. The maximum offset is determined from the application of a taper equal to V:1 (0.6V:1) applied to the intersection width, where V is the design speed in miles per hour (kilometers per hour); see Figure 36-1.H. In restricted locations and where V ≤ 45 mph (70 km/hr), the applied taper may be $V^2/60$ ($V^2/155$). V is selected as follows:

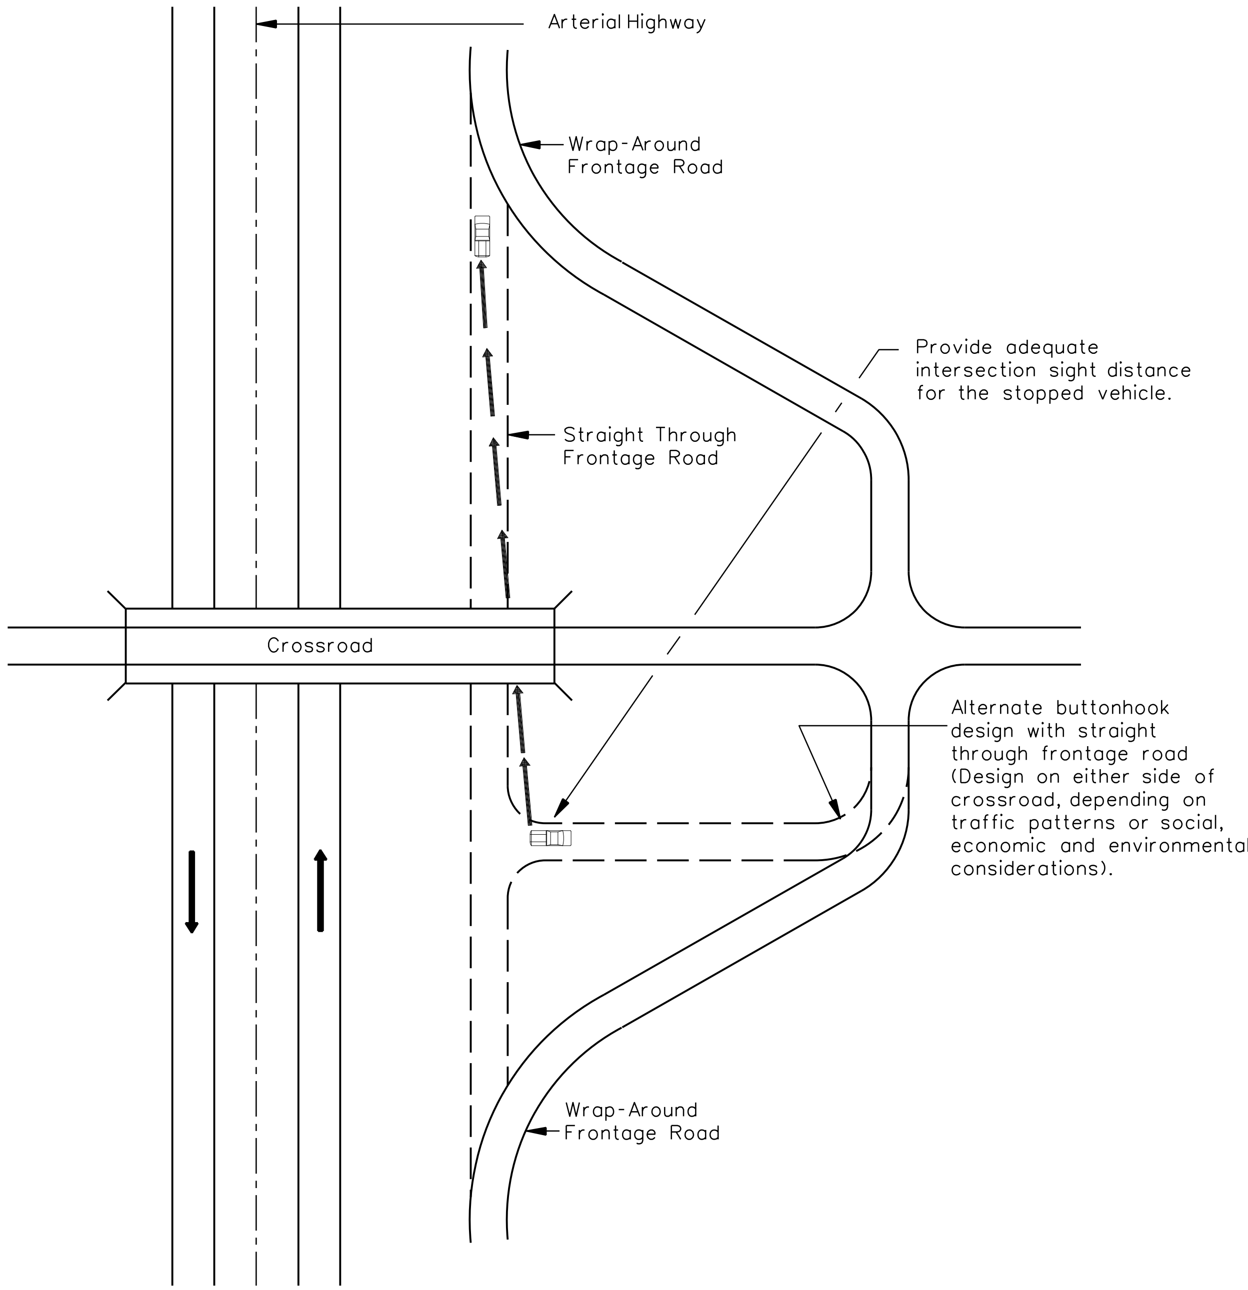
    - V = 20 mph (30 km/hr) for stop-controlled approaches.
    - V = the roadway design speed for the free-flowing approaches at a stop-controlled intersection.
    - V = the roadway design speed for the offset approaches at a signalized intersection.

2. Turning Conflicts. Evaluate the entire intersection for conflicts that may result from turning vehicles at an offset intersection. For example, offsets where the “jog” is to the left may result in significant interference between simultaneous left-turning vehicles.

3. Evaluation Factors. In addition to potential vehicular conflicts, the designer should evaluate the following at existing or proposed offset intersections:

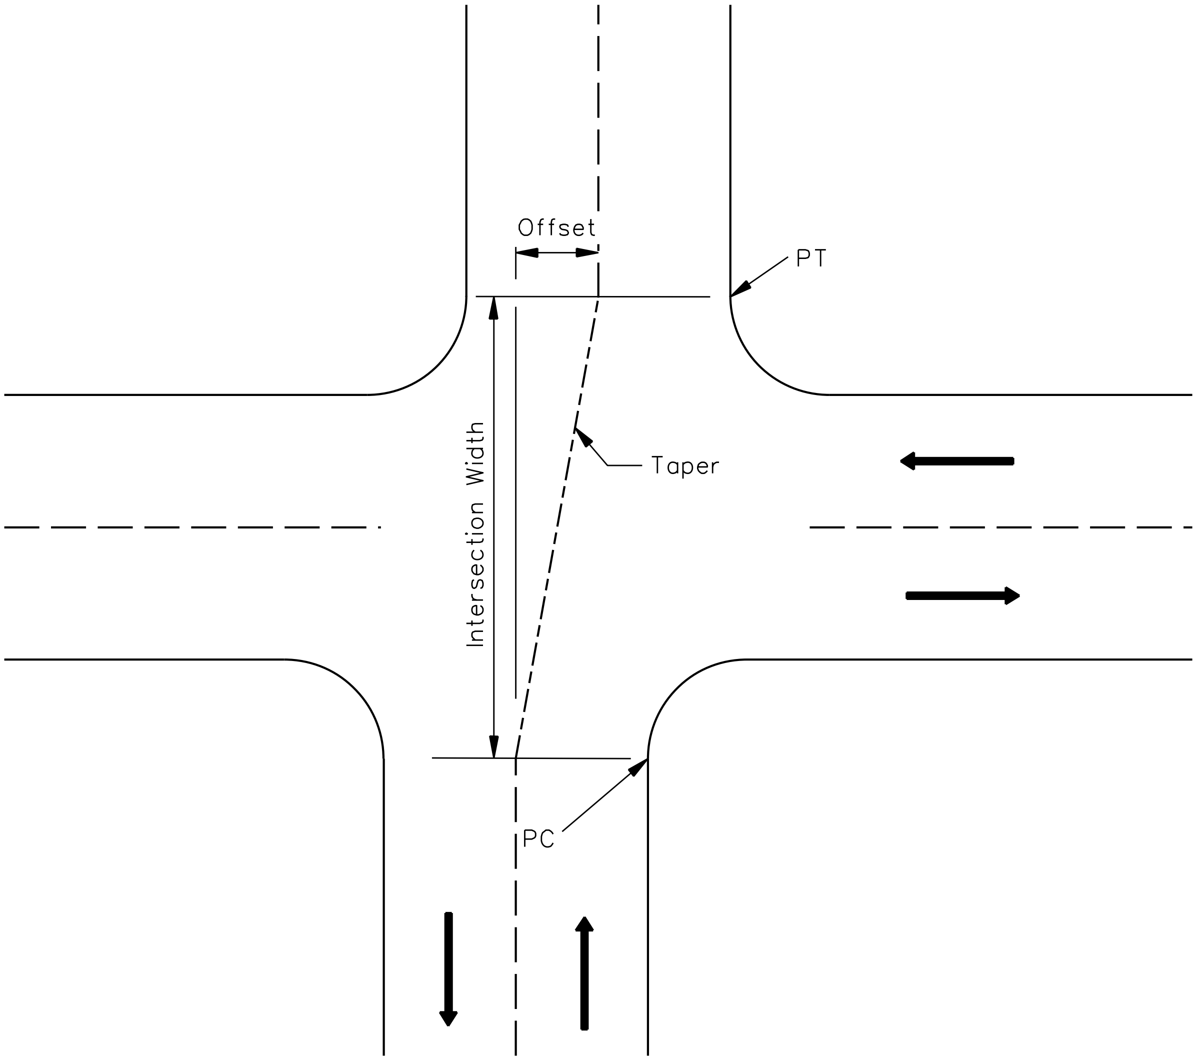
    - through and turning volumes;
    - type of traffic control;
    - impact on all turning maneuvers;
    - intersection geometrics (e.g., sight distance, curb/pavement edge radii); and
    - crash history at existing intersections.

Where existing offset intersections are being considered to remain, the designer should coordinate the intersection design and traffic control requirements with BDE and the district Bureau of Operations.



ALTERNATIVE FRONTAGE ROAD INTERSECTION
(Buttonhook Design)

Figure 36-1.G



Notes:

1. *Desirable taper rate is V:1 (0.6V:1), where V = design speed in mph (km/hr).*
2. *See discussion in Section 36-1.05(c) for more information.*

OFFSET INTERSECTION

Figure 36-1.H

36-1.06 Profiles

Many drivers are unable to judge the effect of substantial profile grades on stopping and accelerating distances. Their normal deductions and reactions may thus be in error at a critical time. The design should avoid combinations of grade lines that make vehicular control difficult at intersections. To accomplish this, consider the profile for all roadway approaches to and through the intersection. The following criteria will apply.

36-1.06(a) Approach Gradients

The profile gradients of intersecting highways should be as flat as practical on those intersection approaches that will be used for storage of stopped vehicles and the crossing of pedestrians. This area is commonly referred to as the storage space or storage platform.

The designer shall consider the following in the design of intersection approach gradients:

1. State Highways. On the mainline highway, the storage platform gradient should be a minimum of 1% and a maximum of 2%, which will optimize operations for motorists and bicyclists and ensure both compliance with ADA standards (see Chapter 58 for information on Accessibility Standards) and proper roadway drainage.

   On important side roads (e.g., other state highway, county highway, local arterial) approaching the state highway, the storage platform gradient should be a minimum of 1% and a maximum of 2% draining away from the mainline highway. Maintain this gradient through the expected storage distance on that leg. At a minimum, provide the storage platform gradient on the side road for a distance of 50 ft to 100 ft (15 m to 30 m) beyond the edge of the mainline traveled way or to the ditch line of an arterial highway. Again, the selection of grades 2% or less will optimize operations for motorists and bicyclists and ensure compliance with ADA standards.

   For new intersection construction projects where pedestrians are a design user of the facility, compliance with accessibility standards is mandatory. For new construction/reconstruction projects involving intersections, intersection gradients complying with ADA criteria should be initially designed and constructed regardless of existing pedestrian presence. Should pedestrian accommodations be added along the facility in the future, applying this approach will ensure ADA compliance can be met without the need for costly intersection reconstruction.

   For existing locations within roadway improvement project limits, intersection gradients greater than 2% may necessitate geometric modifications to the roadway profile to meet accessibility standards, when either marked or unmarked crosswalks exist or are proposed. Sections 58-1.09 and 58-1.10 describe crosswalk cross-slope requirements based on whether or not there is “yield or stop control” for approaching vehicle traffic, and how this can affect roadway approach gradients. Where pedestrians are not a design user of the facility, intersection gradients greater than 3% will require correction of certain design factors (e.g., stopping sight distances, deceleration lengths, traffic signal timing) to produce operating conditions as equivalent as practicable to those on level highways.

Any gradient through an intersection must reflect the practicalities of matching the basic profiles of the intersecting roadways and shoulders. When desirable intersection approach gradients, as discussed above, cannot be achieved due to terrain, right-of-way, or other important concerns on any project defined as an alteration of the facility, see Section 58-1.01, a design exception and/or a request for a maximum extent practicable determination (MEP) may be necessary; see Chapter 31.

2. Local Roads and Streets. For local collectors, local roads or streets, and entrances to the mainline highway, provide a profile that will drain away from the mainline highway. Where a local facility (e.g., township road, county roadway, low-volume town street) intersects a State highway on a tangent section, the side-road storage platform gradient may be a maximum of 4% draining away from the State highway, unless a marked or unmarked crosswalk exists or is proposed across the storage platform of the facility. For these locations, approach gradients steeper than 2% may necessitate geometric modifications to the roadway profile to meet accessibility standards; see Section 58-1.09.

3. Intersection Rollover. The algebraic difference between mainline highway and side road should not exceed the rollover guidelines described in Figure 36-1.E.

4. Grade Lines. The principles for coordinating the horizontal and vertical alignment discussed in Chapter 33 are also applicable to vertical profiles through intersections. In addition, do not place intersections on or near crest vertical curves unless the vertical curve is flat enough for the intersection pavement to be seen assuming decision sight distance criteria.

36-1.06(b) Cross-Section Transitions

One or more of the approaching legs of an intersection may need to be transitioned (or warped) to meet the cross section of the two crossing roads. The following applies:

1. Stop Controlled. Where the minor road is stop controlled, maintain the profile and cross section of the major road through an intersection and transition the cross slope of the stop-controlled roadway to match the major road cross slope and profile.

2. Signalized Intersection. At signalized intersections, or potentially signalized intersections, transition the cross section of the minor road to meet the profile and cross slope of the major road. Where compromises are necessary between two major roadways, provide the smoother riding characteristics to the roadway with the higher traffic volumes and operating speeds.

3. Transition Rates. Where one or both intersecting roadways are transitioned, the designer must determine the length and rate of transition from the typical section to the modified section. Desirably, design the transition to meet the general principles of superelevation transition which apply to that roadway (i.e., open-roadway or low-speed urban street

conditions); see Section 32-3. When these criteria are applied to intersection transition rates, the applied design speed is typically:

- 20 mph (30 km/hr) below the design speed but not less than 30 mph (50 km/hr) for a stop-controlled roadway,
- the highway design speed for a free-flowing roadway, or
- the highway design speed on each roadway of a signalized intersection.

At a minimum and consistent with field conditions, transition the approach pavements of an urban intersection within the curb or radius returns and for rural intersections within a distance of 50 ft (15 m).

36-1.06(c) Profiles at Intersections

Where the cross section of the minor road is warped to meet the major road, provide a vertical curve between the side road approach gradient and the mainline pavement; see Figure 36-1.I. The following vertical curve options are presented in order from the most desirable to the least desirable:

1. Vertical Curves (SSD). The criteria for stopping sight distance as described in Chapter 33 should be used for the vertical curve. Use the design speed discussed in Section 36-1.06(b) to design the vertical curve.

2. Sag Vertical Curves (Minimum Comfort). Under restricted conditions where the SSD criteria is not practical, the sag vertical curves at intersection approaches may be based on the following formulas:

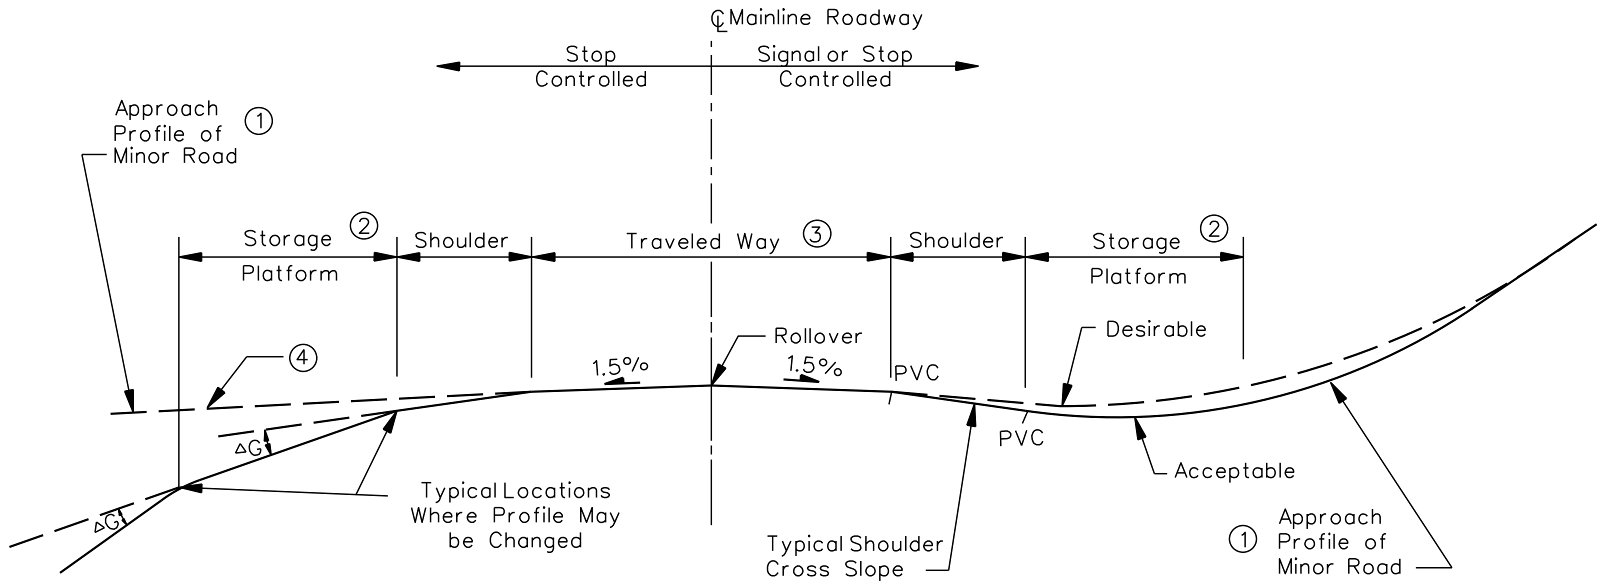
$$K = (0.1V)^2$$ Equation 36-1.1 (US Customary)

$$K = (0.034V)^2$$ Equation 36-1.1 (Metric)

$$L = KA$$ Equation 36-1.2

where:
K = the horizontal distance in ft (meters) needed to produce a 1% change in the gradient along the curve
A = algebraic difference between the two tangent grades, %
V = design speed, mph (km/hr)
L = length of vertical curve, ft (m)

3. Angular Breaks. At stop-controlled intersections, angular breaks are typically provided when warping the cross section of the minor approach to meet the mainline cross section. Figure 36-1.I presents a schematic of vertical profiles through an intersection. Figure 36-1.E provides the maximum rollover guidelines which are also applicable for changes in angular breaks.



Notes:

Desirably, the minor road profile should tie into the mainline travel lane cross slope; however, where the minor road is stop controlled, it will be acceptable for the minor road profile to tie into the mainline shoulder cross slope. Actual field conditions will determine the final design

See Item 1 in Section 36-1.06(a) for storage platform gradients.

At signalized intersections, the most desirable cross slope option will be to transition all approach legs into a planar surface through the intersection and to limit the centerline rollover on the mainline to 2% - 3%.

For a signal controlled minor road descending from the mainline, maintain the travel lane cross slope of the mainline roadway through the length of the storage platform.

VERTICAL PROFILES OF INTERSECTING ROADS

Figure 36-1.I

4. Driveways. For driveway profiles with and without sidewalks, the designer should refer to Section 36-7 and the *IDOT Policy on Permits for Access Driveways to State Highways,* 92 *Ill. Admin. Code* 550.

36-1.06(d) Drainage

Evaluate the profile and transitions at all intersections for impacts on drainage. This is especially important for channelized intersections on curves and grades. This may require the designer to check superelevation transition lengths to ensure flat sections are minimized. Low points on approach roadway profiles should be beyond a raised corner island to prevent water from being trapped and causing ponding.

36-1.07 Intersection Capacity Analysis

Capacity analysis influences several geometric design features including the number of approach lanes, auxiliary lanes, lane widths, channelization, and number of departure lanes. In addition, this analysis in conjunction with the *Illinois Manual on Uniform Traffic Control Devices* will determine whether an intersection may need to be signalized or stop controlled. Any considered change in traffic control should be reviewed with the district Bureau of Operations for concurrence.

It is important that the level of service for a signalized intersection be calculated for each lane group (a lane group may be one or more movements), each intersection approach, and the intersection as a whole. Level of service criteria are provided in the geometric design tables in Part V, Design of Highway Types, of the *BDE Manual*.

Once the minimum level of service has been selected and design traffic volumes are determined, use the *Highway Capacity Manual* and the *Highway Capacity Software* (HCS) to perform the detailed capacity analyses. Ensure that data used in the analyses are applicable for the intersection (i.e., do not assume the program default values are automatically applicable for the intersection). Other capacity and signal analysis programs may be used provided they are approved for use by the BDE. To be eligible for approval, the output results must be comparable to the HCS.

If the intersection is part of a traffic signal system, check the intersection design with an approved traffic progression program. These programs analyze all signalized intersections in the system to determine the overall capacity of the system. HCS is now able to perform both standalone intersection and corridor analyses. Whenever the information is available and relevant to the design, the capacity analysis should include nearby adjacent intersections within the corridor, as both upstream and downstream intersections can have a significant impact on overall capacity and delay. Also, see Figure 36-1.C for signalized intersection spacing guidelines.

In addition, if the capacity analysis at an intersection shows a saturated or over-saturated flow (i.e., flow rate at or over capacity, $v/c \geq 1.0$) for any movement, a multi-period analysis within HCS is necessary to appropriately calculate the effects of residual queue back-up and sustained spillback in determining the actual level of service and delay for the intersection. See the Highway Capacity Manual (HCM) and HCS for more information.

36-1.08 Design Vehicles

36-1.08(a) Types

The design vehicle affects the radius returns, left-turn radii, lane widths, median openings, turning roadways, and sight distances at an intersection. The basic design vehicles used by IDOT for intersection design are:

- P — Passenger car; includes vans and pickup trucks.
- S-BUS-40 (S-BUS-12) — 84-passenger school bus.
- SU-30 (SU-9) — Single-unit truck with an overall vehicle length of 30 ft.
- WB-40 (WB-12) — Tractor/Semitrailer combination with an overall wheelbase of 40 ft (12.2 m).
- WB-50 (WB-15) — Tractor/Semitrailer combination with an overall wheelbase of 50 ft (15.2 m).
- WB-55 (WB-17) — Tractor/Semitrailer combination with an overall wheelbase of 55 ft (16.8 m).
- WB-65/67 (WB-20) — Tractor/Semitrailer combination with an overall wheelbase of 65 ft or 67 ft (20.4 m).
- WB-67D (WB-20D) — Tractor/Semitrailer/Trailer combination with an overall wheelbase of 67 ft (20.4 m).
- P/T — Recreational vehicle, car, and camper trailer.

Figure 36-1.J illustrates the turning characteristics for a typical tractor/semitrailer design vehicle and definitions for terms that make up the characteristics. Figure 36-1.K shows the dimensions of commonly used truck tractors. For IDOT's purposes, the long-haul tractors are used for the WB-65 and WB-67 design vehicles. The city and short haul tractors are used for the remaining multi-unit design vehicles. Figure 36-1.L shows the relationship between the maximum steering angle, effective wheelbase of a tractor, and the centerline turning radius on which the turning paths for combination trucks is based.

Figures 36-1.M through 36-1.U provide vehicular dimensions and turning templates for typical design vehicles. The turning path parameters for the design vehicles in Figures 36-1.M through 36-1.U may vary from the software used for intersection and other types of geometric layout. Vehicle turning software is periodically updated by the software manufacturers to be current with industry standards, while the turning path parameters for the design vehicles are meant to visually represent a turning path. The minimum turning radii shown in the figures are for turns less than 10 mph (15 km/hr).

36-1.08(b) Selection

Figure 36-1.V presents the recommended design vehicles at intersections based on the functional classification of the intersecting highways which the vehicle is turning from and onto. Figure 36-

1.W presents the recommended truck type that should be used based on the Illinois "Designated State Truck Route System." Chapter 43 further discusses the National Truck Network. The design vehicles shown in Figures 36-1.V and/or 36-1.W are for new construction and reconstruction projects. For 3R projects, the design vehicle will be site specific, and it may be a smaller design vehicle than that used for new construction and reconstruction projects.

In addition to Figures 36-1.V and 36-1.W, use the following guidelines when selecting a design vehicle:

1. Minimum Designs. The SU-30 and/or S-BUS-40 design vehicles are generally the smallest vehicles used in the design of State highway intersections. This design reflects that, even in urban residential or sparsely populated rural areas, garbage trucks, delivery trucks, and school buses will be negotiating turns with some frequency. Rural intersections which may serve school bus traffic should, at a minimum, accommodate a turning school bus without encroachment onto the opposing lanes of travel. Intersections of State highways with suburban residential streets should also accommodate, at a minimum an S-BUS-40. Encroachment onto the opposing lanes of travel is permitted, but not desirable. Urban intersections only need to accommodate design vehicles that are expected to use that intersection. See Section 36-2.01 for further discussion on encroachment.

2. Recreational Areas. Recreational areas typically will be designed using the SU design vehicle. This reflects that service vehicles are typically required to maintain the recreational area. Under some circumstances the passenger car with a trailer (P/T) may be the appropriate design vehicle (e.g., campground areas, boat launches).

3. Mixed Use. Some portions of an intersection may be designed with one design vehicle and other portions with another vehicle. For example, it may be desirable to design physical characteristics (e.g., corner islands) for the WB-67 (WB-20) truck but provide painted channelization for the SU design vehicle. This technique can improve safety by providing additional guidance to motorists, bicyclists, and pedestrians at locations where a smaller design vehicle may comprise the majority of usage at an intersection.

4. Turning Template. The intersection design and layout should be checked with an approved computer simulated turning template program or with an actual turning template.

Federal law prohibits limiting the overall length of tractor/semitrailer and tractor/semitrailer/trailer combinations on the National Network; see Section 43-5 for a discussion on the National Network. Thus tractor/semitrailer and tractor/semitrailer/trailer combinations longer than WB-67 are allowed on some Illinois roads without permits, however unless vehicle surveys indicate a need for designing for larger vehicles, designing for WB-67's is adequate for the facilities shown in Figure 36-1.V.

The Illinois Statutes applied the Federal law to all Class I highways. On Class II highways, the Illinois statutes do not have an overall length limits but limits the length from the front axle to the rear axle to 65 ft (WB-65) on Class II highways.

36-1.09 Pedestrians and Bicyclists

In the design of an intersection, safe and convenient movement of pedestrians and bicyclists shall be considered. Where present, pedestrians and bicyclists should be treated as design users of the intersection and given the same consideration in the design process as the design vehicle. Overly wide intersections can significantly increase the crossing distance for pedestrians and bicyclists, resulting in increased exposure that can lead to higher crash potential for vulnerable users. Additionally, longer signal phase times, more potential pedestrian conflicts with turning vehicles, and lower overall intersection capacity can result with very wide intersections.

To address these issues and improve pedestrian and bicycle accommodation, initially consider ways to minimize the outside return radii and therefore overall intersection size. Further, the geometric layout may incorporate refuge islands, curb extensions, raised medians, special markings added for bicyclists, additional traffic signal actuation devices specifically for pedestrians or bicyclists, or other design features. In general, geometry that reduces vehicle turning speeds will improve non-motorized safety performance. Returns and corner island designs can constrain vehicle speeds while adding bicycle/pedestrian refuge areas. Mountable aprons, to accommodate larger design vehicles while affecting smaller vehicle turning paths, are supported by FHWA and are utilized throughout the U.S. to achieve multi-modal goals and address safety concerns.

Place crosswalks at approximate right angles to traffic movements and at locations where they will provide for maximum visibility while meeting both driver and pedestrian expectations. All sight lines to crosswalks and adjacent pedestrian waiting areas, including those within medians, must be free of high vegetation plantings or other obstructions.

Chapter 58 discusses the application of curb ramps at intersections for individuals with disabilities. Chapter 17 provides several applications for accommodating bicycle lanes and pedestrians through an intersection. Crosswalk lighting, which can be an effective safety countermeasure for pedestrian crashes, is covered in Chapter 56. The majority of pedestrian crashes occur in dark conditions.

36-1.10 Pavement Markings/Reflectorized Markers

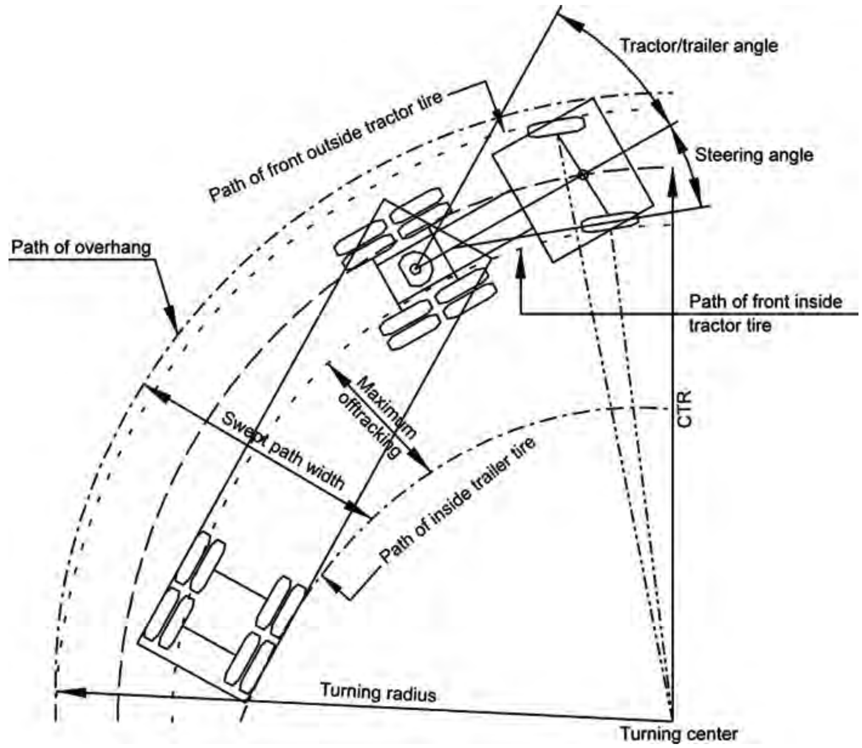
See the Bureau of Operations Departmental Policy TRA-14 and use the current edition of the Bureau of Operation’s *Traffic Policies and Procedures Manual; Pavement Marking Selection, Installation, and Inspection Manual;* the *Manual on Uniform Traffic Control Devices;* and the *Illinois Highway Standards* to select and design the appropriate pavement markings and crosswalks at intersections. Chapter 57 provides general guidelines for the placement of pavement markings and reflectorized markers.

36-1.11 Intersection Lighting

The primary objective of highway lighting is to enhance highway safety. Intersection lighting enables the driver to determine the geometry and condition of the intersection at extended distances thereby simplifying the driving task. This in turn increases driver comfort and reduces fatigue which may contribute to highway safety. Chapter 56 discusses the warrants and design criteria for highway and intersection lighting.

36-1.12 Bus Turnouts

For design of bus turnouts near intersections, see Chapter 58.



Definitions:

1. Turning Radius. The circular arc formed by the turning path radius of the front outside tire of a vehicle. This radius is also described by vehicular manufacturers as the "turning curb radius."

2. Centerline Turning Radius (CTR). The turning radius of the centerline of the front axle of a vehicle with its steering wheels at the steering lock position.

3. Offtracking. The difference in the paths of the front and rear wheels of a tractor/semitrailer as it negotiates a turn. The path of the rear tires of a turning truck does not coincide with that of the front tires. This effect is shown in the drawing above.

4. Swept Path Width. The amount of roadway width that a truck covers in negotiating a turn and is equal to the amount of off-tracking plus the width of the tractor unit. The most significant dimension affecting the swept path width of a tractor/semitrailer is the distance from the kingpin to the rear trailer axle or axles. The greater this distance is, the greater the swept path width.

5. Steering Angle. The average of the angles made by the left and right steering wheels with the longitudinal axis of the vehicle when the wheels are turned to their maximum angle. The Maximum angle controls the minimum turning radius of the vehicle.

6. Tractor/Trailer Angle. The angle between adjoining units of a tractor/semitrailer when the combination unit is placed into a turn. This angle is measured between the longitudinal axes of the tractor and trailer as the vehicle turns. The maximum tractor/trailer angle occurs when a vehicle makes a 180 degree turn at the minimum turning radius and is reached slightly beyond the point where a maximum swept path width is achieved.

SELECTION OF DESIGN VEHICLE AT INTERSECTIONS
(Functional Classification)

Figure 36-1.V

Highway Type	Design Vehicle	Maximum Length of Trailer Allowed (m)	Maximum Length Kingpin to Center Rear Axle (m)
Class I State	WB-67 (WB-20)	53′ (16.16 m)	45.5′ (13.87 m)
Class II State and Local	WB-65 (WB-20)	53′ (16.16 m)	45.5′ (13.87 m)
Non-designated State	WB-55 (WB-17)	53′ (16.16 m)	42.5′ (12.96 m)
Non-designated Local	WB-50 (WB-15)	Not Specified	Not Specified

Notes:

1. *Section 43-1 defines the roadway functional classification system, and the Illinois Vehicle Code, 625 ILCS 5/1-126.1 defines highway designations in the system of State highways. Additionally, 625 ILCS 5/15-107 defines truck lengths and truck access requirements, and 625 ILCS 5/15-116 sets forth State and local agency reporting requirements for Designated Truck Route System routes. The Office of Planning & Programming maintains Designated State Truck Route System maps.*
2. *Any tractor/semitrailer and tractor/semitrailer/trailer vehicle operating on a Class I highway shall have access onto any street or highway for a distance of 1 mile (1.61 km) for the purpose of loading, unloading, and obtaining food, fuel, rest, or repairs, so long there are no signs posted prohibiting such access. Under this condition, the combination truck units allowed access from the Class I highway may be up to 8 ft-6 in. (2.59 m) wide with a 53 foot (16.16 m) long trailer (28.5 ft trailer for tractor/semitrailer/trailer combinations).*
3. *Any tractor/semitrailer vehicle operating on a Class I or II highway shall have access onto any non-designated street or highway for a distance of five miles (8.05 km) on such streets or highways for the purpose of loading, unloading, and obtaining food, fuel, rest, or repairs, provided there are no signs posted prohibiting such access, and if the route is not being used as a thoroughfare between such designated highways.*
4. *Local authorities may designate as Class II any highway within their system. Posting of signs for Class II routes is not required; when large vehicles are prohibited from using streets and highways under local jurisdiction posted signs will identify such restrictions. Local agencies are responsible for reporting to the Department all streets and highways under their jurisdiction designated as Class II highways or affirming that they have no such routes. Specific vehicle prohibitions established by local agencies through ordinance or resolution are compiled by the Department and available on the IDOT website.*

The statutes referred to above do not imply geometric components such as intersection turn radii or driveway aprons be provided to accommodate trucks without encroachment.

DESIGN VEHICLE SELECTION
(Designated State Truck Route System)

Figure 36-1.W

36-2 TURNING RADII

Turning radii treatments for intersections are important design elements in that they influence the operation, safety, and construction costs of the intersection. The designer must ensure that the proposed design is compatible with the expected intersection operations.

36-2.01 Design for Right-Turning Vehicles

The following sections present several basic parameters the designer needs to consider in determining the proper pavement edge/curb line for right-turning vehicles.

36-2.01(a) Design Vehicle

Section 36-1.08 discusses the selection of the applicable design vehicle for different intersections. These vehicles are used to determine the pavement edge or curb line. Note that the design vehicle will determine the turning width, vehicular path width or swept-path width. The assumed speed of the vehicle is less than 10 mph (15 km/hr).

Where present, pedestrians and bicyclists should be treated as design users of the intersection and given the same consideration in the design process as the design vehicle.

36-2.01(b) Inside Clearance

Desirably, the selected design vehicle will make the right turn while maintaining approximately a 2 ft (600 mm) clearance from the pavement edge or face of curb.

36-2.01(c) Encroachment

To determine the amount of acceptable encroachment, the designer should evaluate several factors. These would include traffic volumes, one-way or two-way operations, urban/rural location, and the type of traffic control. For turns made onto local facilities, desirably the selected design vehicle will not encroach into the opposing travel lanes. However, this is not always practical or cost effective in urban areas. The designer must evaluate these encroachment conditions against the construction and right-of-way impacts and the effect on the pedestrian crosswalk distance. If these impacts are significant, and if through and/or turning volumes are relatively low, the designer may consider accepting some encroachment of the design vehicle into opposing lanes; see Figure 36-2.D.

The encroachment allowed into adjacent lanes of the road or street onto which the turn is made will depend on the following:

1. Urban. No encroachment should be allowed into opposing lanes for a right-turning vehicle from a side road or street onto a State route.

2. Rural. For rural intersections, the selected design vehicle should not encroach into the opposing lanes of traffic.

3. Multilane Highways. If there are two or more lanes of traffic in the same direction on the road onto which the turn is made, the selected design vehicle can occupy both travel lanes. Desirably, the right-turning vehicle will be able to make the turn while remaining entirely in the right through lane; see Figure 36-2.C. However, conditions do exist where this is not practical or desirable and can lead to inordinately wide intersections, deficient head-turn angles for right-turning vehicles (see Figure 36-2.E), and excessive pedestrian crossing times. Engineering judgment must be used in creating an intersection design that safely and efficiently accommodates all roadway users.

All intersections of two designated State truck routes should be checked to see if the WB-65 (WB-20) design vehicle can physically make the right-turn without backing up and without impacting curbs, parked cars, utility poles, culvert end sections, mailboxes, traffic control devices, or any other obstructions, regardless of the selected design vehicle or allowable encroachment.

36-2.01(d) Parking Lanes/Shoulders

At many intersections, parking lanes and/or shoulders will be available on one or both approach legs. This additional roadway width may be carried through the intersection. The following will apply:

1. Parking Lanes. Under restricted conditions, the designer may take advantage of shoulder and/or parking lane to ease the problems of large vehicles turning right at intersections with small radius returns. It will be necessary to restrict the parking a significant distance from the intersection. This area should be delineated with striped pavement markings. Parking should be removed from the intersection according to the *ILMUTCD*.

2. Paved Shoulders. At rural intersections, it may be preferable to continue a paved shoulder throughout the radius return. If a shoulder width transition is required, design it according to Figure 36-2.A.

3. Curbing. If certain conditions such as drainage requirements, restricted right-of-way, greater delineation, or the desire to minimize off-tracking warrant the use of curbing along the radius return at rural intersections, terminate the curbing at the shoulder edge and transition the curb height as indicated in Figure 36-2.A. Where posted speeds are 50 mph or greater, use a mountable type curb. If a mountable curb is deemed to be ineffective at the specific location in deterring large trucks from making impermissible maneuvers and unwanted encroachments, a barrier curb may be utilized on a case-by-case basis, so long as a design exception is justified by the district and granted by BDE; see Section 31-7.

36-2.01(e) Pedestrian Considerations

The larger the right-turning radius, the farther pedestrians must walk across the street. This is especially important to persons with disabilities. Therefore, the designer must consider the number and type of pedestrians using an intersection when determining the edge of pavement or curb line design. This may lead to a decision to design a right-turn corner island (small or intermediate) for use as a pedestrian refuge.

36-2.01(f) Visibility of Traffic Control Devices

In addition to providing pedestrian refuge and reducing pedestrian exposure within the intersection by creating several shorter crossing maneuvers rather than a single, longer pedestrian maneuver, raised corner islands may be desirable to improve motorist visibility to traffic control devices, such as traffic signal posts and stop signs. Raised corner islands should be considered where there is current or proposed presence of large vehicles and/or pedestrians at an intersection, where visibility of traffic control devices may otherwise be limited, or where proposed geometrics through the use of a computer simulated turning template program and engineering analyses otherwise dictate. See Section 36-2.02 for more information regarding the use of corner islands.

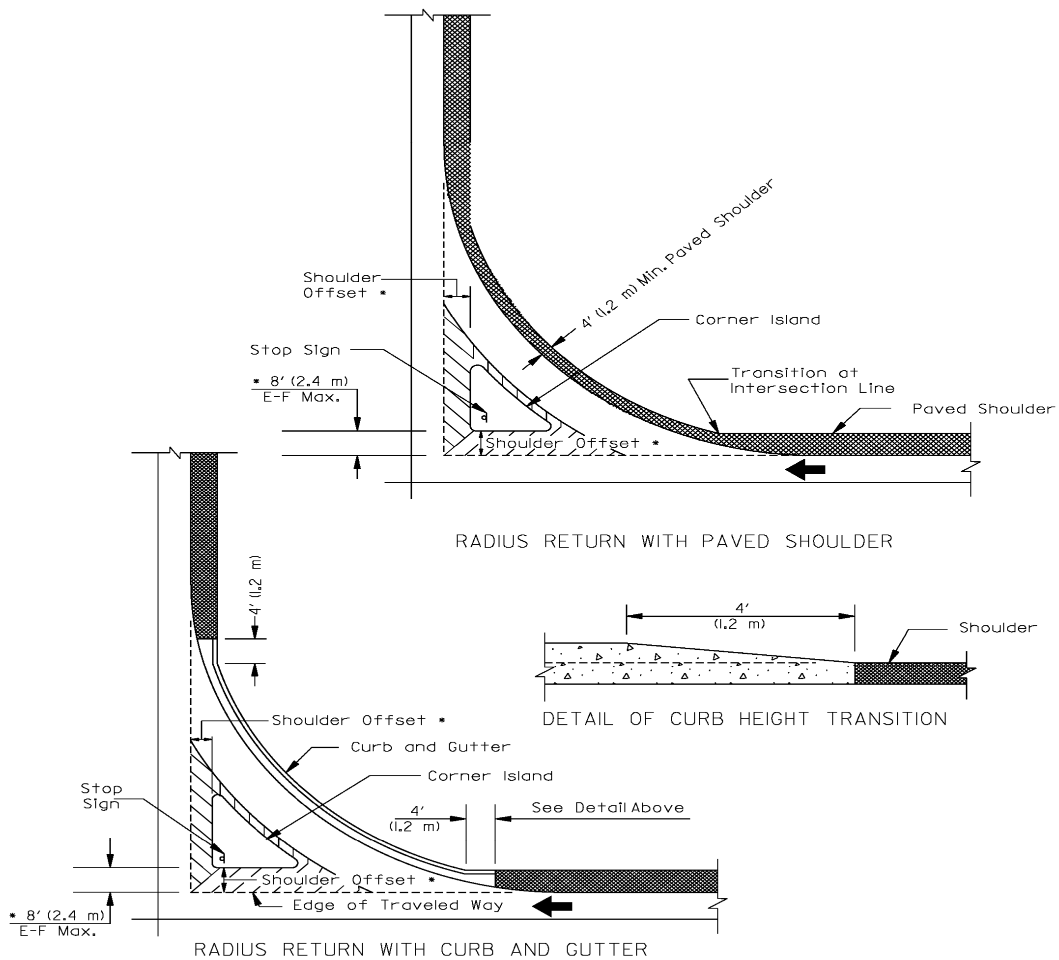
36-2.01(g) Types of Radius Return Designs

Once the designer has determined the basic right-turning parameters (e.g., design vehicle, amount of allowable encroachment, inside clearance, need for corner island), it will be necessary to select the type of turning design for the curb return or pavement edge which will meet these criteria and will fit the intersection constraints.

The simple radius is the easiest to design and construct. However, two-centered or three-centered curves provide a better fit to the transitional turning paths of tractor/semitrailer design vehicles. Because the WB-67, WB-55, or WB-50 (WB-20, WB-17, or WB-15) trucks are allowed on all State highways, the Department has determined that two-centered or three-centered curves are desirable at all major intersections. Note that using these curves may require a corner island to improve visibility of traffic control devices, to reduce pedestrian crossing time exposure, and to provide pedestrian refuge.

Some of the advantages of the two-centered and three-centered curves as compared to the simple radius design include:

- When accommodating a specific design vehicle, they require less intersection pavement than a simple radius design, and especially for angles of turn greater than 90 degrees. For large vehicles, a simple radius is often an unreasonable design unless a corner island is used and, in effect, a turning roadway is provided.
- There are less right-of-way impacts at the intersection corners.
- A simple radius results in greater distances for pedestrians to cross the intersection.



**Note: Only use M-type curb on corner islands.*

RECONSTRUCTION OF LOCAL RESIDENTIAL STREET INTERSECTION AT MULTILANE ARTERIAL ROUTE (Right Turn In of SU Truck)

Figure 36-2.D

36-2.01(h) Turning Template(s)

To determine the preliminary right-turn design, the designer should use the applicable turning template for the selected design vehicle and speed. Check all turning movements of the final intersection design with the applicable turning templates or with a computer simulated turning template program. If computer simulation is used to determine right-turn design, include the printout with the intersection design study.

36-2.01(i) Stop Bar Locations

See the *Illinois Supplement to the Manual on Uniform Traffic Control Devices (ILMUTCD)* regarding stop bar placement at intersections. Stop bar locations should be checked against the criteria in the *ILMUTCD* at wide throat intersections. This is especially important where no corner island is used. On multilane approaches or approaches with corner islands, care should be taken in design to ensure the proposed stop bar placement of one lane does not create a line of sight restriction for the adjacent stopping maneuver. See Section 36-2.02(a) and (c) for more information on stop bar placement when using a corner island.

36-2.01(j) Summary

Figure 36-2.B illustrates the many factors that should be evaluated in determining the proper design for right-turns movements at intersections. In summary, the following procedure applies:

1. Select the design vehicle(s) (Section 36-2.01(a)).
2. Determine the acceptable inside clearance (Section 36-2.01(b)).
3. Determine the acceptable encroachment (Section 36-2.01(c)).
4. Consider the benefits of any parking lanes or shoulders (Section 36-2.01(d)).
5. Consider impacts on pedestrians (Section 36-2.01(e)).
6. Consider the visibility of traffic control devices and determine the need for raised corner islands (Section 36-2.01(f)).
7. Design the radius returns (Section 36-2.01(g)).
8. Check all turning movements of all proposed designs with the applicable vehicular turning templates or computer simulated turning template program (Section 36-2.01(h)).
9. Check the location of stop bars (Section 36-2.01(i)).
10. Using this iterative process, revise the design as necessary to accommodate the right-turning vehicle or determine that it is not practical to meet this design because of adverse impacts. If necessary, prepare a design exception request or seek a maximum extent practicable (MEP) determination for all non-compliant items; see Chapter 31.

36-2.01(k) Local Street Reconstruction

When reconstructing an arterial, the designer often must maintain the existing width on the local street. Figure 36-2.C illustrates the turning path for an SU-30 design vehicle turning out of an existing local street with a 30 ft (9.0 m) radius. Figure 36-2.D illustrates the turning path for an SU -30 design vehicle turning onto an existing local street.

36-2.02 Corner Islands

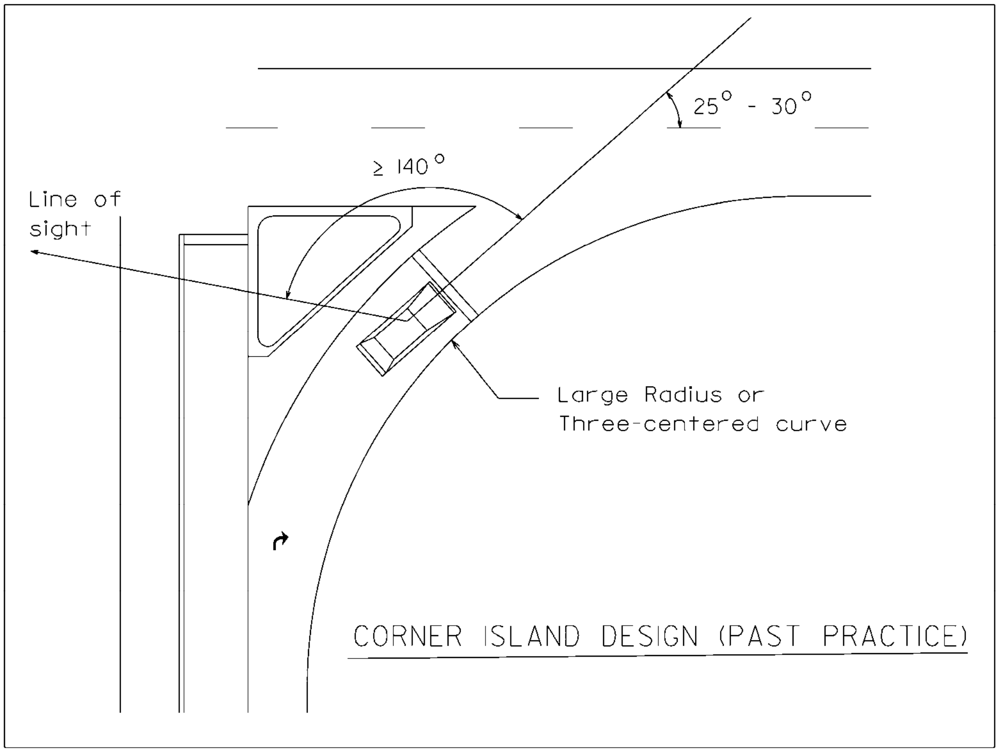
36-2.02(a) General Design Considerations

Raised corner islands, although they will require additional long-term maintenance, often provide substantial benefits, especially in urban environments. Corner islands can create positive driver guidance which may be especially advantageous where a tractor/semi-trailer is used as the design vehicle and/or at oblique angle crossing intersections. Corner islands can also help moderate vehicle turning speeds, provide pedestrian and bicyclist refuge areas, and allow for placement and optimal visibility of signs and signalized traffic control devices that may also include pedestrian signal heads and push buttons. Where non-motorized users will be present, corner islands can provide flush surfaces within the depressed sidewalk that can be used as relatively safe waiting areas for these users, while also shortening crossing distances and allowing a reduction in the time allocated for pedestrian movements.

Safety research shows that right-turn crashes may be of greater concern when one or a combination of any of the following factors exist or is proposed; see Figure 36-2.E:

- Right-turn radius return designed for WB-55 design vehicle or greater,
- Intersection angle less than 75 degrees,
- Right-turn angle between 25 and 30 degrees, or greater than 45 degrees,
- Head-turn angle greater than 140 degrees,
- Right-turning volume greater than 250 vph, or right-turn approach AADT greater than 3,125 vpd, or
- Moderate truck volumes (greater than 5%).

The standard corner island design (described in detail in Section 36-2.02(c)) has been shown to improve intersection sight distance by reducing necessary driver head-turn. As compared to past design practice, the standard design lengthens the approach side of the island along the turning roadway while reducing the length along the departure side of the turning roadway. This provides positive guidance for the approaching vehicle, while optimizing the motorist’s line of sight when completing the right-turn maneuver. This standard corner island design is expected to reduce the potential for right-turn crashes and improve intersection safety.



HEAD-TURN ANGLE CONCERN AT CORNER ISLANDS

Figure 36-2.E

During the design process, assess the factors described in this section with the goal of minimizing right-turning crashes. See Figure 36-2.F for design options. Specifically:

- A standard corner island design incorporating the optimum geometrics should typically be implemented upon initial design and construction of those proposed facilities which include a raised corner island.

- Existing locations with a raised corner island should also be considered for retrofit to the standard corner island design whenever intersection improvements are proposed and existing crash data supports this modification.

36-2.02(b) Design Parameters

The type and size of triangular or corner islands will vary according to the angle of intersection, design vehicle, right-turn operation, available right-of-way, and safety considerations. Figure 36-2.G illustrates the typical designs for corner islands. Also consider the following:

1. Island Sides. The sides of the island are controlled by minimum island size and visibility requirements. The sides should not be less than 12 ft (3.6 m) after rounding the corners. If traffic signal posts or pedestrian accommodations are installed within the island, the sides of the island may need increased above minimum.

2. Island Size. The minimum island size for rural areas is 100 ft^2 (9.5 m^2). For urban islands, the island area typically should be 75 ft^2 (7.0 m^2) but not less than 50 ft^2 (4.7 m^2). When traffic signal equipment or pedestrian accommodations are present within the island, the island size may need increased significantly above these minimums. When two pedestrian crossing directions need to be accounted for within the depressed portions of the island, an island of significant size must be designed to provide a sufficient size for the remaining raised island portions. Note the island area includes the concrete median surface and the top of the curb.

3. Flush or Raised-Curb. For proper delineation of corner islands, under all conditions (e.g., nighttime, rain, fog, snow), the raised-curb design is preferable.

4. Curbing. Only use the M-type curb on corner islands. Also consider the following:

   a. Use M-6 (M-15) curb on islands that are located adjacent to a highway with speeds of 45 mph (70 km/hr) or less.

   b. Use M-4 (M-10) curb on islands that are located adjacent to high-speed traffic (50 mph (80 km/hr) or greater). However, use M-6 (M-15) curb on islands where traffic signal supports, sign truss supports, or any other post with a foundation generally larger than a standard highway sign are present. Note that a stop sign is a standard highway sign.

   c. Use M-6.06 (M-15.15) or M-4.06 (M-10.15) concrete curb and gutter on all sides of islands where the island is offset the shoulder width from the edge of the traveled way.

5. Island Offsets. On streets with outside curb and gutter, offset the corner island face of curb from the edge of the traveled way according to Figure 36-2.G.

   In rural areas or for facilities with shoulders, the corner island is offset the shoulder width, but not greater than 8 ft (2.4 m) to the face of curb; see Figure 36-2.H. If a right-turn deceleration lane is provided on a rural facility, offset the corner island face of curb 8 ft (2.4 m) to the edge of pavement along that approach.

6. Curb Cuts. When a raised corner island or median is utilized, and a depressed sidewalk curb cut will be provided for accommodation of pedestrians and/or bicyclists, always seek to provide a minimum of 6 ft (1.8 m) of refuge width and include detectable warnings at all crosswalk locations, subject to ADA policy (see Chapter 58).

36-2.02(c) Design Techniques

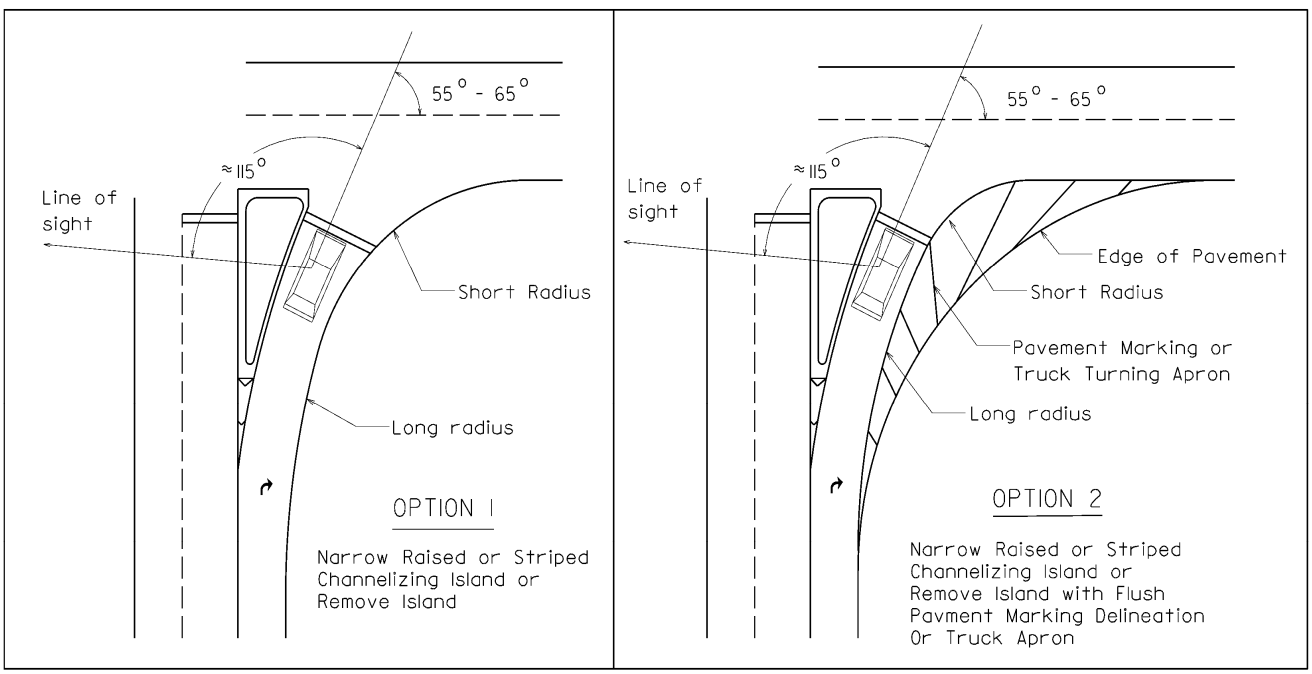
The approach angle for right-turning vehicles is critical in the design of new corner islands or the modification of existing corner islands. If designed without the approach angle in mind, corner island design may impose challenges to the motorist regarding excessive head-turn and reduced sight distance. These challenges in the driving task are further amplified at intersection approaches on heavy skew angles. Figure 36-2.F depicts two options for a standard corner island design that will minimize potentially adverse operating characteristics.

In the design of a corner island, seek to meet or approach a head-turn angle goal of 115 degrees for the line of sight as shown for drivers at the stop bar. To accomplish this, consider the following techniques in developing the proposed geometrics at corner islands:

- Reducing the edge of pavement radius (in conjunction with island modifications),
- Adjusting the stop bar position,
- Reducing the island length adjacent to the mainline roadway,
- Removing or re-designing the raised island, or
- Placing additional pavement markings immediately adjacent to the outside radius, rather than immediately adjacent to the corner island.

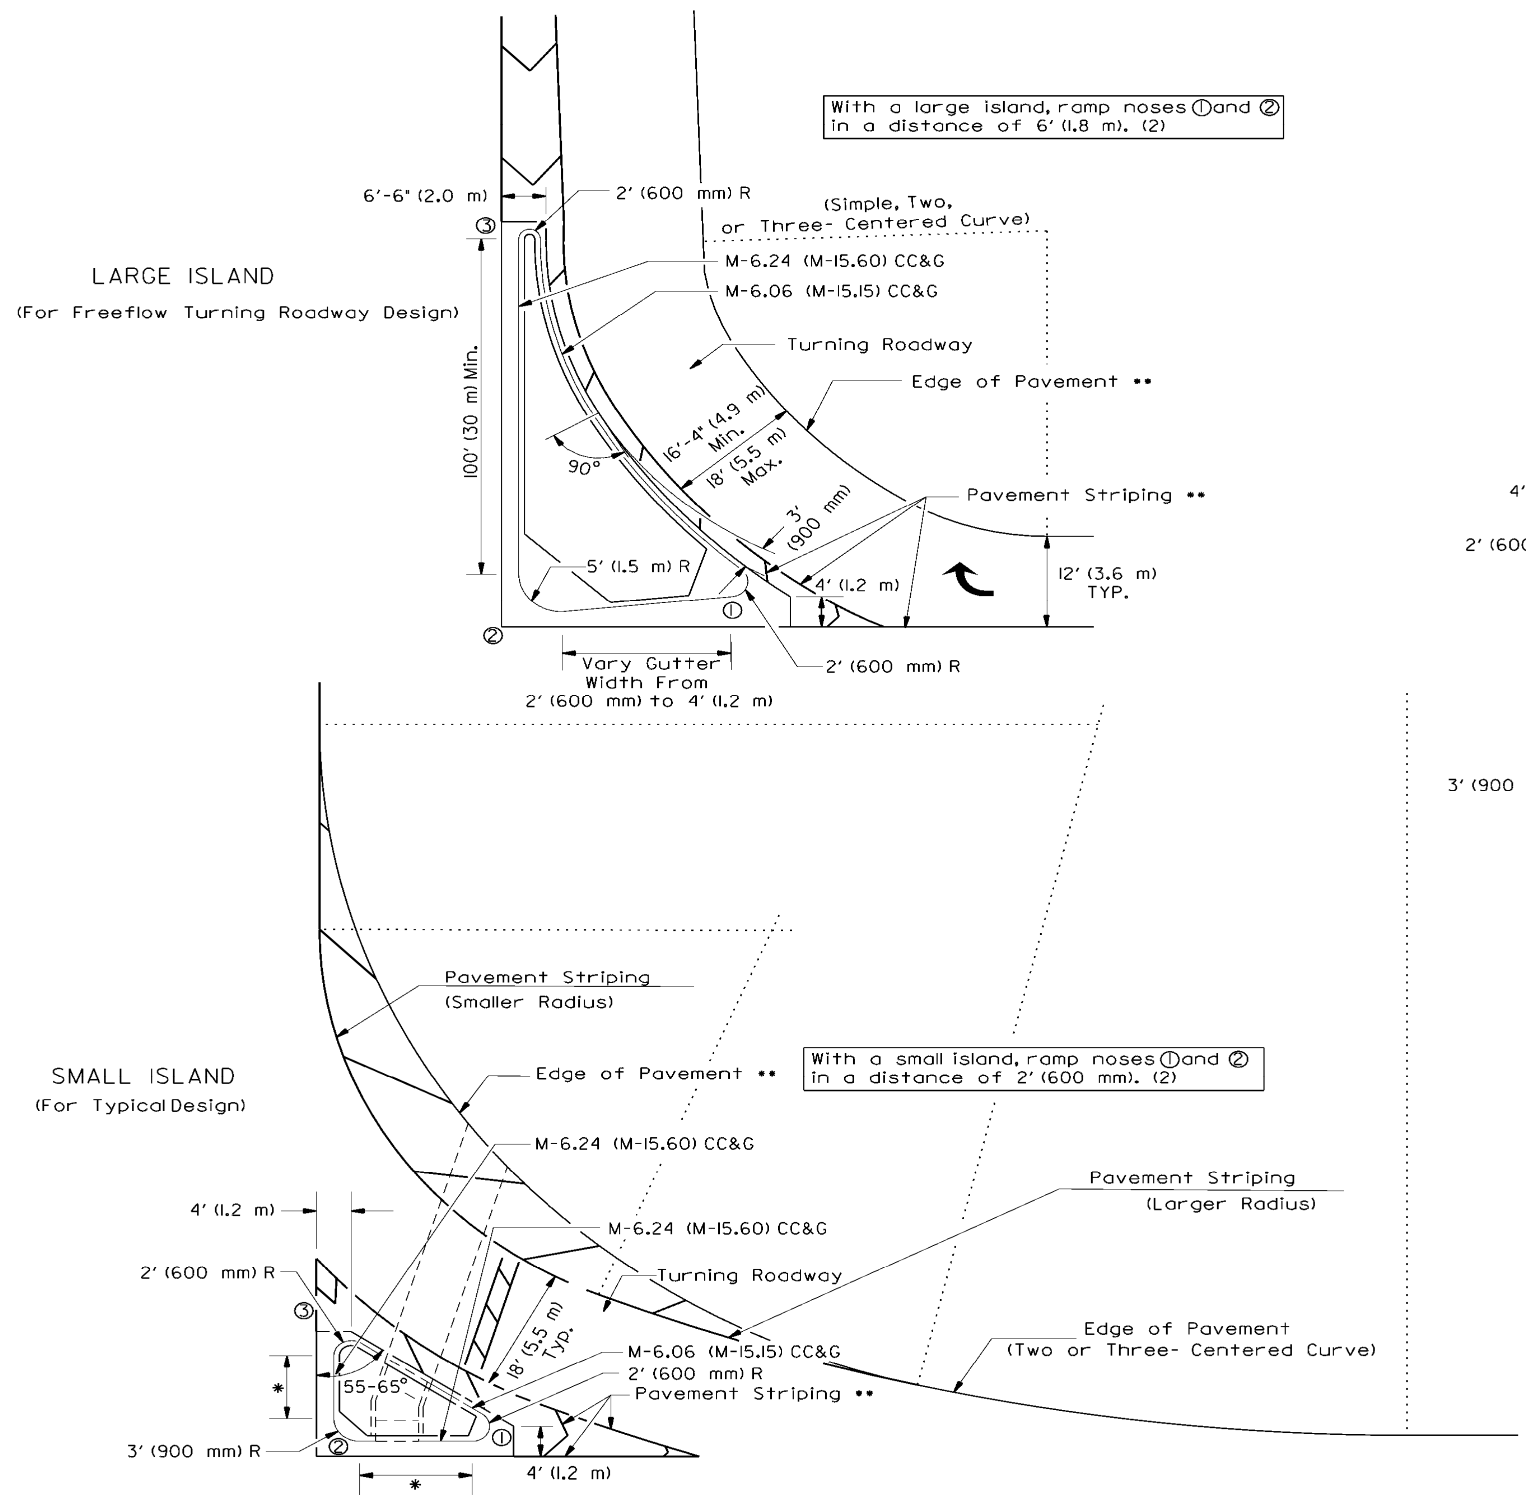
These techniques are suggested to provide good approach visibility for drivers of passenger vehicles, while also allowing large trucks to complete the turn without encroaching onto the curb or shoulder.

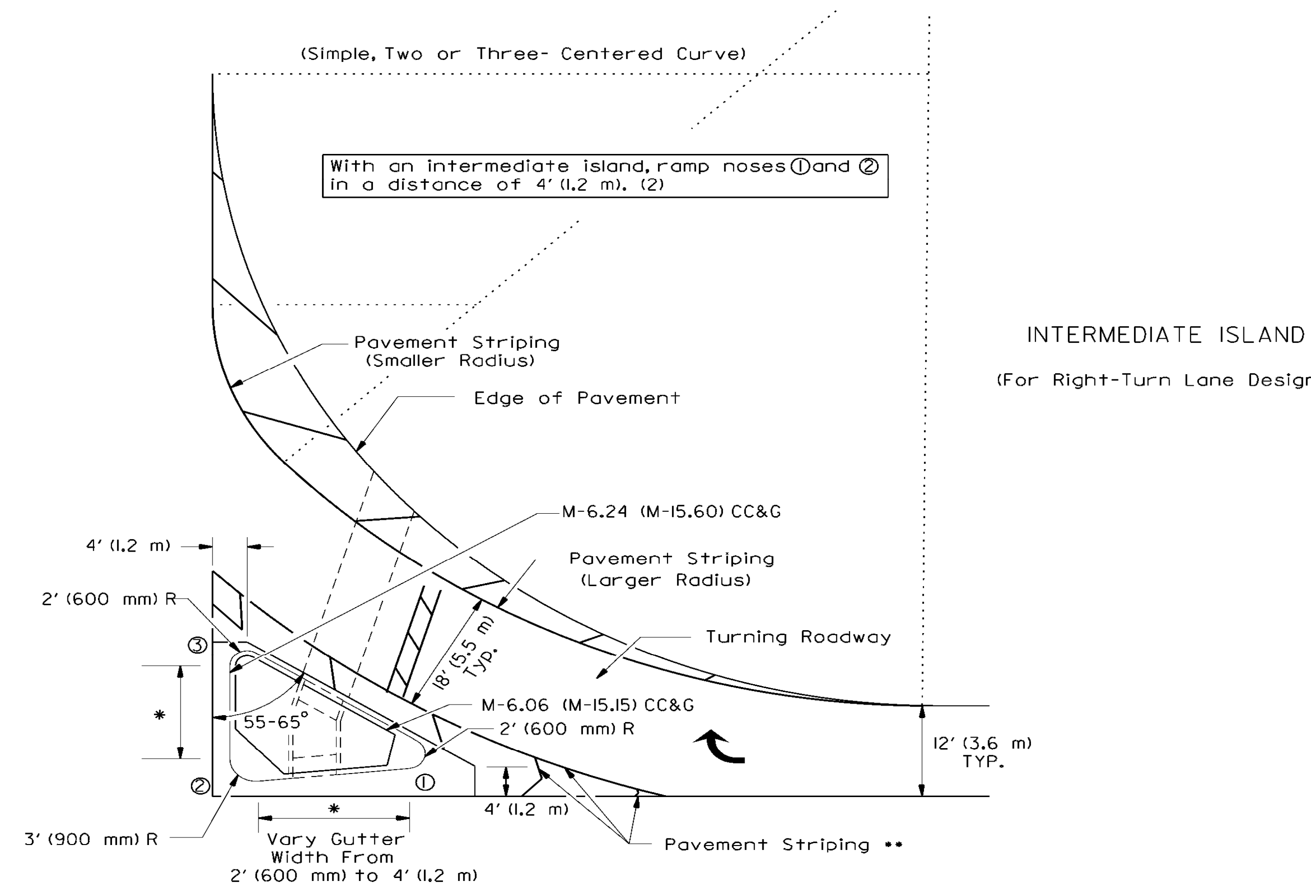
Note that corner island design is not wholly a standardized design procedure; rather, design customization may be needed for urban and rural applications based on site specific factors and engineering judgment. When implementing the standard corner island design at skewed intersections, meeting the head-turn angle goal often becomes very challenging and designs different from those depicted may be necessary. In urban areas, adjustments to the stop bar locations depicted in Figure 36-2.F may be needed to accommodate pedestrian crosswalks and traffic signal equipment.



STANDARD CORNER ISLAND DESIGN OPTIONS

Figure 36-2.F





Notes:

1. *①, ②, ③ - designates a specific corner of island.*
2. *Ramp the ① and ② noses of curbed corner islands unless the curb function is for the protection of pedestrians, signals, light standards, or sign truss supports.*
3. *See the* IDOT Highway Standards *for details of ramping noses.*
4. *All corner radii are to the face of curb at flowline.*
5. *Pedestrian accommodations shown are optional based on pedestrian need.*

* *These dimensions are controlled by the minimum area requirements of the island, as well as guidelines for traffic signal equipment and pedestrian accommodations, when utilized.*

** *These design elements vary by design vehicle.*

FIGURE 36-2.G

36-2.03 Turning Roadways

Where the inner edges of pavements for right turns at intersections are designed to accommodate tractor/semi-trailer combinations or where the desired design permits passenger vehicles to turn at speeds of 15 mph (25 km/hr) or greater, the pavement area at the corner of the intersection may become excessively large for proper control of traffic. To avoid this, a raised corner island is used and the connecting roadway between the two intersection legs is defined as a turning roadway.

36-2.03(a) Guidelines

The need for a turning roadway will be determined on a case-by-case basis. The designer should consider the following guidelines in determining the need for a turning roadway:

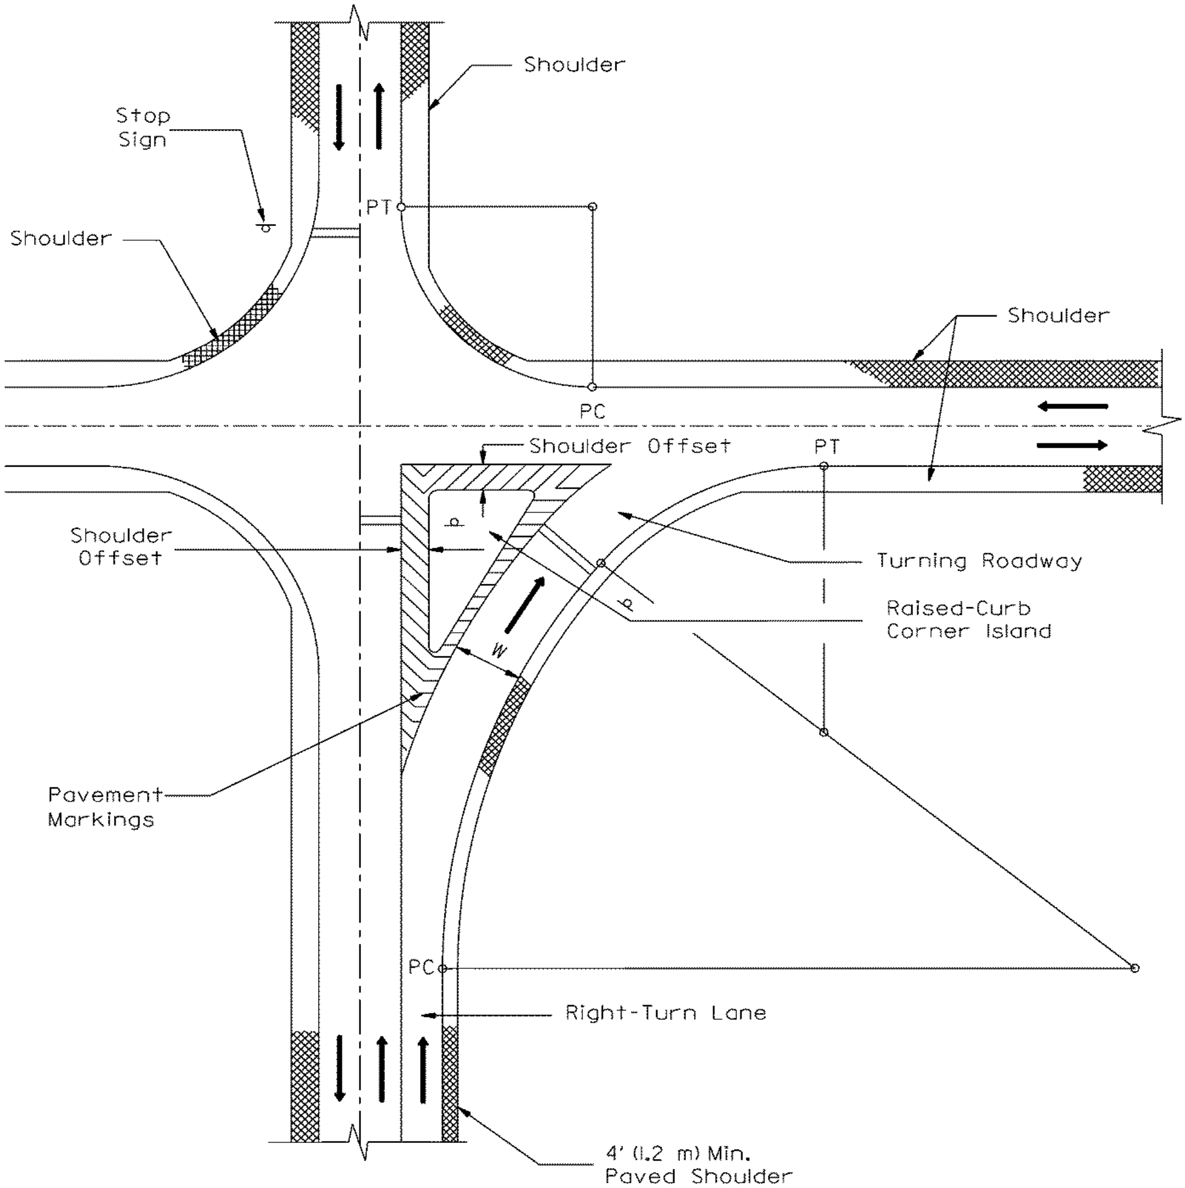
1. Trucks. A turning roadway is usually required when the selected design vehicle is a tractor/semitrailer combination.

2. Island Type and Size. Desirably, the raised corner island size should be at least 100 ft^2 (9.0 m^2). At a minimum, the island should be at least 100 ft^2 (9.0 m^2) in rural areas and 50 ft^2 (4.5 m^2) in urban areas; see Figure 36-2.G.

3. Level of Service. A turning roadway can often improve the level of service through the intersection. At signalized intersections, a turning roadway with a free-flow acceleration lane may significantly improve the capacity of the intersection by removing the right-turning vehicles from the signal phasing. Level-of-service criteria are provided in the geometric design tables in Part V, Design of Highway Types, of the *BDE Manual*.

4. Crashes. Consider using a turning roadway with a right-turn lane if there are significant numbers of rear-end type crashes at an intersection. Turning roadways with larger radii, in conjunction with a right-turn lane, will allow vehicles to make the turning movements at higher speeds and, consequently, should reduce these types of accidents. However, where pedestrians are expected to be present it is important to also consider ways to maximize their visibility and safety.

Figure 36-2.H illustrates two options for turning roadway layout. Typically use a two-centered curve for the radius at the intersection. When designing the turning roadway, consider the effects of corner island design on safety (see Section 36-2.02). The High Speed Design is not recommended where pedestrians will be present.



Notes:

1. *W = Width of turning roadway, see Figure 36-2.I.*

TYPICAL TURNING ROADWAY LAYOUT
(High Speed Design)

Figure 36-2.H
(2 of 2)

36-2.03(b) <u>Design Speed</u>

A turning roadway even at a low design speed (e.g., 10 mph (20 km/hr)) may still provide a significant benefit to turning vehicles regardless of the speed on the approaching highway. Typically, the design speed for a turning roadway will be in the range of 10-20 mph (15-30 km/hr).

36-2.03(c) <u>Width</u>

Turning roadway widths are dependent upon the turning radii design, design vehicle selected, angle of turn, design at edges of the turning roadway, and type of operation. Section 36-1.08 provides the criteria for selection of the appropriate design vehicle at an intersection. Turning roadways are designed for one-way operation and are segregated as follows:

1. <u>Case I</u>. One-lane with no provisions for passing a stalled vehicle on the traveled way.
2. <u>Case II</u>. One-lane with provision for passing a stalled vehicle on the traveled way.
3. <u>Case III</u>. Two-lane operation on the traveled way.

Figure 36-2.I presents guidelines for turning roadway widths for various design vehicles based on the above operations. Selection of the appropriate operation will depend on the intersection and will be determined on a case-by-case basis. The following presents several guidelines to consider:

1. <u>Case I</u>. For most turning roadway designs, use the Case I widths from Figure 36-2.I. The pavement widths in Figure 36-2.I provide an extra 6 ft (1.8 m) clearance beyond the design vehicle's swept path. This additional width provides extra room for maneuverability and driver variances.

2. <u>Case II and III</u>. Case II and III widths are seldom required on turning roadways. This is due to the relatively short roadway lengths involved. The Case II widths may be appropriate where channelized islands are provided next to through traffic lanes. Case III widths are only applicable where two lanes are used through the turning roadway.

3. <u>Larger Vehicles</u>. In selecting the turning roadway width, the designer should also consider the possibility that a larger vehicle may also use the turning roadway. To some extent, the extra 6 ft (1.8 m) clearances in Case I widths will allow for the accommodation of the occasional larger vehicle at a lower speed and with less clearance. For example, a turning roadway designed for a WB-50 (WB-15) with a 100 ft (30 m) radius will still accommodate an occasional WB-55 (WB-17) vehicle. However, it will not accommodate a WB-67 (WB-20) vehicle. If there are a significant number of the larger vehicles using the turning roadway, it should be selected as the design vehicle.

4. <u>Shoulders</u>. For shoulder designs adjacent to turning roadways, see Figures 36-2.A and 36-2.H.

5. <u>Curbing</u>. Where curb and gutter is provided on the left and/or right side of the turning roadway, add the gutter widths to the widths shown in Figure 36-2.I.

TURNING ROADWAY WIDTHS
(Metric)

Figure 36-2.I

36-2.03(d) Horizontal Alignment

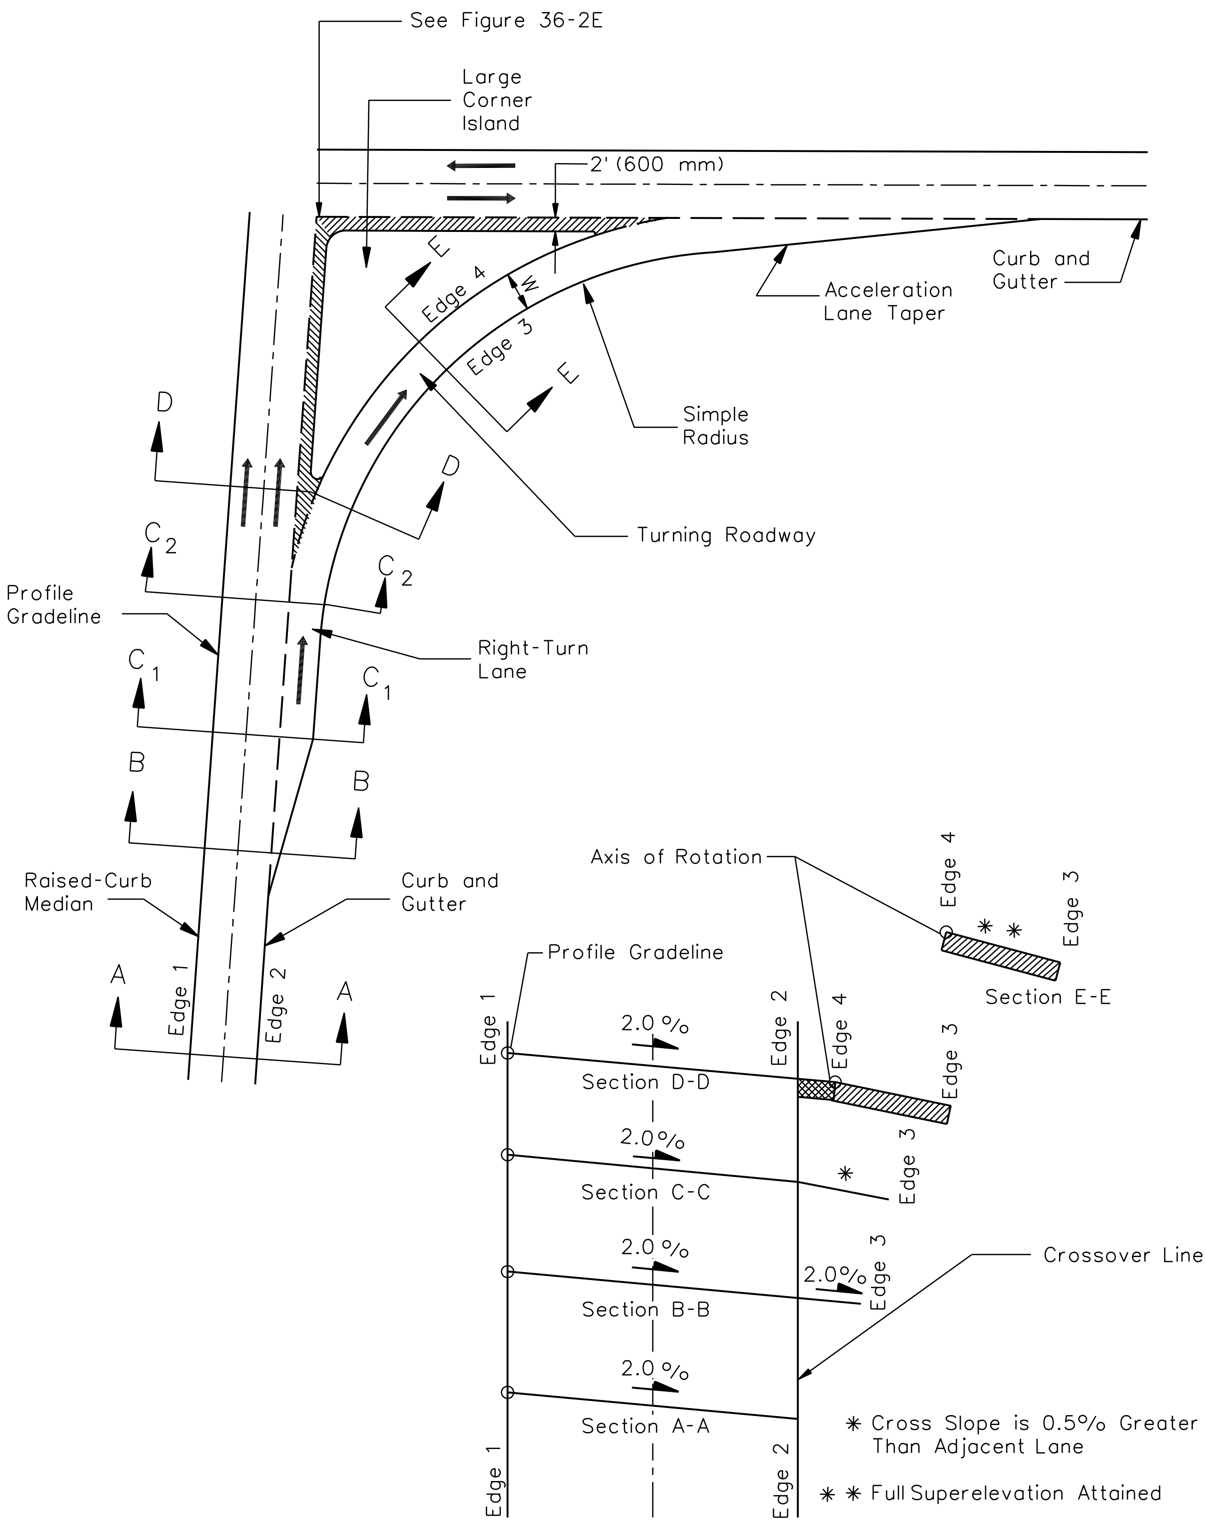
The horizontal alignment for turning roadway design differs from that of open-roadway conditions, which are discussed in Chapter 32. In comparison, turning roadway designs reflect more restrictive field conditions, and less demanding driver expectation and driver acceptance of design limitations. The following assumptions are used to design horizontal alignment for turning roadways:

1. Curvature Arrangement. The radii designs discussed in Section 36-2.01 (e.g., simple radius, two or three-centered curves) are also applicable to turning roadways. For most turning roadway designs, a two-centered curve is desirable. A large simple radius can be used where right-of-way is available and where a higher turning speed is desired (e.g., 20-25 mph (30-40 km/hr)).

2. Superelevation. Turning roadways are relatively short in length as indicated in Figure 36-2.H. This increases the difficulty of superelevating the roadway. For turning roadways developed with two-centered curves, a low design speed (e.g., 10–20 mph (15-30 km/hr)) is appropriate and the superelevation rate will typically be 2%. The maximum superelevation rate for turning roadways should not exceed 4%. This would apply only where a large simple radius is used. The factors that control the amount of superelevation are the need to meet pavement elevations of the two intersecting roadways, providing for drainage within the turning roadway, and design speed. Selection of the appropriate superelevation rate will be based on field conditions and will be determined on a site-by-site basis.

3. Superelevation Development. Figure 36-2.J illustrates a schematic of superelevation development for a turning roadway adjacent to a tangent section of highway and includes both a right-turn lane and an acceleration-lane taper. The actual development will depend upon the practical field conditions combined with a reasonable consideration of the theory behind horizontal curvature. The following criteria should be met:

    - No change in the normal cross slope is necessary up to Section B-B. Here, the width of the right-turn lane is less than 3 ft (1.0 m).
    - At Section C_1-C_1, the full width of the right-turn lane is obtained and should be sloped at 2.5%. The 2.5% cross slope is carried through to C_2-C_2.
    - The full width of the turning roadway should be attained at Section D-D. The amount of superelevation at D-D will depend upon the practical field conditions.
    - Beyond Section D-D, rotate the turning roadway pavement as needed to provide the required superelevation for the design speed of the turning roadway.
    - The superelevation treatment for the exiting portion of the turning roadway should be similar to that described for the entering portion. However, the superelevation rate on the turning roadway at the beginning of the acceleration taper should match the cross slope of the merging highway or street plus 0.5%.



SUPERELEVATION DEVELOPMENT OF TURNING ROADWAY
(High Speed Design - Mainline on Tangent or Curved to the Right)

Figure 36-2.J

Figure 36-2.K illustrates an existing situation where the mainline curves to the left and away from the crossroad. The designer should make every effort to avoid designing intersections on a curve where superelevation is needed. If this is not practical, the designer can compensate for this problem by proposing the use of a parallel right-turn deceleration lane prior to the turning roadway as shown in Figure 36-2.K.

4. Cross Slope Rollover. Figure 36-2.L presents the maximum allowable algebraic difference in the cross slopes between the mainline and the right-turn lane that precedes the turning roadway. In Figures 36-2.J and 36-2.K, this criterion applies between Section A-A and Section D-D. This likely will be a factor only for a superelevated mainline to the left.

5. Minimum Radius. The minimum turning roadway radii are based on the design speed, side-friction factors, and superelevation rate. Figure 36-2.M presents minimum radii for various turning roadway conditions.

36-2.03(e) Deceleration/Acceleration Lanes

Consider the following guidelines for using an acceleration or deceleration lane with turning roadways:

1. Deceleration Lane Guidelines. Consider the following guidelines for including a deceleration lane prior to the turning roadway:

    a. Turning Roadway Design Speed. A right-turn deceleration lane may be considered where the turning roadway design speed is more than 20 mph (30 km/hr) lower than that of the mainline design speed.

    b. Storage Length. A right-turn deceleration lane may be beneficial at signalized intersections where the through lane storage may limit access to the turning roadway. In these cases, the deceleration lane should extend upstream beyond the through lane storage requirements.

2. Acceleration Lane Guidelines. Consider the following guidelines for including an acceleration lane after the turning roadway:

    a. Traffic Condition. Consider providing an acceleration lane where it is desirable to provide a free-flowing traffic merge. The acceleration lane should not be preceded by a stop or yield condition.

    b. Traffic Volumes. Consider providing an acceleration lane where the turning traffic must merge with the through traffic of a high-speed, high-volume facility and/or where there is a high volume of trucks turning onto the mainline.

    c. Sight Distance. Acceleration lanes may be considered if there is inadequate sight distance available to allow the driver to safely merge with the mainline facility.

MINIMUM RADII FOR TURNING ROADWAYS

Figure 36-2.M

d. Right-Turn vs. Left-Turn Lanes. Right-turn acceleration lanes are more common than left-turn acceleration lanes. Left-turn acceleration lanes can be considered only after an engineering study has been completed and approved by BDE.

3. Deceleration Lane Design. For guidance on the design of right-turn deceleration lanes, see Section 36-3.02.

4. Acceleration Lane Design. Consider the following when designing an acceleration lane:

a. Type. Design acceleration lanes at intersections in the same manner as for interchange ramps using the taper design; see Section 37-6.02. Under some circumstances, a parallel-lane design may be more appropriate (e.g., steep upgrade, large volume of trucks). Parallel-lane design criteria are presented in the current edition of the AASHTO *A Policy on Geometric Design of Highways and Streets*.

b. Lengths. Right-turn acceleration lanes should meet the criteria presented in Figure 36-2.N. The "controlling curve" at an intersection is the design speed of the turning roadway or the speed at which a vehicle can make the right turn. The acceleration distance from Figure 36-2.N should be adjusted for grades using the factors presented in Figure 36-2.O. Where there is a significant number of turning trucks, the designer may consider lengthening the acceleration lane to account for their longer acceleration distances.

c. Taper. See Figure 36-2.N for the taper length distance to be provided at the end of the acceleration lane.

36-2.04 Left-Turn Control Radii

For left turns, the motorist generally has a guide at the beginning and end of the turn and an open intersection in the middle. Therefore, the precise alignment of a two-centered or three-centered curve is generally not applicable. Simple curves are typically used for left-turn control radii. Occasionally, a two-centered curve may be desirable to accommodate the off-tracking of large vehicles provided the second curve has a larger radius.

The design values for left-turn control radii are usually a function of the design vehicle, angle of intersection, number of lanes, and median widths. For roadways intersecting at approximately 90 degrees, radii of 50 ft to 80 ft (15 m to 24 m) should typically satisfy all controlling factors. If center divisional islands are present, select control radii so that the nose of each divisional island is no closer than 4 ft (1.2 m) nor greater than 10 ft (3.0 m) from the edge of the traveled way of the intersecting highway. The nose location is also affected by the selected nose radii. For additional guidance on median openings and median nose designs, see Section 36-4.04.

Left-turn control radii for dual-lane turning movements should be larger than those indicated for the single-lane design. See Section 36-3.05 for additional design details.

Figure 36-2.O

36-3 AUXILIARY TURN LANES

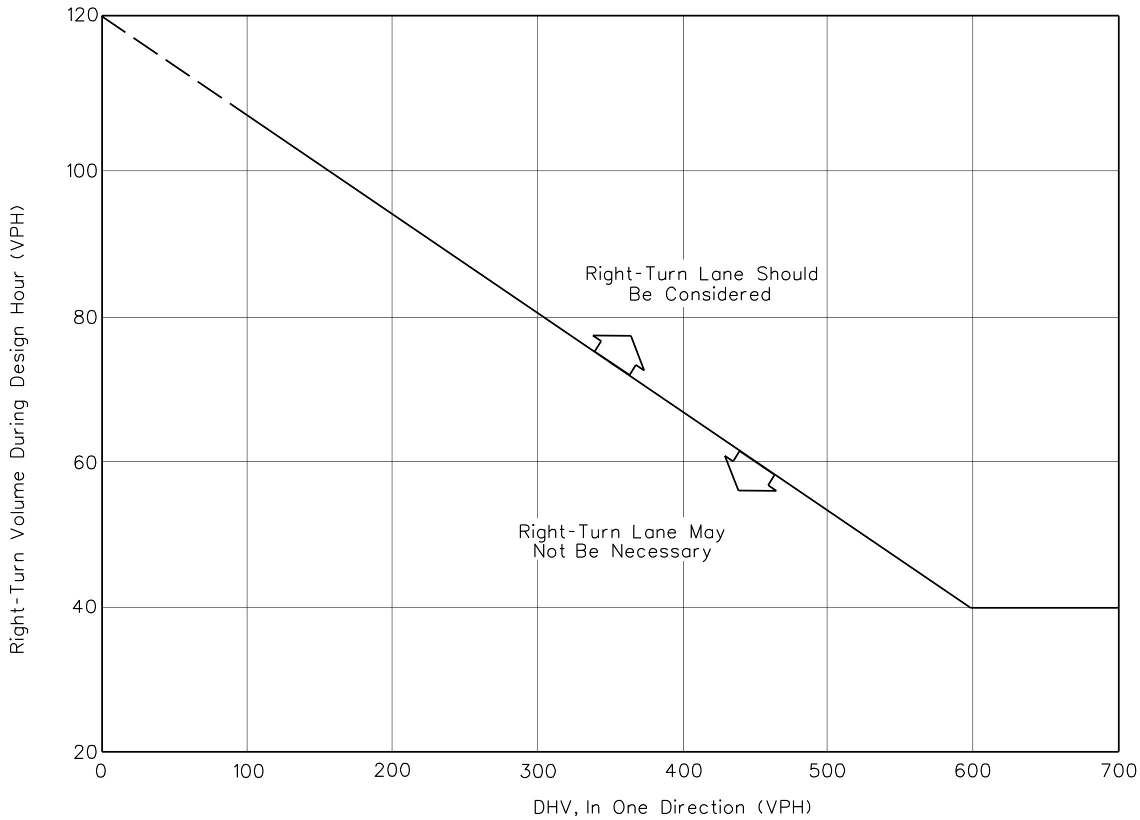
When turning maneuvers for left- and right-turning vehicles occur from the through travel lanes, it typically disrupts the flow of through traffic. This is especially true on high-volume highways. To minimize potential conflicts and to improve the level of service and safety, the use of auxiliary turn lanes may be warranted for intersections.

36-3.01 Turn Lane Guidelines

36-3.01(a) Right-Turn Lane Warrants

The use of right-turn lanes at intersections can significantly improve operations. Consider using an exclusive right-turn lane for the following:

- at any unsignalized intersection on a two-lane urban or rural highway that satisfies the criteria in Figure 36-3.A;
- at any unsignalized intersection on a high-speed, four-lane urban or rural highway that satisfies the criteria in Figure 36-3.B;
- on expressways at all public road intersections where the current ADT on the side road is greater than 250;
- at any intersection where a capacity analysis determines a right-turn lane is necessary to meet the level-of-service criteria;
- at any signalized intersections where the right-turning volume is greater than 150 vph and where there is greater than 300 vphpl on the mainline;
- for uniformity of intersection design along the highway if other intersections have right-turn lanes;
- at any intersection where the mainline is curved to the left and where the mainline curve requires superelevation;
- at railroad crossings where the railroad is located close to the intersection and a right-turn lane would be desirable to efficiently move through traffic on the parallel roadway; or
- at any intersection where the crash experience, existing traffic operations, sight distance restrictions (e.g., intersection beyond a crest vertical curve), or engineering judgment indicates a significant conflict related to right-turning vehicles.



Note: *For highways with a design speed below 50 mph (80 km/hr), with a DHV in one direction of less than 300, and where right turns are greater than 40, an adjustment should be used. To read the vertical axis of the chart, subtract 20 from the actual number of right turns.*

<u>Example</u>

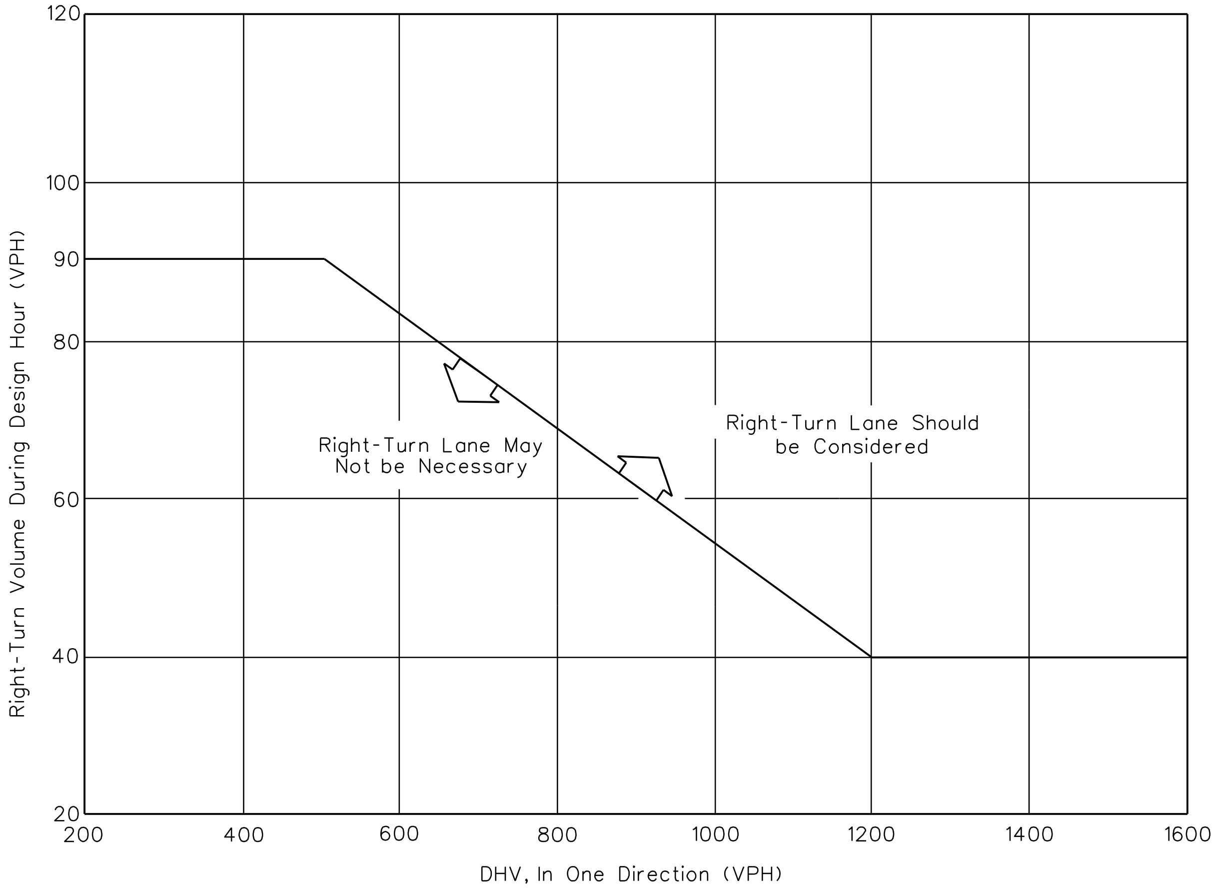
Given:	Design Speed	=	35 mph (60 km/hr)
	DHV (in one direction)	=	250 vph
	Right Turns	=	100 vph

Problem: Determine if a right-turn lane is warranted.

Solution: To read the vertical axis, use 100 - 20 = 80 vph. The figure indicates that right-turn lane is not necessary, unless other factors (e.g., high crash rate) indicate a lane is needed.

GUIDELINES FOR RIGHT-TURN LANES AT UNSIGNALIZED INTERSECTIONS ON TWO-LANE HIGHWAYS

Figure 36-3.A



Note: For speeds less than 50 mph (80 km/hr), see Section 36-3.01(a).

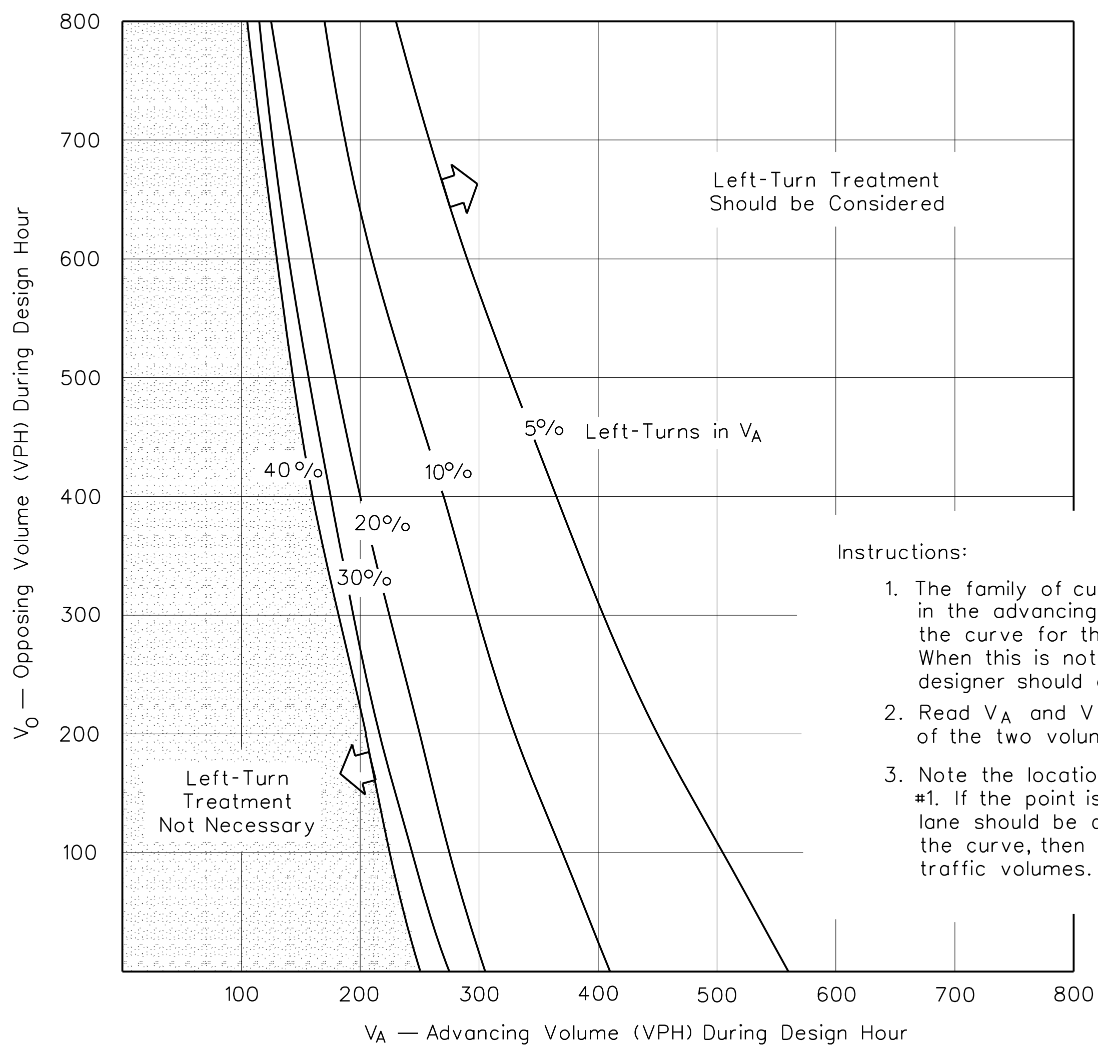
GUIDELINES FOR RIGHT-TURN LANES AT UNSIGNALIZED INTERSECTION ON FOUR-LANE HIGHWAYS
(Design Speed of 50 mph (80 km/hr) or Greater)

Figure 36-3.B

36-3.01(b) Left-Turn Lane Warrants

The accommodation of left turns is often the critical factor in proper intersection design. Left-turn lanes can significantly improve both the level of service and intersection safety. Always use an exclusive left-turn lane at all intersections on divided urban and rural highways with a median wide enough to accommodate a left-turn lane, regardless of traffic volumes. Consider using an exclusive left-turn lane for the following:

- at any unsignalized intersection on a two-lane urban or rural highway that satisfies the criteria in Figures 36-3.C, D, E, F, or G;
- at any signalized intersection where the left-turning volume is equal to or greater than 75 vph for a single turn lane or 300 vph for a dual turn lane;
- at any intersection where a capacity analysis determines a left-turn lane is necessary to meet the level-of-service criteria, including dual left-turn lanes;
- for uniformity of intersection design along the highway if other intersections have left-turn lanes (i.e., to satisfy driver expectancy); or
- at any intersection where the crash experience, traffic operations, sight distance restrictions (e.g., intersection beyond a crest vertical curve), or engineering judgment indicates a significant conflict related to left-turning vehicles.



V_A = Total advancing traffic volume which includes all turning traffic

V_O = Total opposing traffic volume which includes all turning traffic

Instructions:

1. The family of curves represent the percent of left turns in the advancing volume (V_A). The designer should locate the curve for the actual percentage of left turns. When this is not an even increment of five, the designer should estimate where the curve lies.
2. Read V_A and V_O into the chart and locate the intersection of the two volumes.
3. Note the location of the point in #2 relative to the curve in #1. If the point is to the right of the curve, then a left-turn lane should be considered. If the point is to the left of the curve, then a left-turn lane is not warranted based on traffic volumes.

Figure 36-3.G

36-3.02 Turn Lane Design Parameters

36-3.02(a) Turn Lane Widths

The width of the turn lane should be determined relative to the functional class, urban/rural location, and project scope of work (new construction, reconstruction, 3R). Part V, Design of Highway Types, of the *BDE Manual* presents the applicable widths for auxiliary lanes based on these criteria. Desirably, turn-lane widths should be 12 ft (3.6 m) or a minimum of 11 ft (3.3 m). However, for 3R projects, lane widths as narrow as 10 ft (3.0 m) are allowed for urban auxiliary lanes or through lanes on non-designated truck routes; see Chapter 49. The geometric design tables in Part V also provide criteria for the applicable shoulder widths adjacent to auxiliary lanes. In general, the minimum shoulder widths adjacent to a turn lane with shoulders should be 4 ft (1.2 m). For curbed sections, the minimum width of the gutter adjacent to the turn lane should be 6 in. to 24 in. (150 mm to 600 mm), with drainage requirements usually dictating the appropriate width.

36-3.02(b) Turn Lane Lengths

Desirably, the length of a right- or left-turn lane at an intersection should allow for both safe vehicular deceleration and storage of turning vehicles outside of the through lanes. However, this is often not practical. The length of auxiliary lanes will be determined by a combination of its taper length (L_T), deceleration length (L_D), and storage length (L_S). For urban areas, the functional length will be the taper length plus the storage length, or the deceleration length that includes the taper length, whichever is larger. For rural areas, typically the functional length will be the deceleration length that includes the taper length. In most high-speed, low-volume rural situations, the storage length will not be a controlling factor. Figure 36-3.H illustrates a schematic of auxiliary lanes at an intersection.

The following discusses IDOT criteria for turn lane lengths:

1. Taper. The entrance taper into the turn lane may be either a straight or a reverse curve taper. Always use the straight taper across bridges for ease of construction. Figure 36-3.I provides the recommended taper rates for a straight or reverse curve taper. Where the highway is on a curved alignment, the taper of the turn lane should be more pronounced than usual to ensure that the through motorists are not inadvertently directed into the turn lane. This is accomplished by shortening the taper length. Where the entrance taper is shortened, ensure that the overall deceleration distance from Figure 36-3.I is still provided for the turn lane.

2. Deceleration. For rural facilities, the deceleration distance (L_D) should meet the criteria presented in Figure 36-3.I. The following will apply:

   a. Design Speed. The deceleration length will depend upon the mainline design speed and the proposed type of operation at the end of the turn lane. These design speeds are provided in the geometric design tables in *Part V, Design of Highway Types*.

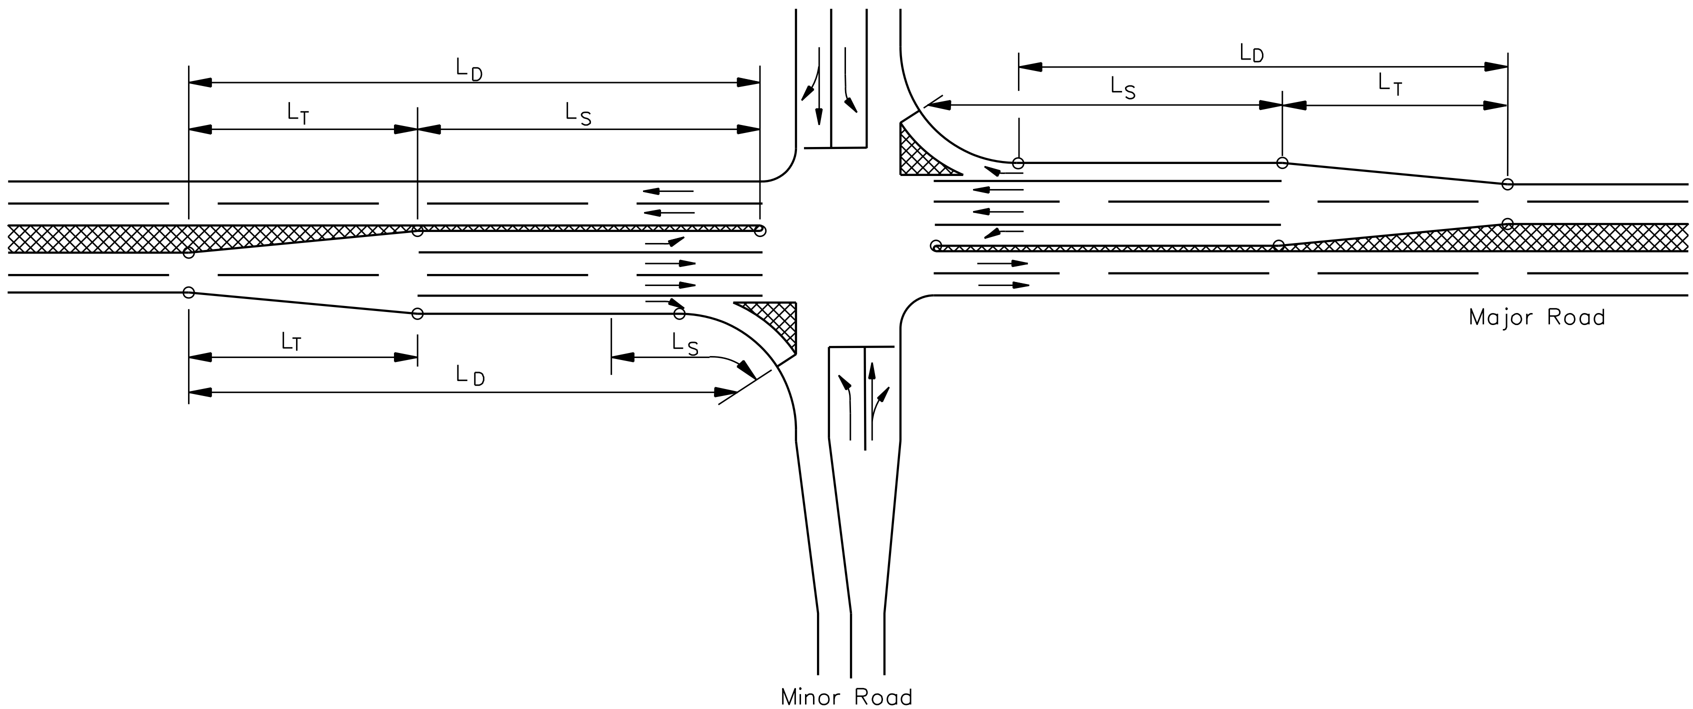
b. Location. The deceleration distance includes the taper lengths. For left turns, the deceleration distance is usually measured beginning at the end of the left-turn control radii. For right turns, the deceleration distance may be set at either one of two locations; see Figure 36-3.H. At intersections with minor public roads (e.g., frontage roads, service drives, local roads with current ADT volumes less than 400), a design speed of 50 mph (80 km/hr) may be used to determine the deceleration length.

c. Strategic Regional Arterials (SRA). For SRA routes, the minimum storage length should be 150 ft (45 m).

d. Grades. Where grades are greater than 3%, adjust the deceleration distance using the factors in Figure 36-3.I.

e. Urban. These distances are desirable on urban facilities; however, this is not always feasible. Under restricted urban conditions, deceleration may have to be accomplished entirely within the travel lane. For these cases, the length of full-width turn lane will be based solely on providing adequate vehicular storage (i.e., L_D = 0.0 ft (0.0 m)).

f. Trucks. Where it is determined that a turn lane will be used by a large number of trucks, increase the length of the deceleration distance by approximately 30%. This will compensate for the braking constraints of large trucks.



Note: The schematic of the major road (free flowing) also applies to all legs of a signalized intersection.

Key:
L_T = Taper length
L_D = Deceleration length
L_S = Storage length

See Section 36-3.02(b) for additional guidance.

DECELERATION DISTANCES FOR TURNING LANES

Figure 36-3.I

3. Storage Length (Signalized Intersections). The storage length (L_S) for turn lanes should be sufficient to store the number of vehicles likely to accumulate during the red phase of the signal cycle in the design hour. The designer should consider the following in determining the recommended storage lengths for signalized intersections:

   a. Determine the distance using the criteria for signalized intersections in the *Highway Capacity Manual* and Highway Capacity Software, or use the following formula:

$$\text{Storage Length (ft)} = \frac{(1-G/C)(DHV)(1+\frac{\%\text{trucks}}{100})(2 \text{ x } 25)}{(\#\text{ cycles per hour})(\#\text{ traffic lanes})} \quad \text{(US Customary)}$$

$$\text{Storage Length (ft)} = \frac{(1-G/C)(DHV)(1+\frac{\%\text{trucks}}{100})(2 \text{ x } 25)}{(\#\text{ cycles per hour})(\#\text{ traffic lanes})}$$

Equation 36-3.1 (US Customary)

$$\text{Storage Length (m)} = \frac{(1-G/C)(DHV)(1+\frac{\%\text{trucks}}{100})(2 \text{ x } 7.5)}{(\#\text{ cycles per hour})(\#\text{ traffic lanes})}$$

$$\text{Storage Length (m)} = \frac{(1-G/C)(DHV)(1+\frac{\%\text{trucks}}{100})(2 \text{ x } 7.5)}{(\#\text{ cycles per hour})(\#\text{ traffic lanes})}$$

Equation 36-3.1 (Metric)

where:	G	=	green time (sec)
		=	g(protected) + g(unopposed/permitted) time values from HCM analysis (sec)
	C	=	cycle length (sec)
	DHV	=	Design Hourly Volume (vph) for turn lane

   b. Where right-turns-on-red are permitted or where separate right-turn signal phases are provided, the length of the right-turn lane may be reduced due to less accumulation of turning vehicles. The storage length (L_S) needed for a separate right-turn lane is measured from the stop bar for the right-turning roadway; see Figure 36-3.H.

   c. At signalized intersections, the designer should also consider that entry into right- and left-turn lanes may be blocked by the signal storage needs of the adjacent through lanes. If this occurs, provide longer lengths of turn lanes.

4. Storage Length (Unsignalized Intersections). To determine the minimum storage length for unsignalized intersections, complete an unsignalized intersection capacity analysis based on guidance provided in the *Highway Capacity Manual* and output provided by Highway Capacity Software. Then utilize the vehicle queuing information from the analysis output, length of a typical vehicle, and estimation of heavy vehicles at the intersection to determine the expected storage length.

5. Minimum Turn Lane Length. With safety improvement or 3R type projects, the full width length of the right- or left-turn lanes may be 115 ft (35 m) plus the taper length.

36-3.03 Left-Turn Lane Design

36-3.03(a) General Criteria

In addition to the criteria for left-turn lane widths and lengths discussed in Section 36-3.02, the designer should consider the following general criteria:

1. Transition Areas. Do not locate left-turn lanes within any portion of a channelized approach island which is transitional in width. Allow the median width to be fully developed before beginning any additional tapers. If at all possible, refrain from placing tapers within the limits of another taper.

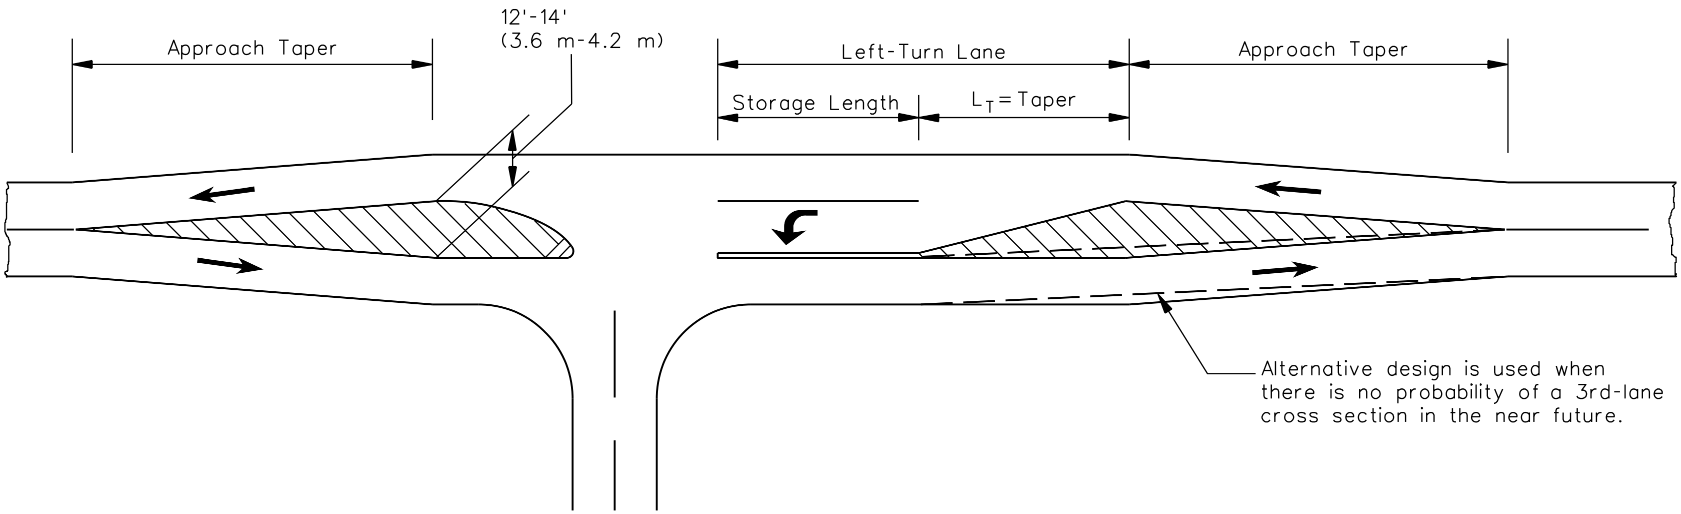
2. Taper Design. Figures 36-3.H, 36-3.J, and 36-3.K illustrate the use of a straight-line taper. Figure 36-3.L illustrates the use of reverse curves for an entrance taper.

3. Offset Turn Lanes. Providing an offset design ensures that opposing left-turning motorists can see past one another to view oncoming through traffic. Offset left-turn lanes can be either a parallel or tapered type.

4. Indirect Turns. Where operational or safety concerns preclude the use of typical left-turn lanes, the designer may consider the use of indirect left turns or jughandles that cross the mainline or intersect the crossroad at a different location. Because these require special consideration and treatment, they must be developed in consultation with BDE.

5. Opposing Left-Turning Traffic. If simultaneous and opposing left-turn lanes are proposed, the designer must ensure that there is sufficient space for all turning movements. Desirably, the separation between pavement markings should be 10 ft (3.0 m). If space is unavailable, it will be necessary to alter the signal phasing to allow the two directions of turning traffic to move through the intersection on separate phases. See Section 36-3.05 for additional guidance.

6. Opposing Through Traffic. Where more than two through traffic lanes will oppose the movement from a left-turn lane, the left-turns should be operated only as a protected movement. This is because crash issues can result from permitted phasing as left-turning drivers can have difficulty processing approaching vehicles from more than two oncoming lanes.



APPROACH TAPER RATES FOR FLUSH CHANNELIZATION					
Present Posted Speed (mph)	Design Speed	Approach Taper Rates: Widening on Both Sides	Approach Taper Rates: Widening All on One Side	Left-Turn Lane: Taper Rate	Left-Turn Lane: Storage Length*
≥50	50 mph (80 km/h)	50:1	40:1	15:1	115 ft (35 m)
45	45 mph (70 km/h)	45:1	35:1	13:1	115 ft (35 m)
40/35	40 mph (60 km/h)	40:1	30:1	11:1	115 ft (35 m)
≤30	30 mph (50 km/h)	35:1	25:1	9:1	115 ft (35 m)

** Storage lengths may be increased if necessary.*

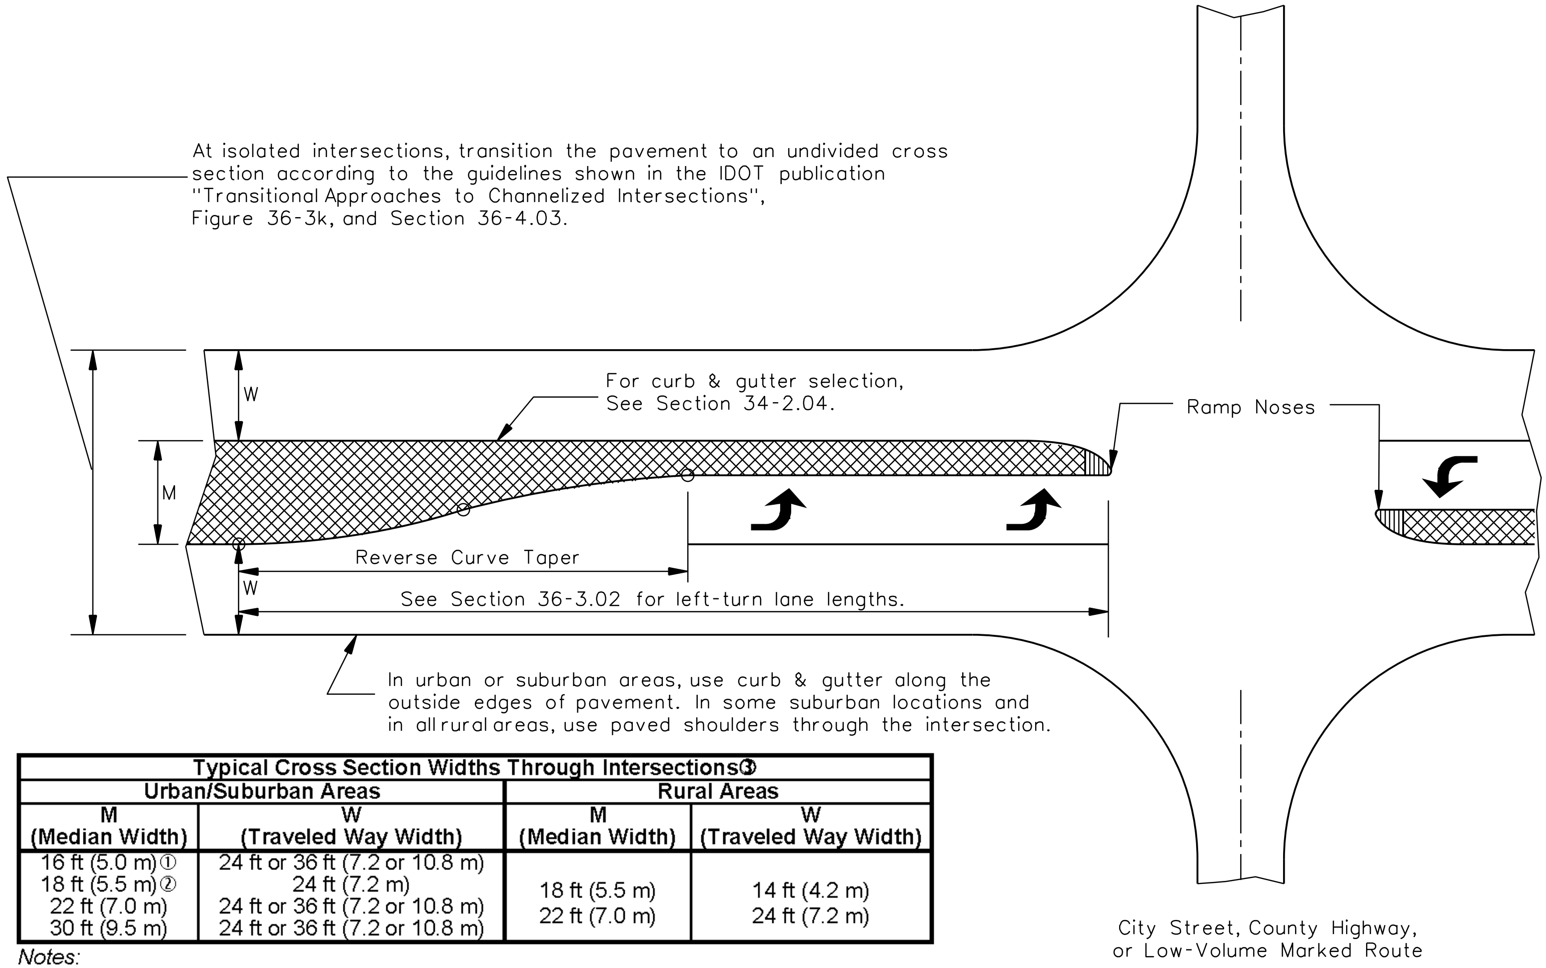
(New Construction/Reconstruction Projects)

Figure 36-3.K



Typical Cross Section Widths Through Intersections③			
Urban/Suburban Areas		Rural Areas	
M (Median Width)	W (Traveled Way Width)	M (Median Width)	W (Traveled Way Width)
16 ft (5.0 m)①	24 ft or 36 ft (7.2 or 10.8 m)	18 ft (5.5 m)	14 ft (4.2 m)
18 ft (5.5 m)②	24 ft (7.2 m)	22 ft (7.0 m)	24 ft (7.2 m)
22 ft (7.0 m)	24 ft or 36 ft (7.2 or 10.8 m)		
30 ft (9.5 m)	24 ft or 36 ft (7.2 or 10.8 m)		

Notes:

① This width of curbed median usually is used on city streets where a traversable median is desired between intersections.

② Generally, this width of raised-curb median should not be used on city streets with unsignalized intersections and median crossovers.

③ For additional guidance on median and traveled way widths, see the geometric design tables in Part V, Design of Highway Types.

RAISED-CURB CHANNELIZED INTERSECTION
(Parallel Left-Turn Lane)

Figure 36-3.L

36-3.03(b) <u>Parallel Left-Turn Lanes Without Offset</u>

Figures 36-3.J through 36-3.N and the following provide the design criteria for left-turn lanes that are adjacent and parallel to the through traveled way and are not offset:

1. <u>Two-Lane Facilities</u>. For safety improvements and 3R projects, use a flush median design at isolated intersections as shown in Figure 36-3.J. For new construction or reconstruction projects, a channelized left-turn lane with a flush island or a raised-curb island may be used depending on specific site conditions. Figure 36-3.K illustrates the flush design and Figure 36-3.L illustrates the raised-curb median design. Both figures depict parallel left-turn lanes with negative left-turn lane offset. Additional design details may be needed to incorporate a tapered left-turn lane or positive offset left-turn lane design to improve sight distance and safety; see Section 34-3. Where the raised-curb median is channelized back to a two-lane traveled way, use the criteria discussed in the IDOT publication, *Transitional Approaches to Channelized Intersections*, Figure 36-3.K, and Section 36-4.03(a).

2. <u>Narrow Raised-Curb Medians</u>. Left-turn lanes generally will be the parallel design. This design is illustrated in Figure 36-3.L. To properly develop left-turn lanes for new construction and reconstruction projects, see the footnotes in Figure 36-3.L. Additional design details may be needed to incorporate a tapered left-turn lane or positive offset left-turn lane design to improve sight distance and safety; see Section 34-3.

3. <u>Narrow Expressway Medians</u>. Left-turn lanes generally will be the parallel design due to restricted right of way. This is illustrated in Figure 36-3.M. Figure 36-3.M also illustrates how to terminate a median barrier before the development of the left-turn lane. Additional design details may be needed to incorporate a tapered left-turn lane or positive offset left-turn lane design to improve sight distance and safety; see Section 34-3.

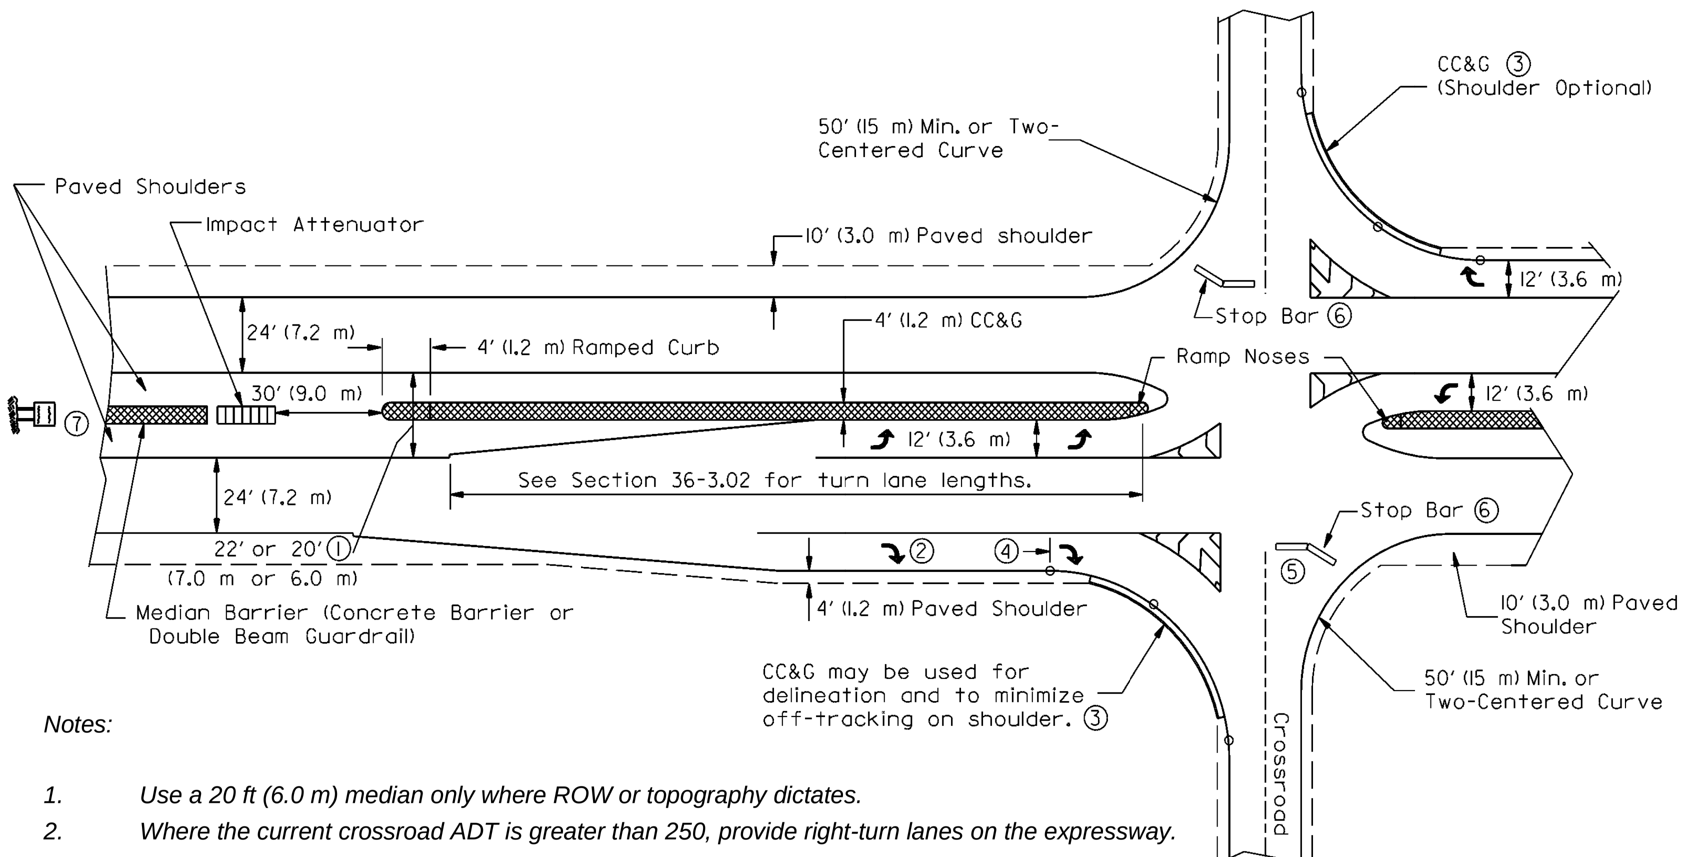
4. <u>Multilane Highways with Wide Medians</u>. Figure 36-3.N illustrates a typical parallel left-turn lane design with a wide depressed median. When using this design, consider the following:

    - This design is generally only used where the current crossroad ADT is less than 1500 and where the current left-turn DHV in each direction from the mainline is no greater than 60 vph.

    - On existing expressways or multilane facilities, median widths of 40 ft to 70 ft (12.0 m to 21.5 m) are allowed to remain in place.

    - On new construction or reconstruction projects, use a median width of 50 ft (15 m) and median slopes of 1V:6H.

    - Additional design details may be needed to incorporate a tapered left-turn lane or positive offset left-turn lane design to improve sight distance and safety; see Section 34-3.

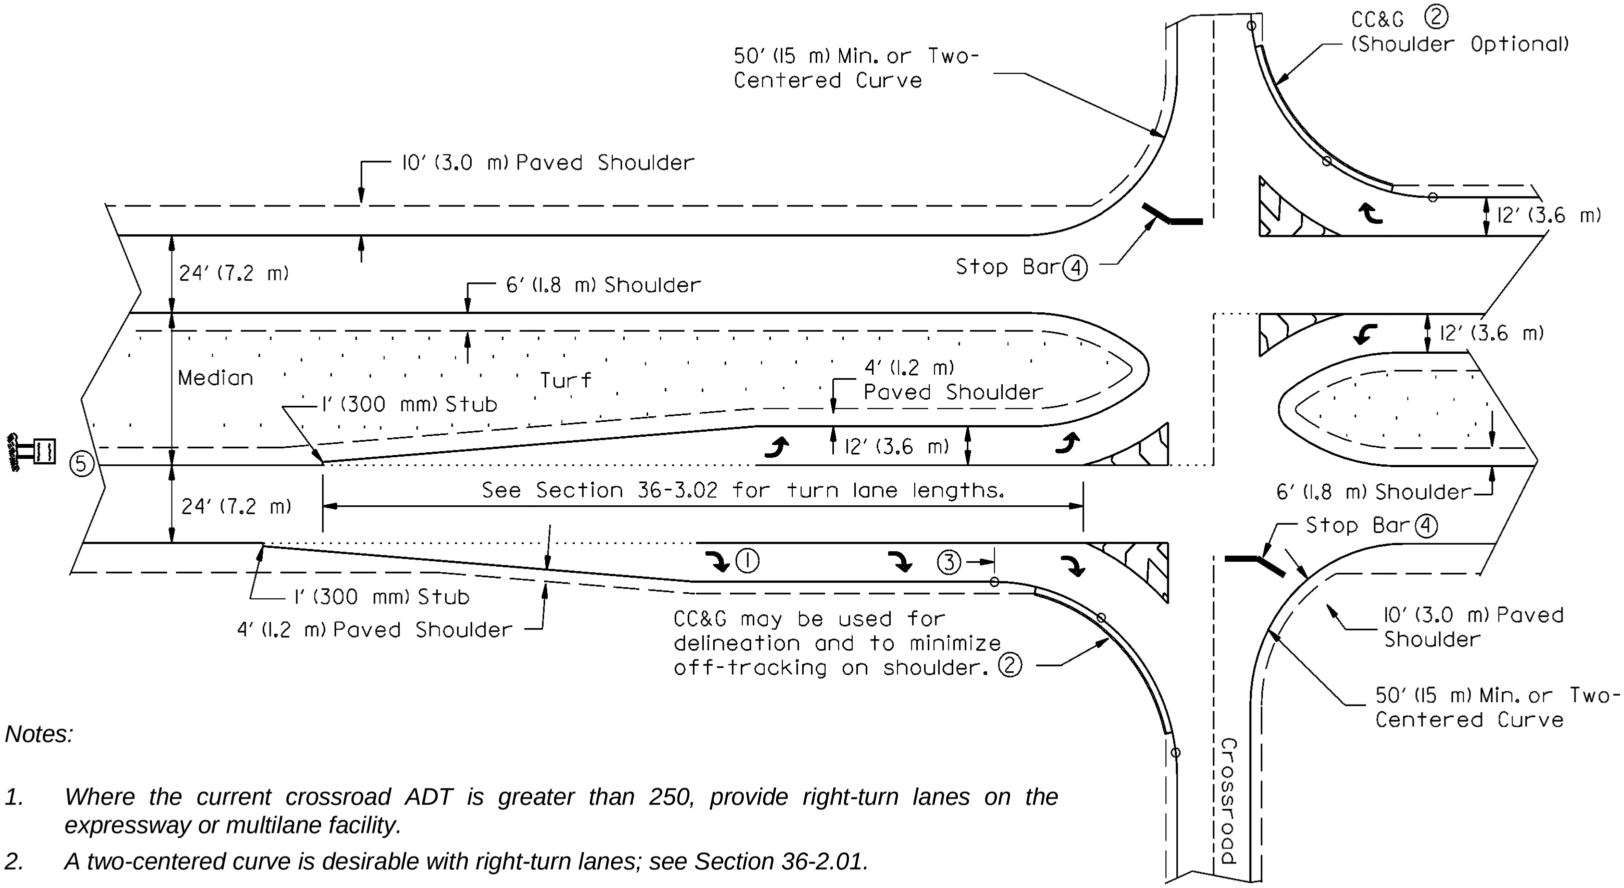


Notes:

1. *Use a 20 ft (6.0 m) median only where ROW or topography dictates.*
2. *Where the current crossroad ADT is greater than 250, provide right-turn lanes on the expressway.*
3. *A two-centered curve is desirable with right-turn lanes; see Section 36-2.01.*
4. *End the right-turn deceleration length at the beginning of the radius return.*
5. *Intersection sight distance must be checked for the vehicle on the side road for the line of sight past the median barrier.*
6. *For proper placement of a stop sign, a small triangular corner island may be required on the crossroad approach to the expressway.*
7. *See the Bureau of Operations'* Policy and Procedures Manual *for proper placement of advance guide signs.*

EXPRESSWAY INTERSECTION WITH MEDIAN BARRIERS
(Design Speed ≥ 50 mph (80 km/hr) and Narrow Median with Restricted ROW)

Figure 36-3.M



Notes:

1. *Where the current crossroad ADT is greater than 250, provide right-turn lanes on the expressway or multilane facility.*
2. *A two-centered curve is desirable with right-turn lanes; see Section 36-2.01.*
3. *End the right-turn deceleration length at the beginning of the radius return.*
4. *For proper placement of a stop sign, a small triangular corner island may be required on the crossroad approach to the expressway.*
5. *See the Bureau of Operations'* Policy and Procedures Manual *for proper placement of advance guide signs.*

See Section 36-3.03(b) for additional design details.

EXPRESSWAY OR MULTILANE FACILITY WITH A WIDE MEDIAN ≥ 40 ft (12 m)
(Parallel Left-Turn Lane Design without Offset)

Figure 36-3.N

36-3.03(c) Offset Left-Turn Lanes

Offset left-turn lanes can consist of either a tapered design or a parallel design. Figures 36-3.O through 36-3.S illustrate the various designs for offset left-turn lanes. In addition, the designer should consider the following:

1. Tapered Offset Left-Turn Lanes. Figure 36-3.O(1) illustrates a typical tapered offset left-turn lane design in a wide median. Figure 36-3.O(2) provides the details on the channelization portion of the offset design. The advantages of the tapered offset design versus a parallel lane design without an offset is that the offset design provides better visibility for the turning motorist to the opposing traffic, decreases the possible conflict between opposing left-turning vehicles, and serves more left-turning vehicles in a given time period. In addition, the designer should consider the following:

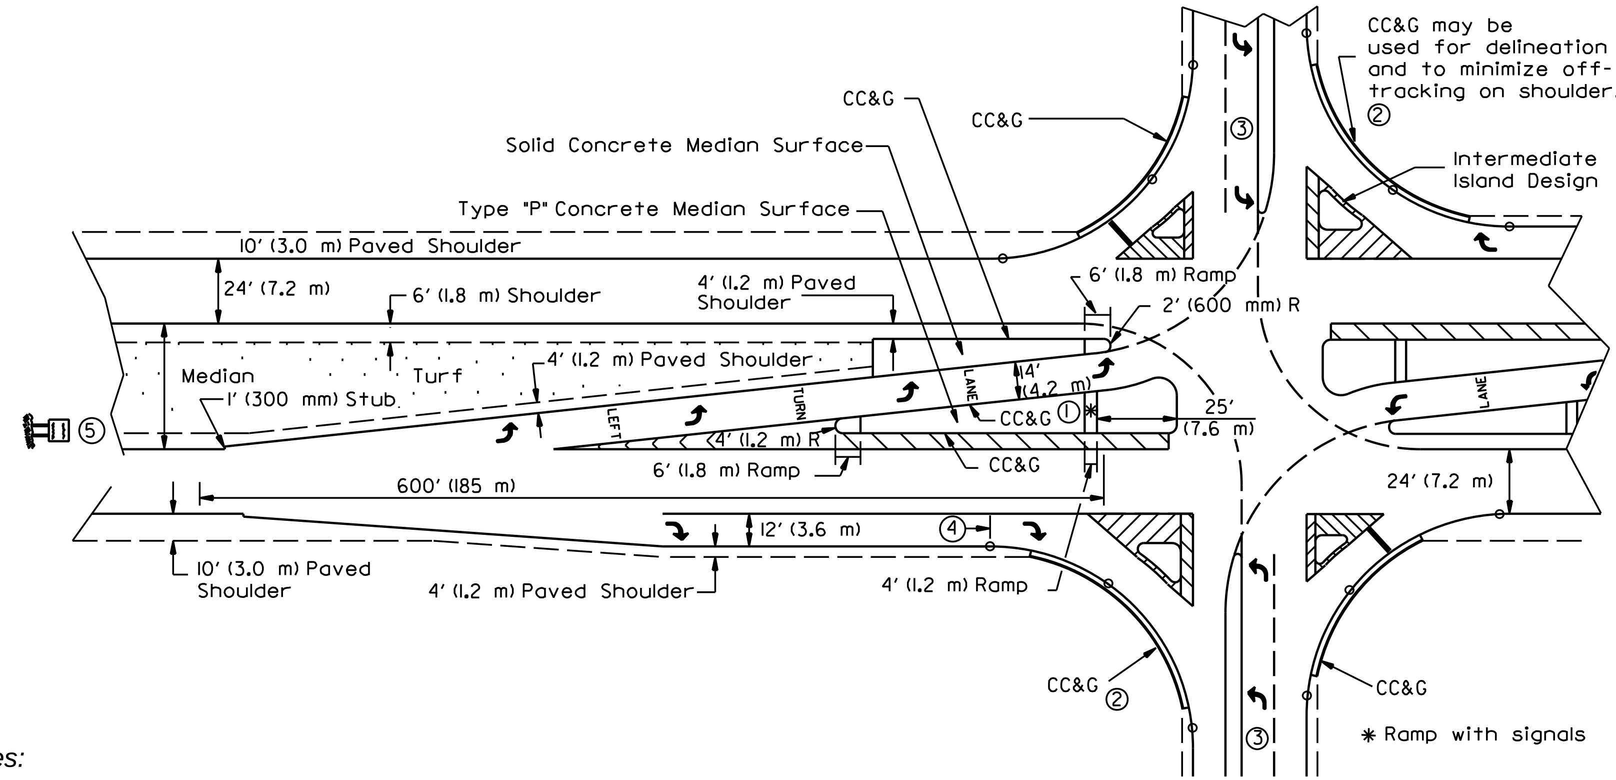
    a. Guidelines. Provide a tapered offset left-turn lane design where at least two of the following are applicable:

        - the median width is equal to or greater than 40 ft (12 m) and only one left-turn lane in each direction on the mainline highway is required for capacity;
        - the current mainline ADT is 1500 or greater and the left-turn DHV in each direction from the mainline is greater than 60 vph. Under these conditions, vehicles waiting in opposing left-turn lanes have the probability of obstructing each other's line of sight; and
        - the intersection will be signalized.

    b. Median Widths. Median widths of 40 ft to 70 ft (12 m to 21.5 m) are allowed to remain in place on existing expressways or multilane facilities. On new construction or reconstruction projects, use a median width of 50 ft (15 m) and median slopes of 1V:6H.

    c. Curb and Gutter. Use M-4 (M-10) curb and gutter on all corner and channelizing island, unless signals are placed within the island. In this situation, use M-6 (M-15) curb and gutter.

2. Parallel Offset Left-Turn Lanes. By maximizing sight distance for left-turning vehicles, parallel offset left-turn lanes offer similar advantages as the tapered design. However, they may be used at intersections with medians less than 40 ft (12 m) but greater than 13 ft (4.0 m). Figures 36-3.P, 36-3.Q, and 36-3.R illustrate the plan views for parallel offset left-turn lanes for median widths of 16 ft, 18 ft, and 22 ft (5.0 m, 5.5 m, and 7.0 m), respectively. Figure 36-3.S provides the typical section design criteria for all three median widths.



Notes:

1. *Place drainage inlets in the M-4.24 (M-10.60) gutter to facilitate drainage within the left-turn bay.*
2. *A two-centered curve is desirable with right-turn lanes; see Section 36-2.01.*
3. *Where a left-turn lane is required, design the median as a raised-curb median for delineation. Where no median is proposed, the minimum traveled way width should be 22 ft (6.6m).*
4. *End the right-turn deceleration length at beginning of the radius turn.*
5. *See the Bureau of Operation's* Policy and Procedures Manual *for proper placement of guide sign.*

Consider providing lighting at this intersection.

TYPICAL SECTION WITH PARALLEL OFFSET LEFT-TURN LANES

Figure 36-3.S

36-3.04 Right-Turn Lane Design

36-3.04(a) General

Section 36-3.02 provides design criteria for right-turn lane widths and lengths. Right-turn lanes may be designed with or without turning roadways depending on site conditions. Figures 36-3.H, 36-3.M, 36-3.N, and 36-3.O(1) illustrate typical designs for right-turn lanes. For information on the design of offset right-turn lanes see item (c) below.

36-3.04(b) Access within Right-turn Lanes

Because of potential conflicts with right-turning traffic, commercial entrances should not be allowed within the limits of the right-turn lane storage or taper.

36-3.04(c) Offset Right-turn Lanes

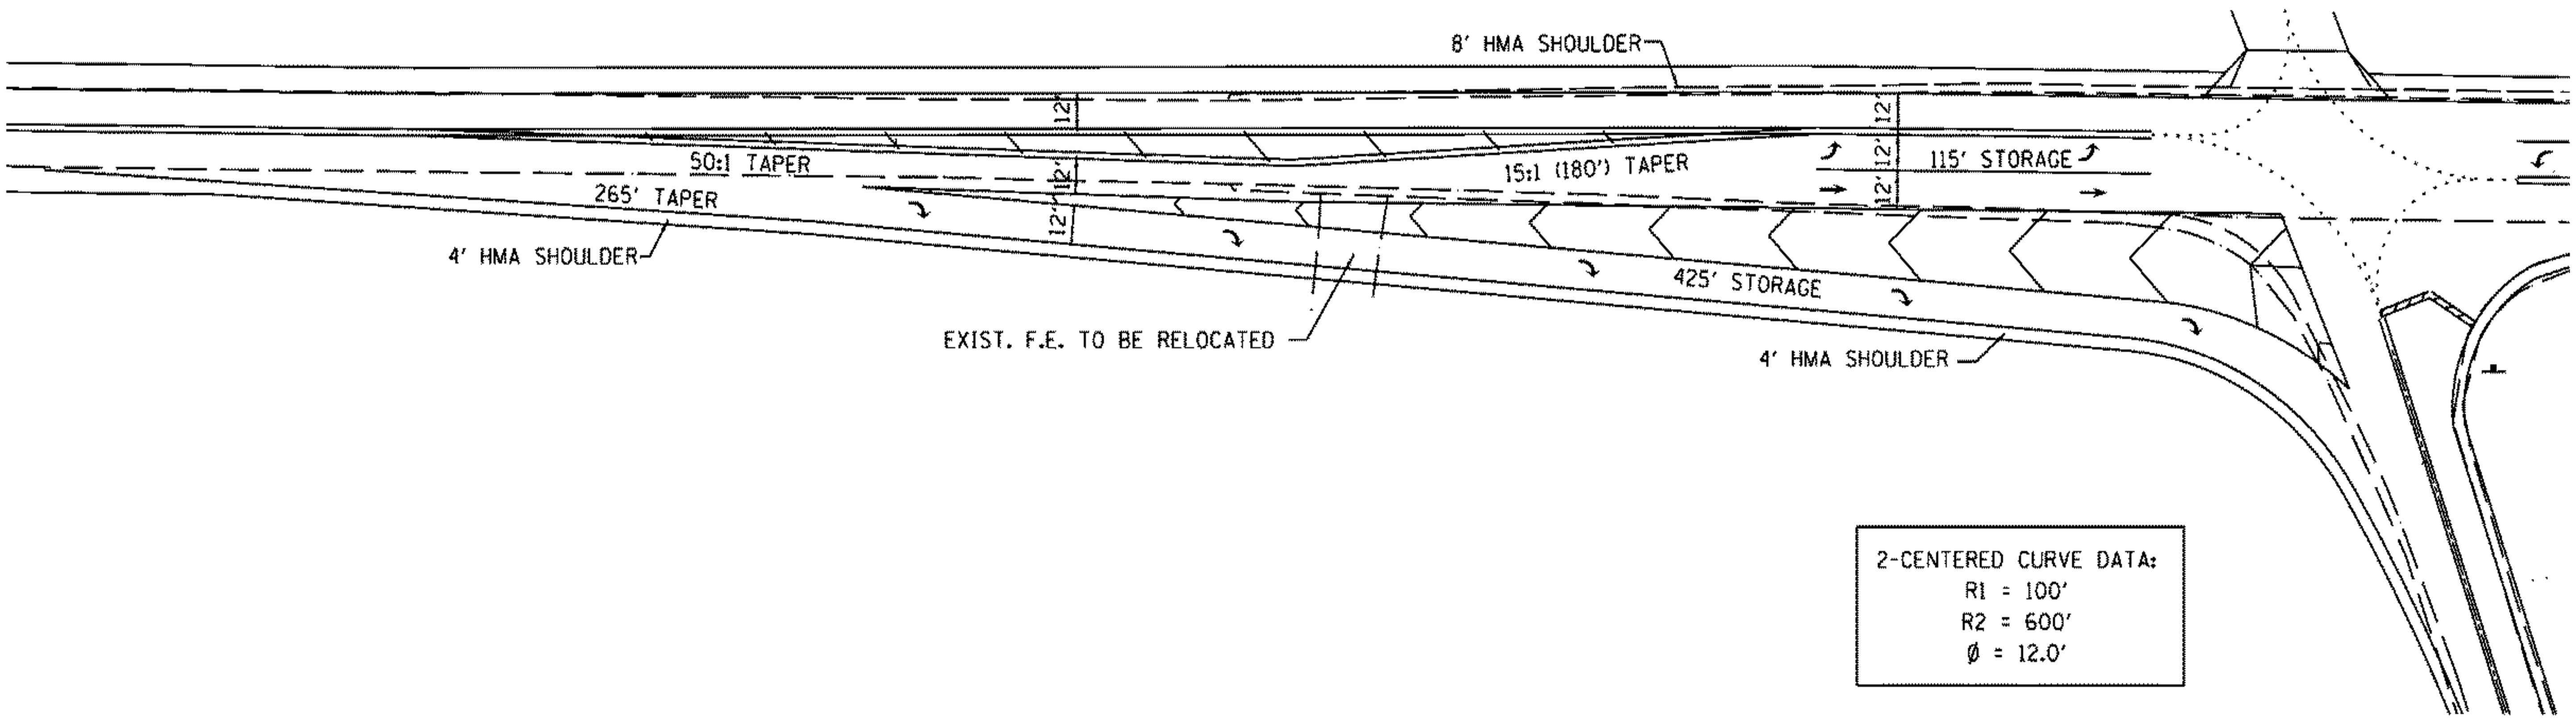
A potential problem in installing exclusive right-turn lanes at intersections is that vehicles in the right-turn lane on the major road, especially buses and large trucks, may block the minor-road drivers' view of through traffic approaching from the left. This can lead to crashes between vehicles departing from the minor road and those proceeding through on the major road. To reduce the potential for crashes of this type, right-turn lanes can be offset laterally so that vehicles in the right-turn lanes do not obstruct the view of the minor road driver. Figure 36-3.T(1) illustrates a typical tapered design for an offset right-turn lane at a high speed rural location. Alternatively, a parallel offset right-turn lane design can be considered which achieves the same sight distance enhancement objectives. An example of the parallel design is shown in Figure 36-3.T(2).

When an exclusive right-turn lane is proposed or currently exists within the project at an unsignalized tee or four-legged intersection, the use of an offset right-turn lane should be considered for the initial construction or as an intersection improvement, respectively, when any of the following factors exist or are proposed within the project's design life:

- Heavy volume of right-turning vehicles;
- High proportion of heavy vehicles (large trucks and buses) in the right-turning traffic stream, which may impede sight distance to the adjacent through lane(s) of traffic;
- Mainline horizontal curvature which reduces available sight lines, or
- Multi-lane crossroad approach.

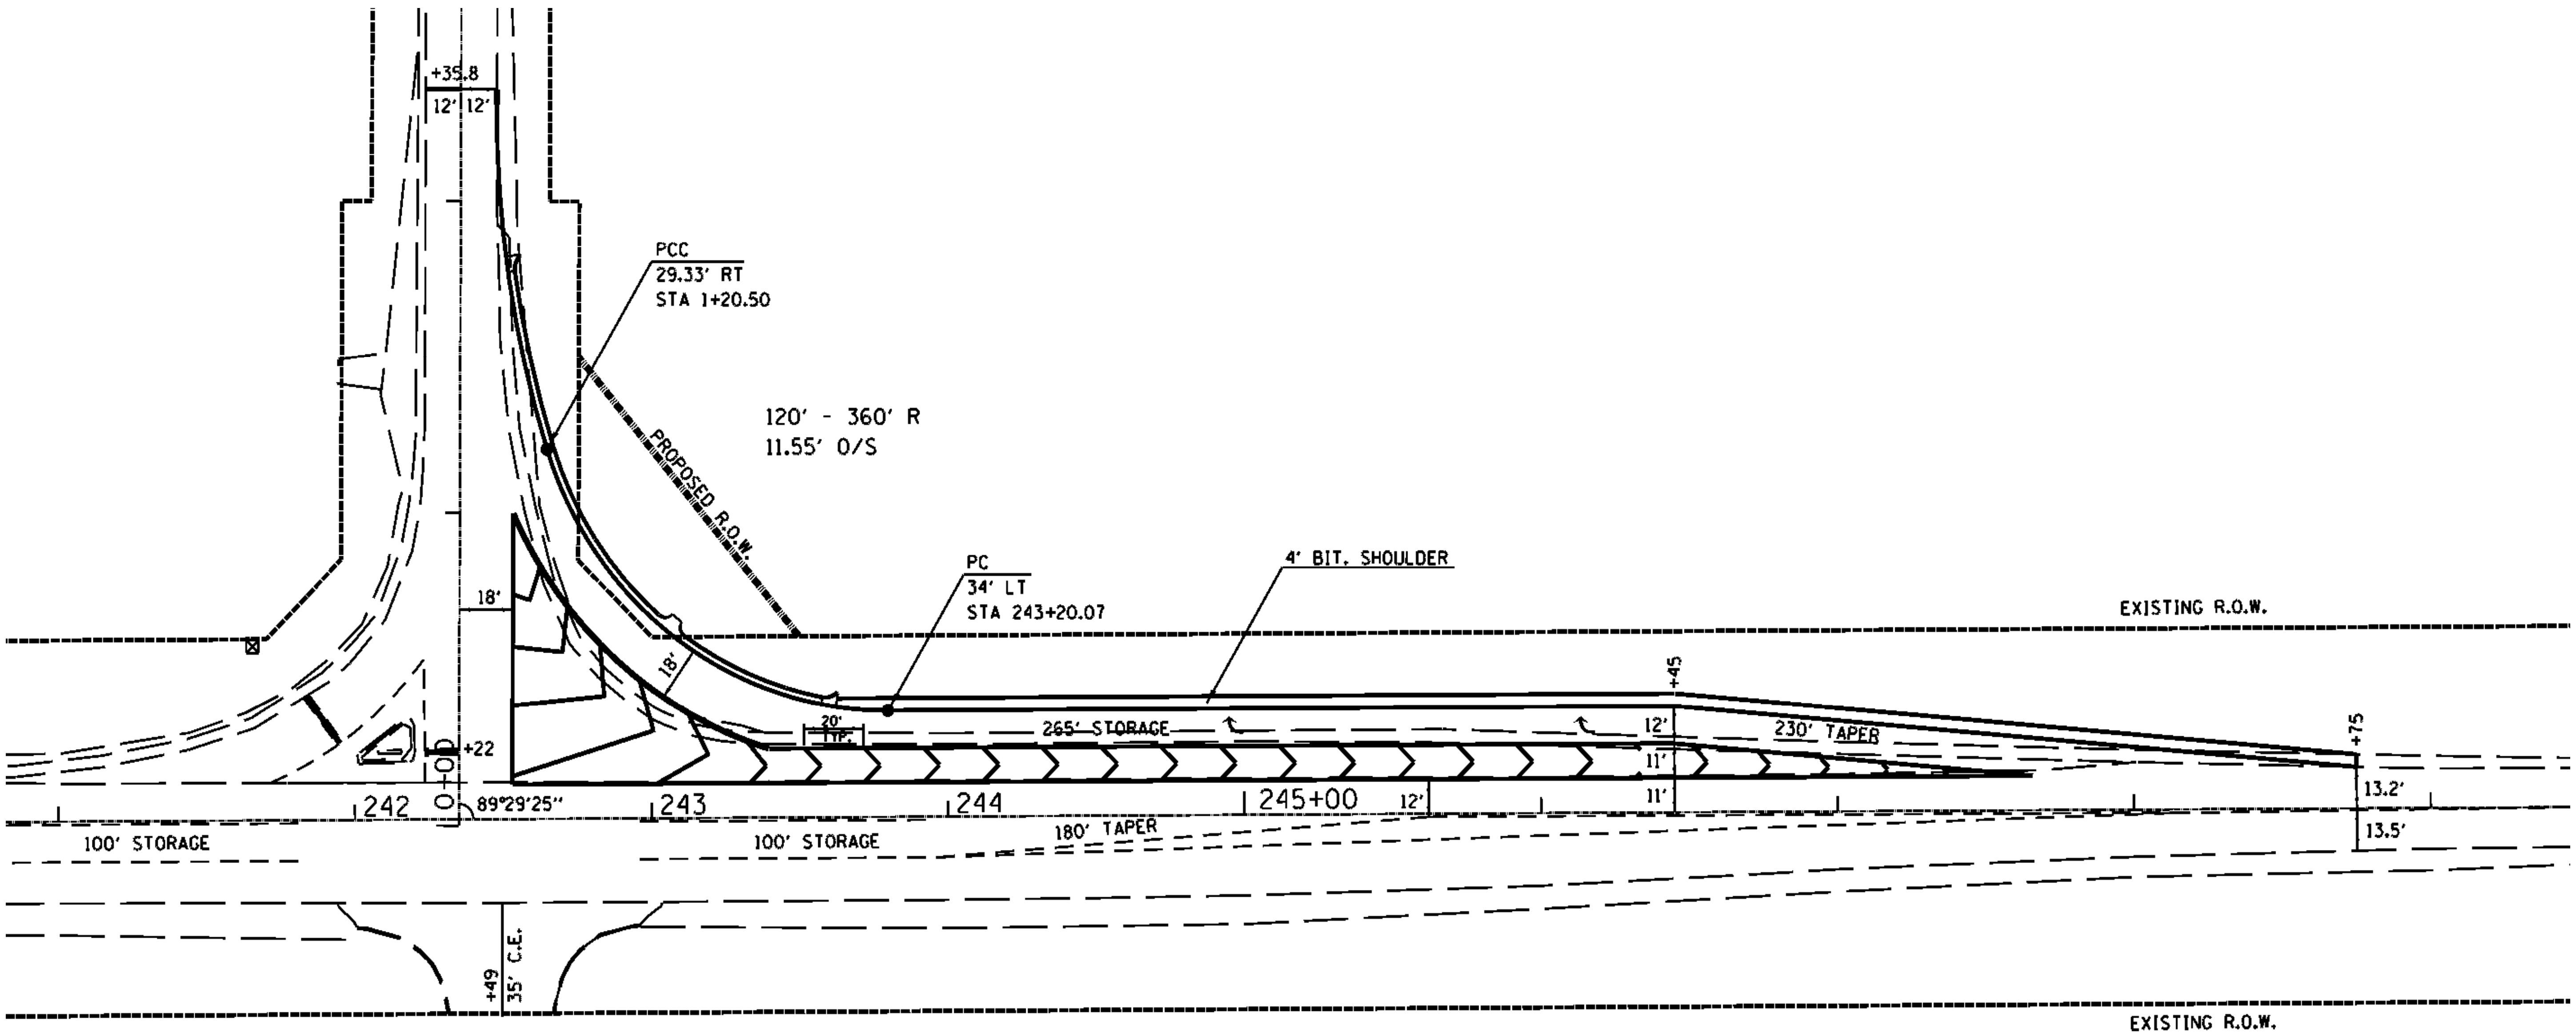
Existing crash data should also be used to support the decision to either install an offset right-turn lane or maintain or install a traditional right-turn lane, on existing routes.

Installation of offset right-turn lanes increases the overall width of the intersection. The additional width lengthens intersection crossing times thereby increasing pedestrian and bicyclist exposure



TAPERED OFFSET RIGHT-TURN LANE DESIGN EXAMPLE

Figure 36-3.T(1)



PARALLEL OFFSET RIGHT-TURN LANE DESIGN EXAMPLE

Figure 36-3.T(2)

within the intersection. This increase in exposure for these vulnerable users, in addition to the higher travel speeds that often result from this type of design, could lead to additional crash risks. A pedestrian refuge island could be installed between the offset right-turn lane and through lanes to mitigate these risks. However, raised islands should not typically be used on high speed approaches. Where pedestrians and bicyclists will be present, additional consideration should therefore be given before implementing offset right-turn lanes. In cases where an on-street bike lane is provided along the mainline, an offset right-turn lane would not typically be used.

36-3.05 Dual Turn Lanes

36-3.05(a) Guidelines

At intersections with high-turning volumes throughout the day, dual left- and/or right-turn lanes may be considered. However, multiple turn lanes may cause problems with right-of-way, lane alignment, local access, traffic signal phasing and visibility, signing locations, accommodating pedestrians, and erratic movements for turning drivers. In place of dual right-turn lanes, and while addressing pedestrian safety concerns, the designer may consider providing a turning roadway with a design speed of 15 mph (25 km/hr) or more and a free-flow, right-turn acceleration lane; see Section 36-2.03. Dual left- and/or right-turn lanes are generally considered where:

- there is insufficient space to provide the necessary length of a single turn lane because of restrictive site conditions (e.g., closely spaced intersections);
- based on a capacity analysis, the necessary time for a protected left-turn phase for a single lane becomes unattainable to meet the level of service criteria (average delay per vehicle); and/or
- more than 300 vph are projected to be turning.

Dual left and right-turn lanes should only be used with signalization providing a separate protected turning phase. Since a protected signal phase may increase signal inefficiencies that may negatively affect overall delay and level of service (LOS), it may be more prudent to provide a single left- or right-turn lane, and with it, a permissive left-turn signal and/or the allowance of right-turns on red if the volume warranting dual turn lanes only occurs for one or two hours of the day. However, permissive left-turns across three lanes of opposing through traffic should be avoided.

36-3.05(b) Design

Figure 36-3.V illustrates the more important design elements for dual left-turn and right-turn lanes. Figure 36-3.W illustrates a typical cross section for a dual left-turn lane design. In addition, the designer should consider the following:

1. Taper Length. Taper lengths for dual turn lanes should be a minimum of 300 ft (90 m); see Figure 36-3.V.

2. Turning Radii. The turning radii for dual left-turns should be a minimum of 90 ft (27 m). This will allow for two vehicles to comfortably negotiate the turns side-by-side.

Two-Lane Left-Turn Facilities		
Inner Radius	**Traveled Way Edge Design**	**Minimum Width of Departure Opening**
90 ft to 160 ft (27 m to 49 m)	Shoulder and Shoulder Curb and Shoulder Curb and Curb	35 ft (10.5 m) E-E 35 ft (10.5 m) + GW 35 ft (10.5 m) + GWs
160 ft to 250 ft (50 m to 75 m)	Shoulder and Shoulder Curb and Shoulder Curb and Curb	33 ft (9.8 m) E-E 33 ft (9.8 m) + GW 33 ft (9.8 m) + GWs

GW = Gutter Width E-E = Edge to Edge

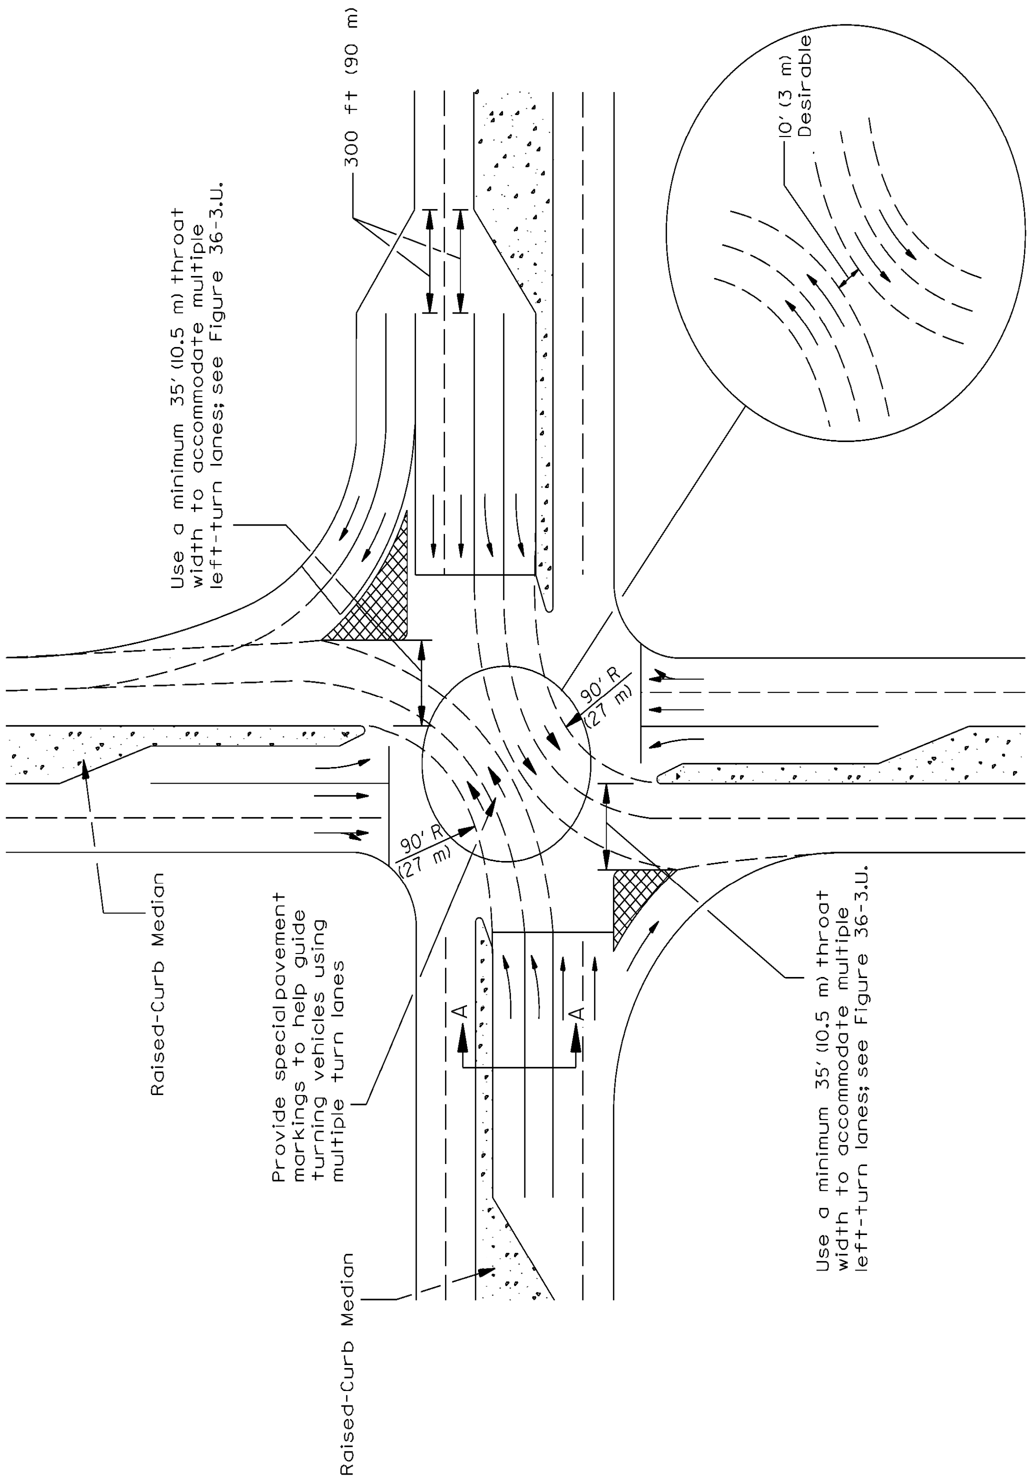
MINIMUM DEPARTURE OPENINGS FOR DUAL LEFT-TURN LANES

Figure 36-3.U

3. Throat Width. On dual left-turn lanes, the presence of center and corner islands may lead to an increase in shy distances that will restrict turning paths, therefore, the design width of the left-turning paths is critical. Also, the magnitude of the inner radius influences the amount of off-tracking and, as such, the required width of the turning path. Figure 36-3.U gives the minimum widths of two-lane, left-turn departure openings based on the dimension of the inner radius and on the design of the traveled way edges at the most critical location of off-tracking. A computer simulated turning template program should be used when possible to check turning path/throat width design.

4. Median Widths and Type. Dual left-turn lanes require a minimum median width of 30 ft (9.0 m). For access management, the median shall be barrier curb, where the design speed is less than 50 mph (80 km/hr). If the design speed is 50 mph (80 km/hr) or greater, a divided median should be considered or mountable curb should be utilized. The median approaching the left turn lanes should fully shadow the dual left-turn lanes. If the median width approaching (upstream) the intersection is less than 30 ft (9.0 m), 30 ft (9.0 m) minimum median width and barrier type curb should extend, at a minimum, throughout the length of the left turn bay taper and storage up to the stop bar.

5. Special Pavement Markings. Consult with the District Bureau/Section of Traffic or the Bureau of Operations in the Central Office for the use of pavement marking within the intersection to effectively and safely guide two lines of vehicles turning abreast.

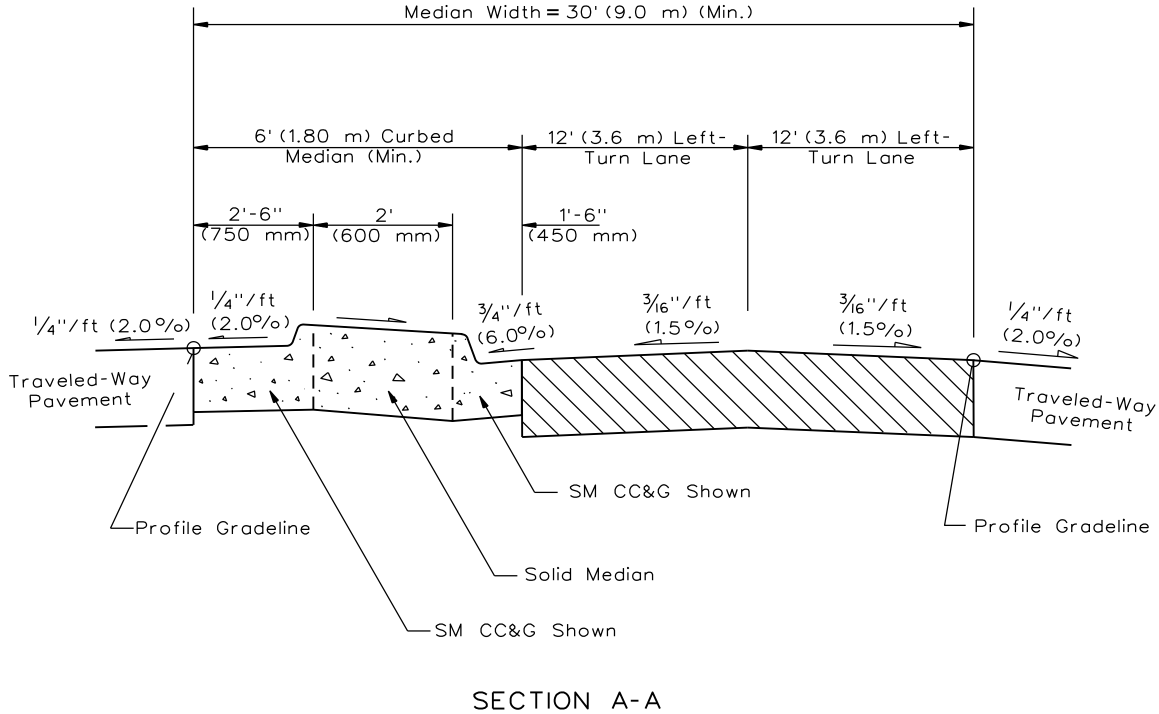


SCHEMATIC FOR DUAL LEFT AND RIGHT-TURN LANES
(Raised-Curb Median)

Figure 36-3.V

6. Opposing Left-Turning Traffic. If opposing dual left-turn lanes are proposed, the designer must ensure that there is sufficient space for all turning movements. Desirably, the separation between the outside edges of the opposing left-turn turning paths should be 10 ft (3.0 m); see Figure 36-3.V. If space is unavailable, it will be necessary to alter the signal phasing to allow the two directions of turning traffic to move through the intersection on separate phases.

7. Turning Templates. The turning paths for multiple turn lanes must be checked for conflicts by using the applicable turning templates or a computer simulated turning template program. The designer should assume that the selected design vehicle will turn from the outside lane of the multiple turn lanes. Desirably, the inside vehicle should be an SU but, as a minimum, the inside vehicle can be assumed to be a passenger car turning side by side with the selected design vehicle. Include a printout of the computer simulated turning paths with the IDS, if applicable.



Note: See Figure 36-3.U for location of Section A-A.

TYPICAL SECTION WITH DUAL LEFT-TURN LANES
(Raised-Curb Median and Posted Speed < 50 mph (80 km/hr))

Figure 36-3**.W**

36-4 CHANNELIZING ISLANDS AND MEDIAN TREATMENTS

Several of the design elements described in this chapter require flush or raised channelizing islands and/or median treatments within the intersection area. Some intersections, especially those with oblique angle crossings, result in large paved areas that may cause motorists to wander from natural or expected paths and may cause long pedestrian crossings. These movements may result in conflicts and/or unpredictable operations, and could be enhanced by incorporating channelizing islands or medians in the design of the intersection.

At rural locations where higher speeds are prevalent, flush channelizing medians and islands can be used in conjunction with left-turn lanes and for turning roadways. In urban areas where speeds generally are lower, but where traffic volumes are generally higher, raised channelizing islands are used in conjunction with added lanes primarily to increase capacity and safety at the intersection.

36-4.01 Island Types

Islands can be grouped into the following classifications. Most island types serve multiple functions:

1. Corner/Directional Islands. Directional or corner triangular islands control right-turn movements by providing positive alignment guidance. Section 36-2.02 discusses corner islands.

2. Center Channelizing Islands. Center channelizing islands (also known as channelizing medians) separate opposing traffic flows, alert the driver to the crossroad ahead, and regulate traffic through an intersection. These islands are often introduced at intersections on undivided highways and are particularly advantageous in controlling left-turns at skewed intersections.

3. Refuge Islands. Refuge islands may include both corner islands and center channelizing islands, and function to aid and protect pedestrians who cross a wide roadway. These islands may be required for pedestrians where complex signal phasing is used and may permit the use of two-stage crossings. Their use may also increase traffic signal efficiency by allowing the time allocated for pedestrian movements to be reduced. In order to qualify as a pedestrian refuge area islands must have raised curb and certain minimum dimensions, including 6 ft (1.8 m) between curb faces.

36-4.02 Selection of Island Type

Islands may be some combination of flush, traversable, raised-curb, or turf, and could be triangular or elongated in shape. Selection of an appropriate type of channelizing island should be based on:

- traffic characteristics;
- cost considerations;
- location type (urban, suburban, or rural);

- degree of access management desired,
- safety of all roadway users, and
- maintenance considerations.

The remainder of this section offers guidance on the selection and design of islands and medians.

36-4.02(a) Flush or Traversable Islands

Flush islands, which are delineated by pavement markings (e.g., paint, thermoplastic, epoxy), or traversable islands, which are delineated by M-2 (M-5) curbs, are appropriate:

- on highways to delineate separate left-turn lanes (flush or traversable);
- in restricted locations where delineation of vehicular paths is desirable, but space for larger, raised-curb islands is not available (flush);
- in areas where better long-term visual delineation is needed at night and during inclement weather, but space for raised-curb islands is not available (traversable);
- to separate opposing traffic streams on low-speed urban streets (flush or traversable); and/or
- for temporary channelization during construction (flush).

36-4.02(b) Raised-Curb Islands

Raised-curb islands are bordered by barrier (B-type) or mountable (M-type) curb at least 4 in. (100 mm) high, and are appropriate as follows:

- on low-speed highways where the primary function is to provide positive separation for opposing traffic movements;
- at locations requiring positive delineation of vehicular paths, such as where a major route turns or at intersections with unusual geometry (including approaches to roundabouts);
- where the island is intended to prohibit or prevent traffic movements (e.g., wrong-way movements or to manage access within the intersection);
- where the number of lanes and/or volume of traffic being crossed by motorists attempting to turn left from adjacent entrances in the vicinity of the intersection would otherwise pose safety concerns;
- where traffic back-ups on the mainline intersection approach could otherwise cause sight distance restrictions to traffic turning from either the mainline or adjacent entrances in the vicinity of the intersection;
- where a primary or secondary island function is to provide a location for traffic signal poles or signs; and/or
- where one function of the island is to provide a pedestrian refuge.

Raised-curb islands and medians are generally not used in rural environments, but may be utilized to address specific safety and operational concerns at rural intersections having the following characteristics:

- on the crossroad through an interchange to delineate median crossovers and turn lanes, and to prevent wrong-way movements, and
- at unusual or complex intersection configurations where higher visibility would promote greater safety and more efficient traffic operations.

Where curb and gutter is proposed in rural areas with design speeds of 50 mph (80 km/h) or greater, use only mountable curbs, offset the curb faces from the edges of pavement by up to the shoulder width, and consider providing supplemental intersection illumination. In addition, provide prismatic reflectors on the top of curbs to enhance delineation of the island and turn lanes at night. Section 34-2.04 provides further guidance on the types of curbing used for islands.

36-4.02(c) <u>Pavement Edge Islands</u>

Channelizing islands formed by pavement edges generally only apply to rural or suburban areas. One example of this channelization type is where a divided four-lane facility with a median ditch section is temporarily tapered to a two-lane highway section. This reduction of the four lanes down to two is considered channelization. See Chapter 45 for details of these channelized approaches.

36-4.03 <u>Design of Islands and Median Treatments</u>

36-4.03(a) <u>Channelizing Islands</u>

Special care is necessary in their design of channelizing islands to ensure that they do not become a hazard. The designer should consider the following criteria:

1. <u>Nose</u>. Place the noses of raised-curb islands so that they are conspicuous to approaching motorists and clear of the assumed vehicular paths. This clearance should be both physical and visually apparent so that drivers will not shy away from the island.

2. <u>Nose Ramping</u>. Ramp the approach nose of raised-curb according to the criteria presented in the *IDOT Highway Standards*. Nose ramping is applicable where:

   - a raised-curb median or curbed centerline channelization is introduced to separate opposing lanes of traffic;
   - a change is made from a flush or traversable two-way, left-turn lane to a raised-curb median; and
   - median crossovers or openings are outlined with curb and gutter.

   At locations that are designed for pedestrian refuge, and/or include traffic signal poles or light standards, nose ramping is typically not done.

3. Alignment. Provide a smooth, free-flowing alignment both into and out of the divided roadway. On entering the channelized approach, widen the traveled way out opposite the curbed nose and gradually transition it to the normal divided traveled way width. Also, provide a gradual transition on the departure side of the divided roadway. Where two lanes are being funneled down to one lane on the departure side of the channelizing island, provide sufficient pavement width and/or an outside paved shoulder at the curbed nose to provide some lateral escape clearance for merging vehicles. This addresses a situation where, for example, a motorist has failed to observe the single lane warning signs and is mistakenly operating two abreast as the vehicle approaches the transition to two-lane, two-way operations.

4. Island Size. Traffic channelizing islands should be designed to command the driver's attention. Island shapes and sizes are unique at every intersection. For raised-curb islands introduced at isolated intersections, the divisional island should be designed according to the IDOT publication *Transitional Approaches to Channelized Intersections* and Figure 36-3.L. Also, see Figure 36-4.A. For flush, channelizing islands introduced at isolated intersections; see Figures 36-3.J and 36-3.K.

5. Island Length. The island should be of sufficient length to forewarn a motorist of an approaching intersection and to provide space for the proper development of a free-flowing alignment. The edge of the traveled way, the width of the divided roadways, and the width of the center channelizing island normally control the length of island and the pavement edge radii.

6. Delineation. Channelizing islands should be delineated based on their size, location, and function. Raised-curb islands present the most positive means of delineation. Where space is limited, use paint to delineate the island. Raised pavement markers, curb-top reflectors, or paint striping can be used in advance of, and around, an island to help alert the driver of an approaching island. These traffic control devices are especially important at the approach to raised-curb divisional islands.

   Round the approach and merging ends of curbed islands according to Figure 36-4.A.

7. Offsets. Figure 36-4.A provides guidance on the applicable offsets that should be used with curbed-channelizing islands.

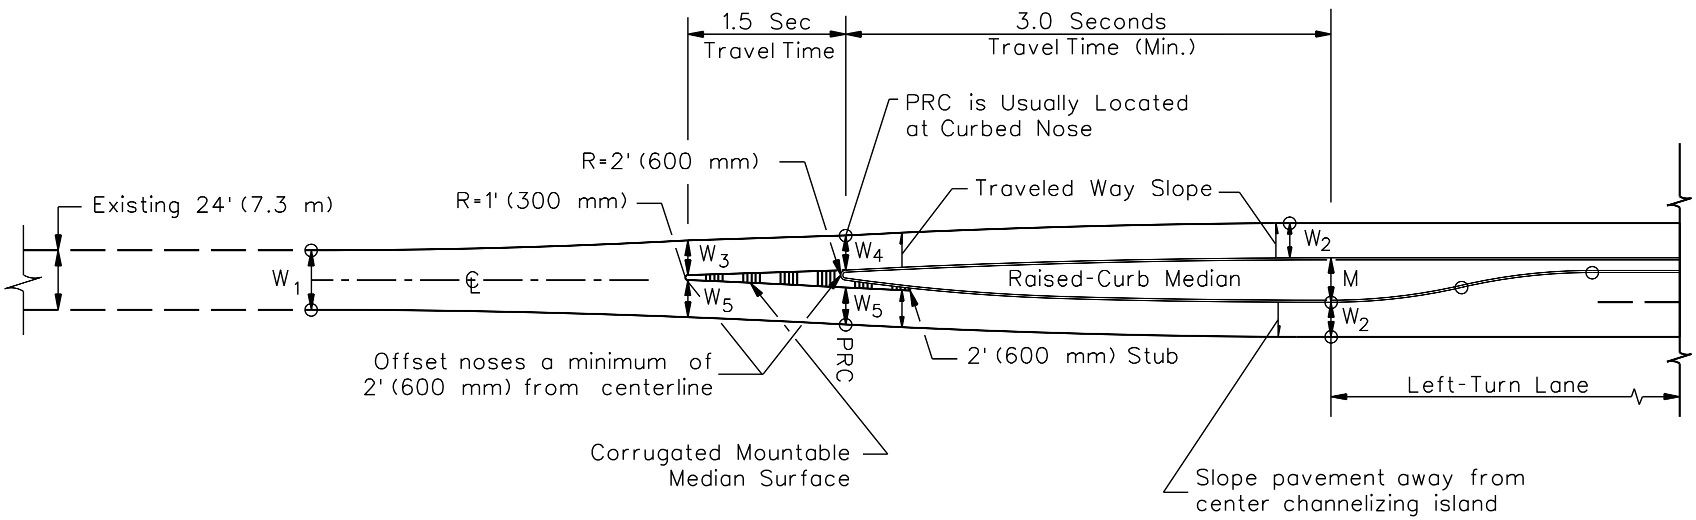
8. Corrugated Median Surface. In advance of the curbed nose of a divisional island, provide a sufficient length of corrugated median that allows the driver enough warning time to move away from the raised-curb island. Use 1½ seconds of travel time based on the design speed to determine the length of the corrugated surface.

9. Cross Slopes. With center curbed-channelizing islands up to approximately 32 ft (9.5 m) wide, and where such islands are located on tangent segments or on very flat curvature, the length of the island normally provides sufficient distance for gradual lateral shifts of traffic either to the right (entering) or to the left (departing). Because the required lateral shifts usually are not greater than the normal rate of lane shifts made during a passing measure, the cross slope of the pavement through the channelized approach can be unidirectional at 3/16″/ft (1.5%) or 1/4″/ft (2%) and should be sloped away from the island.

10. Stopping Sight Distance. At a minimum, provide stopping sight distance to the ramped nose of the island. Desirably, provide decision sight distance to the ramped nose.

11. Typical Designs. Figure 36-4.A illustrates a typical curbed divisional island and applicable approach treatment. Guidance for standardized designs based on various design speeds, pavement widths, and island widths are provided in IDOT's *Transitional Approaches to Channelized Intersections*. This document can be found on the IDOT website. For flush-channelizing islands, see Figures 36-3.J and 36-3.K.

12. Simplicity. Do not introduce divisional islands in areas which can create confusion due to complexity or which cause excessive restrictions. Complex intersections, which present multiple choices of movement, are undesirable. Ensure that the design remains simple to minimize the potential for driver confusion.



Notes:

1. *For additional design details, see the IDOT publication* Transitional Approaches to Channelized Intersections.
2. *The length and shape of channelizing islands derived from the above sketch also may be used as a guide for determining a flush, center island design.*
3. *If W_2 = 14 ft (4.2 m), use a 3/16″/ft (1.5%) drainage slope on the traveled way.*
4. *If W_2 = 22 ft (6.6 m) or 24 ft (7.2 m), use a 1/4″/ft (2.0%) drainage slope on the traveled way.*
5. *Ramp nose at W_4 location.*

M = *See Figure 36-3.L for typical median widths*

W_1 = *Undivided approach width*

W_2 = *Divided approach width*

$W_3 = \frac{W_1}{2}$ *or 14 ft (4.2m), whichever is larger*

$W_4 = \frac{W_3 + W_2}{2}$, desirable

$W_5 = W_2 + 1$ *ft (300 mm)*

TYPICAL CHANNELIZING ISLAND DESIGN
(Raised-Curb Medians)

Figure 36-4.A

36-4.03(b) Pedestrian Refuge Within Islands

Raised islands may be incorporated into the design of signalized intersections for multiple reasons. The FHWA notes that overall safety will usually be enhanced in urban and suburban areas if crosswalks at signalized intersections direct pedestrians through raised curb islands with adequate space for refuge. These areas allow pedestrians to break major street crossings into multiple shorter stages. This allows for shorter cycle lengths and places pedestrians in locations that make them more highly visible to drivers.

Concerns related to the provision of raised median refuge and raised corner island refuge may include added right of way, challenges in snow removal, the need for future island repairs, and the potential for more fixed object hazards immediately adjacent to traffic. Consider providing delineation of refuge islands using curb-mounted delineators. To the extent possible, locate signal poles outside intersection returns. Coordinate with district operations staff regarding the advantages of refuge areas and to hear any operational concerns. Weigh trade-offs related to any return widening required to create space for raised corner islands. Ideally, provide a balanced design that includes raised pedestrian refuge features within a compact overall intersection footprint.

See Sections 36-2.02 and 36-2.03 for overall design guidance applicable to corner islands, and Section 58-1 for the application of ADA criteria at intersections. Refer also to Section 17-4 for additional pedestrian intersection design guidance.

Corner islands at urban and suburban intersections must meet all requirements for pedestrian accessibility and refuge. Rather than designing with sloped curb ramps it is often preferable to maintain pedestrian access routes (PARs) at pavement-level through islands. Standard 424031 provides details for median pedestrian crossings that include curb ramps, and Standard 606001 shows the associated depressed curb requirements. By keeping the PAR at pavement level there will typically be no grade breaks within the island; depressed curb in those cases can be optional. In either case, the portion of raised island surrounding the PAR area(s) should be of sufficient size to distinguish it as a raised island and to make it easily constructible.

The minimum PAR width at all points through islands shall be 5 ft (1.5 m). Corner islands will often serve as the junction of three crosswalks and will have multiple PARs that each must meet accessibility requirements. Consider each PAR independently and ensure that the cross slope along each is 2.0 percent or less.

At signalized locations pedestrian pushbuttons and pedestrian signal heads will typically be incorporated into any raise island that provides refuge opportunities. Exceptions may occur, however, for raised medians where cycle lengths are sufficient to clear pedestrians through the entire crossing of a leg. There may be a need for two or three pushbuttons and pedestrian signal heads within a corners island. In those cases, size limitations will make it acceptable to provide less than the preferred 10 ft (3.0 m) separation between pushbuttons. The face of each pushbutton should be parallel to the crosswalk to be used, and buttons should be offset sufficiently such that users of each pushbutton location can simultaneously dwell within the island. Criteria for both the maximum side reach offset and minimum pole distance from face of curb must be satisfied. Within these constraints minimize the total number of poles within each island. Provide pushbutton extensions as necessary to achieve a fully accessible design within required reach ranges. Keep utility covers out of the PAR to the extent possible.

To further inform design that incorporates refuge areas, refer to the Central Bureau of Operations' document entitled *Policy on Pedestrian Pushbutton Locations and Accessible Pedestrian Signals,* Section 4E.08 of the *Manual on Uniform Traffic Control Devices,* and Sections R403, R406, and R407 of the *draft PROWAG*.

36-4.04 Median Openings

36-4.04(a) Location/Spacing

Property owners and/or local agencies may desire that median openings be provided on divided highways at all public roads and major traffic generators. However, this may result in close intersection spacing that may impair the operation of the facility. The following recommended minimum spacings should be evaluated when determining the location for a median opening:

1. Rural Facilities. Median openings should be at least ½ mile (800 m) apart and, desirably, 1 mile (1.6 km) apart, subject to public service requirements and as determined by an engineering study.

2. Urban Facilities. The desirable minimum spacing between median openings should be approximately ¼ mile (400 m). At a minimum, the spacing of median openings should be far enough apart to allow for the development of exclusive left-turn lanes with proper lengths.

For both rural and urban facilities, the available sight distance in the vicinity of a median opening is also a factor in the determination of its location. In addition, on some facilities, commercial establishments with heavy truck traffic may dictate the location of median openings. For additional details on the location and spacing of median openings, see Chapters 45 through 48.

36-4.04(b) Design

Figure 36-4.B presents a general figure for the design of a median opening at an intersection. The following will apply to the design of median openings:

1. Design Vehicle. Use the largest vehicle that will be making a left turn with some frequency. See Section 36-1.08 for guidelines in selecting the design vehicle.

2. Encroachment. The desirable design will allow the design vehicle to make a left turn and to remain entirely within the through inside lane of the divided facility. In addition, the turning vehicle should be no closer than 2 ft (600 mm) to the inside curb or inside edge of pavement. However, depending on traffic control or available intersection sight distance, it would be acceptable for the design vehicle to occupy both travel lanes; see Figure 36- 4.B.

3. Length of Opening. The length of a median opening should properly accommodate the turning path of the design vehicle. The minimum length is the largest of the following:

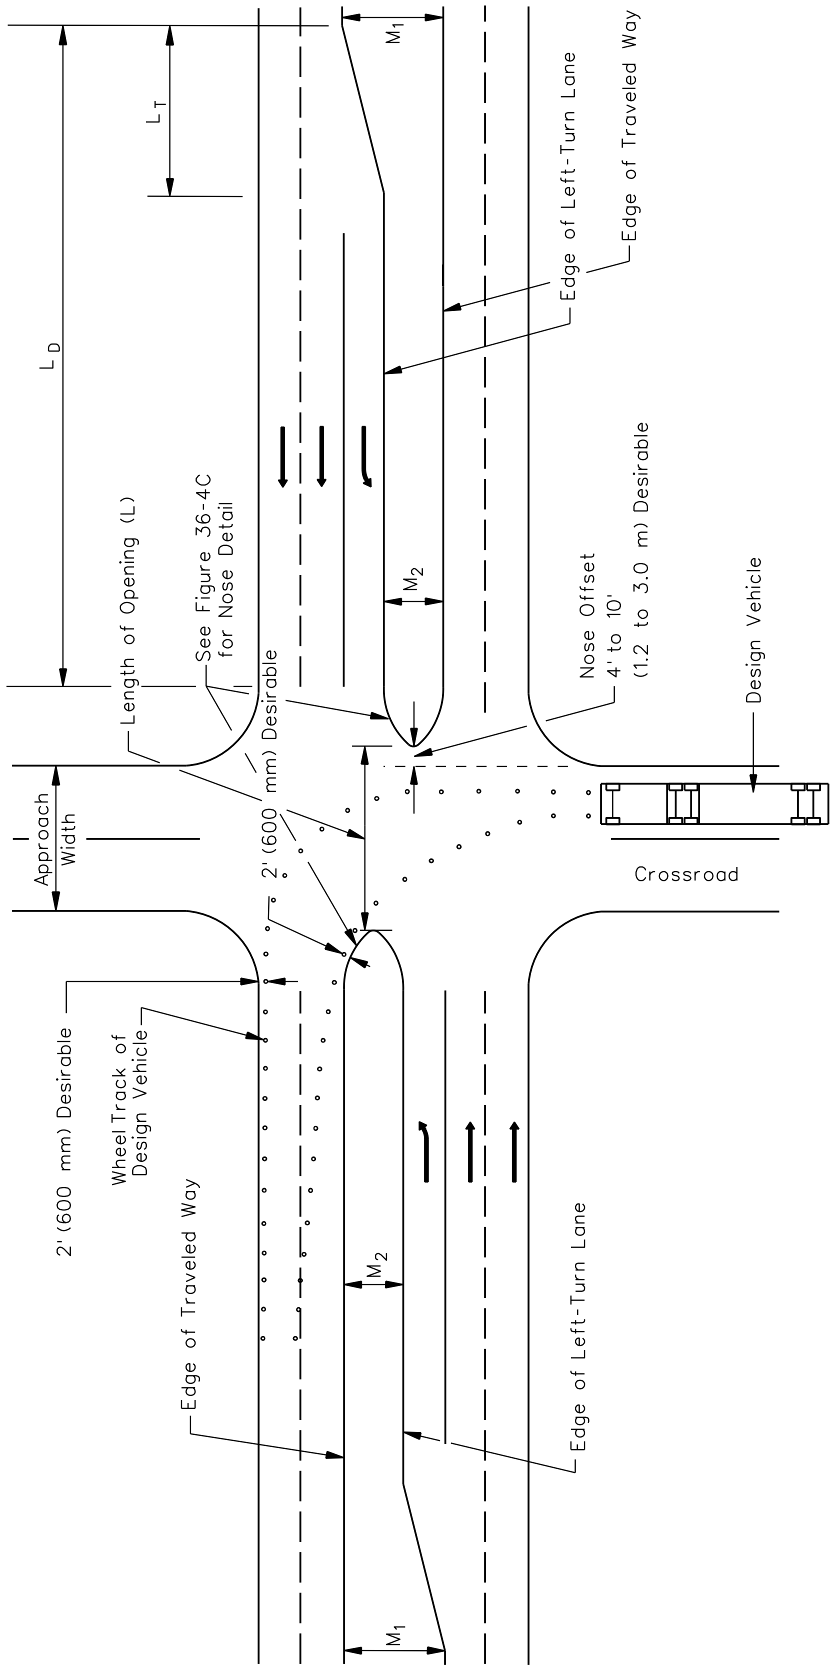
   - approach width plus 8 ft (2.4 m), including crossroad median width;
   - approach width plus the width of shoulders, including crossroad median width;
   - the length based on the selected design vehicle; or
   - 40 ft (12 m).

   Evaluate each median opening individually to determine the proper length. Consider the following factors in the evaluation:

   a. Turning Templates. Check the proposed design with the turning template for the selected design vehicle. Give consideration to the frequency of the turn and to the encroachment onto adjacent travel lanes or shoulders by the turning vehicle.

   b. Nose Offset. At four-leg intersections, traffic traveling through the median opening (going straight) will pass the nose of the median end (semicircular or bullet nose). To provide a sense of comfort for these drivers, the offset between the crossroad through travel lane (extended) and the median nose should be at least 4 ft (1.2 m).

   c. Lane Alignment. Provide a design where the lanes line up properly across the intersection. Consider the use of tapered left-turn lanes within the median to provide additional sight distance to oncoming traffic at both signalized and unsignalized median crossings.



Note: See discussion in Section 36-4.04(b) for minimum L criteria.

MEDIAN OPENING DESIGN

Figure 36-4.B

d. Location of Crosswalks. Wherever pedestrians may be present and geometrics allow, consider a crosswalk design that intersects a raised median near the nose to provide a refuge area.

e. Traffic Control. The geometrics engineer should coordinate with the district Bureau of Operations on the design of the intersection for signing, striping, and traffic control.

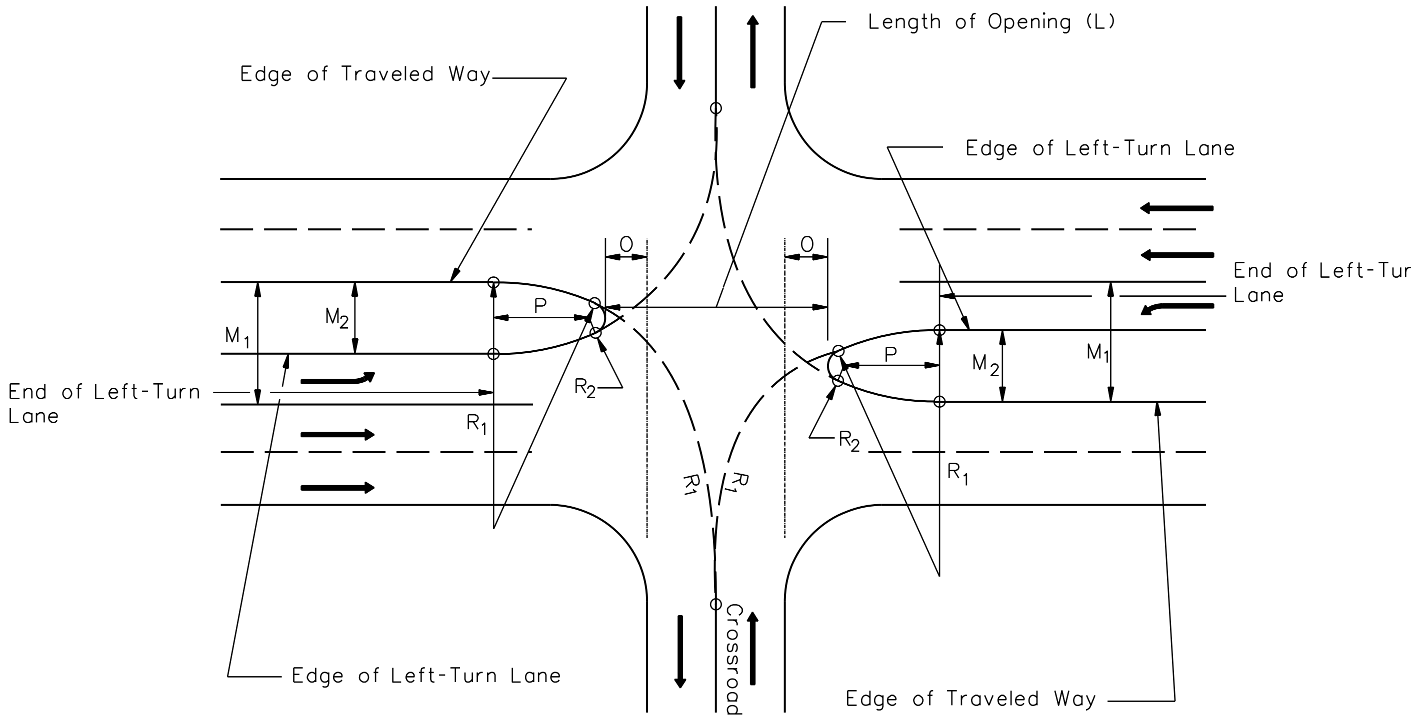
4. Median Nose Design. The shape of the nose at median openings is determined by the width of the median (M_1) or (M_2). The two basic types of median nose designs are the semicircular design and bullet-nose design. The following summarizes their usage:

- For medians up to 4 ft (1.2 m) in width, there is little operational difference between the two designs.
- The semicircular design is generally acceptable for median widths (M_1) up to 10 ft (3.0 m).
- For medians (M_1) wider than 10 ft (3.0 m), use the bullet-nose design. Also use this design for the divisional island remaining after locating a left-turn lane in median.
- As medians become successively wider, the minimum length of the median opening becomes the governing design control.

For the bullet-nose design, a compound curvature arrangement should be used. Figure 36-4.C provides the typical details for a median opening with a bullet-nose design.

5. U-turns. Median openings are sometimes used to accommodate U-turns on multilane divided highways and urban arterials. Preferably, a smaller vehicle should be able to begin and end the U-turn on the inner lanes next to the median. Figure 36-4.D provides the minimum median widths for U-turn maneuvers for various design vehicles and various levels of encroachment. Check the U-turn design with the applicable turning template. For inner-lane-to-shoulder designs it is often appropriate to incorporate an extended pavement area, or loon, so that larger design vehicles making frequent U-turns may do so within an area of full-depth pavement.

6. Sight Distance. Check all median openings for applicable sight distance criteria; see Section 36-6.



L	=	Length of median opening. See discussion in Section 36-4.04(b) for minimum L values.
M_1	=	median width measured between the two edges of the inside travel lanes
M_2	=	width of divisional island (raised-curb or depressed) remaining after the width of the left-turn (if present) has been subtracted from the median width (M_1)
O	=	Nose offset.
P	=	As shown in figure.
R_1	=	variable, based on design vehicle and median width (M_2)
R_2	=	M_2/5 to edge of left-turn lane
R_2	=	M_1/5 to edge of traveled way where a left-turn lane is not present
		R_2 is typically rounded up to the next highest whole number

MEDIAN NOSE DESIGN
(Multilane Divided Highways)

Figure 36-4.C

Type of Maneuver		M - Min. width of median for design vehicle

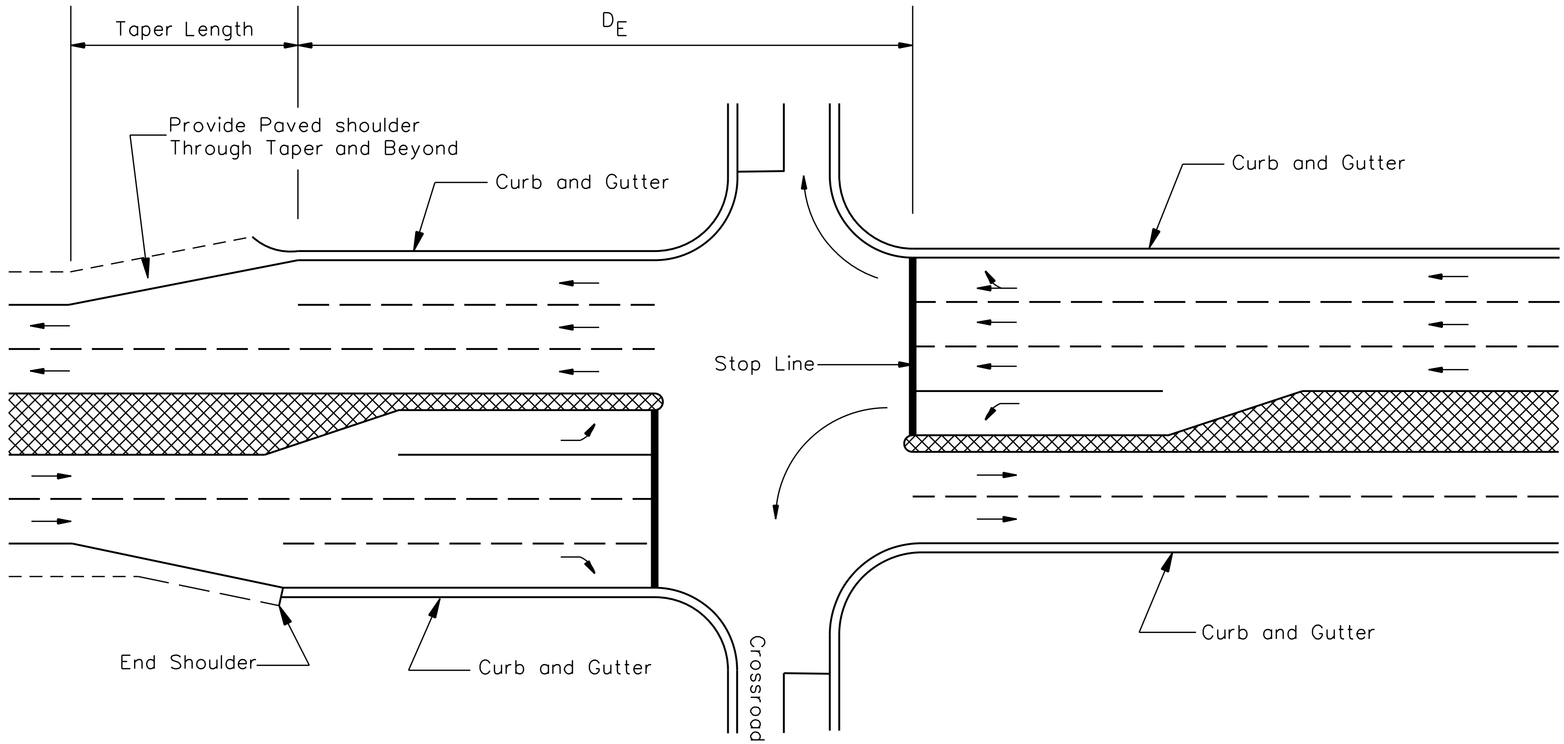
MINIMUM WIDTHS NEEDED FOR U-TURNS
(Multilane Divided Highways)

Figure 36-4.D

36-5 EXTENSION OF THROUGH LANES BEYOND AN INTERSECTION

Where traffic volumes drop off considerably after passing a crossroad, one lane can be dropped beyond the intersection. A lane may be dropped downstream as an exclusive turn lane or with a merging taper into the adjacent through lane. In either scenario, proper highway signing and pavement striping is critical in order to convey the upstream lane drop to the motorist.

To fully realize capacity benefits and to provide for a safe merge when utilizing a merging taper, the through lanes must be extended beyond the intersection for a defined minimum distance. Figure 36-5.A provides preliminary design criteria for determining the minimum distance a lane should be extended beyond an intersection. For higher volume locations, additional length beyond the minimum may be required for the formation of adequate gaps in traffic that will minimize conflicts during merging. Each intersection should therefore be designed on a case-by-case basis, considering all site specific factors.



US Customary			Metric		
Design Speed (mph))	D_E (ft)	Taper Length (ft)	Design Speed (km/h)	D_E (m)	Taper Length (m)
30	160	540	50	40	162
35	215	540	60	70	162
40	320	540	70	110	162
45	430	540	80	160	180
50	585	600	90	235	180
55	780	600	100	325	180
60	1010	600	110	455	180
65	1300	600			
70	1750	600			

Notes:

1. *D_E is that distance required by a vehicle to accelerate from a stop to 5 mph (10 km/hr) below the design speed of the highway.*

2. *The taper distance is calculated assuming a 12 ft (3.6 m) lane and a taper rate of 45:1 for design speeds of 45 mph (70 km/hr) or less or 50:1 for design speeds of 50 mph (80 km/hr) or greater.*

EXTENSION OF THROUGH LANE BEYOND AN INTERSECTION

Figure 36-5.A

36-6 INTERSECTION SIGHT DISTANCE

36-6.01 General

At each intersection the potential exists for vehicles to conflict with each other when entering, exiting, or crossing the intersection. The designer should provide sufficient sight distance for a driver to perceive these potential conflicts and to perform the necessary actions needed to negotiate the intersection safely. The additional costs and impacts to achieve this sight distance are often justified based on the safety and operational considerations.

Because all intersections on State highways are either stop controlled or signalized, no guidelines are provided for no control or yield-controlled intersections. For these types of intersections, the designer is referred to NCHRP Report 383, *Intersection Sight Distance* for guidance and/or the AASHTO *Policy on the Geometric Design of Highways and Streets*.

36-6.02 Design Procedures

The Department uses gap acceptance as the conceptual basis for its intersection sight distance (ISD) criteria. The ISD criteria used by the Department is intended to find a balance between an acceptable level of safety and what can be provided at an intersection on a practical basis. This ISD methodology ensures than an intersection operates smoothly without forcing a vehicle on the major road to stop. As the crossroad vehicle makes the turn and accelerates, field studies have indicated that mainline vehicles reduce their speed to approximately 70% of the mainline design speed to compensate for the entering vehicle.

The intersection sight distance is obtained by providing clear sight triangles both to the right and left as shown in Figure 36-6.A. The lengths of legs of these sight triangles are determined as follows:

1. Minor Road. The length of leg along the minor road is based on two parts. The first is the location of the driver’s eye on the minor road. This distance is not wholly based on the location of the stop bar, but instead through research on how far away from through traffic the stopping motorist feels comfortable, even potentially after a two-stop process (stop at stop bar, then pull up and stop at a safe spot closer to the edge of pavement that maximizes sight lines). This distance is typically assumed to be 14.4 ft (4.4 m) from the edge of the major road traveled way, but can be increased due to sight specific issues. The second part is based on the distance to the center of the vehicle on the major road. For right-turning vehicles, this is assumed to be the center of the closest travel lane from the left. For left-turning vehicles, this is assumed to be the center of the closest travel lane for vehicles approaching from the right.

2. Major Road. The length of the sight triangle or ISD along the major road is determined using the following equation:

3.

$$b = ISD = 1.467\ V_{major}\ t_c$$ Equation 36-6.1 (US Customary)

$$b = ISD = 0.278\ V_{major}\ t_c$$ Equation 36-6.1 (Metric)

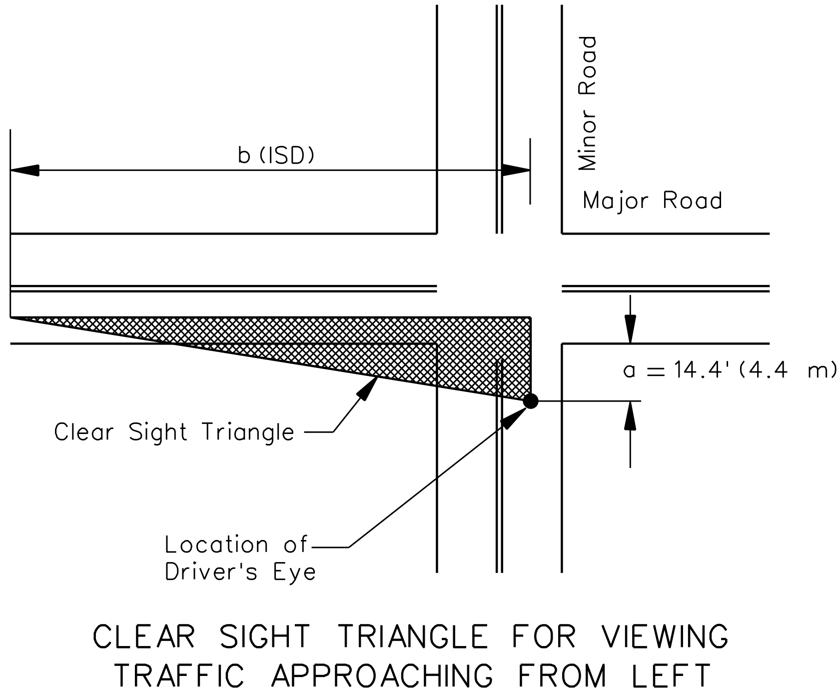
where:

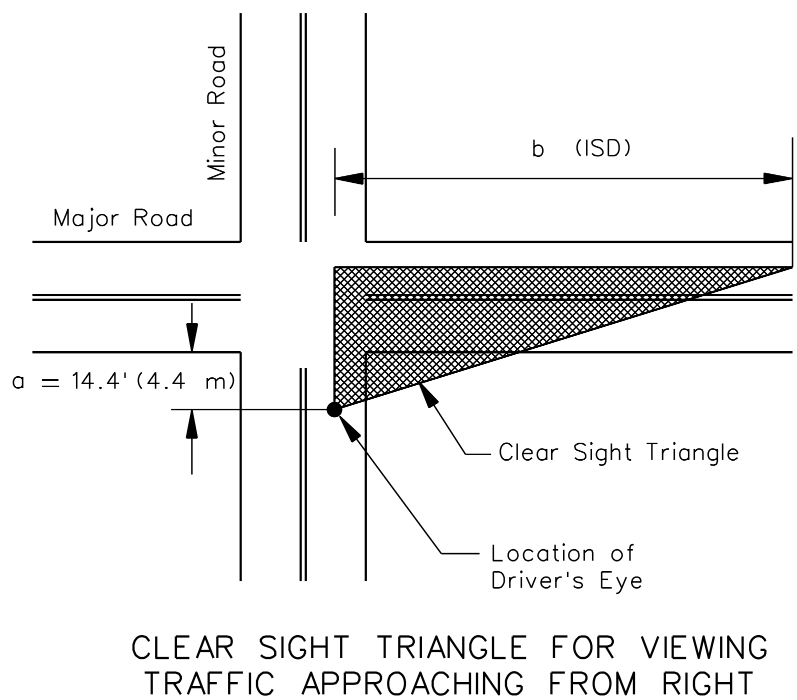
b	=	length of sight triangle along the major road or ISD, ft (m)
ISD	=	Intersection Sight Distance, ft (m)
V_{major}	=	design speed of major road, mph (km/hr)
t_c	=	critical gap for entering or crossing the major road, sec

The critical gap time (t_c) varies according to the design vehicle, the grade on the minor road approach, the number of lanes on the major roadway, the type of operation, and the intersection skew.

Within this clear sight triangle, if practical, remove or lower any object that would obstruct the driver's view. These objects may include buildings, parked or turning vehicles, trees, hedges, tall crops, unmowed grass, fences, retaining walls, and the actual ground line. In addition, where an interchange ramp or crossroad intersects the major road near a bridge on a crest vertical curve, items such as bridge parapets, piers, abutments, guardrail, or the crest vertical curve itself may restrict the clear sight triangle. Figure 36-6.B illustrates, in both the plan view and profile view, the application of the clear sight triangles at an interchange ramp. This figure also applies to any crossroad intersection.

The height of eye for passenger cars is assumed to be 3.5 ft (1080 mm) above the surface of the minor road. The height of object for an approaching vehicle on the major road is also assumed to be 3.5 ft (1080 mm). An object height of 3.5 ft (1080 mm) assumes that a sufficient portion (9 in. (225 mm)) of an oncoming passenger car must be seen to identify it as an object of concern by the minor road driver. Using the 3.5 ft (1080 mm) height for both vehicles assumes that each driver can see and recognize the other vehicle. If there are a sufficient number of trucks on the minor road or ramp to warrant their consideration, use Figure 36-6.C to determine the appropriate eye height for the minor road vehicle.





CLEAR SIGHT TRIANGLES FOR STOP-CONTROLLED INTERSECTIONS

Figure 36-6.A

36-6.03 Stop-Controlled Intersections

Where traffic on the minor road or an exit ramp of an intersection is controlled by stop signs, the driver of the vehicle on the minor road must have adequate sight distance for a safe departure from the stopped position. This assumes that the approaching vehicle comes into view just as the stopped vehicle begins it departure. The following sections discuss the application of the Department's ISD methodology at stop-controlled intersections.

36-6.03(a) Turns Onto Major Roadway

To determine the intersection sight distance for vehicles turning left or right onto the major road, the designer should use Equation 36-6.1 and the gap times (t_c) presented in Figure 36-6.D. Figure 36-6.D also presents adjustments to the gap times for multilane facilities and steep grades on the minor road approach. These adjustments are further discussed below. Figure 36-6.E provides the ISD values for typical design vehicles on two-lane, level facilities. The designer should also consider the following:

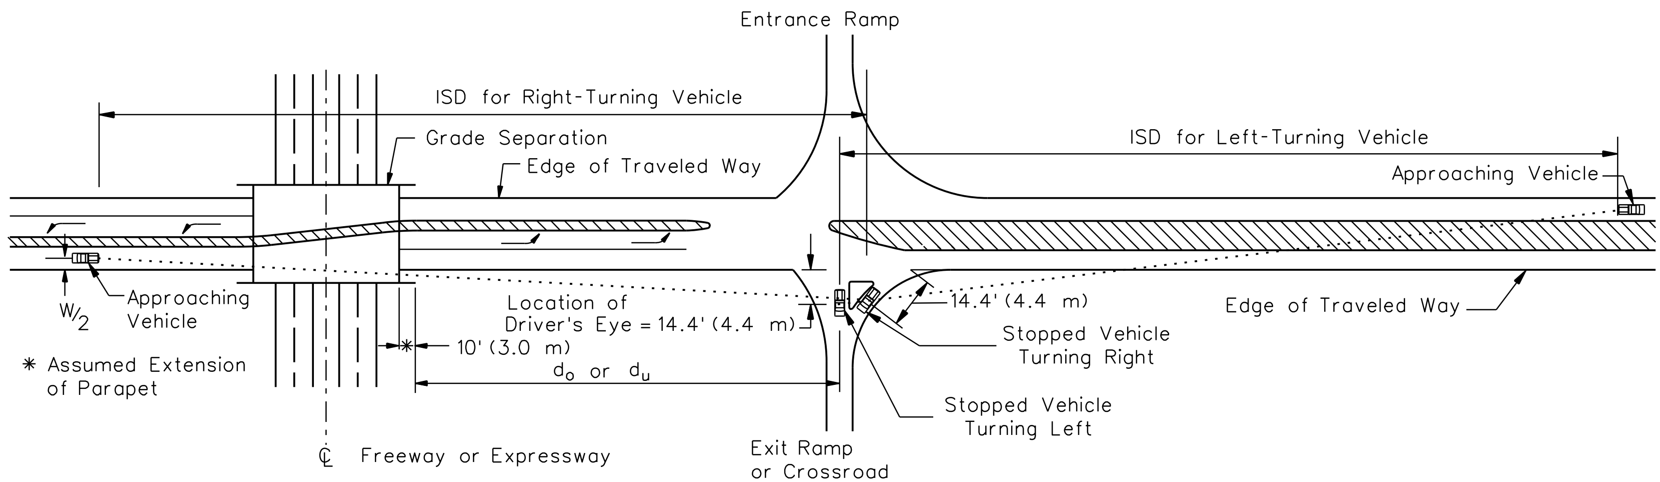
1. Turning Maneuver. There is only a minimal difference in the base gap acceptance times between the left- and right-turning drivers. Consequently, only one gap time is provided for both the left- and right-turning vehicle onto the major road. See Figure 36-6.B.

2. Multilane Facilities. For multilane facilities, the gap acceptance times presented in Figure 36-6.D may need to be adjusted to account for the additional distance required by the turning vehicle to cross the additional lanes or median. The following will apply:

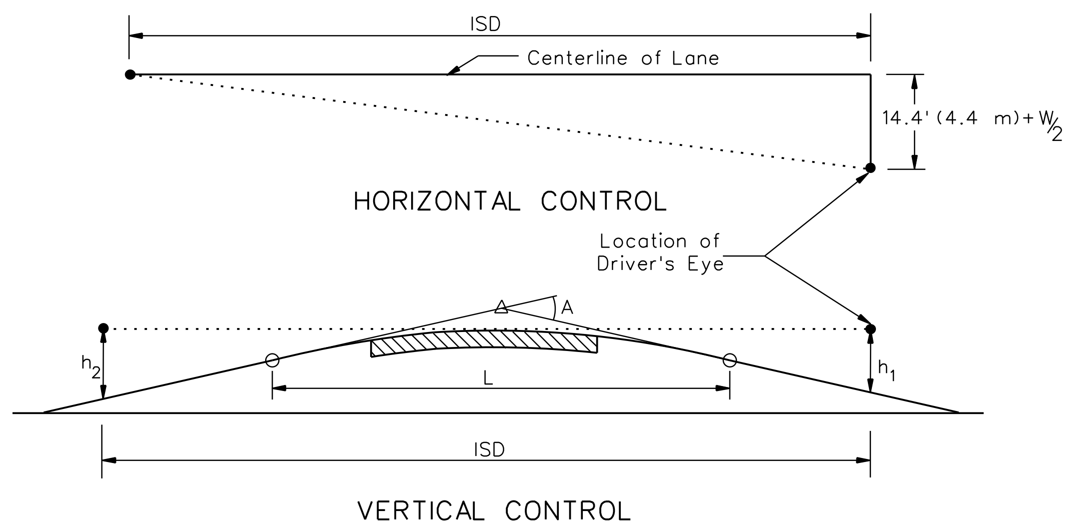
    a. Left-Turns. For left-turns onto multilane highways without a median, add 0.5 seconds for passenger cars or 0.7 seconds for trucks for each additional lane from the left, in excess of one, to be crossed by the turning vehicle. Assume that the left-turning driver will enter the left most travel lane on the far side of the major road.

    b. Right Turns. Because the turning vehicle is assumed to be turning into the nearest right through lane, no adjustments to the gap times are required. This is the same for either two-lane or multilane facilities.

    c. Medians. Depending on the median width, it also may be necessary to add additional time to the base gap time; see Item 3.



ISD – intersection sight distance, ft (m)
d – minimum distance needed from back of parapet extension or side of structure to vehicle position, ft (m)
do – when minor road is over
du – when minor road is under
A – maximum algebraic difference of grades (%)
L – Length of crest vertical curve, ft (m)
W – width of lane, ft (m)
h_1 – height of eye, see Figure 36-6.C
h_2 – height of obstacle = 3.5 ft (1080mm) (passenger car assumed)



INTERSECTION SIGHT DISTANCE CONTROLS

Figure 36-6.B

20-Year ADT of Tractor/ Semitrailers on Exit Ramp or Crossroad	**Approaching Vehicle on Mainline[(2)]**	**Stopped Design Vehicle on Crossroad [(1)]**
ADT $\leq$ 40	Passenger Car h_2 = 3.5 ft (h_2 = 1080 mm)	Passenger Car h_1 = 3.5 ft (h_1 = 1080 mm)
40 < ADT $\leq$ 100	Passenger Car h_2 = 3.5 ft (h_2 = 1080 mm)	Single Unit (SU) or Bus h_1 = 6 ft (h_1 = 1.8 m)
ADT > 100	Passenger Car h_2 = 3.5 ft (h_2 = 1080 mm)	Tractor/Semitrailers (MU) h_1 = 8 ft (h_1 = 2.5 m)

Notes:

1. *h_1 - Assumed height of eye for stopped motorist.*
2. *h_2 - Assumes 9 in. (225 mm) of top of approaching vehicle can readily be seen by stopped motorist.*
3. *Where a mainline crest vertical curve lies close to an intersection of a crossroad or ramp, it may be necessary to increase the length of the vertical curve (designed for either existing or proposed stopping sight distance) or to reduce the grades in order to obtain the proper ISD in the vertical plane.*

DESIGN VEHICLES USED TO DETERMINE AVAILABLE ISD ALONG A CROSSROAD

Figure 36-6.C

Design Vehicle	Gap Acceptance Time (t_c) (sec)
Passenger Car	7.5
Single-Unit Truck	9.5
Tractor/Semitrailer	11.5

Note: Times are for turns onto a two-lane highway without a median and may require adjustments to the base time gaps.

Adjustments:

1. *<u>Multilane Highways</u>. The following will apply:*

   - *For left turns onto two-way multilane highways without a median, add 0.5 seconds for passenger cars or 0.7 seconds for trucks for each additional lane from the left, in excess of one, to be crossed by the turning vehicle. See discussion in Section 36- 6.03(a) for additional guidance.*

   - *For right turns, no adjustment is necessary.*

2. *<u>Minor Road Approach Grades</u>. If the approach grade on the minor road exceeds +3%, the following will apply:*

   - *For right turns, multiply 0.1 seconds times the actual percent grade on the minor road approach and add this number to the base time gap.*

   - *For left turns, multiple 0.2 seconds times the actual percent grade on the minor approach and add this number to the base time gap.*

3. *<u>Major Road Approach Grade</u>. Major road grade does not affect calculations.*

GAP ACCEPTANCE TIMES
(Left and Right Turns From Minor Road)

60 km/hr	126 m	159 m	192 m
70 km/hr	146 m	185 m	224 m
80 km/hr	167 m	212 m	256 m
90 km/hr	188 m	238 m	288 m
100 km/hr	209 m	264 m	320 m
110 km/hr	230 m	291 m	352 m

Notes:

1. *These ISD values assume turns onto a two-lane facility without a median.*
2. *These ISD values assume a minor road approach grade $\leq$ +3%.*

INTERSECTION SIGHT DISTANCES FOR TWO-LANE HIGHWAY
(Left and Right Turns From Minor Road)

Figure 36-6.E

3. Left Turns Through Medians.

   a. Narrow Medians. For a facility that does not have a median wide enough to store a stopped design vehicle, divide the median width by 12 ft (3.6 m) to get the corresponding number of lanes and then use the criteria in Item 2a above to determine the additional time factor.

   b. Wide Medians. For a facility that does have a median wide enough to store a stopped design vehicle, the designer should evaluate the sight distance needed in two separate steps:

      - First, with the design vehicle stopped on the side road, use the gap acceptance times for a vehicle turning right or use Figure 36-6.E directly to determine the applicable ISD. Under some circumstances, it may also be necessary to check the straight through crossing maneuver to determine if it is the critical movement. Straight through crossing criteria are discussed in Section 36-6.03(b).

      - Second, with the design vehicle stopped in the median, assume a two-lane roadway design and use the gap acceptance times for a vehicle turning left or use Figure 36-6.E directly to determine the applicable ISD.

   Section 36-6.07 provides an example of school bus crossing a wide median.

4. Approach Grades. If the approach grade on the minor road exceeds 3%, see the criteria in Figure 36-6.D.

5. Trucks. At some intersections (e.g., near truck stops, interchange ramps, grain elevators), the designer may want to use the truck as the design vehicle for determining the ISD. The gap acceptance times (t_c) for single-unit and tractor/semitrailer trucks are provided in Figure 36-6.D. Calculated ISD values for two-lane roadways are presented in Figure 36-6.E. The height of eye for these vehicles is discussed in Section 36-6.02 as shown in Figure 36-6.C.

36-6.03(b) Vehicle Crossing Mainline

In the majority of cases, the intersection sight distance for a crossing maneuver is less than that required for a left- or right-turning vehicle. However, in the following situations, the straight through crossing sight distance may be the more critical movement:

- where left and/or right-turns are not permitted from a particular approach and the crossing maneuver is the only legal or expected movement (e.g., indirect left turns);

- where the design vehicle must cross more than four travel lanes or, with medians, the equivalent distance; or

- where a substantial volume of heavy vehicles cross the highway and there are steep grades on the minor road approaches.

Use Equation 36-6.1 and the gap acceptance times (t_c) and adjustment factors in Figure 36-6.F to determine the ISD for crossing maneuvers. Where narrow medians are present which cannot store the design vehicle, include the median width in the overall width to determine the applicable gap time. Divide this overall width by 12 ft (3.6 m) to determine the corresponding number of lanes for the crossing maneuver. Add 0.5 seconds for passenger cars or 0.7 seconds for trucks for each additional lane, in excess of two, to be crossed by the design vehicle.

Design Vehicle	Gap Acceptance Time (t_c) (sec)
Passenger Car	6.5
Single-Unit Truck	8.5
Tractor/Semitrailer	10.5

Note: Times are for crossing a two-lane highway without a median.

Adjustments:

1. *Multilane Highway. Where the design vehicle is crossing a major road with more than two lanes and/or where there is a narrow median which cannot store the design vehicle, add 0.5 seconds for passenger cars or 0.7 seconds for trucks for each additional lane in excess of two. See the discussion in Section 36-6.03(b) for additional guidance.*

2. *Approach Grade. If the approach grade on the minor road exceeds +3%, multiply 0.1 seconds times the actual percent grade of the minor road approach and add this number to the base time gap.*

GAP ACCEPTANCE TIMES
(Vehicle Crossing Mainline)

Figure 36-6.F

36-6.03(c) Four-Way Stop

At intersections with all-way stop control, provide enough sight distance so that the first stopped vehicle on each approach is visible to all the other approaches. The ISD criteria for left- or right-turning vehicles as discussed in Section 36-6.03(a) are not applicable in this situation. Often intersections are converted to all-way stop control to address limited sight distance at the intersection. Therefore, providing additional sight distance at the intersection is unnecessary.

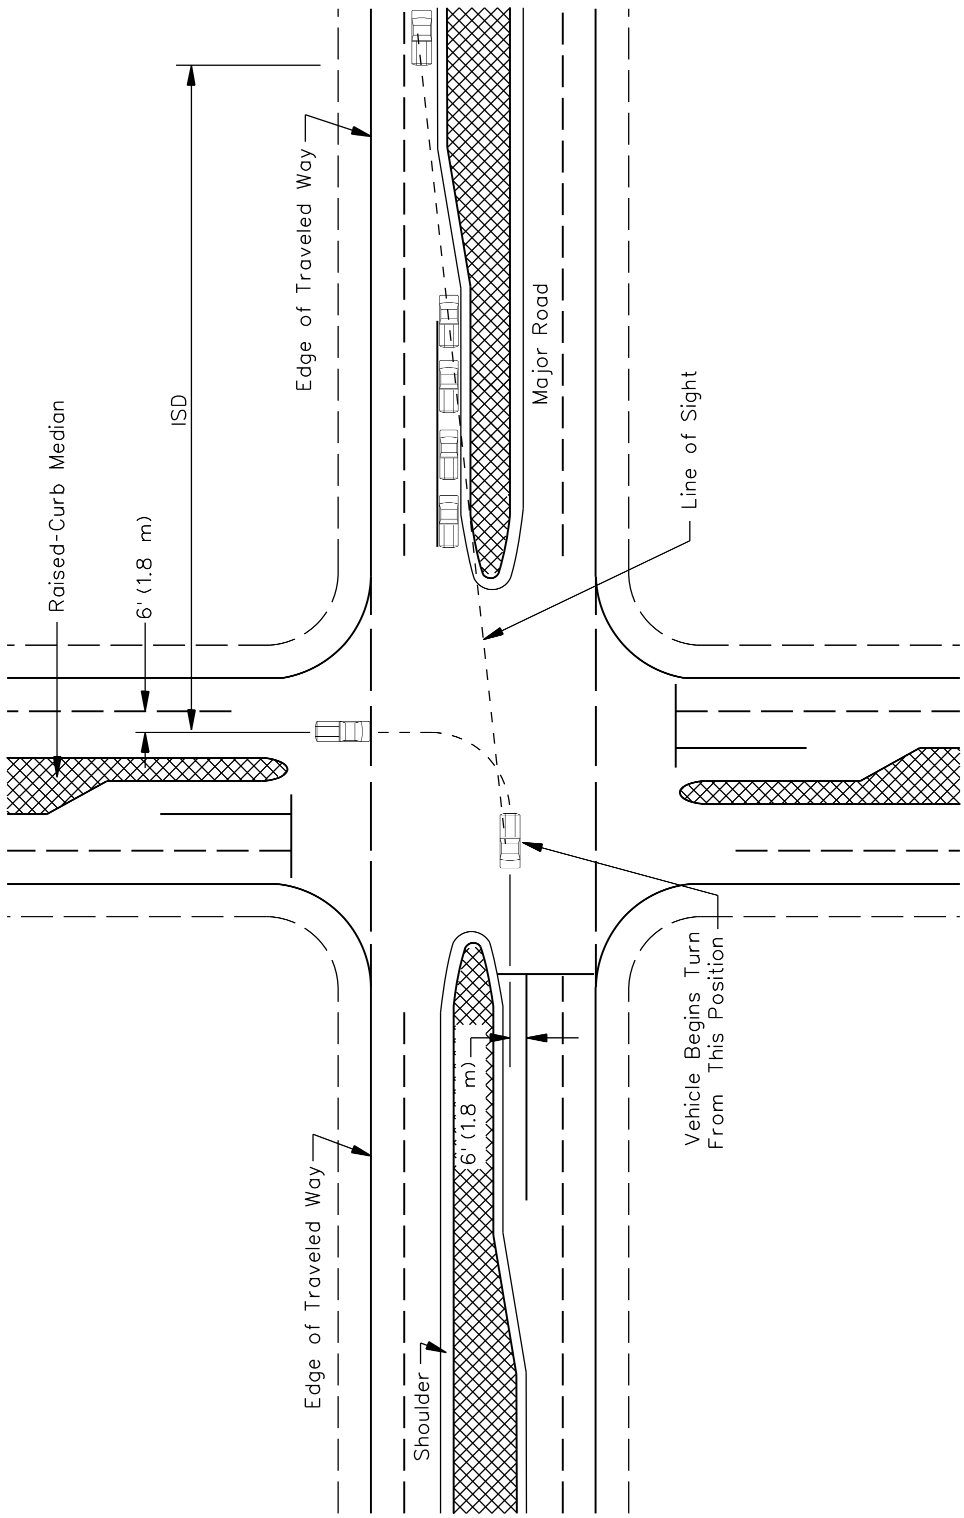
36-6.04 Signal-Controlled Intersections

At signalized intersections, provide sufficient sight distance so that the first vehicle on each approach is visible to all other approaches. Traffic signals are often used at high-volume intersections to address accidents related to restricted sight distances. Therefore, the ISD criteria for left- or right-turning vehicles as discussed in Section 36-6.03(a) is typically not applicable at signalized intersections. However, where right-turn-on-red is allowed, check to see that the ISD as presented in Section 36-6.03(a) for a stop-controlled right-turning vehicle is available to the left. If it is not, this may warrant restricting the right-turn-on-red movement. In addition, if the traffic signal is placed on two-way flash operation (i.e., flashing amber on the major-road approaches and flashing red on the minor-road approaches) under off-peak or nighttime conditions, provide the ISD criteria as discussed in Section 36-6.03(a) for a stop-controlled intersection.

36-6.05 Left Turns From the Major Road

At all intersections, regardless of the type of traffic control, the designer should consider the sight distance needs for a stopped vehicle turning left from the major road. This situation is illustrated in Figure 36-6.G. The driver will need to see straight ahead for a sufficient distance to turn left and clear the opposing travel lanes before an approaching vehicle reaches the intersection. In general, if the major highway has been designed to meet the stopping sight distance criteria, intersection sight distance only will be a concern where the major road is on a horizontal curve, where there is a median, or where there are opposing vehicles making left turns at an intersection. Sight distance for opposing left turns may be increased by offsetting the left-turn lanes; see Section 36-3.03(c).

Use Equation 36-6.1 and the gap acceptance times (t_c) from Figure 36-6.H to determine the applicable intersection sight distances for the left-turning vehicle. Where the left-turning vehicle must cross more than one opposing lane, add 0.5 seconds for passenger cars or 0.7 seconds for trucks for each additional lane in excess of one. Where medians are present and the left-turn lanes are not offset, the designer will need to consider the median width in the same manner as discussed in Section 36-6.03. Figure 36-6.I provides the ISD values for typical design vehicles and two common left-turning situations on a facility without a median.



Note: See Section 36-6.05 for discussion and application

INTERSECTIONS SIGHT DISTANCE CONTROLS
(Left Turns from the Major Road)

Figure 36-6.G

Design Vehicle	Gap Acceptance Time (t_c) (sec)
Passenger Car	5.5
Single-Unit Truck	6.5
Tractor/Semitrailer	7.5

Adjustments: Where left-turning vehicles cross more than one opposing lane, add 0.5 seconds for passenger cars or 0.7 seconds for trucks for each additional lane in excess of one. See Section 36-6.05 for additional guidance on median widths.

GAP ACCEPTANCE TIMES
(Left Turns From Major Road)

Figure 36-6.I

36-6.06 Effect of Skew

Where is it is impractical to realign an intersection which is greater than 30 degrees from perpendicular, adjust the gap acceptance times presented in the above sections to account for the additional travel time required for a vehicle to make a turn or cross a facility. At oblique-angled intersections, determine the actual path length for a turning or crossing vehicle by dividing the total distance of the lanes and/or median to be crossed by the sine of the intersection angle. If the actual path length exceeds the total width of the lanes to be crossed by 12 ft (3.6 m) or more, apply the applicable adjustment factors; see Figure 36-6.J.

Design Speed (V_{major})	ISD

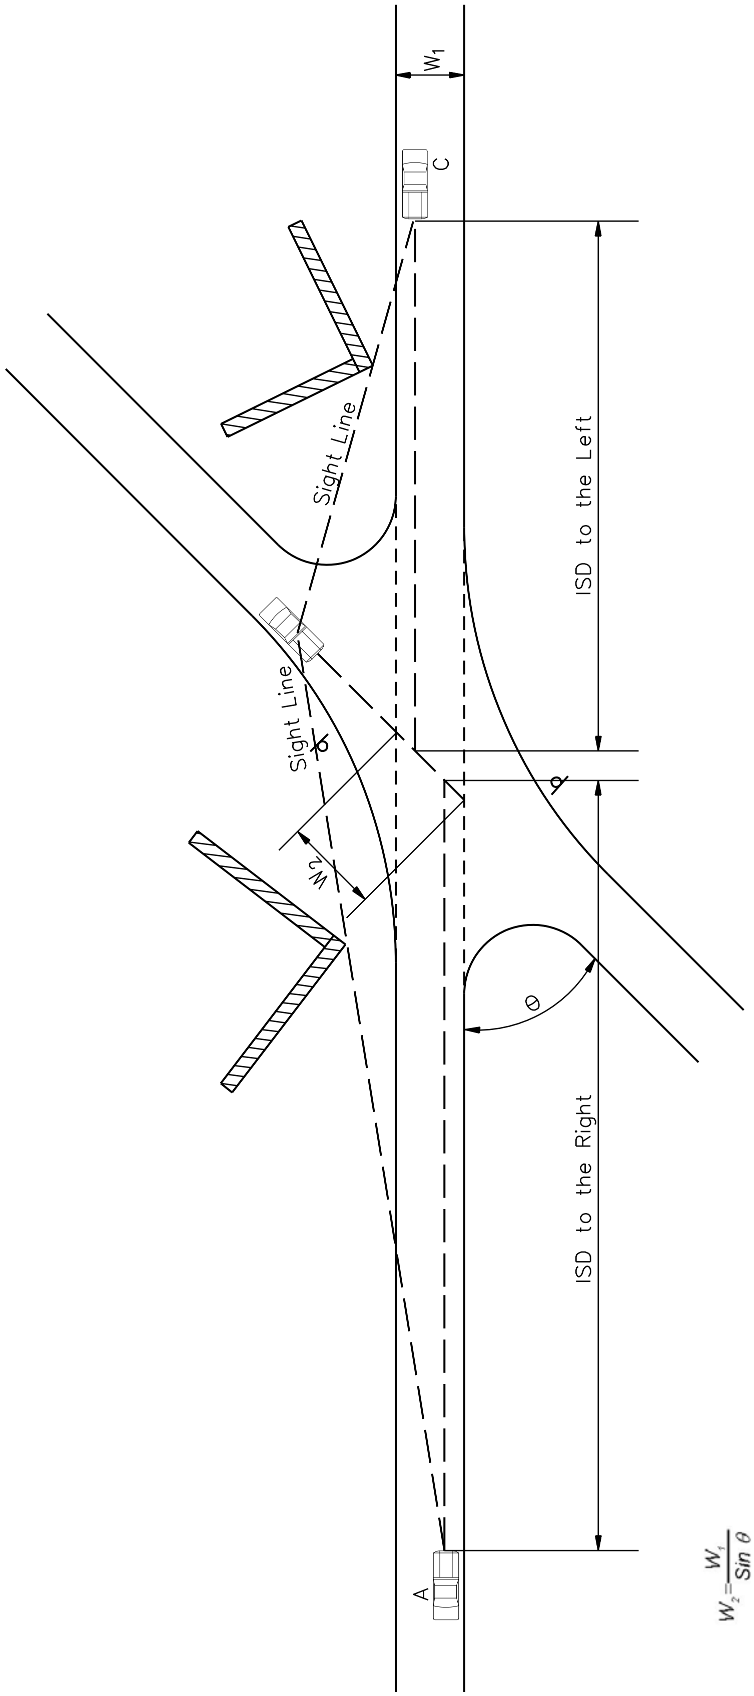
Note: Assumes no median on major road.

INTERSECTION SIGHT DISTANCES
(Left Turns From Major Road)

Figure 36-6**.J**



$$W_2 = \frac{W_1}{\sin \theta}$$

Where: W_1 = Major road traveled way width, ft (m)
W_2 = Adjusted width for skew, ft (m)
θ = Intersection angle

SIGHT DISTANCE AT SKEWED INTERSECTIONS

Figure 36-6.K

36-6.07 Examples of ISD Applications

The following three examples illustrate the application of the ISD criteria:

Example 36-6.07(1)

Given: Minor road intersects a four-lane highway with a TWLTL.
Minor road is stop controlled and intersects major road at 90 degrees.
Design speed of the major highway is 45 mph.
All travel lane widths are 12 ft.
The TWLTL width is 12 ft.
Grade on minor road is 1%.
Trucks are not a concern.

Problem: Determine the intersection sight distance needed to the left and right of the minor road; see Figure 36-6.B.

Solution:

1. For the passenger car turning right, the ISD to the left can be determined directly from Figure 36-6.E, because the right-turning motorist is assumed to turn into the near lane. For the 45 mph design speed, the ISD to the left is 500 ft.

2. For the passenger car turning left, the ISD to the right must reflect the additional time required to cross the additional lanes and TWLTL; see in Section 36-6.03(a). The following will apply:

   a. First, determine the extra width required by the one additional travel lane and the TWLTL and divide this number by 12 ft:

   $$\frac{(12+12)}{12} = 2 \text{ lanes}$$

   b. Next, multiply the number of lanes by 0.5 seconds to determine the additional time required:

   (2 lanes)(0.5 sec/lane) = 1.0 second

   c. Add the additional time to the basic gap time of 7.5 seconds and insert this value into Equation 36-6.1:

   ISD = (1.467)(45)(7.5 + 1.0) = 561 ft

   Provide an ISD of 561 ft to the right for the left-turning vehicle.

3. Check the passenger vehicle crossing the mainline, as discussed in Section 36-6.03(b). The following will apply:

a. First determine the extra width required by the two additional travel lanes and the TWLTL and divide this number by 12 ft:

$$\frac{(12 + 12 + 12)}{12} = 3.0 \text{ lanes}$$

b. Next, multiply the number of lanes by 0.5 seconds to determine the additional time required:

(3.0 lanes)(0.5 sec/lane) = 1.5 seconds

c. Add the additional time to the basic gap time of 6.5 seconds and insert this value into Equation 36-6.1:

ISD = (1.467)(45)(6.5 + 1.5) = 530 ft

The 530 ft for the crossing maneuver is less than the 561 ft required for the left-turning vehicle and, therefore, is not the critical maneuver.

4. Prepare a scaled drawing in the horizontal and vertical planes and graphically check to determine if the applicable ISD is available.

Example 36-6.07(2)

Given: Minor road intersects a four-lane divided highway.
Minor road is stop controlled and intersects major road at 90 degrees.
Design speed of the major highway is 60 mph.
All travel lane widths are 12 ft.
The median width is 50 ft.
Grade on minor road is +2%.
The design vehicle is a 64-passenger school bus that is 35.8 ft long.

Problem: Determine the intersection sight distance needed to the left and right of the minor road; see Figure 36-6.B.

Solution:

1. For a school bus, assume a SU design vehicle for gap acceptance times.

2. For the school bus turning right, the ISD to the left can be determined directly from Figure 36-6.E. For the 60 mph design speed, the ISD to the left is 840 ft.

3. Determine if the straight through crossing maneuver is critical; see Section 36-6.03(b). No adjustments are required to the base time of 8.5 seconds. Therefore, use Equation 36-6.1 directly:

ISD = (1.467)(60)(8.5) = 750 ft

The crossing maneuver ISD is less than the right-turning maneuver and, therefore, is not critical.

4. For the school bus turning left, it can be assumed the school bus can safely stop in the median (i.e., 50 ft minus 35.8 ft). The ISD to the right can be determined directly from Figure 36-6.E. For the 60 mph design speed, the ISD to the right for the left turn is 840 ft. The crossing maneuver will not be critical.

5. Prepare a scaled drawing in the horizontal and vertical planes and graphically check to determine if the applicable ISD is available.

<u>Example 36-6.07(3)</u>

Given: Minor road intersects a four-lane divided highway.
Minor road is stop controlled and intersects major road at 90°.
Design speed of the major highway is 50 mph.
All travel lane widths are 12 ft.
Existing median width is 48 ft.
Traffic signals are likely within 10 years.
Current mainline ADT is 1600 and left-turn volumes exceed 60 vph.
Trucks are not a concern.

Problem: Determine the intersection design and sight distance for a vehicle turning left from the major road.

Solution:

1. From Section 36-3.03(c), the recommended left-turn lane design is a tapered offset left-turn lane.

2. Because the offset left-turn lane design places vehicles near the median edge of the opposing lanes, no adjustment is necessary for the median width in computing the gap acceptance time.

3. For the left-turning vehicle, the ISD can be determined directly from Figure 36-6.I. For the 50 mph design speed and crossing two lanes, the required ISD is 480 ft.

4. Prepare a scaled drawing in the horizontal and vertical planes and graphically check to determine if the applicable ISD is available.

36-7 DRIVEWAYS, ENTRANCES, AND MINOR SIDEROADS

Section 36-7.01 discusses the design of proposed driveways, entrances, and minor side road approaches to State highways; as well as modifying the connections of existing driveway, entrance, or minor side road approaches to State highways in conjunction with new construction, reconstruction, or 3R highway projects.

Chapter 5 and the Bureau of Operations' *Maintenance Policy Manual* provide information regarding necessary local agency agreements and maintenance obligations on state highway projects with side roads or local participation.

Section 36-7.02 provides general information regarding the highway access permit process for new or revised individual entrances to a State highway. For detailed information regarding requirements for the construction or modification of permitted access to State Highways or the access permit process in general, refer to the Bureau of Operations publication entitled, *Handbook for the Policy on Permits for Access Driveways to State Highways*. The information in the *Handbook* is governed by the *Illinois Highway Code sections 605 ILCS 5/4-209, 4-210, 4-211 and 4-212* and *92 Ill. Admin. Code 550*.

For information regarding access management concepts, objectives, benefits, and techniques, see Chapter 35.

For additional access management concepts applicable to Strategic Regional Arterials, see Chapter 46.

36-7.01 <u>General Considerations</u>

The Department has the authority to make access revisions pursuant to the *Illinois Highway Code, 605 ILCS 5/4-211*. During the design of highway reconstruction projects or when changes in operational conditions warrant review and potential revisions, sideroads, driveways and entrances to public or non-public facilities may be altered, relocated, or eliminated after notification and appropriate discussion with the local agency or property owner. (For public connections to State highways, public involvement may be required. See Chapter 19). Any such revisions will typically be accomplished at Department expense for existing access locations that are legally permitted. Owners or developers who construct access facilities not in accordance with the approved access permit or without an access permit, must correct or remove the access within a specified period of time as directed by the Department; otherwise the Department will cause the removal or closure of the access facility at the owner's expense.

Although all types of property tracts need access to and from public roadways and are guaranteed that right by the *Illinois Highway Code*, *605 ILCS 5/4-209, 4-210, 4-211, 4-212,* the nature of that need varies according to the type of facility (see *605 ILCS 5/8-102, 8-103* regarding access to freeways), land use (e.g., agricultural, industrial, commercial, or residential), the characteristics of the mainline roadway (urban, suburban, or rural), and safety considerations. Details of the access design depend on factors such as the volume of traffic, the types of vehicles using the entrance, and adjacent compatible land uses.

In all cases for new construction, reconstruction, or 3R projects, district staff are required as part of the roadway project to examine what changes are needed to existing side roads, entrances and driveways, and to document any recommended changes in the Phase I Engineering Report. See Chapter 11 for Phase I Engineering Report guidelines. The designer must exercise good judgment that reflects an understanding of traffic characteristics when categorizing a particular entrance and applying appropriate design standards.

36-7.01(a) Definitions

The following definitions are used in the design of driveways, entrances, and side roads. Note for the purposes of this section, the terms "entrance" and "driveway" will be used interchangeably.

1. Access Facility. A driveway, entrance, or side road approach facilitating vehicular movement between abutting property or right-of-way and a State highway. Normally, it includes only the part of the driveway, entrance, or side road that lies within the established right-of-way limits of the State highway.

2. Commercial Entrance (CE). A driveway that provides access to a single property or business being used for commercial purposes (such as office, retail, or services) or industrial purposes, or provides access for more than a single-family residence or duplex, or more than two single family residences sharing a common entrance.

3. High-Volume Commercial Entrance. A driveway that provides access to a development with substantially more trips than average commercial generators. Such developments are characterized by large parking areas, high-type access facilities, and traffic volumes of sufficient magnitude to have a pronounced effect on the safety and capacity of adjacent streets and highways. Examples of high-volume commercial generators include shopping centers, industrial complexes, office parks, and sports stadiums.

4. Non-Commercial Entrance. A driveway that provides access to a single-family residence, a duplex, or to not more than two single family residences on adjacent properties which are served by a common entrance. Also provides access to agricultural land, including field entrances, but excluding entrances used for the sale of agricultural products to the general public.

5. Private Entrance (PE). A special type of non-commercial access facility that provides access to a single-family residence, or to not more than two single family residences on adjacent properties which are served by a common entrance.

6. Field Entrance (FE). A special type of non-commercial access facility that provides access to land for agricultural uses.

7. Street or Side Road Approach. A special type of access facility that provides a direct connection between a State highway and an intersecting public road.

36-7.01(b) Construction Projects Involving Proposed Entrances

New entrance design practices should consider the following concerns and variables:

- Convenient and safe vehicle ingress and egress;
- Functional classification and design/posted speeds of mainline;
- ADT's and heavy vehicle percentages of mainline and entrance;
- Access control limits, density of access points, and mainline roadway operations;
- Proposed parcel usage and size of entrance design vehicle;
- Interactions with other nearby entrances or side streets;
- Accessibility and safety of all pedestrians (including individuals with disabilities), and incorporation of proper ADA requirements;
- Interactions where bicycle lanes or side paths are present;
- Interactions where public transportation stops are in the vicinity of the driveway;
- Terrain and drainage; and
- Visibility and sight distance requirements.

These considerations will affect entrance geometric design details such as alignment, entry shape (radius returns or side flares), width, grade, and cross slope, in addition to related design items such as sidewalk or bike path alignment and the location of first available parking bays beyond the entrance.

See Figure 36-7.A for general design guidelines for proposed entrances and driveways abutting the State highway system. Also see Sections 36-7.01(d) – (g) of this manual and the *Handbook for the Policy on Permits for Access Driveways to State Highways* for additional design information specific to IDOT. Additionally, *NCHRP Report 659* provides detailed guidance for the geometric design of new driveways and entrances.

36-7.01(c) Construction Projects Involving Existing Entrances

When the Department undertakes the improvement of an existing roadway, district staff must examine limits of the entire project for safety, sight distance, and operational issues. In all cases for new construction, reconstruction, or 3R type projects, the designer is required to examine what changes are needed to existing side roads, major entrances, and driveways, and to document any recommended changes in the Phase I Engineering Report. See Chapter 11 for Phase I Engineering Report guidelines. For any existing entrance that does not meet design, safety or operational criteria, contact the property owner during the project development phase to discuss the potential or observed issues, historical crash data, and current safety analyses of the subject location. Identify and discuss potential solutions for closing, reconstructing, or realigning the entrance to improve safety and operational objectives. Do not allow such substandard entrances to remain without addressing the issues.

For basic design parameters to remain in place for various entrance types, see Figure 36-7.A. See also Sections 36-7.01(d) – (g) of this manual, the *Handbook for the Policy on Permits for Access Driveways to State Highways* and *NCHRP Report 659* for additional design information.

36-7.01(d) Construction Projects Involving Proposed Sideroads

Construction projects involving proposed sideroads intersecting a State highway should adhere to the following procedures, depending on project scope:

- For new sideroads being constructed through the development process, follow the general procedures for driveway and entrance permits; see Section 36-7.02 and the *Handbook for the Policy on Permits for Access Driveways to State Highways*.
- For new sideroad intersections being constructed as part of the state highway improvement, follow the design guidelines set forth throughout Chapter 36, as well as either New Construction/Reconstruction or 3R guidelines, as appropriate.
- For new sideroad intersections being constructed as a locally led project, see the *Bureau of Local Roads and Streets Manual*.

36-7.01(e) Construction Projects Involving Existing Sideroads

Construction projects involving existing sideroads intersecting a State highway should adhere to the following procedures, depending on project scope:

- Intersections with existing sideroads should be evaluated on all New Construction/Reconstruction projects using the design criteria presented throughout Chapter 36. Revisions should be made to the existing facility when operational and safety factors dictate.

- Intersections with existing sideroads should be evaluated on all 3R projects using the criteria presented in Section 49-3.06. Revisions should be made to the existing facility when operational and safety factors dictate.

(Figure Parameters)

(3 of 3)

36-7.01(f) Driveway Profiles

An important item to consider in the design of new entrances or the evaluation of existing entrances is the change in grade without a vertical curve.

Desirably, vertical curves should be used to connect slopes of different grades. Where the change in grade of the entrance is critical, the designer should insert a vertical curve to prevent a vehicle from bottoming out. To prevent drag, vertical curves should be used where a hump or dip is greater than 6 inches (150 mm) within a wheel base length of approximately 10 ft (3.0 m). To prevent center or overhang drag, with some allowance for load and bounce, crest vertical curves should not exceed a 3 inch (80 mm) hump in a 10 foot (3.0 m) chord, and sag vertical curves should not exceed a 2 inch (50 mm) depression in a 10 foot (3.0 m) chord. Based on these constraints, the maximum grade on driveways, and the maximum algebraic difference in grade where an omission of a vertical curve may be considered, are shown in Figure 36-7.B.

If sidewalks intersect with the driveway profile, the profile must be adjusted to fit policy sidewalk slope criteria. See Figure 36-7.C and the *Illinois Highway Standards* for compliant sidewalk details. Also Chapter 58 provides additional accessibility discussion.

For considerations in the design of sideroad profiles, see Section 36-1.06.

	Non-Commercial Rural	**Non-Commercial Urban**	**Commercial Rural**	**Commercial Urban**	**High-Volume Commercial Entrance**	**Streets and Roads**
Maximum Grade on Driveway Proper	12% (1)	8% (1)	10% (1)	6% (1)	4% (1)	Design as a Local Road
Maximum Algebraic Difference in Grades where Omission of Vertical Curve may be Considered	6%	8%	3%	6%	Use Vertical Curves See Section 36-7.01(d)	

(1) Note: If sidewalk or a side path is present adjacent to the entrance, the entrance grade used shall be broken to allow the extension of the sidewalk or side path through the entrance at a maximum cross slope of 2% (1.5% preferred). See Figure 36-7.C.

36-7.01(g) Driveway Sight Distance

Section 36-6 discusses intersection sight distance (ISD) criteria for State highway intersections with public roads on new construction or reconstruction projects. Section 49-3.06(e) discusses intersection sight distance criteria for State highway intersections with public roads on 3R projects.

Desirably, these criteria, depending on project type, will also apply to intersection sight distances for exiting vehicles at driveways and entrances, however, the use of full intersection criteria may not always be practicable. It is important to check for sight obstructions (e.g., buildings, trees, hedges, bushes, fences, signs) in the vicinity of the driveway entrance which may restrict sight lines, and to reduce sight line constraints to the extent possible. To perform the check for exiting vehicles, it is reasonable to assume an eye location of approximately 12 ft (3.6 m) from the edge of traveled way. As a minimum, provide stopping sight distance (SSD) for an approaching vehicle on the traveled way to an exiting vehicle at a driveway. Locations of non-compliant sight distance identified during project development must still meet the lesser 3R SSD requirements found in Section 49-3.06(e), When driveway sight distance cannot be provided to the minimum 3R distances, note and discuss this issue at a district coordination meeting with warrant justification and documentation as a Level Two design exception. See Section 31-7 regarding the design exception process.

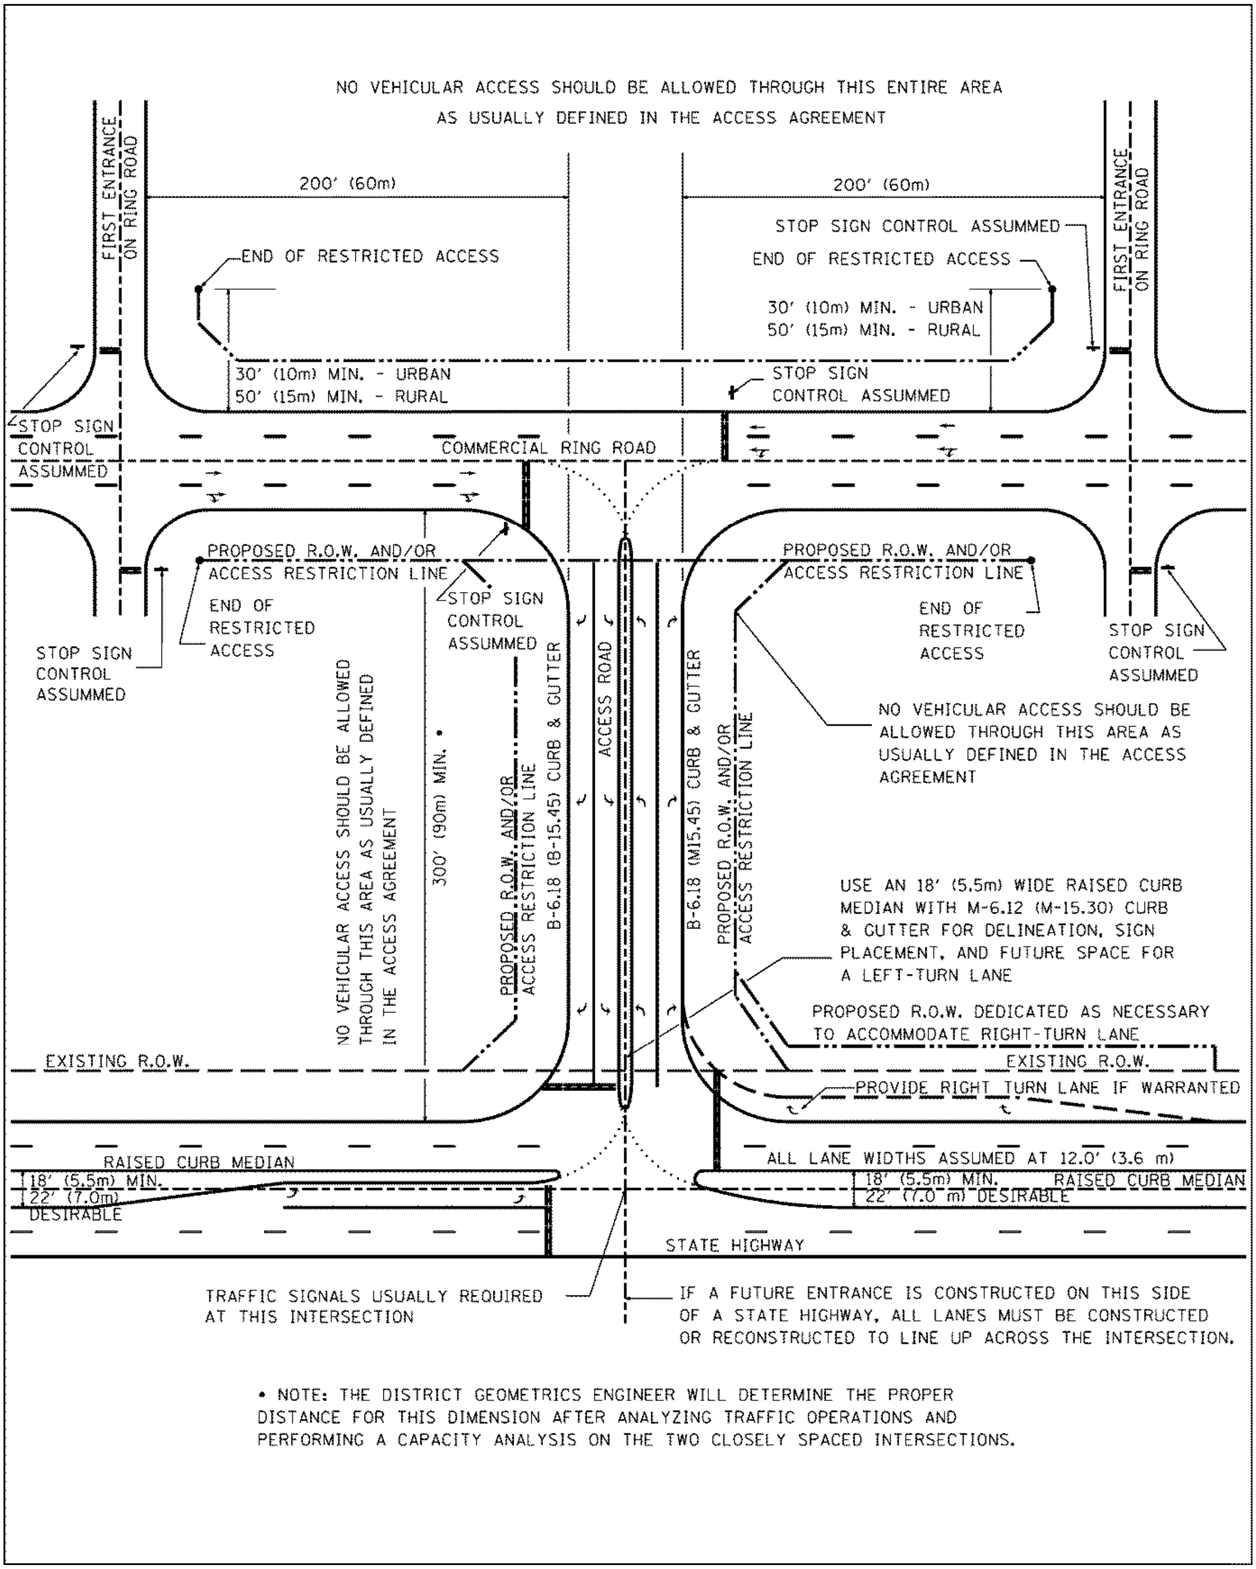
36-7.01(h) Auxiliary Lanes

Consider using deceleration and acceleration lanes at high-volume commercial entrances, especially on high speed or high volume arterials. Section 36-3 further discusses the design and guidelines for using auxiliary lanes. In addition to traffic-volume considerations, it may be necessary to provide a right-turn lane into a driveway if the change in grade is abrupt at the driveway entrance. Where a separate right-turn lane is provided, no part of the auxiliary lane taper should encroach on the radius return of an adjacent intersecting side road.

36-7.01(i) Typical Entrance Drawings

Closely spaced or improperly designed entrances may cause operational problems, especially when high volume roadways and/or high-volume driveways are involved. Also, operational and safety problems can result if driveways are located too close to side road intersections. As an aide in the design process, typical drawings have been developed and provided for various access scenarios. See the following for additional information:

- Illustrations 2 and 4 through 10 of the *Handbook for the Policy on Permits for Access Driveways to State Highways* provide typical entrance drawings applicable to both the design and permitting processes.
- Figures 35-7.E and 46-2.C give examples of right-in/right-out channelized driveways, which may be an effective alternative in improving safety and operations for entrances in close proximity to intersections.
- Figures 35-7.B through 35-7.I provide details of general access management scenarios that can be applied to commercial entrance design.



TYPICAL HIGH VOLUME COMMERCIAL ENTRANCE
(TEE INTERSECTION TO A STATE HIGHWAY WITH NO ACCESS CONTROL)
Figure 36-7.D

Entrances to major developments adjacent to State highways are designed using the same criteria required for street intersections. Figure 36-7.D shows a typical design for a high-volume commercial entrance to a State highway. Modifications of this typical design are possible and would be dependent on specific factors such as the classification of the State highway, traffic flow characteristics of the two closely spaced intersections, results of a capacity analysis, potential for safety issues, and the potential immediate or future need for traffic signals on the ring road resulting in the need for proper vehicular storage.

36-7.02 Entrance/Driveway Access Permit Process

The State statutes listed in Section 36-7.01 grant the Department authority to permit driveways and entrances to State highways. The IDOT Bureau of Operations publication entitled, *Handbook for the Policy on Permits for Access Driveways to State Highways* contains the detailed procedures for obtaining new or revised access to State highways. The general procedure is noted below.

1. General Permitting Procedures. An access permit is required for the construction of any new access facility, or the revision of an existing access facility, within the right-of-way of a State highway when the work is to be done by any person or agency other than the Department. Such proposed entrance work is reviewed by district staff to ensure conformance with Departmental policies.

   Access permits are issued by the permit's unit of the appropriate district office. In some cases where the curbing along a State highway is maintained by a municipality, permits for access work may be issued by that municipality with the Department's concurrence. The district office will advise an applicant of the appropriate issuing authority. In all cases where the proposed access is to a State highway, final jurisdiction concerning the permit will remain with the Department. No work shall be undertaken on State right-of-way until the person or agency has received an approved access permit and after a notice is provided to the permits unit that driveway construction is to begin.

   An approved access permit only covers the use of entrances, driveways, and/or side roads for land uses *as* permitted. Changes in land use, land use density, or ownership typically void any individual permit and necessitate new permit applications. Within a development, access to individual parcels subsequently established must be by internal circulation. Therefore, include all phased development as part of an original permit in order to maintain the integrity of the access facility and avoid the reconstruction of the access facility in the future.

2. Procedures for Platting Developments. In accordance with the *Plat Act, 765 ILCS 205/2*, for municipalities with population less than one million, the local agency must submit the plat to the appropriate district's plats and plans office for approval, and the Department has 90 days to respond to the submittal in writing. Failure by the Department to respond within 90 days, once submitted, allows the public agency to approve the plat without Departmental concurrence. For municipalities with population greater than one million, Department approval is not required for the local agency to approve the plat, although

coordination with the Department is preferable to assure overall conformance to local and Departmental policies on land subdivision, safety, and access control.

3. Procedures for Major Developments. The approval process for a proposed access facility to a major development adjacent to a State highway is a two-part process.

   The first part of the approval process for major developments involves initial planning. During this first phase, a traffic study, intersection design study, and hydraulic study may be required to be submitted by the developer for review and approval to both State and local roadway agencies.

   The developer is required to meet and discuss the proposed development with the Department's district personnel prior to beginning such studies. It is recommended that appropriate local roadway agency representatives also be in attendance in order to discuss additional local regulations and access requirements. This preliminary meeting is held to discuss the Department's access permitting process and policy requirements well in advance of the developer's decisions on final arrangement of buildings, internal driveways, and parking facilities, and must involve the entire developable area rather than only a portion of the property or only along the State highway frontage of the proposed development. This helps to ensure that proposed access to the facility will operate satisfactorily beyond any proposed initial phase of development. The preliminary discussions provide a proposed framework for the required analysis and also help to ensure that the final entrance location(s) to the State highway and proposed layout of the development will be acceptable to both the Department and municipality, while also compatible with adjacent land development.

   The meeting discussion should also include the need for, and requirements of, hydraulic, traffic, and intersection design studies for the proposed development. These studies shall be completed by the developer's engineering consultant at the developer's expense and submitted to the district's permit unit for review, coordination, and approval. The permits unit will forward the studies to other district bureaus and units as necessary for adequate review to ensure all Departmental policies are met.

   The planning documents that may need to be submitted, depending on project scope and size, are:

   a. Hydraulic Study. Drainage collected by ditches, gutters, or pipes on private property shall not be discharged into the highway drainage system unless expressly approved by the Department. The hydraulic study must include all calculations necessary in assessing stormwater run-off for the proposed facility and for mitigating potential increases in flow or flow-rate onto the State system. The study must show that proposed storm water detention is provided on private property and that runoff which enters the State's drainage system does not exceed that which naturally occurs from the property to be developed.

   b. Traffic Study. The traffic study must project traffic being generated by the proposed development out to a 20-year design life from the date of proposed construction (as mandated in Figure 31-4.A), assess warrants for the potential mitigation of development traffic through permitted improvements such as the addition of travel lanes or traffic signals, and propose potential locations of development ingress/egress that meet Department operational and safety criteria for both the mainline and side road or entrance. Depending on traffic being generated by the proposed development, the developer's engineer may need to analyze additional intersections adjacent to the proposed development to assess potential impacts to capacity and public safety. These requirements will be discussed at the initial meeting with the Department.

After the initial meeting, and only after total site traffic is submitted to and reviewed and approved by district personnel, shall the developer's engineering consultant use the capacity analysis results of the traffic study to assess and recommend proposed locations of optimal ingress/egress, and the need, in accordance with IDOT policy, for mitigation of development traffic through permitted improvements. Potential improvements may consist of additional lanes or existing lane extensions (both through and/or turn lanes) or modifications to existing traffic control, including the addition of traffic signals or proposed changes to existing traffic signal timing.

c. Intersection Design Study. Only after completion and approval of the traffic study, can work begin on the intersection design study (IDS), if required. See Chapter 14 for IDS warrants and requirements.

The second part of the approval process for major developments involves the preparation of detailed design construction plans for the entrance or new intersection. The detailed design, including intersection or entrance details and design of the stormwater runoff and detention system(s) for the development, must be one which provides good service to users while at the same time minimizes interference to the safe and efficient movement of through highway traffic. This second part of the process requires obtaining an entrance permit pursuant to the *Illinois Highway Code*, *605 ILCS 5/4-210*. See the *Handbook for the Policy on Permits for Access Driveways to State Highways* for a typical example of a highway permit application. See Figure 36-7.D for a typical example of an entrance to a major development.

In addition to the guidelines listed above, an Access Agreement is also required for most major developments. The district permits unit will be responsible for preparing and finalizing an Access Agreement with the developer. See the *Handbook for the Policy on Permits for Access Driveways to State Highways* for a typical example of an Access Agreement. The Access Agreement must be signed by the developer before an access permit can be issued for this type of entrance or new intersection.

4. Access Restrictions for Major Developments. With any new major access point, it is important to consider managing access to the development to preserve the operational integrity of the highway system. This is most easily achieved by an entrance or side road design which will minimize the likelihood of traffic queuing out onto the highway from the development and will not provide inordinate vehicular delay or deficient levels of service through the standard 20-year design period. See Section 31-4.02 regarding design year

selection. See Section 31-4.04 regarding Level of Service criteria.

As an aide to ensure operational integrity of both routes upon initial construction of the proposed development and in the future, a restriction to full access should be created along the proposed development entrance or side road for a sufficient distance beyond the nearest mainline edge of travel way. This access restriction dimension is typically established at 300 ft (90 m) minimum, but can be increased as needed based on proposed side road traffic and capacity; see Figure 36-7.D. The access restriction is generally defined within the Intersection Design Study completed for the proposed intersection, and is also placed as a note and dimension on the subdivision plat at the time of development. The access restriction is then established as part of the plat of right-of-way dedication for the proposed entrance or side road following general Land Acquisition guidelines. For more on the Department’s access management principles; see Section 35-6.

36-8 INTERSECTION DESIGN NEAR RAILROADS

These design guidelines apply to all State highway geometric improvement projects where the route is adjacent and parallel to a railroad. Where an at-grade railroad crossing is within 200 ft (60 m) of an intersection, the design should address efforts to keep vehicles from stopping or storing on the tracks. This applies to either signal- or stop-controlled intersections. Intersection designs within 200 ft (60 m) of a grade crossing, or greater than 200 ft (60 m), if capacity and queuing analyses determine that queuing will be possible over the grade crossing, should be coordinated with the Illinois Commerce Commission's Railroad Safety Section as soon as possible during the design phase. For roundabout intersections near railroads; see Section 36- 9.02 (d).

The following factors should be identified and considered during the planning stages:

1. Clear Storage Distance. Consider alternative designs that provide a minimum distance of 75 ft (23 m) between the proposed intersection stop bar and a point 6 ft (1.8 m) from the closest rail.

2. Space for Vehicular Escape. On the far side of any railroad crossing, consider providing an escape area for vehicles (e.g., shoulder with curb and gutter behind the shoulder, flush medians, flush-corner islands, right-turn acceleration lanes, improved corner radii).

3. Conflicting Commercial Access. Left-turn vehicular movements that may inhibit the clearance of queued traffic on the approaches to railroad tracks should be discouraged. If entrances exist on the street approach, consider using design features that would eliminate the problems (e.g., left-turn lane, raised-curb median). Entrances should be placed at a sufficient distance from an at-grade railroad crossing to ensure that the turning path of a passenger vehicle is completed and on tangent at the stop line in advance of the warning devices. No part of an entrance should be placed closer to the track(s) than the warning devices or the stop line extended perpendicular to the roadway centerline, except in the case of entrances used exclusively by railroads to access railroad property.

4. Pre-Signal Traffic Signals. Pre-signals should be installed at a grade crossing where the distance between the stop bar and the nearest rail is 56 ft (17.0 m) or less. If the crossing is on a State highway, or if a high percentage of multi-unit vehicles cross the tracks, then pre-signals should be installed where the distance between the stop bar and the nearest rail is 81 ft (24.7 m) or less. If pre-signals are required on the near side of the tracks, a raised-curb median may be necessary adjacent to the tracks to provide for proper placement of signals. When pre-signals are included in the design, all left turn movements must be designed as protected only for all legs (or split-phase on the highway-railroad grade crossing legs in conjunction with protected only left turns on the parallel street). Exceptions to some of these requirements may include the use of 4-quadrant gates at the highway-railroad grade crossing and/or the use of flashing yellow arrows on the street paralleling the tracks. Flashing yellow arrow designs (protected-permitted or permitted left-turn phasing) on the street paralleling the tracks may be considered as long as a red left arrow is displayed towards the crossing during the entire railroad preemption sequence. The pre-signal indications terminate before the associated downstream intersection indications terminate on a cycle-by-cycle basis. This should be simulated in the

corresponding capacity analysis as extended amber and all-red times (12-14 seconds per pre-signal phase terminated), which can lead to significant delay and detrimental level-of-service results. This will affect required storage length calculations for many movements as overall intersection delay will significantly increase. Storage length calculations on the highway-railroad grade crossing leg shall not include the area between the pre-signal and intersection.

5. Restricted Intersection Capacity. During periods of frequent railroad preemption of traffic signals, consider the effects of reduced traffic flow, lack of progression on the street paralleling the tracks, and traffic backups. Available computer programs should be used to analyze different capacity and operational scenarios and to recommend any countermeasures. Plans for geometric changes proposed at or near intersections having railroad preemption of traffic signals should be coordinated with the Illinois Commerce Commission's Railroad Safety Section.

6. Sight Restrictions. Review and analyze sight distance triangles along railroad tracks and eliminate any restrictions. Guidance on this analysis can be found in AASHTO, *A Policy on Geometric Design of Highways and Streets*. Notify the ICC of any obstructions on railroad right-of-way.

7. Protected Left-Turn Storage. On the street that parallels the tracks, analyze the storage length needed for left-turns into the side street and across the tracks during preemption of the traffic signals. Without the proper storage length available, this could cause backups into the through lanes.

8. Right-Turn Lanes. On the street which runs parallel to the railroad and where an actuated NO RIGHT TURN SIGN is proposed in conjunction with railroad preemption, a right-turn lane should be considered for the right-turn movement across the tracks. The auxiliary lane provides a refuge for right-turning vehicles during railroad preemption and eliminates the problem of traffic temporarily blocking the through lanes.

9. Side Street Left-Turn Lane Capacity. On streets that cross railroad tracks, provide sufficient left-turn storage lengths that will avoid the problem of left turns spilling out onto through lanes and blocking the through lanes.

10. Other. See the Bureau of Operations *Policies and Procedures Manual* and memorandum for additional information.

36-9 INTERSECTION CONTROL EVALUATION

The Intersection Control Evaluation (ICE) process is a means to identify, evaluate, and document intersection alternatives to identify optimal geometric and control solutions. The ICE process provides warrants for intersection type selection based on benefit cost, including alternative intersection designs that do not have traditional traffic volume-based warrants. The ICE process does not replace engineering judgment but introduces quantifiable factors to inform the decision-making process and introduces predictive safety analysis into the design process.

36-9.01 Applicability of ICE Analysis

An ICE analysis may be performed during Phase I for new and reconstruction projects. ICE analysis may be performed as a part of a safety review of an existing intersection, local agency projects that intersect state jurisdiction routes, or to address operational concerns including change of access and permit proposals. For reconstruction an ICE analysis should consider existing intersection performance.

Scope is generally focused on the isolated intersection or intersections under evaluation. Evaluation may need to expand if:

- adjacent intersections or ramp terminals will be affected by:
  - + substandard spacing and/or queue formation
  - + horizontal, vertical, or cross-sectional changes
- modifications are planned to an intersection within a coordinated signal system.

36-9.02 Design Year

ICE analysis shall be completed for the project design year. Refer to Section 31-4.02.

36-9.03 ICE Process

The ICE process has seven steps:

1. Evaluate the intersection with the Capacity Analysis for Planning of Junctions (CAP-X) tool to screen three or more intersection types that provide adequate capacity.
2. Evaluate the intersection with the Safety Performance for Intersection Control Evaluation (SPICE) tool to identify the top three performing types,
3. Review CAP-X and SPICE results against existing safety data using the BSPE Safety Tiers (CCOF) and Intersection Initiative tools,
4. Perform a benefit cost analysis of the alternatives using the IDOT's B/C tool,
5. Check design controls and examine level of service of the preferred alternatives(s) through HCM methods,
6. Review the proposed alternatives with the District Safety Committee and select the preferred design, and
7. Document the process for inclusion in the project report.

36-9.03(a) CAP-X Analysis

CAP-X is a sketch planning tool to screen intersection types for adequate capacity. The tool is used to identify three or more intersection types for further analysis that have adequate capacity for effective traffic operations and are feasible for the location. CAP-X allows the ICE process to focus on intersection types that will most likely function; however further capacity analysis for level of service is required for the final selected intersection as a part of the Intersection Design Study (IDS) process. Examine at a sketch planning level the feasibility of the intersection configurations. Feasibility may be precluded by right of way needs, surrounding terrain, and access.

36-9.03(b) SPICE Analysis

SPICE is a screening tool to evaluate several intersection configurations at one time. The SPICE Tool uses Safety Performance Functions (SPFs) from the Highway Safety Manual to select appropriate Crash Modification Factors (CMFs) to predict crash frequency and severity for the intersection types selected. Select three or more intersection configurations for continued analysis based on predictive crash performance. Less configurations may be selected if local feasibility precludes them. Document reasons for selecting less than three configurations.

36-9.03(c) Safety Data Review

Examine the location for crash type and severity through the BSPE Safety Tiers () and Intersection Initiative. Report the CCOF and Intersection Initiative Safety Tier levels on the ICE template. Note that this crash data will also be used in part for the B/C analysis.
Evaluate each proposed intersection configuration performance against the indicated crash types. Rate them on the ICE template. Rate expected performance based on three categories:

1. Proposed intersection configuration addresses all predominate crash types.
2. Proposed intersection configuration addresses severe crash types.
3. Proposed intersection configuration does not address predominate crash types.

36-9.03(d) B/C Analysis

Examine each intersection configuration with the BSPE Benefit Cost tool using the crash data. Alternative intersection designs require manual input of CMFs. Document the name, year, and crash types of studies used for CMF. Avoid use of more than two CMFs as the combined effect of the factors is not well researched. A predicted B/C may be created by inputting the predicted crash performance from SPICE. Multiply the SPICE predicted performance by 10 years and round to the nearest whole number. Input the SPICE fatal and injury prediction at the ratio given by past performance. Input the number of total SPICE predicted crashes as PDO category all crash, minus the number of fatal and injury crashes. The total K&A and PDO crashes shall match between the SPICE spreadsheet and the B/C tool. These assumptions will provide a conservative result. The calculated benefit cost ratio is a tool for rationalizing intersection control selection but is not the only factor as will be discussed in 36-11.03(f).

36-9.03(e) Design Controls

Analyze selected intersection configurations for design controls. Before analysis consult the project engineer for Phase I factors that may rule out a design, such as environmental or local commitments. For alternative intersections special attention is given to sight distance (Section 31-3), level of service (Section 36-1.07) and turning geometry (Section 36-2). For signalized intersections special attention is given to signal head location, phasing, and left turn protected phasing capacity vs safety benefits. Intersection configurations shall meet MUTCD warrants for stop or signal control. Delay shall be calculated as with an Intersection Design Study. However, some innovative intersection designs are not able to be modeled by HCS software and engineering judgement may be used to decide if detailed simulation analysis is required beyond the volume to capacity ratio of the sketch planning tool.

36-9.03(f) District Safety Committee Review

The District Safety Committee shall review the selected intersection configurations. The preferred design should be selected by project scope, predicted safety improvement, B/C analysis, life cycle cost, capacity analysis and delay, and anticipated traffic operations and maintenance. The preferred design should be examined against recent crash data that may not be included on the Safety Tiers and CCOF.

36-9.03(g) Documentation

The designer shall document the ICE process on BDE 3610 (Intersection Configuration Evaluation Recommendation).

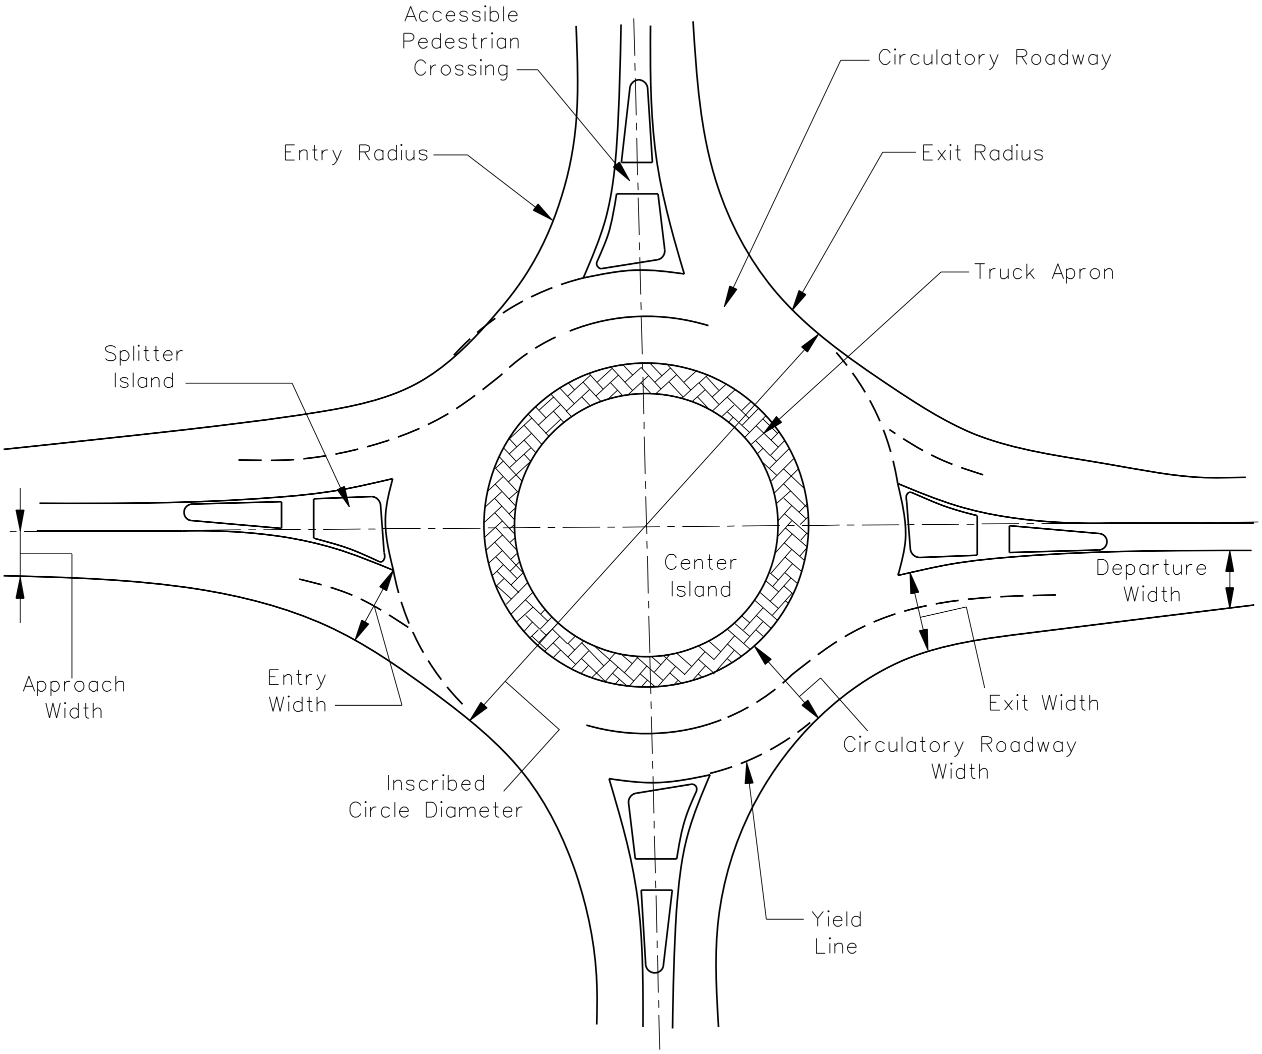
36-10 ROUNDABOUTS

36-10.01 General

Roundabouts are a type of circular intersections in which traffic travels counterclockwise (in right-hand traffic countries) around a central island. Specific design and traffic control features define and distinguish roundabouts from traffic circles. These features include yield control of all entering traffic, channelized approaches that deflect traffic flow, and appropriate geometric curvature to ensure that travel speeds on the circulatory roadway are typically less than 30 mph (50 km/hr). Figure 36-10.A illustrates the key components of a roundabout.



ROUNDABOUT ELEMENTS

Figure 10.A

When operating within their capacity, roundabouts typically operate with lower vehicle delays than other intersection forms and control types. With no conflicts within a roundabout it is unnecessary for traffic to come to a complete stop. When queues exist at one or more approaches, traffic within the queues usually continues to move, and this is typically more tolerable to drivers than a stopped or standing queue.

Studies have shown that compared to other types of intersections, roundabouts have:

Improved safety:
- Elimination of high conflict angles;
- Lower operating speeds; and
- Fewer vehicular conflict points.

Reduced congestion:
- Efficient during peak hours and other times, and
- Typically less delay.

Reduced pollution and fuel use:
- Fewer stops and hard accelerations, and
- Less time idling.

Reduced costs:
- No signal equipment to install, power, and maintain, although some savings may be offset by the need and cost of illumination;
- Smaller roundabouts may require less right-of-way than traditional intersections; and
- Often less pavement needed.

Complement other common community values:
- Quieter operation, and
- More functional and aesthetically pleasing.

Public acceptance of roundabouts is often one of the biggest challenges facing a jurisdiction that is planning to install its first roundabout. Without the benefit of explanation or first-hand experience and observation, the public is likely to incorrectly associate roundabouts with older, nonconforming traffic circles that they have either experienced or about which they have heard. Equally possible, without adequate education, the public (and agencies alike) will often have a natural hesitation or resistance against changes in their driving behavior and driving environment. In this situation, a proposal to install a roundabout may initially experience a negative public reaction. However, the history of the first few roundabouts installed in the United States also indicated that public attitude toward roundabouts improved significantly after construction. A survey conducted of jurisdictions across the United States reported a significant negative public attitude toward roundabouts prior to construction (68% of the responses were negative or very negative), but a positive attitude after construction (73% of the responses were positive or very positive).

36-10.02 Roundabout Selection

36-10.02(a) Comparison of Performance of Alternative Intersection Types

A roundabout is often compared to other intersection types, usually either a stop- or signal-controlled intersection. To simplify the selection process, the following generalized information is offered for a planning-level operational comparison of control modes:

- A roundabout will almost always provide a higher capacity and lower delays than all-way stop-controlled operating with the same traffic volumes.
- A roundabout is unlikely to offer better performance in terms of lower overall delays than two-way stop control (TWSC) at intersections with minor movements (including cross-street entry and major-street left turns) that are not experiencing, nor predicted to experience, operational problems under TWSC.
- A single-lane roundabout may be assumed to operate within its capacity at any intersection that does not exceed the peak-hour volume warrant for signals.
- A roundabout that operates within its capacity will generally produce lower delays than a signalized intersection operates with the same traffic volumes and right-of-way limitations.

Unlike traffic signal control, there are no warrants for roundabouts currently included in the ILMUTCD. Instead of warrants a roundabout may be evaluated at a sketch planning level for volume to capacity and predicted safety performance through the Intersection Configuration Evaluation (ICE) procedure in 36-9.

36-10.02(b) Selection Consideration Factors

In determining whether to use a roundabout or a more traditional intersection at a site, consider the following:

1. Safety. The frequency of crashes at an intersection is related to the number of conflict points at an intersection, as well as the magnitude of conflicting flows at each conflict point. A conflict point is a location where the paths of two vehicles, or a vehicle and a bicycle or pedestrian diverge, merge, or cross each other. For example, the number of vehicle-vehicle conflict points for four-leg intersections drops from 32 to 8 with roundabouts, a 75% decrease. Fewer conflict points mean fewer opportunities for collisions. Also, a roundabout has zero vehicle crossing points.

   The severity of a collision is determined largely by the speed of impact and the angle of impact. The higher the speed and the higher the angle of impact the more severe the collision. Roundabouts reduce in severity or eliminate many severe conflicts that are present in traditional intersections.

2. Construction Costs. The costs of installing roundabouts will vary significantly from site to site. A roundabout may cost more or less than a traffic signal, depending on the amount of new pavement area and the extent of other roadway work required. At some existing

unsignalized intersections, a traffic signal can be installed without significant modifications to the pavement area or curbs. In these instances, a roundabout is likely to be more costly to install than a traffic signal, as the roundabout can rarely be constructed without significant pavement and curb modifications. Consideration of maintenance and power should be included with the long-term signal costs.

However, at new sites, and at signalized intersections that require widening at one or more approaches to provide additional turn lanes, a roundabout can be a comparable or less expensive alternative. While roundabouts typically require more pavement area at the intersection, they may require less pavement width on the upstream approaches and downstream exits if multiple turn lanes associated with a signalized intersection can be avoided. The cost savings of reduced approach roadway widths is particularly advantageous at interchange ramp terminals and other intersections adjacent to grade separations where wider roads may result in larger bridge structures.

In most cases, a roundabout is more expensive to construct than the two-way or all-way stop-controlled intersection alternatives.

3. Movements. Roundabouts tend to treat all movements at an intersection equally. Each approach is required to yield to circulating traffic, regardless of whether the approach is a local street or major arterial. In other words, all movements are given equal priority. This may result in more delay to the major movements than might otherwise be desired.

   This problem is most acute at the intersection of high-volume major streets with low- to medium-volume minor streets (e.g., major arterial streets with minor collectors or local streets). Therefore, the overall street classification system and hierarchy should be considered before selecting a roundabout (or stop-controlled) intersection. This limitation should be specifically considered on emergency response routes in comparison with other intersection types and control. The delays depend on the volume of turning movements and should be analyzed individually for each approach.

4. Vehicle Delay and Queue Storage. When operating within their capacity, roundabout intersections typically operate with lower vehicle delays than other intersection forms and control types. With a roundabout, it is unnecessary for traffic to come to a complete stop when no conflicts are present. Where there are queues on one or more approaches, traffic within the queues usually continues to move. This is typically more tolerable to drivers than a stopped or standing queue. The performance of roundabouts during off-peak periods is particularly good in contrast to other intersection forms, typically with very low average delays.

5. Signal Progression and Access. It is common practice to coordinate traffic signals on arterial roads to minimize stops and delay to through traffic on the major road. By requiring coordinated platoons to yield to traffic in the circulatory roadway, the introduction of a roundabout into a coordinated signal system may disperse and rearrange platoons of traffic if other conflicting flows are significant, thereby reducing progressive movement. To minimize overall system delay, it may be beneficial to divide the signal system into subsystems separated by the roundabout, assigning each subsystem its own cycle.

The traffic performance of the combination roundabout-signal system should be tested in advance with traffic modeling software. In some cases, total delay, stops, and queues will be reduced by the roundabout. The number of available gaps for midblock unsignalized intersections and driveways may also be reduced by the introduction of roundabouts, although this may be offset by the reduced speeds near roundabouts. In addition, roundabouts can enable safe and quick U-turns that can substitute for more difficult midblock left turns, especially where there is no left turn lane.

6. Environmental Factors. Roundabouts may provide environmental benefits if they reduce vehicle delay and the number and duration of stops compared with another alternative. Even where there are heavy volumes, vehicles continue to advance slowly in moving queues rather than coming to a complete stop. This may reduce noise and air quality impacts and fuel consumption significantly by reducing the number of acceleration/deceleration cycles and the time spent idling. In general, if stop or yield control is insufficient, traffic through roundabouts generates less pollution and consumes less fuel than traffic at fixed-time signalized intersections. However, vehicle-actuated signals typically cause less delay, less fuel consumption, and fewer emissions than roundabouts as long as traffic volumes are low. During busy hours, vehicle-actuated signals tend to operate like fixed-time signals, and the percentage of cars that must stop becomes high.

7. Space Requirements. Roundabouts usually require more space for the circular roadway and central island than the rectangular space inside traditional intersections. Therefore, roundabouts may have a significant right-of-way impact on the corner properties at the intersection, especially when compared with other forms of unsignalized intersection. The dimensions of a traditional intersection are typically comparable to the envelope formed by the approaching roadways. However, to the extent that a comparable roundabout would outperform a signal in terms of reduced delay and thus shorter queues, it will generally require less queue storage space on the approach legs.

   If a signalized intersection requires long and/or multiple turn lanes to provide sufficient capacity or storage, a roundabout with similar capacity may require less space on the approaches. As a result, roundabouts may reduce the need for additional right-of-way on the links between intersections, at the expense of additional right-of-way requirements at the intersections themselves. The right-of-way savings between intersections may make it feasible to accommodate parking, wider sidewalks, planter strips, wider outside lanes, and/or bicycle lanes in order to better accommodate pedestrians and/or bicyclists. Another space-saving strategy is the use of flared approach lanes to provide additional capacity at the intersection while maintaining the benefit of reduced spatial requirements upstream and downstream of an intersection.

   At interchange ramp terminals, paired roundabouts have been used to reduce the number of lanes in freeway over- and underpasses. In compact urban areas, there are typically signalized intersections at both ends of overpass bridges, necessitating two additional overpass lanes to provide capacity and storage at the signalized intersections.

8. Older Drivers. Roundabouts assist older drivers by reducing the speed at the intersection (i.e., conditions change more slowly allowing for more time to make proper responses), providing less complicated situations and decision-making, judging gaps is easier and mistakes are rarely fatal, providing less demand to accurately judge speeds of traffic, and reducing the required visual scans.

9. Corner Property Access. Access to corner properties may be restricted or require driveways to be offset at roundabouts due to the prohibition of driveways within the circulatory roadway.

10. Operations and Maintenance Costs. Compared to signalized intersections, a roundabout does not have signal equipment that requires constant power, periodic light bulb and detection maintenance, and regular signal timing updates. Roundabouts, however, can have higher landscape maintenance costs, depending on the degree of landscaping provided on the central island, splitter islands, and perimeter. Illumination costs for roundabouts and signalized intersections are similar.

    Drivers sometimes face a confusing situation where they approach a signalized intersection during a power failure, but such failures have minimal temporary effect on roundabouts or any other unsignalized intersections, other than the possible loss of illumination. The service life of a roundabout is significantly longer, approximately 25 years, compared with 10 years for a typical signal.

11. Traffic Calming. A series of roundabouts can have secondary traffic calming effect on streets by reducing vehicular speeds. Speed reduction at roundabouts is caused by geometry rather than by traffic control devices or traffic volume. Consequently, speed reduction can be realized at all times of day and on streets of any traffic volume. It is difficult to speed through an appropriately designed roundabout with raised channelization that forces vehicles to physically change direction. In this way, roundabouts can complement other traffic calming measures.

    Roundabouts have also been used successfully at the interface between rural and urban areas where speed limits change. In these applications, the traffic calming effects of roundabouts force drivers to slow and reinforce the notion of a significant change in the driving environment.

12. Aesthetics. Roundabouts offer the opportunity to provide attractive entries or centerpieces to communities. However, hard objects in the central island directly facing the entries are a safety hazard. The portions of the central island and, to a lesser degree, the splitter islands that are not subject to sight-distance requirements offer opportunities for aesthetic landscaping. Pavement textures can be varied on the aprons as well. They can also be used in tourist or shopping areas to facilitate safe U-turns and to demarcate commercial uses from residential areas. Avoid “attractive nuisances” in the central island, which could attract pedestrians to cross the circulating roadway for closer inspection.

13. Pedestrian Conflicts. If a queuing analysis determines frequent interruptions from pedestrians to the traffic flow at the exit, causing traffic to regularly back into the circulatory

roadway, consideration should be given to a conventionally controlled intersection instead of a roundabout.

36-10.02(c) Locations

Consider providing roundabouts at intersections having one of more of the following conditions:

- intersections with high crash rates/high severity rates;
- intersection with complex geometry (e.g., more than four approaches);
- rural intersections with high-speed approaches;
- freeway interchange ramp terminals;
- closely spaced intersections;
- closely spaced offsetting intersections;
- replacement of all-way stops;
- replacement of signalized intersections;
- at intersections with high left-turn volumes;
- replacement of two-way stops with high side-street delay;
- intersections with high U-turn movements;
- transitions from higher-speed to lower-speed areas (traffic calming);
- where aesthetics are important; and
- where accommodating older drivers is an objective.

Roundabouts are not appropriate everywhere. Intersections that may not be good candidates include those with topographic or site constraints that limit the ability to provide appropriate geometry, those with highly unbalanced traffic flows (i.e., very high traffic volumes on the main street and very light traffic on the side street), and isolated intersections in a network of traffic signals.

Roundabouts often require more space in the immediate vicinity of the intersection than a comparable stop-controlled or signalized intersection. This space requirement is dictated by a number of factors, including the size and shape of the roundabout (e.g., circular versus noncircular). However, in the context of a corridor, the additional space needed in the vicinity of a roundabout may be offset by reduced space needed between intersections.

36-10.02(d) Types

1. Single-lane. A single-lane roundabout can be assumed to operate acceptably if the sum of the entering and circulating volumes for each approach is less than 1000 vph. Maximum entering design speeds based on a theoretical fastest path [fastest path discussed in Section 36-10.04(b)] of 20 mph to 25 mph (30 km/hr to 40 km/hr) are recommended at single-lane roundabouts. Generally, the diameter of the inscribed circle of a single-lane roundabout ranges from 105 ft to 150 ft (32 m to 46 m) with the larger size capable of accommodating a WB-67 (WB-20) design vehicle. The typical maximum service volume is 25,000 vpd.

Single-lane roundabouts are much simpler for bicyclists than multilane roundabouts since they do not require bicyclists to change lanes to make left-turn movements or otherwise select the appropriate lane for their direction of travel. In addition, at single-lane roundabouts, motorists are less likely to cut off bicyclists when exiting the roundabout. These are important factors for selecting a single-lane roundabout over a multi-lane roundabout in the short term, even when long-term traffic predictions suggest that a multilane roundabout may be desirable.

2. Multilane. Multilane roundabouts have at least one approach with at least two lanes on the entries or exits. Multilane roundabout design tends to be less forgiving that single-lane roundabout design. Geometry, pavement markings, and signs must be designed together to create a comprehensive system to guide and regulate road users who are traversing roundabouts.

   Key considerations for all multilane roundabouts include:

   - Lane arrangements to allow drivers to select the appropriate lane on approach and navigate through the roundabout without changing lanes.
   - Alignment of vehicles at the entrance line into the correct lane within the circulatory roadway.
   - Accommodation of side-by-side vehicles through the roundabout.
   - Alignment of the legs to prevent exiting-circulating conflicts.
   - Accommodation for all travel modes.

   At multilane roundabouts, maximum entering design speeds of 25 mph to 30 mph (40 km/hr to 50 km/hr) are recommended based on a theoretical fastest path [fastest path discussed in Section 36-10.04(b)] assuming vehicles ignore all lane lines. Generally, the inscribed circle diameter of a multilane roundabout ranges from 150 ft to 250 ft (46 m to 76 m). Roundabouts with three-or four-lane entries may require larger diameters of 180 ft to 350 ft (55 m to 100 m) to achieve adequate speed control and alignment. The typical maximum service volume for a two-lane roundabout is 45,000 vpd.

3. Mini. With a diameter less than 100 ft, the mini roundabout is smaller than the typical single-lane roundabout. The smaller diameter is made possible by the use of a fully traversable central island to accommodate large vehicles, as opposed to the typical single-lane roundabout where the diameter must be large enough to accommodate a multi-unit within the circulatory roadway (and truck apron if applicable) without it needing to travel over the central island. The small footprint of a mini-roundabout offers flexibility in working within constrained sites. The typical maximum service volume is 15,000 vpd.

36-10.03 Public Involvement

Public acceptance of roundabouts is often one of the biggest challenges facing a jurisdiction that is planning to install its first roundabout, thus the use of Context Sensitive Solution principles is recommended for regions new to roundabout operations. Without the benefit of explanation or first-hand experience and observation, the public (and agencies alike) is likely to incorrectly associate roundabouts with older, non-conforming traffic circles that they have either experienced or heard about.

In such a situation, a proposal to install a roundabout may initially experience a negative public reaction. However, the history of roundabouts installed in the United States also indicates that public attitude toward roundabouts typically improves significantly after construction. Surveys conducted by the Insurance Institute for Highway Safety reported a significant negative public attitude toward roundabouts prior to construction (41% oppose), but a positive attitude after construction (63% positive or very positive).

A variety of techniques have been used successfully in the United States to inform and educate the public about new roundabouts. Some of these include public meetings, websites, informational brochures and videos, and announcements in the newspaper or on television and radio. A public involvement process should be initiated as soon as practical, preferably early in the planning stages of a project while other intersection forms are being considered.

The FHWA has brochures promoting roundabouts available for distribution at public meetings as well as informational videos for viewing. If a roundabout has been constructed in the vicinity, make recommendations for the public to visit the site or discuss with officials within the jurisdiction in which the roundabout is located. Include animated traffic software to show roundabout operations. Other states have created informational videos and brochures of their own which they have used successfully.

36-10.04 Geometric Design

The geometric design of a roundabout requires the balancing of competing design objectives. Designing a roundabout is a process of determining the optimal balance between safety provisions, operational performance, accommodation of the design vehicle, and consideration of non-motorized travel modes.

Roundabout design is an iterative process where a variety of design objectives must be considered and balanced within site-specific constraints. Individual geometric components are not independent of each other; the interaction between the components of the geometry is more important than the individual pieces. Favoring one component of design may negatively affect another. When developing a design, the trade-offs of safety, capacity, cost and so on must be recognized and assessed throughout the design process. A common example of such a trade-off is accommodating large trucks on the roundabout approach and entry while maintaining low design speeds. Increasing the entry width or entry radius to better accommodate a large truck may simultaneously increase the speeds that passenger vehicles enter the roundabout. Therefore, the designer must balance these competing needs and may need to adjust the initial design parameters. To both accommodate the design vehicle and maintain low speeds, additional design modifications could be required, such as offsetting the approach alignment to the left or increasing the inscribed circle diameter of the roundabout.

Once a roundabout location, an initial inscribed diameter, and approach alignment are identified, the design can be more fully developed to include establishing the entry widths, circulatory roadways width, and initial entry and exit geometry. Once the initial designs for the entries and exits on each approach have been laid out, performance checks should be undertaken to evaluate the design versus the principles (including fastest path and design vehicle accommodation) to identify any required design refinements. Based on the performance checks, it may be necessary to perform design iterations to adjust the inscribed circle diameter, approach alignments, roundabout locations, and/or entry and exit design to improve the composition of the design.

36-10.04(a) Design Speed

A well-designed roundabout reduces vehicle speeds upon entry and achieves consistency in the relative speeds between conflicting traffic streams by requiring vehicles to negotiate the roundabout along a curved path. Speed management is often a combination of managing speeds at the roundabout itself and managing speeds on the approaching highways. In urban settings, entering vehicles negotiate a curve sharp enough to slow speeds to about 15 mph to 20 mph (25 km/hr to 30 km/hr); in rural settings, entering vehicles may be held to somewhat higher speeds of 30 mph to 35 mph (50 km/hr to 55 km/hr). Within the roundabout and as vehicles exit, low speeds are maintained by the deflection of traffic around the center island and the relatively tight radius of the roundabout at the exit lanes. Low speeds aid in the smooth movement of vehicles into, around, and out of a roundabout.

Maximum entering design speeds based on a theoretical fastest path of 20 mph to 25 mph (30 km/hr to 40 km/hr) are recommended at single-lane roundabouts. At multilane roundabouts, maximum entering design speeds of 25 mph to 30 mph (40 km/hr to 50 km/hr) are recommended based on a theoretical fastest path assuming vehicles ignore all lane lines.

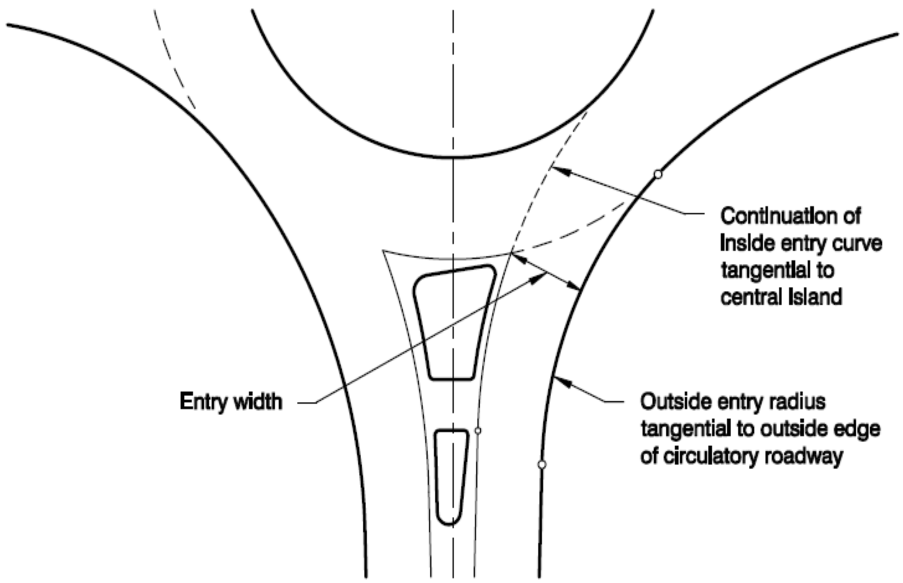
36-10.04(b) Vehicle Paths

1. Natural Path. The natural path is the path approaching vehicles will tend to naturally take through the roundabout geometry, assuming there is traffic in all approach lanes. The natural path does not have sudden changes in curvature. It has transitions between tangents and curves and between consecutive reversing curves. Secondly, it means that consecutive curves should be of similar radius. If a second curve has a significantly smaller radius than the first curve, the driver may be traveling too fast to negotiate the turn and may not be able to stay within the lane.

   With single-lane roundabouts, it is relatively simple to achieve the speed objectives. With a single traffic stream entering and circulating, there is no conflict between traffic in adjacent lanes. The outside curb line of the entry is commonly designed curvilinearly tangential to the outside edge of the circulatory roadway. Likewise, the projection of the inside (left) edge of the entry roadway is commonly curvilinearly tangential to the central island. Figure 36-10.B shows a typical single-lane roundabout entrance design.

   A good multilane entry design aligns vehicle into the appropriate lane within the circulatory roadway. Likewise, the design of the exits should also provide appropriate alignment to allow drivers to intuitively maintain the appropriate lane. These alignment considerations often compete with the fastest path speed objectives.

A useful surrogate used by some practitioners for capturing the effects of entry speed, path alignment, and visibility to the left is the entry (phi) angle. Typically, entry angles are between 20 and 40 degrees. The entry (phi) angle is discussed in Section 36-10.4(h).



SINGLE-LANE ROUNDABOUT ENTRY DESIGN

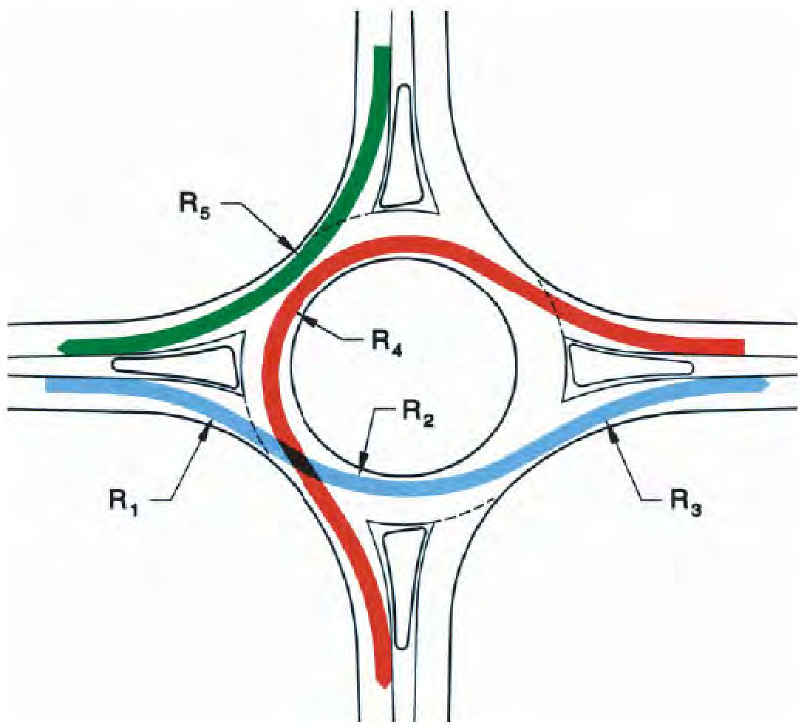
Figure 10.B

2. Fastest Path. Fastest path is a critical element in the design of roundabouts. The fastest path is the smoothest, flattest path possible for a single vehicle, in the absence of other traffic and ignoring all lane markings. The fastest path through a roundabout is drawn to ensure that the geometry imposes sufficient curvature to achieve a safe design speed.

The fastest path is drawn for a vehicle traversing through the entry, around the central island, and out the relevant exit. The fastest path must be drawn for all approaches and all movements, including left-turn movements. Note that the fastest path methodology does not represent expected vehicle speeds, but rather theoretically attainable entry speeds for design purposes.

Figure 36-10.C illustrates and gives a description of the five fastest paths that must be checked for each approach.

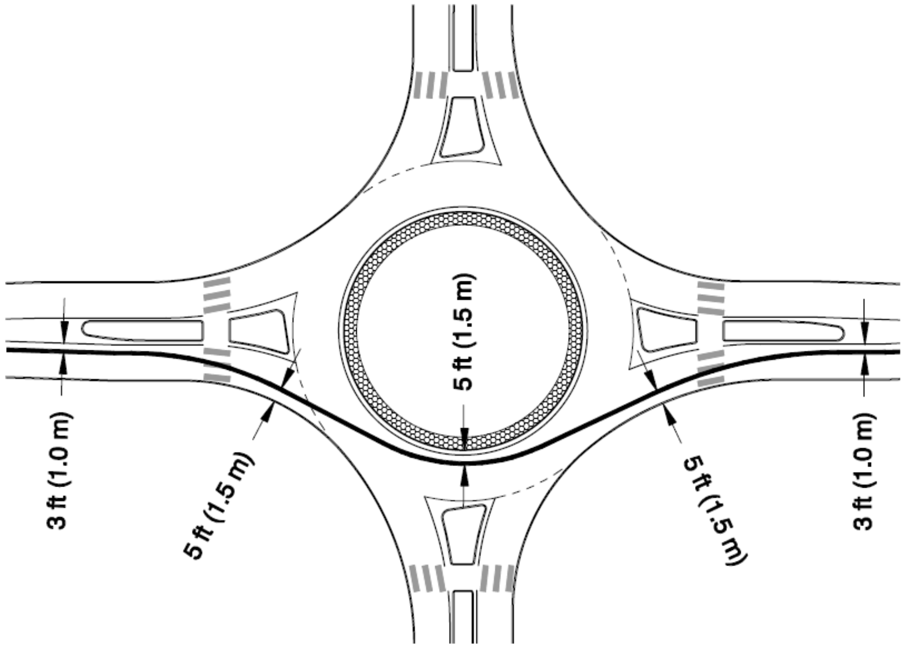
To determine the speed of a roundabout, the fastest path allowed by the geometry is drawn. The design speed of the roundabout is determined from the smallest radius along the fastest allowable path. The smallest radius usually occurs on the circulatory roadway as the vehicle curves to the left around the central island. Figure 36-10.D and Figure 36-10.E illustrate the construction of the fastest through paths at a single-lane roundabout and a multilane roundabout, respectively.



Radius	Description
Entry Path Radius, R_1	The minimum radius on the fastest through path prior to the yield line. This is not the same as Entry Radius.
Circulating Path Radius, R_2	The minimum radius on the fastest through path around the central island.
Exit Path Radius, R_3	The minimum radius on the fastest through path into the exit.
Left Turn Path Radius, R_4	The minimum radius on the path of the conflicting left-turn movement.
Right Turn Path Radius, R_5	The minimum radius on the fastest path of a right-turning vehicle.

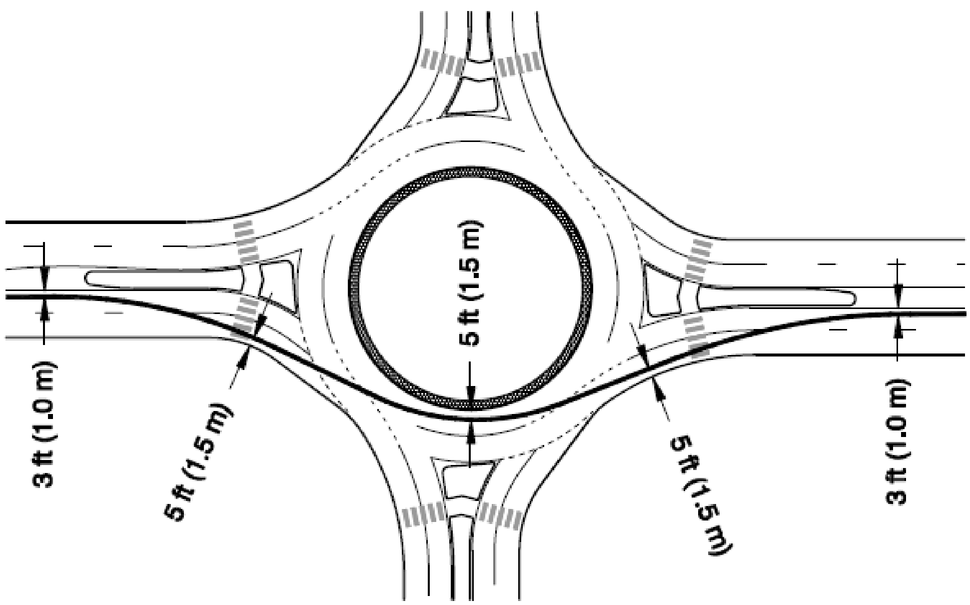
FASTEST PATH RADII

Figure 36-10.C



OFFSETS AND FASTEST THROUGH PATH FOR A SINGLE-LANE ROUNDABOUT

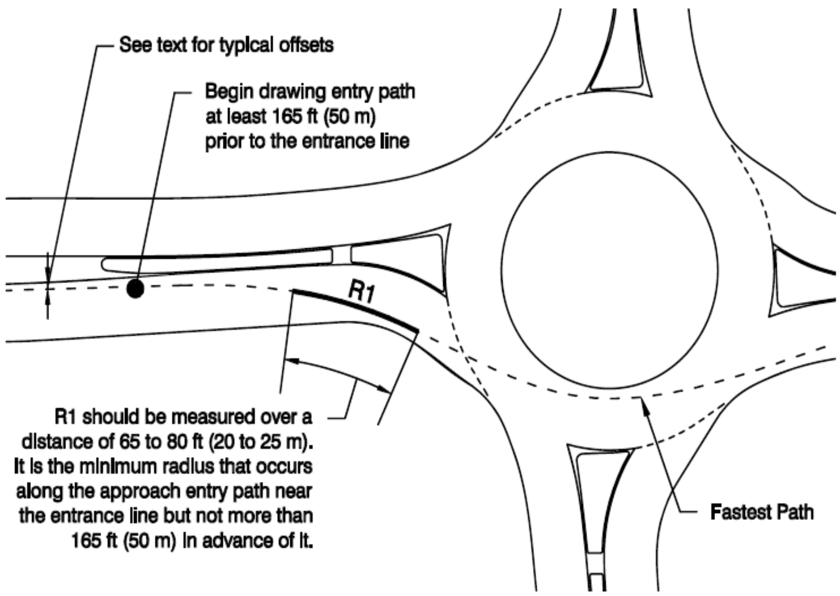
Figure 36-10.D



OFFSETS AND FASTEST THROUGH PATH FOR A MULTI-LANE ROUNDABOUT

Figure 36-10.E

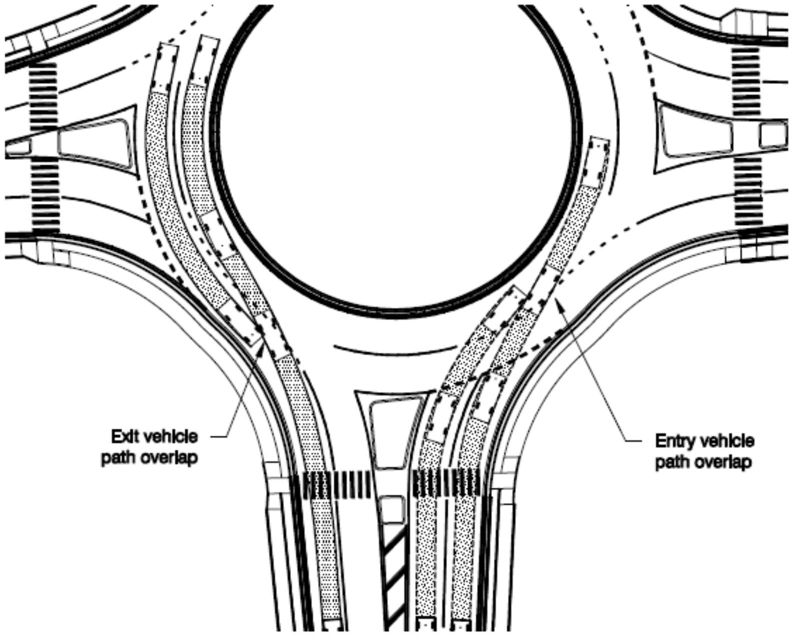
When drawing the fastest path, use spiral curves or place a tangent of approximately three (3) seconds of travel distance between consecutive curves to account for the time it takes for a driver to rotate the steering wheel. The entry path radius, R_1, is a measure of the deflection imposed on a vehicle prior to entering the roundabout. The ability of the roundabout to control speed at the entry is a proxy for determining the potential safety of the roundabout and whether drivers are likely to yield to circulating vehicles. The construction of the fastest path should begin at least 165 ft (50 m) prior to the entrance line using the appropriate offsets identified in Figure 36-10.D and Figure 36-10.E. The R_1 radius should be measured as the smallest best-fit circular curve over a distance of at least 65 ft to 80 ft (20 m to 25 m) near the entrance line. See Figure 36-10.F for additional guidance.



ENTRY PATH RADIUS

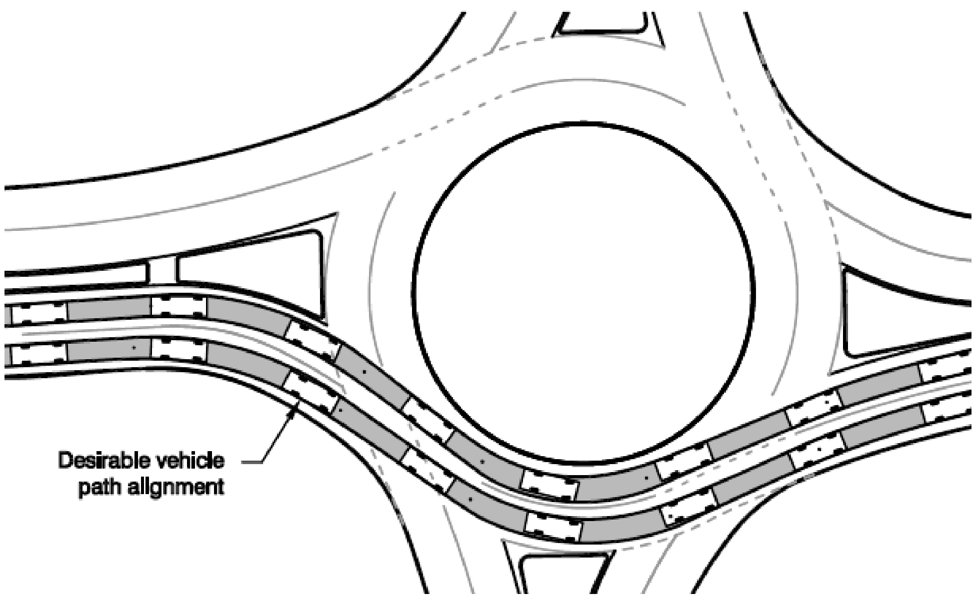
Figure 36-10.F

3. Vehicle Path Overlap. Vehicle path overlap occurs within the circulatory roadway of multilane roundabouts when the natural path through the roundabout of one traffic stream overlaps the path of another. The main consequence of vehicle path overlap is reduced capacity because vehicles will tend to not fully utilize both entry lanes. Also, path overlap can create safety problems since the potential for sideswipe and single-vehicle crashes is increased. The most common type of path overlap is where vehicles in the left lane on entry are cut off by vehicles in the right lane due to inadequate entry path alignment. Path overlap can also occur upon the exit from the roundabout where the exit radii are too small or the overall exit geometry does not adequately align the vehicle paths into the appropriate lanes. See Figure 36-10.G for examples of vehicle overlap. The desired result of the entry design is for vehicles to naturally be aligned into their correct lane within the circulatory roadway, as illustrated in Figure 36-10.H.



PATH OVERLAP AT A MULTILANE ROUNDABOUT

Figure 36-10.G



DESIRABLE VEHICLE PATH ALIGNMENT

Figure 36-10.H

36-10.04(c) Speed Consistency

Consistency between the speeds of various movements within the intersection can help to minimize conflicts between adjacent traffic streams. Minimize relative speeds that occur between conflicting traffic streams and between consecutive geometric elements. The speed differential should be no more than approximately 10 mph to 15 mph (15 km/hr to 25 km/hr). These values are typically achieved by providing a low absolute maximum speed for the fastest entering movement.

36-10.04(d) Design Vehicle

Passenger buses should be accommodated within the circulatory roadway without tracking over the truck apron, which could jostle bus occupants. Where the design dictates the need to accommodate large design vehicles within their own lane, there are a number of design considerations that come into play. First a larger inscribed circle diameter and entry/exit radii may be required to accommodate the design vehicle and maintain speed control. Another technique for accommodations on the entry is to provide gore striping, i.e., a striped vane island between the entry lanes. This method can help center the vehicles within the lane and allow a cushion for off-tracking by the design vehicle. Also, the use of a mountable truck apron [discussed in Section 36-10.04(i)] around the perimeter of the central island can provide the additional width needed for the off-tracking of the trailer wheels.

36-10.04(e) Non-motorized Design Users

This group includes bicyclists, pedestrians, skaters, and strollers. There are two general design issues that are most important for non-motorized users. First, lowering the speeds of motorized vehicles make roundabouts both easier to use and safer for non-motorized users. Therefore, the use of low design speeds is recommended in areas where non-motorized users are common. Second, one-lane roundabouts are generally easier and safer for non-motorized users than multilane roundabouts.

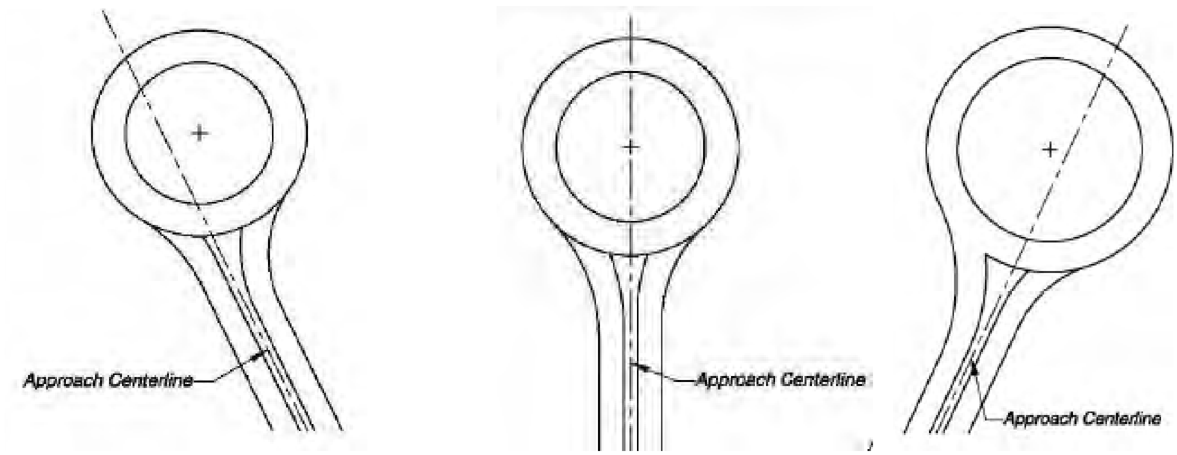
See Sections 36-10.7(a) and 36-10.7(b) for discussion on pedestrian and bicycle accommodations, respectively, and the design of splitter islands to accommodate the same.

36-10.04(f) Size

The inscribed circle diameter is the distance across the circle inscribed by the outer edge of the circulatory roadway, i.e., the sum of the central island diameter plus twice the circulatory roadway width. For single-lane roundabouts, the inscribed circle diameter typically should be at least 105 ft (32 m) to accommodate a WB-50 (WB-15) design vehicle and 130 to 150 ft (40 to 46 m) to accommodate a WB-67 (WB-20) design vehicle. Truck aprons are typically needed to keep the inscribed circle diameter reasonable while accommodating the larger design vehicles. Generally, the inscribed circle diameter of a multilane roundabout ranges from 150 ft to 250 ft (46 to 76 m).

36-10.04(g) Alignment of Approaches and Entries

The alignment of an approach affects the amount of deflection (speed control) that is achieved, the ability to accommodate the design vehicle, and the visibility angles to adjacent legs. There are three alternatives to the approach alignment: Offset to the left of center; alignment through the center; and offset to the right of center. Figure 36-10.I shows examples of the three approach alignments.



Offset Alignment Left **Alignment Through Center** **Offset Alignment Right**

ENTRY ALIGNMENT ALTERNATIVES

Figure 36-10.I

1. Alignment Through Center. A common starting point in design is to center the roundabout so that the centerline of each leg passes through the center of the inscribed circle. This location typically allows the geometry of a single-lane roundabout to be adequately designed such that vehicles will tend to maintain slow speeds through both the entries and exits. The radial alignment also makes the central island more conspicuous to approaching drivers and minimizes roadway modifications required upstream of the intersection.

2. Offset Left Alignment. An offset of the centerline to the left of the roundabout's center point will typically increase the deflection achieved at the entry to improve speed control and is the preferred alignment of the Department. A disadvantage that may result is the possibility of a tangential exit that may provide less speed control for the downstream pedestrian crossing.

3. Offset Right Alignment. Approach alignments that are offset to the right of the roundabout's center point typically do not achieve satisfactory results, primarily due to a lack of deflection and lack of speed control that result from this alignment, thus should be

avoided. An offset-right alignment brings the approach in at a more tangential angle and reduces the opportunity to provide sufficient entry curvature. Vehicles may enter the roundabout too fast and are less likely to yield to vehicles in the circulating roadway.

4. Approach Curve. As long as the offset left alignment is utilized, simple entry curves will provide sufficient deflection to reduce entry speeds. With the offset left alignment, additional approach curves should not be needed. With a radial design or if high entry speeds exist, an S-curve or a series of reverse curves may be needed to slow approaching vehicles. Do not superelevate the approach curves as superelevation would counter the affect curve deflection has for speed control. High entry speed design is discussed in more detail under Section 36-10.4(t), “Rural Roundabouts.”

36-10.04(h) Entry Design

1. Single-lane Entry Design. The design of the entry curvature should balance the competing objectives of speed control, adequate alignment of the natural paths, and the need for appropriate visibility lines. The entry curb radius should produce a maximum design speed of 20 mph to 25 mph (30 km/hr to 40 km/hr) on the theoretical fastest path. The entry curb radius should not be confused with the entry path curve, (R_1 in Figure 36-10.C) defined by the fastest vehicular travel path through the entry geometry.

   The typical design for the entry curb radius for single lane entry approach alignment is to align the outside (right) curb line of the entry curvilinearly tangential to the outside edge of the circulatory roadway. Likewise, the projection of the inside (left) edge of the entry roadway is commonly curvilinearly tangential to the central island. Figure 36-10.A shows the components discussed. The entry radius at urban single-lane entries typically range from 50 ft to 100 ft (15 m to 30 m). The entry curb radius should produce an appropriate design speed on the fastest vehicular path.

   Entry from high-speed approaches is started upstream by establishing designs which encourage drivers to slow down in advance of the roundabout. A recommended method to achieve speed reduction is through the use of successive reverse curves. An acceptable speed change on successive geometric elements through the approach is approximately 12 mph (20 km/hr). Tangent segments must be place between reverse curves to allow drivers to rotate the steering wheel between the reverse curves. Refer to the fourth point under Section 36-10.04(t) for further direction on high-speed approaches.

   Another important principle in the design of an entry is sight distance and visibility. The angle of visibility to the left must be adequate for entering drivers to comfortably view oncoming traffic from the immediate upstream entry or from the circulatory roadway. Sections 36-10.4(o) and 36-10.4(p) discuss sight distance issues.

2. Multilane Entry Design. The entry geometry should provide adequate horizontal curvature to channelize drivers into the circulatory roadway to the right of the central island. The desired result of the entry design is for vehicles to naturally be aligned into their correct lane within the circulatory roadway.

   The use of small entry radii [less than 45 ft (14 m)] at multilane roundabout entries may produce low entry speeds, small fastest path radii (R_1), and reduced capacity, but often leads to vehicle path overlap [discussed in Section 36-10(b)] on the entry, since the geometry of the outside (right) lane tends to lead vehicles into the inside (left) circulatory lane; see Figure 36-10.J. Values of R_1 in the range of 175 ft to 275 ft (53 m to 84 m) are generally preferable. This results in a design speed of 25 mph to 30 mph (40 km/hr to 50 km/hr).

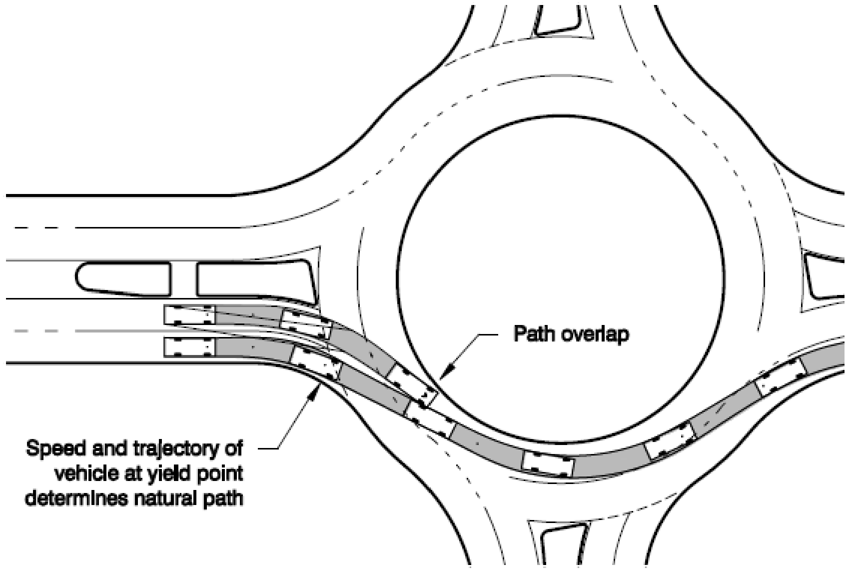
   A common technique to promote good path alignment for multilane entry approaches is to use a compound curve or curve followed by a tangent. This design consists of an initial small-radius entry curve [65 ft to 120 ft (20 m to 35 m)] set back at least 20 ft (6.0 m) from the edge of the circulatory roadway. A short section of large-radius [greater than 150 ft (45 m)] or a tangent is fitted between the entry curve and the circulatory roadway to align vehicles into the proper circulatory lane at the entrance line. See Figure 36-10.K for a layout of the entry curve described above.

3. Entry Angle Phi (Φ). A useful surrogate used by some practitioners for capturing the effects of entry speed, path alignment, and visibility to the left is the entry angle phi (Φ). Typically Φ entry angles are between 20 and 40 degrees. Refer to the Wisconsin DOT Roundabout Guide for the uses of the phi angle.

36-10.04(i) Entry Width

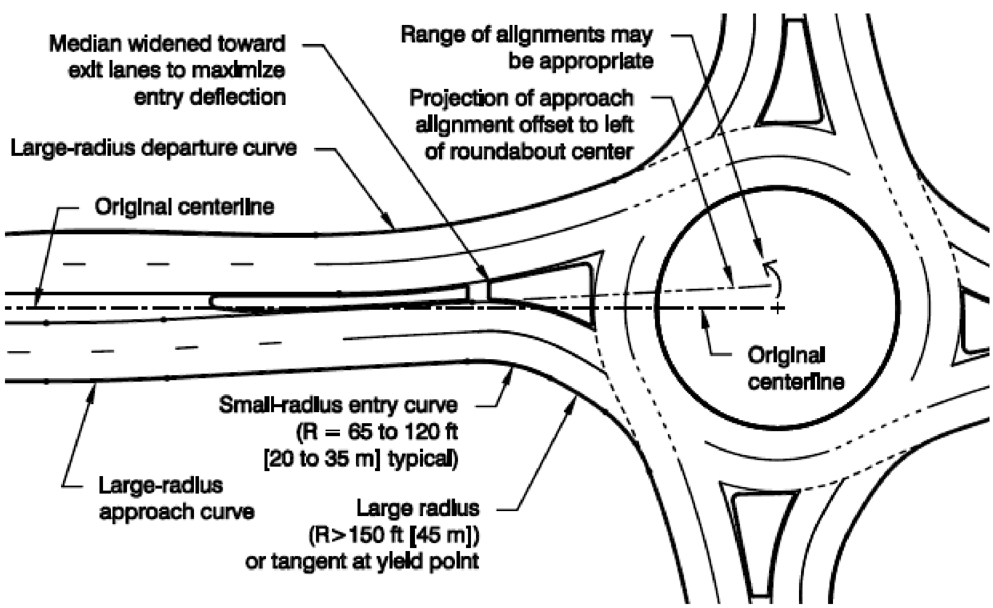
1. Single-lane Entries. Entry width at single lane entries is measured from the point where the entrance line intersects the left edge of traveled way to the right edge of the traveled way, along a line perpendicular to the right curb line as shown in Figure 36-10.A. Typical entry widths for single-lane entrances range from 14 ft to 18 ft (4.2 m to 5.5 m). The entry is often widened through a flare from the upstream approach width.

2. At Multilane Entries. A typical entry width for a two-lane entry ranges from 24 ft to 30 ft (7.2 m to 9 m) and 36 ft to 45 ft (11 m to 14 m) for a three-lane entry. The entry width should be primarily determined based upon the number of lanes identified in the operational analysis combined with the turning requirements for the design vehicle.



ENTRY VEHICLE PATH OVERLAP

Figure 36-10.J



MINOR APPROACH OFFSET TO INCREASE ENTRY DEFLECTION

Figure 36-10.K

36-10.04(j) Circulatory Roadway Width

The required width of the circulatory roadway is determined from the number of entering lanes and the turning requirements of the design vehicle. Except opposite a right-turn only lane, the circulating width should be at least as wide as the maximum entry width and up to 120% of the maximum entry width.

1. Single-lane Roundabouts. For single-lane roundabouts, the circulatory roadway width usually remains constant throughout the roundabout. Typically, circulatory roadway widths range from 16 ft to 20 ft (4.9 m to 6.1 m). A truck apron will often be needed within the central island to accommodate larger design vehicles but maintain a relatively narrow circulatory roadway to adequately constrain vehicle speeds. Additional discussion of truck aprons is provided in Section 36-10.04(l). To avoid jostling passengers the circulatory roadway, width should be wide enough to accommodate a bus without use of the truck apron.
2. Multilane Roundabouts. The circulatory roadway width is usually governed by the design criteria relating to the types of vehicles that may need to be accommodated adjacent to one another through a multilane roundabout. It is acceptable for multi-unit vehicles to encroach upon adjacent lanes. Multilane circulatory roadway lane widths typically range from 14 ft to 16 ft (4.2 m to 4.9 m).

36-10.04(k) Central Island

The central island is the raised non-traversable area (except for mini-roundabouts and the truck apron) surrounded by the circulatory roadway. If a truck apron is provided the truck apron is part of the central island. The island is typically landscaped for aesthetic reasons and raised about 3 ft to enhance driver recognition of the roundabout upon approach. A circular central island is preferred because the constant radius circulatory roadway helps promote constant speeds around the central island, but oval or irregular shapes can be used at irregularly shaped intersections such as offsetting intersections.

Roundabouts in rural environments typically need larger central islands than urban roundabouts to enhance their visibility, accommodate larger design vehicles, enable better approach geometry to be designed in the transition from higher speeds, and be more forgiving to errant vehicles.

Avoid “attractive nuisances” in the central island, which could encourage pedestrians to cross the circulating roadway for closer inspection.

36-10.04(l) Truck Aprons

A truck apron provides additional paved area to allow the over-tracking of large semi-trailer vehicles upon the central island without compromising the deflection for smaller vehicles. A traversable truck apron is typical for most roundabouts to accommodate large vehicles while minimizing other roundabout dimensions. The truck apron should be designed such that they are traversable to trucks but discourage passenger vehicles from using them by distinguishing the apron from the circulatory roadway. Distinguishing characteristics include bordering at the edge of the circulating roadway with a raised 2 in. or 3 in. (50 mm to 75 mm) curb and constructing the apron with a different surface or color from the circulating roadway. The recommended maximum cross slope of the truck apron is 1.5% sloping to the roadway or outside to be compatible with the drainage within the inscribed circle. The minimum width for the truck apron is 12 ft (3.6 m). Figure 36-10.L shows a multi-unit truck utilizing a truck apron.

The vertical design of the truck apron should be reviewed to confirm that there is sufficient clearance for low-boy type trailers which may have only 6 in. to 8 in. (150 mm to 200 mm) between a level roadway surface and the bottom of the trailer.

LARGE TRUCK OVERTOPPING THE TRUCK APRON

Figure 36-10.L

36-10.04(m) <u>Exit Design</u>

The exit curb radii are usually larger than the entry curb radii in order to minimize the likelihood of congestion and crashes at the exits. This, however, is balanced by the need to maintain low speeds through the pedestrian crossing on the departure. The exit curb radius is commonly designed to be curvilinearly tangential to the outside edge of the circulatory roadway. Likewise, the projection of the inside (left) edge of the exit roadway is commonly curvilinearly tangential to the central island.

1. Single-lane Exits. Single-lane exits in urban environments should be designed to enforce slow exit path speeds to maximize safety for pedestrians crossing the exiting stream. Pedestrian activities should be considered at all exits except where separate pedestrian facilities or other restrictions eliminate the likelihood of pedestrian activity in the foreseeable future.

   For designs using an offset-left approach alignment, the exit design may require much larger radii, ranging from 300 ft to 800 ft (90 m to 240 m) or greater. These radii may provide acceptable speed through the pedestrian crossing area given that the acceleration characteristics of the vehicles will typically result in a practical limit to the speeds that can be achieved on the exit. The fastest-path methodology can be used to verify the exit speed.

2. Multilane Exits. Inadequate horizontal design of the exits can result in exit vehicle path overlap. If the exit radius on a multilane exit is too small, traffic on the inside of the circulatory roadway will tend to exit into the outside exit lane on more comfortable turning radius causing vehicle path overlap, similar to that occurring at entries.

36-10.04(n) Splitter Islands

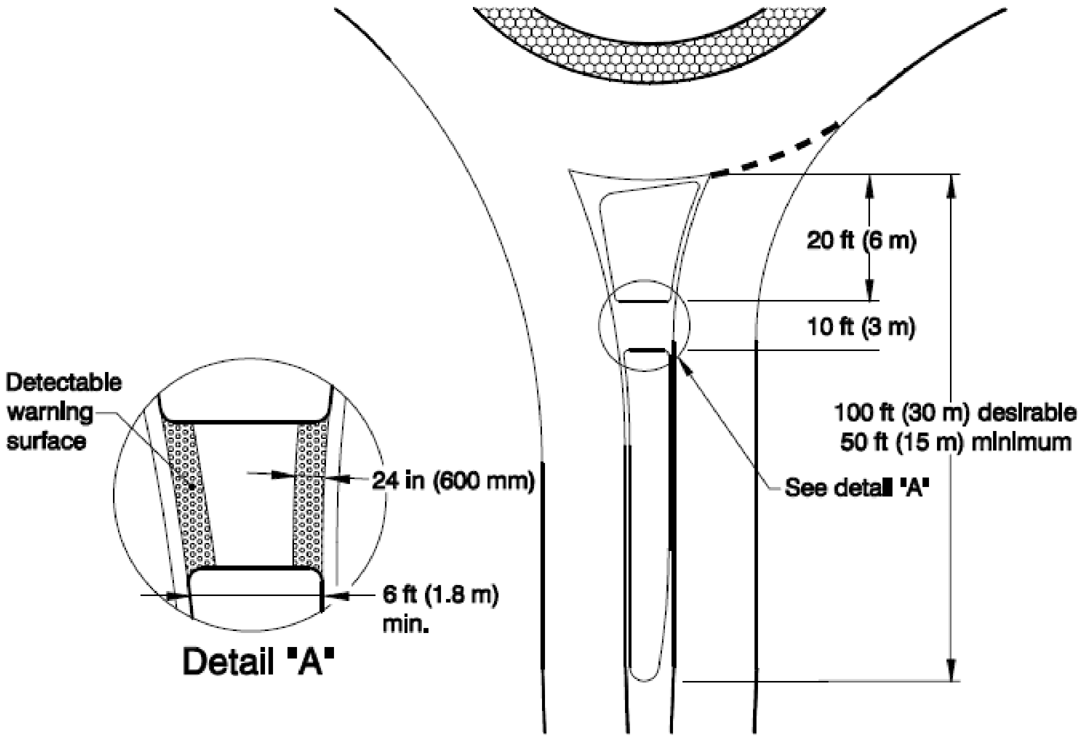
Purposes of a splitter island are to provide refuge for pedestrians, assist in controlling speeds, guide traffic into the roundabout, physically separate entering and exiting traffic streams, control access, and deter wrong-way movements. Additionally, splitter islands can be used as a place for mounting signs. Splitter islands should be provided on all the legs of a roundabout.

A properly designed splitter island deflects traffic and positions vehicles into a correct alignment to enter the circulatory roadway. This deflection is critical to slowing vehicles before they enter the circulatory roadway. The splitter island should have enough curvature to block a direct path to the central island for approaching vehicles.

When used as a pedestrian refuge, splitter islands shall be a minimum of 6 ft (1.8 m) and preferably 8 ft (2.4 m) from the back of the curb to the back of the curb within the pedestrian refuge area. The total length of the raised island should generally be at least 50 ft (15 m), although 100 ft (30 m) is desirable, to provide sufficient protection for pedestrians and to alert approaching drivers to the geometry of the roundabout. On higher speed roadways, splitter island lengths of 150 ft (45 m) or more are often beneficial; see Figure 36-10.M.

The raised portion of the island controls access to adjacent driveways. Refer to Section 36-10.5(e) for a discussion on access control strategies for the approach and departure of a roundabout.

If the roadway does not have a median at the approach to the splitter island, the approach should have a corrugated median and the nose should be ramped.



MINIMUM SPLITTER ISLAND DIMENSIONS

Figure 36-10.M

36-10.04(o) <u>Stopping Sight Distance</u>

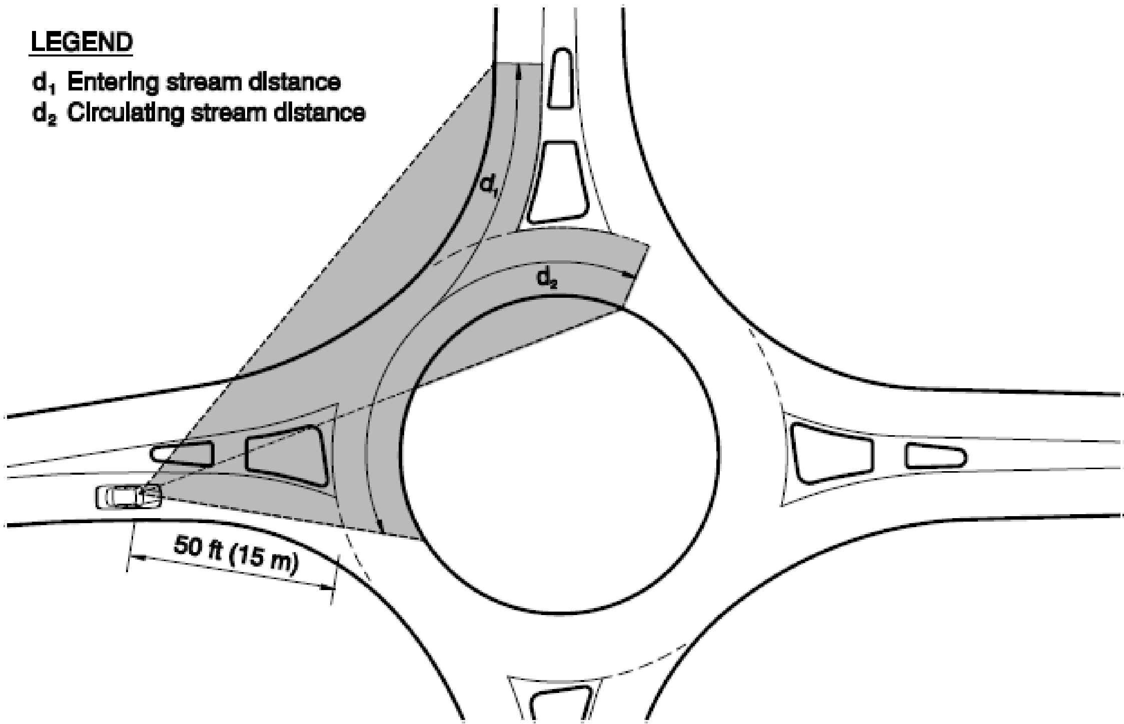
Stopping sight distance should be provided at every point within a roundabout and on each entering and exiting approach.

36-10.04(p) <u>Intersection Sight Distance</u>

Intersection sight distance is the distance required for a driver without the right-of-way to perceive and react to the presence of conflicting vehicles. Intersection sight distance is achieved through the establishment of sight triangles that allow a driver to see and safely react to potentially conflicting vehicles. The only locations requiring evaluation of intersection sight distance within roundabouts are the entries.

The sight triangle is bound by a length of roadway defining a limit away from the intersection on each of the two conflicting approaches and by a line connecting those two limits. For roundabouts, these legs should be assumed to follow the curvature of the roadway, and thus distances should be measured not as straight lines but as distances along the vehicular path.

Figure 36-10.N presents a diagram showing the method for determining intersection sight distance. The following two subsections discuss each of the approaching sight limits.



INTERSECTION SIGHT DISTANCE

Figure 36-10.N

1. Approach Leg of Sight Triangle. The length of the approach leg of the sight triangle should be limited to 50 ft (15 m). This value is intended to require vehicles to slow down prior to entering the roundabout, which supports the need to slow down and yield at the roundabout entry and allows drivers to focus on the pedestrian crossing prior to entry.

2. Conflicting Leg of Sight Triangle. A vehicle approaching an entry to a roundabout faces conflicting vehicles within the circulating roadways and on the immediate upstream entry. In most cases it is best to provide no more than the minimum required intersection sight distance on each approach. Excessive intersection sight distance can lead to higher vehicle speeds that reduce the safety of the intersection for all road users.

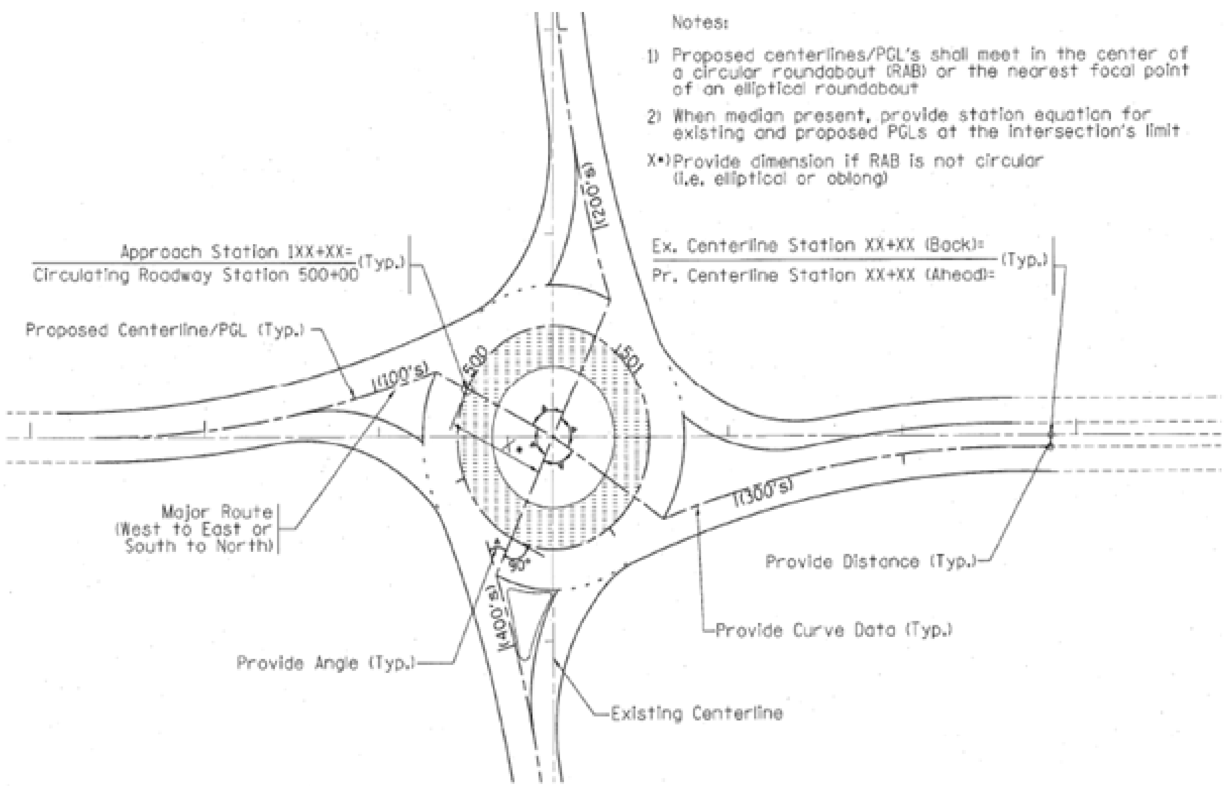
Section 6.7.3.2 of *NCHRP Report 672, Roundabouts: An Informational Guide,* defines the limits of the intersection sight triangle and the methodology of calculating the lengths of each leg.

36-10.04(q) Vertical Considerations

Components of vertical alignment design for roundabouts include profiles, superelevation, approach grades, and drainage.

1. Profiles. Each approach profile should be designed to the point where the approach baseline intersects with the central island. A profile for the central island is then developed that passes through these four points (in the case of a four-legged roundabout). The approach roadway profiles are then readjusted as necessary to meet the central island profile.

   Another method has the PGL/profile line following the inside exit path side of the splitter island making it a physical/tangible line to follow for plan prep and construction. From the intersection of the PGL/profile and the outside of the circulatory roadway the PGL/profile line runs across the circulatory roadway to the center of the central island; see Figure 36- 10.O.



ALTERNATIVE PGL/PROFILE LAYOUT

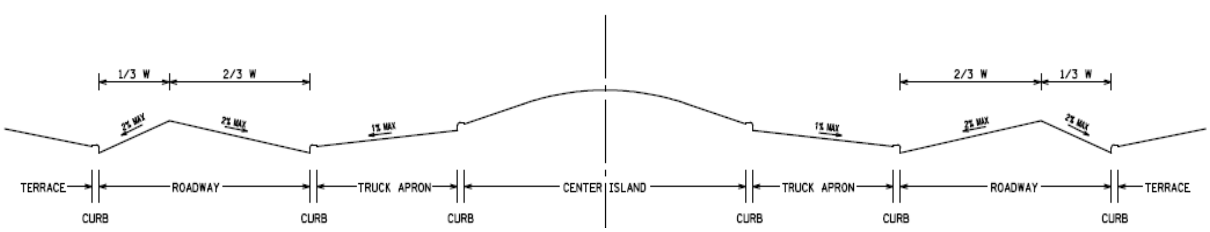
Figure 36-10.O

2. Superelevation/Cross Slope. Two primary methods for the superelevation of the circulating roadway are recommended: outward sloping or crowned circulating roadway. Outward sloping is the most common type of vertical design, especially for single-lane roundabouts. Outward sloping means the pavement slopes away from the central island. When the outward sloping cross section is used, the circulating roadway is graded independently of each approach, with the circulatory roadway draining outward with a grade of 1.5% to 2%.

   Crowned circulatory roadways consists of approximately 2/3 width sloping toward the central island and 1/3 width sloping outward. Exact location of the crown may vary according to the joint plan and future staging. The cross slopes should range from 1.5% to 2%. Placing the crown 2/3 of the width into the circulatory roadway is more compatible for lowboy trailers by allowing more height to raise the low-boy bed. The intent is to minimize the occurrence of the trailer bottoming-out upon the curb of the truck apron. Figure 36-10.P shows an example of a cross section of a roundabout with a crowned circulatory roadway.

3. Approach Grades. Grades of the approach legs should follow guidelines in Section 36-1.06(a).

4. Drainage. If the circulating roadway slopes away from the central island, inlets will generally be placed on the outer curb line of the roundabout. For circulating roadways that are crowned, drainage inlets will be required along the central island, since a portion of the circulating roadway drains toward the central island.



CIRCULATORY ROADWAY AND TRUCK APRON CROSS SECTION

Figure 36-10.P

36-10.04(r) Bus Stop Locations

Transit considerations at a roundabout are similar to those at a conventional intersection.

1. Nearside stops. If an approach has only one lane and capacity is not an issue on that entry, the bus stop could be located at the pedestrian crossing in the lane of traffic. Do not locate the bus stop at the pedestrian crossing for entries with more than one lane because vehicles in the lane next to the bus may not see pedestrians as pedestrians use the crossing. For multilane approaches, a nearside bus stop can be included in the travel lane as long as it is set back at least 50 ft (15 m) from the crosswalk.

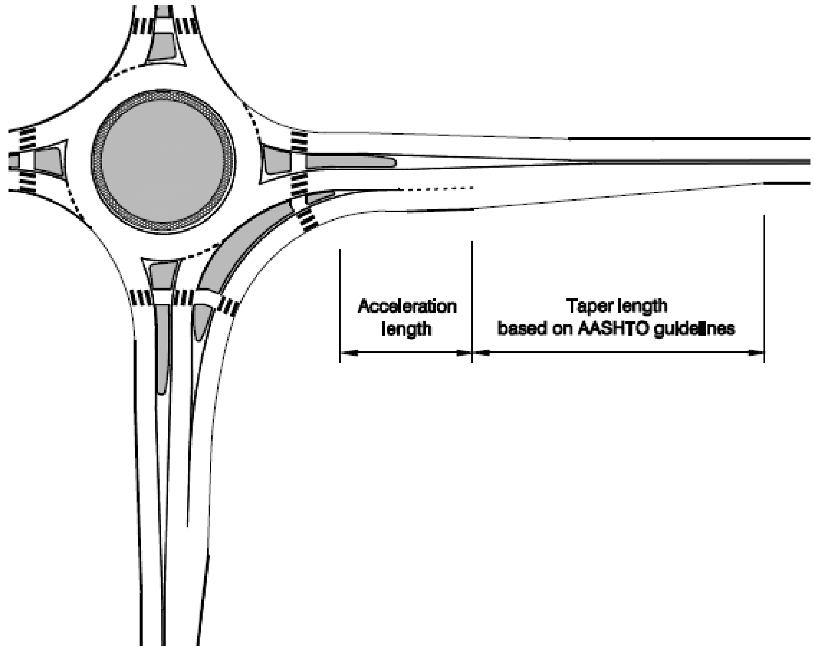
2. Far-side stops. Bus stops should be located carefully to minimize the probability of vehicle queues spilling back into the circulatory roadway. This typically means that bus stops located on the far side of the intersection need to have pullouts or be further downstream than the splitter island. If a pullout is used, position the pullout beyond the pedestrian crossing to improve visibility of pedestrians to other exiting vehicles. Pedestrian access routes to transit should be designed for safety, comfort, and convenience. If demand is significant (e.g., near a station or terminus), pedestrian crossing capacity should be taken into account.

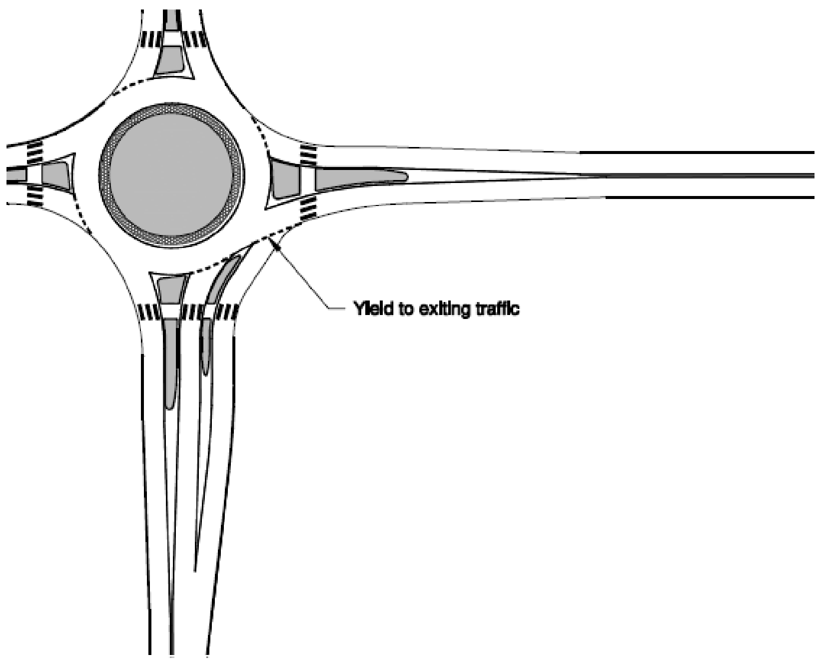
36-10.04(s) Right-turn Bypass Lane

A right-turn bypass lane allows right-turning traffic to bypass the roundabout, providing additional capacity for the through and left-turn movements at the approach. Bypass lanes are most beneficial when the demand of an approach exceeds its capacity and a significant proportion of the traffic is turning right. In some cases, the use of a right-turn bypass lane can avoid the need to build an additional entry or circulatory lane. To determine if a right-turn bypass lane should be used, the capacity and delay calculations should be performed. A right-turn bypass lane should only be implemented where needed, especially in urban areas with pedestrian and bicycle activities. There are two options for right-turn bypass lanes: Figure 36-10.Q gives examples of both a full and partial bypass lane.

1. Full bypass. A full bypass lane carries the bypass lane parallel to the adjacent exit roadway, and then merges it into the main exit lane.

2. Partial bypass. A partial bypass lane, with or without a vane, provides a yield-controlled entrance onto the adjacent exit roadway. This option is generally better for bicyclists and pedestrians and is recommended as the preferred option in urban areas where pedestrians and bicyclists are prevalent. The partial bypass lane should direct the vehicle to the adjacent leg's splitter island to minimize the likelihood of the driver using the bypass lane as a though lane.





RIGHT TURN BYPASS LANES
(Top view, full bypass. Bottom view, partial bypass)

Figure 36-10.Q

36-10.04(t) Rural Roundabouts

Roundabouts located on rural roads often have special design considerations because approach speeds are higher than for urban or local streets, and drivers are less likely to expect to encounter speed interruptions. The primary safety concern in rural locations is to make drivers aware of the roundabout with ample distance to comfortably decelerate to the appropriate speed. The design of a roundabout in a high-speed environment typically employs all the techniques of a roundabout in a lower-speed environment, with greater emphasis on the items presented below.

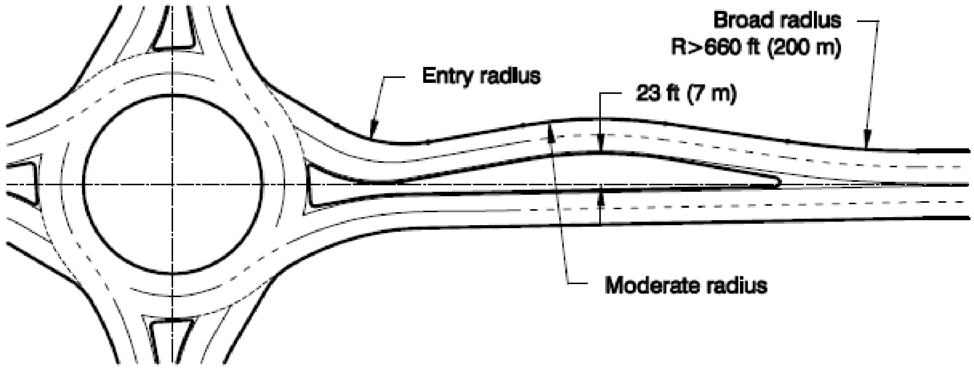
1. Visibility. The potential for single-vehicle crashes can be minimized with attention to proper visibility of the roundabout and its approaches. Where possible, the geometric alignment of approach roadways should be constructed to maximize the visibility of the central island and the shape of the roundabout. Where adequate visibility cannot be provided solely through geometric alignment, additional treatments (signing, pavement markings, advanced warning beacons, etc.) should be considered. Note that many of these treatments are similar to those that would be applied to rural stop-controlled or signalized intersections.

2. Curbing. Narrow shoulder widths and curbs on the outside edges of pavement generally give drivers a sense they are entering a more controlled setting, causing them to naturally slow down. Thus, when installing a roundabout on an open rural highway, curbs should be provided at the roundabout and on the approaches, and consideration should be given to reducing shoulder widths. Extend the curbing from the approach for at least the length of the required deceleration to the roundabout.

3. Splitter Islands. Splitter islands should generally be extended upstream of the entrance line to the point at which entering drivers are expected to begin decelerating comfortably. A minimum of 200 ft (60 m) is recommended for high-speed approaches.

4. Approach Curves. The radius of an approach curve (and subsequent vehicular speeds) has a direct impact on the frequency of crashes at roundabouts. A study has shown that decreasing the radius of an approach curve generally decreases the approaching rear-end vehicle crash rate and the entering-circulating and exiting-circulating vehicle crash rates. On the other hand, decreasing the radius of an approach curve may increase the single vehicle crash rate on the curve. This may encourage drivers to cut across lanes and increase sideswipe crashes on the approach.

   One method to achieve speed reduction in order to reduce crashes at the roundabout is the use of successive reverse curves on the approaches; see Figure 36-10.R. By limiting the reduction in the design speed on successive reverse curves to approximately 12 mph (20 km/hr), the crash rate was reduced. Provide tangents between successive reverse curves of approximately 3 seconds of travel distance to allow a change in rotation of the steering wheel and do not superelevate the curves. A report recommended the approach speed be limited to no more than 35 mph (60 km/hr) immediately prior to the entry curves to minimize high-speed rear-end crashes and entering-circulating vehicle crashes.



USE OF SUCCCESSIVE CURVES ON HIGH-SPEED APPROACHES

Figure 36-10.R

36-10.04(u) Mini-roundabouts

A mini-roundabout is characterized by a smaller diameter and traversable island. Mini-roundabouts are best suited to environments where speeds are already low and environmental constraints would preclude the use of a larger roundabout with a raised central island.

Mini-roundabouts operate in the same manner as larger roundabouts, with yield control on all entries and counterclockwise circulation around a central island. Due to the small footprint, large vehicles are typically required to travel over the fully traversable central island, but buses should be accommodated within the circulatory roadway to avoid jostling passengers by running over a traversable central island.

36-10.04(v) Staging Single-Lane versus Multilane Roundabout

When projected traffic volumes indicate that a multilane roundabout is required for future year conditions, engineers should evaluate the duration of time that a single-lane roundabout would operate acceptably before requiring additional lanes. Where a single lane roundabout should be sufficient for much of its design life, engineers should evaluate whether it is best to first construct a single-lane roundabout until traffic volumes dictate the need for expansion to a multilane roundabout. One reason to stage the construction of a multilane roundabout is that future traffic predictions may never materialize due to the significant number of assumptions that must be made when developing volume estimates for a 20 or 30-year design horizon. Also, non-motorized users are better accommodated on single-lane roundabouts.

Single lane roundabouts are generally simpler for motorists to learn and are more easily accepted in new locations. This, combined with fewer vehicle conflicts, should result in a better overall crash experience and allow for a smooth transition into the ultimate multilane build-out of the intersection.

When considering an interim single-lane roundabout, the engineer should evaluate the right-of-way and geometric needs for both the single-lane and multilane configurations.

Two methods to expand from a single-lane to a double lane roundabout:

1. Expansion to the outside. When using this option, care should be taken to provide adequate geometric features, including entry and splitter island design, to ensure that speed reduction and adequate natural paths can be provided at build-out. This configuration has the potential to be less of a disruption to vehicular traffic during the expansion since the majority of the improvements are on the outside of the roadway.

2. Expansion to the inside. Expansion to the inside involves adding any necessary lanes for the ultimate configuration to the inside of the interim roundabout configuration, with the outer curbs and inscribed circle diameter remaining the same in both interim and ultimate configurations. This allows the engineer to set the outer limits of the intersection during the initial construction and limits the future construction impacts to surrounding properties during widening, as sidewalks. drainage features, and outer curb lines will not typically require adjustments.

36-10.05 Operational Performance

The operational performance of roundabouts is relatively simple, although the techniques used to model performance can be quite complex. A few features are common to the modeling techniques employed by all analysis tools:

- Drivers must yield the right-of-way to circulating vehicles and accept gaps in circulating traffic stream. Therefore, the operational performance of a roundabout is directly influenced by traffic patterns and gap acceptance.

- As with other types of intersections, the operational performance of a roundabout is directly influenced by its geometry

Influences to roundabout operations follow:

1. Gap Acceptance. The operation of vehicular traffic at a roundabout is determined by gap acceptance: Entering vehicles look for and accept gaps in circulating traffic. The low speed of a roundabout facilitates these gap acceptance practices. Furthermore, the operational efficiency (capacity) of roundabouts is greater at lower circulating speeds because of the following two phenomena.

    - The faster the circulating traffic, the larger the gaps that entering traffic will comfortably accept. This translates to fewer acceptable gaps and therefore more instances of entering vehicles stopping at the yield line.

    - Entering traffic, which is first stopped at the yield line, requires even larger gaps in the circulating traffic in order to accelerate and merge with the circulating traffic. The faster the circulating traffic, the larger this gap must be. This translates into fewer acceptable gaps and therefore longer delays for entering traffic.

2. Traffic Flow and Driver Behavior. The capacity of a roundabout decreases as the conflicting flow increases. In general, the primary conflicting flow is the circulating flow that passes directly in front of the subject entry. Exiting flow may also affect a driver's decision on when to enter the roundabout. This phenomenon is similar to the effect of the right-tuning stream approaching from the left side of a two-way stop-controlled intersection. Another behavioral affect occurs when both the entering and conflicting flow volumes are high. Limited priority (where circulating traffic adjusts its headway to allow entering vehicles to enter) or priority reversal (where entering traffic forces circulating traffic to yield) may occur.

3. Geometry. Geometry plays a significant role in the operational performance of a roundabout in a number of key ways:

   - It affects the speed of vehicles through the intersection, thus influencing their travel time by virtue of geometry alone (geometric delay).
   - It dictates the number of lanes over which entering and circulating vehicles travel. The width of the approach roadway and entry determine the number of vehicle streams that may form side-by-side at the yield line and govern the rate at which vehicles may enter the circulating roadway.
   - It can affect the degree to which flow in a given lane is facilitated or constrained. For example, the angle at which a vehicle enters affects the speed of that vehicle, with entries that are more perpendicular requiring lower speeds and thus longer headway. Likewise, the geometry of multilane entries may influence the degree to which drivers are comfortable entering next to one another.
   - It may affect the driver's perception of how to navigate the roundabout and their corresponding lane choice approaching the entry. Improper lane alignment can increase friction between adjacent lanes and thus reduce capacity. Imbalanced lane flows on an entry can increase the delay and queuing on an entry despite the entry operating below its theoretical capacity.

Lane changes within circulating lanes should not be required other than when a lane is added within the circulatory roadway. A lane added within the circulating roadway does not create any additional conflicts.

36-10.05(a) Entering, Circulating, and Exiting Volumes

The analytic methods in the *Highway Capacity Manual* allow the assessment of the operational performance of an existing or planned one-lane or two-lane roundabout when given traffic demand levels.

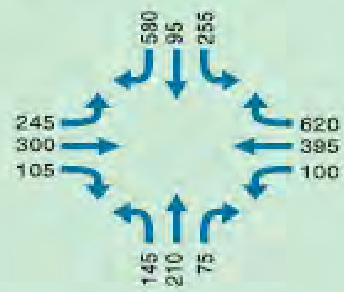
1. Determining Roundabout Flow Rates. The circulating flow rate opposing a given entry is defined as the flow conflicting with the entry flow of that leg. See Exhibit 21-11 of the 2010 *Highway Capacity Manual* (HCM). For example the movements that contribute to the northbound circulating flow rate (shown as $v_{c,NB}$ in Exhibit 21-11 of the HCM) are the movements that flow in front of the northbound entry, which are the eastbound through, eastbound left-turn, eastbound U-turn, southbound Left-turn, southbound U-turn, and westbound U-turn movements.

Conversion of Turning-Movement Volumes to Roundabout Volumes

Prior to conducting a roundabout analysis, turning-movement volumes must first be converted to roundabout volumes.

Turning-Movement Data

- Percent heavy vehicles for all movements = 2%
- Peak Hour Factor (PHF) = 0.97



Step 1: Convert Movement Demand Volumes to Flow Rates

Each turning-movement volume given in the problem is converted to a demand flow rate by dividing by the peak-hour factor. As an example, the northbound left volume is converted to a flow rate in passenger cars per hour as follows:

$$v_{NBL} = \frac{V_{NBL}}{PHF} = \frac{145}{0.97} = 149 \text{ pc/h}$$

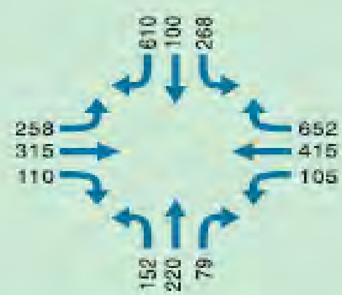
Step 2: Adjust Flow Rates for Heavy Vehicles

The flow rate for each movement may be adjusted to account for vehicle stream characteristics as follows (northbound left turn illustrated):

$$f_{HV} = \frac{1}{1 + P_T(E_T - 1)} = \frac{1}{1 + 0.02(2 - 1)} = 0.980$$

$$v_{NBL,pce} = \frac{v_{NBL}}{f_{HV}} = \frac{149}{0.980} = 152 \text{ pc/h}$$

The resulting adjusted flow rates for all movements accounting for Steps 1 and 2 are therefore computed as follows:



CONVERSION OF TURNING-MOVEMENT VOLUMES TO ROUNDABOUT VOLUMES

Figure 36-10.S

(1 of 2**)**

Conversion of Turning-Movement Volumes to Roundabout Volumes

Step 3: Determine Entry Flow Rates by Lane

The entry flow rate is calculated by summing up the movement flow rates that enter the roundabout. For single-lane roundabouts, all approach volumes are summed together. Additional lane-use calculations are required for multilane roundabouts.

The entry flow rates are calculated as follows for the south leg (northbound entry):

$$v_{e,NB,pce} = v_{NBU,pce} + v_{NBL,pce} + v_{NBT,pce} + v_{NBR,e,pce}$$
$$= 0 + 152 + 220 + 79 = 451 \text{ pc/h}$$

Step 4: Determine Circulating Flow Rates

The circulating flow is calculated for each leg. The circulating volumes are the sum of all volumes that will conflict with entering vehicles on the subject approach. For the south leg (northbound entry), the circulating flow is calculated as follows:

$$v_{c,NB,pce} = v_{WBU,pce} + v_{SBL,pce} + v_{SBU,pce} + v_{EBT,pce} + v_{EBL,pce} + v_{EBU,pce}$$
$$= 0 + 268 + 0 + 315 + 258 + 0 = 841 \text{ pc/h}$$

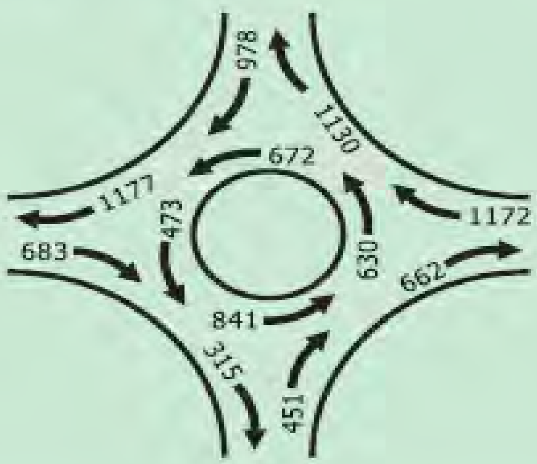
Step 5: Determine Exiting Flow Rates

The exiting flow is calculated for each leg by summing all flow that will be exiting the roundabout on a particular leg. For the south leg (northbound entry), the exiting volume is calculated as follows:

$$v_{ex,pce,NB} = v_{NBU,pce} + v_{WBL,pce} + v_{SBT,pce} + v_{EBR,e,pce}$$
$$= 0 + 105 + 100 + 110 = 315 \text{ pc/h}$$

Result

The following figure illustrates the final volumes converted into roundabout entering, exiting, and circulating flow rates.



CONVERSION OF TURNING-MOVEMENT VOLUMES TO ROUNDABOUT VOLUMES

Figure 36-10.S

(2 of 2**)**

2. Conversion of Turning-Movement Volumes to Roundabout Volumes. See Figure 36-10.S. After determining the demand flow rate, by dividing by the peak-hour factor, and then adjusting for heavy vehicles to determine the passenger car equivalents, one can determine the entry flow rates, circulating flow rates, and the exiting flow rates.

- Entry flow rates are calculated by summing up the movement flow rates that enter the roundabout. For single-lane roundabouts, all approach volumes are summed together. Additional lane-use calculations are required for multilane roundabouts.

- Circulating flow rates are the sum of all volumes that are expected to conflict with entering vehicles on the subject approach.

- Exiting flow rates are calculated for each leg by summing all flow that will be exiting the roundabout on a particular leg.

The exiting flow rate for a given leg is used primarily in the calculation of conflicting flow for right-turn bypass lanes and in determining queuing at exit–side crosswalks. For example, the movements contributing to the southbound exiting flow rate (shown as $v_{ex,SB}$ in Exhibit 21-12 of the HCM) are the eastbound right-turn, southbound through, westbound left-turn, and northbound U-turn movements.

36-10.05(b) Capacity

The maximum flow rate that can be accommodated at a roundabout entry depends on two factors: The circulating flow rate in the roundabout that conflicts with the entry flow, and the geometric elements of the roundabout. The larger gaps in the circulating flow are more useful to the entering drivers and more than one vehicle may enter each gap. As the circulating flow increases, the size of the gaps in the circulating flow decreases, thus the rate at which vehicles can enter also decreases.

The geometric elements of the roundabout also affect the rate of entry flow. The most important geometric elements are the width and number of lanes at entry, and the circulatory roadway width within the roundabout. Two entry lanes permit nearly twice the rate of entry flow compared to one lane. A wider circulatory roadway allows vehicles to travel side-by-side or staggered, which creates a tighter group of vehicles, thereby providing longer gaps.

1. Single-lane Roundabout Entry Capacity. A single-lane roundabout can be expected to handle 25,000 vpd and peak-hour flows between 2000 vph and 2500 vph. This rate exceeds 1900 vph, which is the typical single-lane capacity of a signalized intersection. This higher rate is achievable for several reasons. First, this is the total of all the approaches of the roundabout, not a single approach. Second, because of multiple approaches and right turns, much of the traffic does not conflict and may enter the intersection nearly simultaneously.

2. Single-lane Exit Capacity. It is difficult to achieve an exit flow on a single lane of more than 1400 vph, even under good operating conditions for vehicles (i.e., tangential alignment, and no pedestrians or bicyclists). Under normal urban conditions, the exit lane capacity

should be in the range of 1200 vph to 1300 vph. Therefore, exit flows exceeding 1200 vph may indicate a lower LOS or the need for a multilane exit.

3. Multilane Roundabout Capacity. For planning purposes, multilane roundabouts (two-lane entries) can be expected to handle ADT's between 25,000 vpd and 45,000 vpd and peak-hour flows between 2500 vph and 4500 vph.

4. Pedestrian Effects on Entry and Exit Capacity. Pedestrians crossing at a marked crosswalk that have priority over entering motor vehicles can have a significant effect on the entry capacity. In such cases, if the pedestrian crossing volume and circulating volume are known, multiply the vehicular capacity by a factor, f_{ped}, according to the relationship shown in Exhibit 21-18 or Exhibit 21-20 of the 2010 *Highway Capacity Manual* (HCM) for single-lane and double-lane roundabouts, respectively. Note that the effects of conflicting pedestrians on the approach capacity decrease as conflicting vehicular volumes increase, as entering vehicles become more likely to have to stop regardless of whether pedestrians are present. Consult the (HCM) for additional guidance on the capacity of pedestrian crossings if the capacity of the crosswalk itself is an issue. A similar concern may occur at the roundabout exit where pedestrians cross.

36-10.05(c) Capacity Software

IDOT requires the current version of Signalized (and unsignalized) Intersection Design and Research Aid (SIDRA) for capacity analyses of roundabouts. SIDRA closely follows the methods used in the *Highway Capacity Manual* (HCM), which IDOT requires for computing highway capacity analyses. SIDRA software also includes alternative tools for applications beyond the ability of the HCM.

36-10.05(d) Traffic Control

Vehicles entering the roundabout must yield to the traffic within the circle. A YIELD sign is required at the entry along with the appropriate pavement markings. There is no traffic control within the circular roadway.

36-10.05(e) Access Control

Roundabouts can be used at key public and private intersections to facilitate major movements and enhance access management. Major commercial driveways may be allowed as legs of the roundabout, however, installation of a roundabout strictly for access to private development is discouraged. Minor public and private access points between roundabouts can be accommodated by partially or fully restricted two-way stop-controlled intersections, with the roundabouts providing U-turn opportunities.

Most of the principles used for access management at conventional intersections can also be applied at roundabouts. Property access within the vicinity of an individual roundabout intersection must be carefully evaluated. If an access, such as a driveway, is necessary within an intersection a roundabout should be discouraged at the location. As a corollary to this, do not include driveways within the circulating area of a roundabout. Driveways introduce conflicts into the circulating roadway, including acceleration and deceleration. Traditional driveways do not discourage wrong way movements as a splitter island does.

Access points should be no closer to the roundabout intersection than the splitter islands. On a larger consideration, access points near roundabouts are governed by a number of factors:

1. Capacity of the Minor Movements at the Access Point. While roundabouts may allow for fewer lanes between intersections, the traffic pattern that emerges from roundabouts can have a significant impact on existing midblock access. Unlike the platooned flow typically downstream of a signalized intersection, traffic passing in front of an access point downstream of a roundabout should be more randomly distributed. As a result, an access point downstream of a roundabout may have less capacity and higher delay than one downstream of a traffic signal.

2. Need to Provide Left-turn Storage on the Major Street to Serve the Access Point. For all but low-volume driveways, it is desirable to provide separate left-turn storage for access points downstream of a roundabout to minimize the likelihood that a left-turning vehicle could block the major street traffic. If an access point is necessary and left turn access is permitted, it should be located far enough from the splitter island of the roundabout that the required deceleration and storage lengths can be provided.

3. Sight distance needs. A driver at the access point should have proper intersection sight distance. Vehicles within the roundabout should be visible when approaching or departing the roundabout.

36-10.06 Safety

The use of roundabouts is a proven safety strategy for improving intersection safety by eliminating or altering conflict types, reducing crash severity, and causing drivers to reduce speeds as they proceed into and through the intersections. This is true for urban, suburban, and rural environments in replacing two-way stop and signal controls. While overall crash frequencies have been reduced, the crash reductions are most pronounced for motor vehicles, less pronounced for pedestrians, and equivocal for bicyclists and motorcyclists depending on the study and bicycle treatments.

The reasons for the increased safety level at roundabouts are:

- Roundabouts have fewer vehicular conflict points in comparison to conventional intersections and the potential for the most severe types of conflicts, such as right angle and left turn head-on crashes, is greatly reduced with roundabout use.

- Lower absolute speeds generally associated with roundabouts decrease the braking distance required to avoid potential conflicts. Low vehicle speeds help reduce crash severity, making fatalities and serious injuries much less common at roundabouts.

- Since most users travel at similar speeds through roundabouts, crash severity can be reduced compared to some traditionally controlled intersections.

- Pedestrians need only cross one direction of traffic at a time at each approach as they traverse roundabouts (i.e., crossing in two stages), as compared with many traditional intersections. Pedestrian-vehicle conflict points are reduced at roundabouts; from the pedestrian perspective, conflicting vehicles come from fewer directions.

NCHRP Report 572*, Roundabouts in the United States* and NCHRP Report 672*, Roundabouts: An Informational Guide* include intersection-level crash prediction models to evaluate the safety performance of an existing roundabout relative to its peers, and in the estimation of the expected safety changes, if a roundabout is contemplated for constructions at an existing conventional intersection.

Although the frequency of crashes is most directly tied to volume, the severity is most directly tied to speed. Therefore, careful attention to the design speed of a roundabout is fundamental to attaining good safety performance.

36-10.07 Pedestrian and Bicycle Accommodations

As with the motorized design vehicle, the design criteria for non-motorized potential roundabouts users (bicyclists, pedestrians, wheelchairs, etc.) shall be considered when developing many of the geometric components of a roundabout design. There are two general design issues that are most important for non-motorized users. First, lower motorized vehicle speeds make roundabouts both easier to use and safer for non-motorized users. Second, one-lane roundabouts are generally easier and safer for non-motorized users than multilane roundabouts. When non-motorized users are a significant consideration, do not design a multilane roundabout when a single lane roundabout should be sufficient.

36-10.07(a) Pedestrians

Pedestrian activities shall be considered at all roundabouts except where separate pedestrian facilities or other restrictions eliminate the likelihood of pedestrian activity in the foreseeable future.

Pedestrians desire crossing locations as close to the roundabout as possible to minimize out-of-direction travel. The further the crossing is from the roundabout, the more likely pedestrians will choose a shorter route that may put them in greater danger. In general, at a minimum, locate the pedestrian crossing one car length or approximately 20 ft (6.0 m) upstream from the yield point and place the crossing at full vehicle-length-increments from the yield line for crossings further from the yield line.

For pedestrian safety the crossing should not be located too far back from the yield line so that entering vehicle speeds are not sufficiently reduced or exiting vehicles are accelerating. It may be appropriate to design the pedestrian crossing at two or three car lengths from the yield point at some multilane entries. At single-lane roundabouts in urban environments, exits should be designed to enforce low exit path speeds to maximize safety for pedestrians crossing the exiting stream.

At roundabouts with multilane pedestrian street crossings, a pedestrian activated signal should be provided for each multilane segment of each pedestrian street crossing. A pedestrian signal found to be effective in increasing yielding rates is the rectangular rapid flashing beacon. Pedestrian hybrid beacons (commonly referred to as HAWK signals) are not recommended for pedestrian signals at roundabouts.

Regardless of the type of pedestrian signal, the operation for a pedestrian crossing a roundabout approach should be done in two stages. A single-stage pedestrian signal can result in excessive amount of delay to vehicular traffic. At two-stage signalized pedestrian crossings, there are two separate pedestrian walk intervals, one for crossing the entry roadway and one for crossing the exit roadway.

Roundabouts with single lane approach and exit legs are not required to provide pedestrian activated signals. If a roundabout consists of multilane and single lane pedestrian crossings consider including pedestrian activated signals at the single lane pedestrian street crossings for consistency.

The raised splitter island width shall be a minimum of 6 ft (1.8 m) wide (from the back-of-curb to the back-of-curb) at the crosswalk to adequately provide shelter for users and to provide the minimum width for the use of detectable warnings within the splitter island.

Roundabout operations at the exit can be affected by pedestrian use of the crosswalk. A queuing analysis at the exit crosswalk may determine that a crosswalk location of more than one vehicle length from the circulatory roadway may be desirable to reduce the likelihood of queuing into the circulatory roadway due to pedestrians crossing. Also, it may be easier for pedestrians to visually distinguish exiting vehicles from circulating vehicles at crosswalks located further from the roundabout. If a queuing analysis determines frequent interruptions from pedestrians to the traffic flow at the exit, causing traffic to regularly back into the circulatory roadway, consideration should be given to a conventionally controlled intersection instead of a roundabout.

The draft Public Rights-of-Way Accessibility Guidelines (PROWAG) from the United States Access Board include a requirement to provide a detectable edge treatment between sidewalks and roundabouts wherever pedestrian crossings are not intended, such as adjacent to the perimeter of the circulatory roadway, along the approaches, or along the exit/entrance radii.

Landscape strips are an effective method to provide a detectable edge treatment. Landscape strips provide many benefits, including increased comfort for pedestrians, room for street furniture and snow storage, and a buffer to allow for the overhang of large vehicles as they navigate the roundabout. Also, the setback discourages pedestrians from crossing to the central island or cutting across the circulatory roadway of the roundabout. The setback helps guide pedestrians with vision impairment to the designated crosswalk.

If the sidewalk must be flush with the back of the curb, provide a detectable edge treatment along the street side of the sidewalk. If chains, fences, or railings are used for edge treatment, the bottom of the edge treatments shall be no higher than 15 in. (380 mm) above the sidewalk. Detectable warning surfaces, such as truncated domes, shall not be used for edge treatment because detectable warning surfaces indicate the flush transition between the sidewalk and the roadway. In addition to chains, fences, or railings, low shrubs or grass may be used for edge treatments.

36-10.07(b) Bicycles

Bicyclists' decisions at roundabouts depend on how the bicyclist chooses to travel through the intersection. If traveling as a vehicle, as is often the case for experienced cyclists and cyclists in lower volume and low speed environments, the decision process mirrors that of motorized vehicles. Effective designs that constrain motorized vehicles to speeds more compatible with bicycle speed, around 15 mph to 20 mph (20 km/hr to 30 km/hr), are much safer for bicyclists. If traveling as a pedestrian, as is often the case for less experienced cyclists and cyclists in higher traffic volume environments, the decision process mirrors that of pedestrians.

Although the best design provides bicyclists the choice of proceeding through the roundabout as either a vehicle or as a pedestrian, in general, bicyclists are better served by being treated by roundabout designers as vehicles. When entering traffic volumes are projected to be large (i.e., greater than 12,000 ADT), look at other options such as shared use-paths, which provide a physical separation from vehicles around the periphery of the roundabout.

If bicycle lanes are provided on the roadway approaches provide a ramp from the roadway to a shared-use path prior to the intersection to allow a bicyclist to exit the roadway and proceed around the intersection safely through the use of cross walks if the bicyclist is uncomfortable mixing with vehicles. Consider bicycle ramps and a shared-use path around the circulatory roadway for bicycle accommodations even if no sidewalks or shared-use paths are proposed approaching the roundabout. Continue the shared-use path around the circulatory roadway, but separate from the circulatory roadway, where bicycle use is expected. Do not provide bike lanes within the circulatory roadway.

For bicycle design considerations through a roundabout; see Section 17-2.04.

36-10.08 Parking

Parking within the circulatory roadway is prohibited. Parking on entries and exits to the roundabout should be set back far enough so as not to hinder roundabout operations or to impair visibility of pedestrians.

36-10.09 Illumination

For a roundabout to operate satisfactorily, a driver must be able to enter the roundabout, move through the circulating traffic, and separate from the circulatory stream in a safe and efficient manner. Pedestrians must also be able to safely use the crosswalks. To accomplish this, a driver must be able to perceive the general layout and operation of the intersection in time to make the appropriate maneuvers at all times of the day. Adequate lighting shall therefore be provided at all roundabouts including those in rural locations.

Lighting of roundabouts provides:

1. visibility from a distance for users approaching the roundabout;

2. visibility of the key conflict areas to improve users' perception of the layout and visibility of other users within the roundabout;

3. additional visibility for signing and pavement markings; and

4. visibility of pedestrians at and within the crosswalks.

The effectiveness of auto headlights is limited in a roundabout due to the constrained curve radius, making the roadway lighting system very important for nighttime visibility of obstructions and hazards. Approach lighting should provide good perception of the presence of the roundabout.

See Section 56-2.08 for more guidance on lighting for roundabouts.

36-10.10 Signing and Delineation

Pavement marking and signs are integral to the design of roundabouts, especially multilane roundabouts. The *ILMUTCD*, the latest version of FHWA's *Standard Highway Signs*, and any applicable state and local standards govern the design and placement of traffic control devices, including signs, pavement markings and signals. Consult the Bureau of Operations or Bureau of Traffic within the respective District of the roundabout location for specific standards for delineating and signing roundabouts.

Entry lanes should be well referenced, especially for multilane roundabouts, which should have cars in their proper lane at the approach so lane changing is not required through circulating lanes. Signs should be located where they have the maximum visibility for road users, but a minimal likelihood of even momentarily obscuring pedestrians and bicyclists.

A YIELD sign is required at the entry along with the appropriate pavement markings. There is no traffic control within the circular roadway.

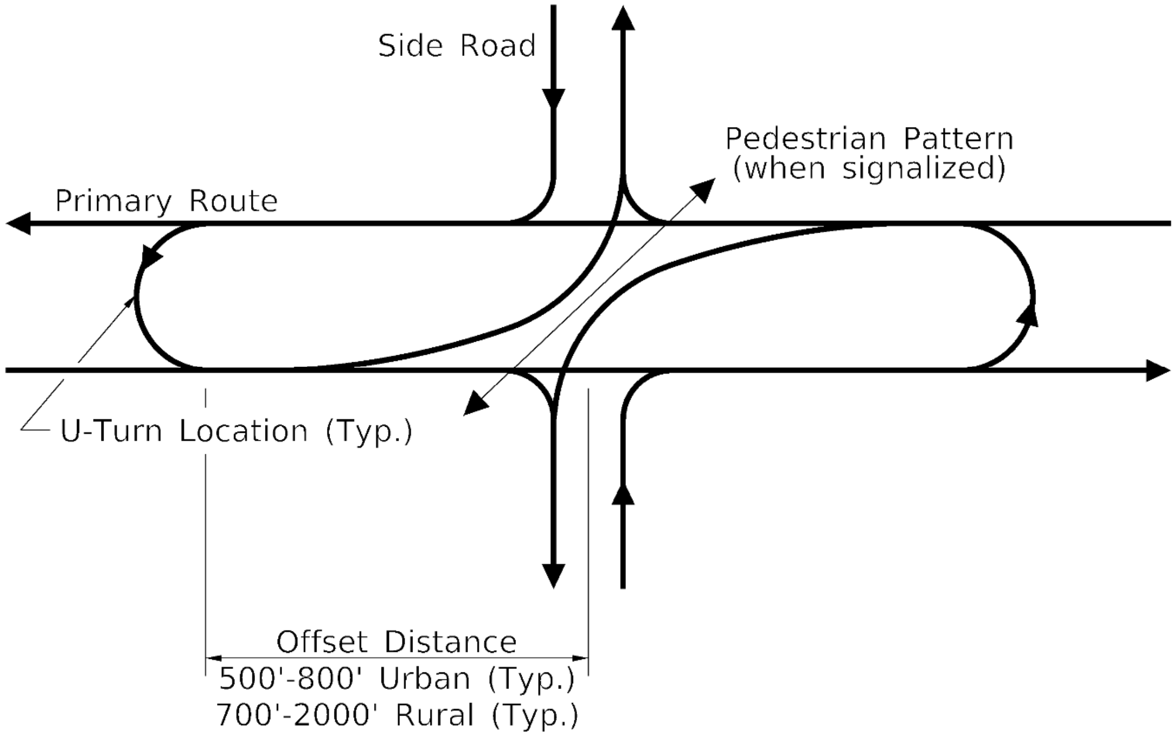
36-11 ALTERNATIVE INTERSECTIONS

Some nontraditional intersection designs may offer substantial advantages, under certain conditions, compared to conventional at-grade intersections or grade-separated interchanges. This section provides background information and design guidance for RCUT, MUT, DLT and CGT intersections.

36-11.01 Restricted Crossing U-turn Intersections

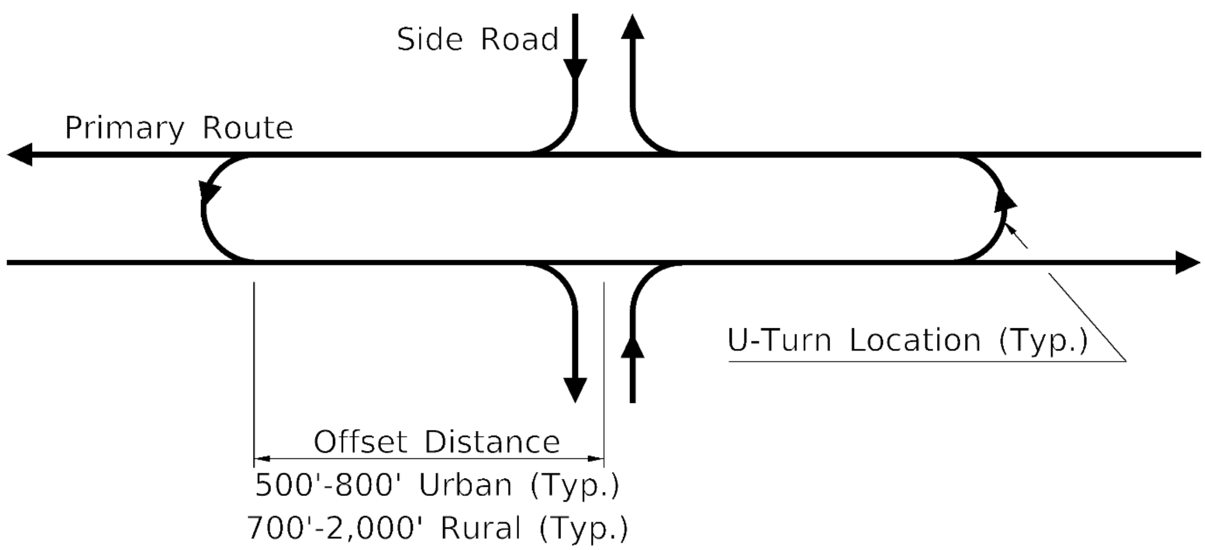
Restricted Crossing U-Turn intersections (RCUTs) are also referred to as *superstreets* (where signalized locations are in series) or *J-turn* intersections (if unsignalized). These intersections may be an effective design option for addressing operational and/or safety concerns along urban multi-lane arterials and high-speed multi-lane highways (expressways). At an RCUT all traffic enters the primary route via right-turns. The left-turn and through traffic approaching on the side (or minor) road is redirected to a U-turn maneuver at a downstream median opening (crossover), and drivers then continue along the mainline or turn back (right) onto the side road. Figure 36-11.A shows a schematic of the most common RCUT type. Left turn lanes allow for direct left-in access, while movements from the side road are right-in, right-out. Crossovers for U-turns are typically located 500 ft to 2,000 ft (150 m to 600 m) downstream of the main intersection, with locations dependent on mainline speed and geometric factors. If present at signalized RCUTs, pedestrians would be directed to cross the primary route in a diagonal fashion, from one corner to the opposite corner. See Section 36-11.1(f) for guidance on pedestrian accommodation.

In some cases, left turns off of the primary route are also eliminated, with that traffic redirected beyond the main intersection to the crossover for U-turns as shown schematically in Figure 36-11.B. This design could be appropriate based on a history of mainline left-turn crashes, very low mainline left-turn demand, or constrained intersection sight distance in rolling terrain. In either design type, signalization at the main intersection could be considered for the allowed turning vehicles or for pedestrians; signalization of the U-turn movements may also be considered when an ILMUTCD signal warrant is met. Other unique RCUT designs are illustrated in Figure 36-11.C and Figure 36-11.D.



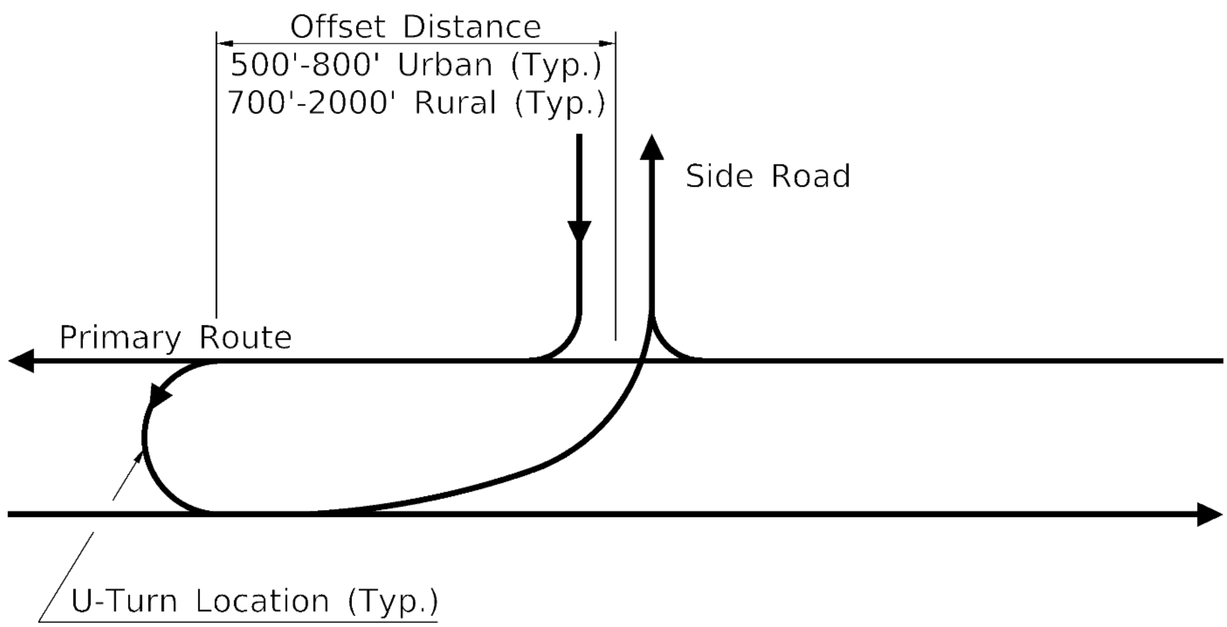
RCUT SCHEMATIC WITH MAINLINE DIRECT LEFT TURNS

Figure 36-11.A



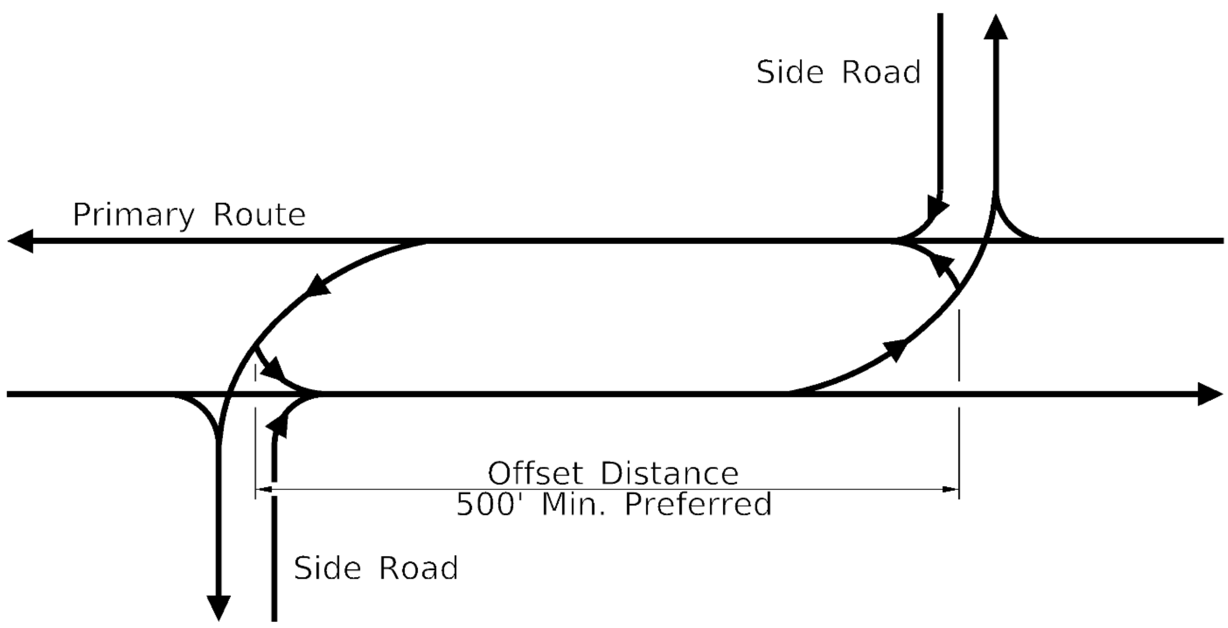
RCUT SCHEMATIC WITHOUT MAINLINE DIRECT LEFT TURNS

Figure 36-11.B



THREE LEGGED RCUT SCHEMATIC

Figure 36-11.C



OFFSET RCUT SCHEMATIC

Figure 36-11.D

RCUTs improve safety performance by causing drivers to split their driving task into a series of low-complexity decisions and allowing them to find adequate gaps more easily. Based on the changes in movement types, crashes that do occur at RCUTs tend to be less severe than those that occur at traditional full-access intersections, whether signalized or 2-way stop-controlled. RCUTs may be used along urban and suburban roadways with medians as narrow as 18 ft (5.5 m), and on high-speed rural open-median facilities. Signalized RCUT corridors can be developed by converting multiple intersections along high-ADT primary routes.

An overall layout showing common features of an RCUT is shown in Figure 36-11.E. A more detailed example of a rural RCUT intersection and adjacent median crossover is provided in Figure 36-11.F. The primary route may have either four or six lanes, and side roads may have two or four lanes. The most common situation will be a four-lane mainline and two-lane minor road. Signal warrants should always be checked for the redirected traffic patterns created by the main RCUT intersections and U-turn crossovers. Note that meeting a warrant does not mean that signals will be required; signalization is an operational and safety decision. When provided, two-phase signals are the norm at both the main intersection and the U-turn location(s). If traffic volumes are expected to grow substantially after initial opening, an RCUT design can provide for additional turn lanes and/or signalization to be added later through phased implementation.

RCUT intersections and corridors may be especially suitable where:

- There is heavy through and/or heavy left-turn volumes on primary route approaches;
- The ratio of the minor road approach volume to the total intersection approach volume is less than 0.20;
- The primary route left-turning volume per lane is greater than 80 percent of the minor road traffic per lane moving concurrently during a signal phase;
- During peaks the intersection is heavily-congested with signal phase failures (LOS F) occurring for through and/or left-turn traffic on the primary route;
- Corridor access management is desirable;
- The history of intersection crashes, both overall and for turning and angle crashes, shows rates above the statewide average for peer group locations; or
- Sight distance constraints for left turns onto or off of the primary route seem to have led to crashes or documented near-misses.

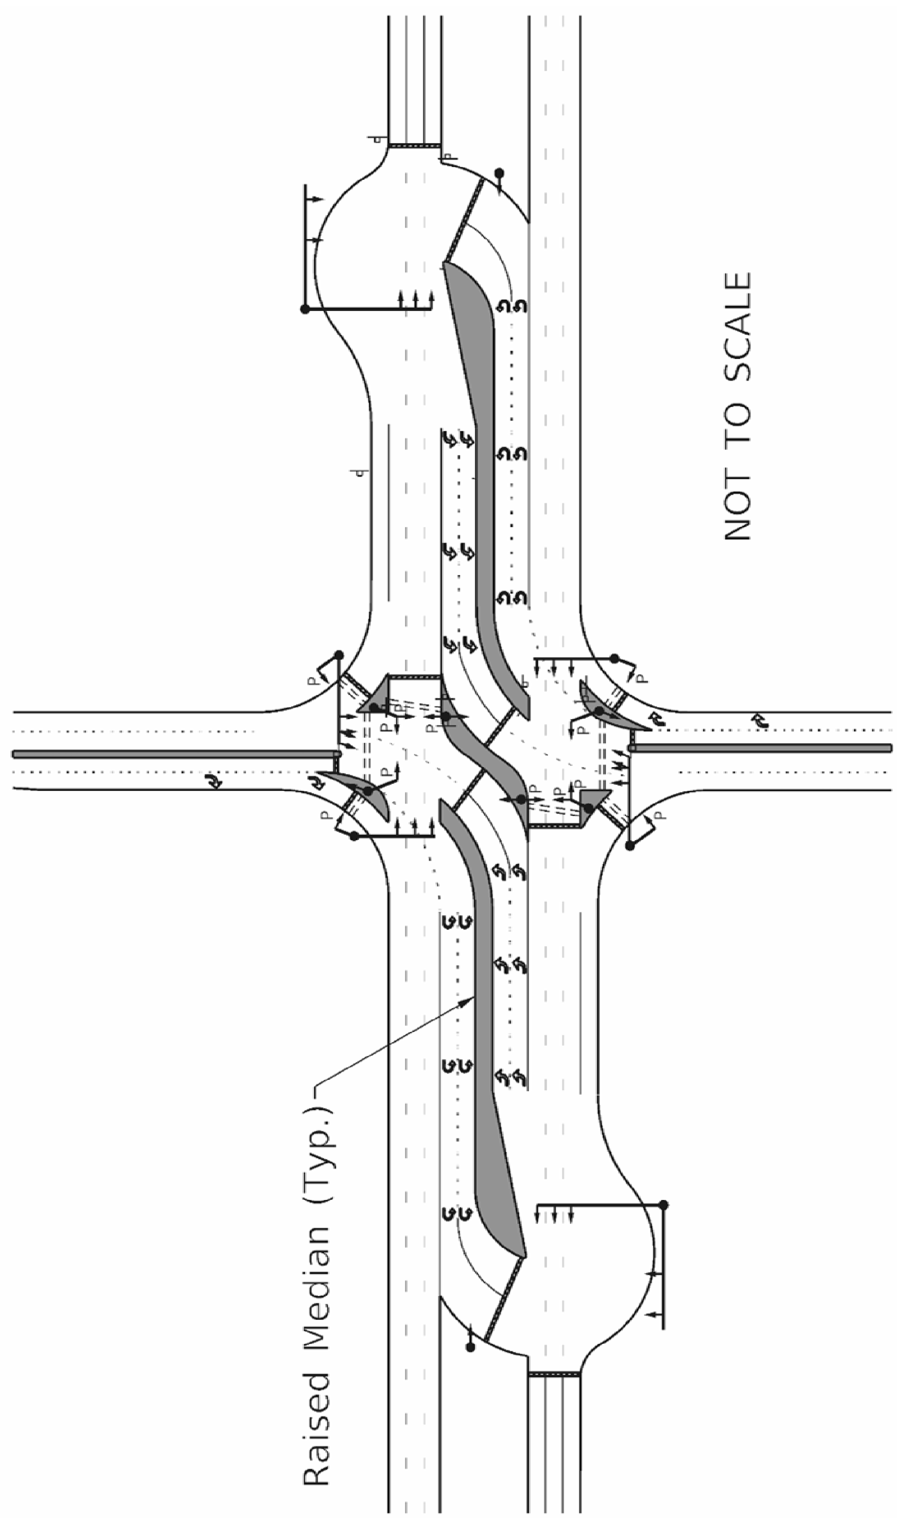
RCUTs may be less effective where there are heavy through and left-turn volumes from the side road approaches. Concerns may include extra travel time incurred by side road drivers and/or congestion related to the U-turn movements. Both an operational analysis and a safety performance assessment are typically necessary. Refer to Chapters 49 or 50 for operational criteria associated with arterial and freeway projects.

36-11.01(a) General Design Considerations

The spacing from the main intersection to the U-turn crossover, the “offset distance”, is influenced by several factors. For rural unsignalized locations a very conservative design would consider the acceleration, weaving, and deceleration maneuvers using the combined peak-hour through and side road volumes. Offset distance would be the sum of acceleration distance (moving into the mainline assuming a merge), weaving length (for moves from the right lane to the left lane along the expressway), and deceleration (left-turn lane) length. If the U-turn is unsignalized, similar calculations could be applied to the return path. This procedure for setting offset distance is overly conservative in practice. The criteria for the weaving length is not fully applicable, and weaving distances can usually be ignored. The designer may consider providing an acceleration lane in accordance with Figure 36-2.L for slow moving (heavy truck) traffic entering the mainline.

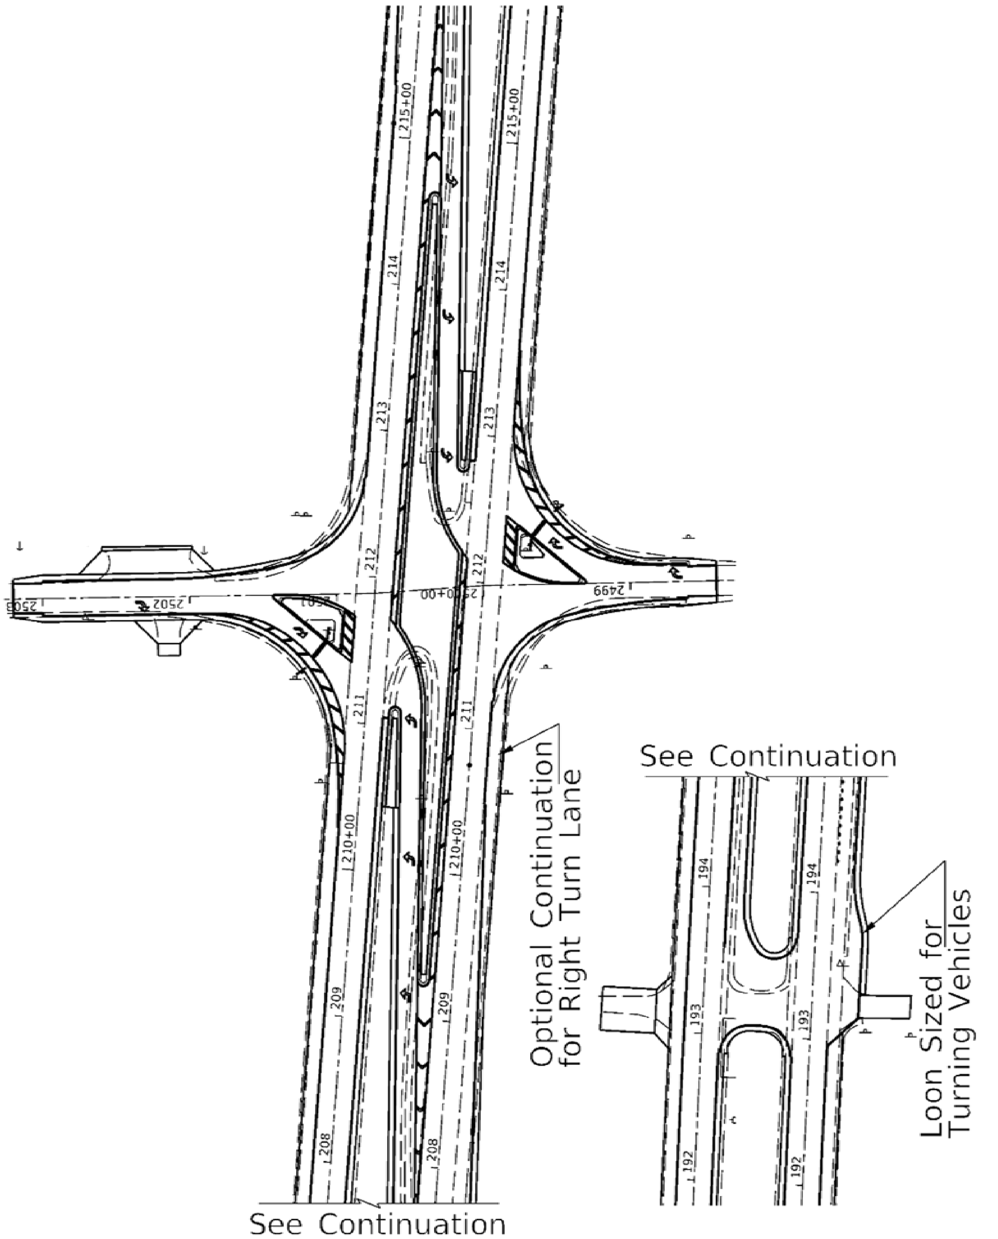
For a two-lane minor road and four-lane mainline, a 500 ft to 800 ft (150 m to 240 m) offset distance will typically suffice in urban/suburban areas. A 700 ft to 2,000 ft (210 m to 600 m) offset distance is often appropriate for rural high-speed locations. Consider the need for guide signs and the presence of trucks in setting design offset distances. Values at the higher end of these ranges involve more out-of-direction travel but may decrease the probability of queue spillback and also provide more time and space for drivers to read signs and change lanes. Closer spacing reduces driving distances and travel times and is typically favored by drivers. The designer should consider these factors as well as topography, sight lines, and access points when setting offset distances.

The main intersection must physically eliminate the possibility of side road through and left-turn movements by inserting raised curb and wide grass areas in conjunction with left turn channelization. However, coordination with state and local emergency services may affect design details. The crossover intersection must clearly guide turning movements and allow for the design vehicle(s) to complete U-turns within the pavement. Accommodating these movements typically require widening pavement for a “loon” area along the far side of the mainline, as depicted in Figures 36-11.E and 36-11.F. The designer may incorporate low-volume existing and relocated driveways, or minor side roads, into a crossover intersection; provide channelization and where applicable an additional signal phase. Consider intersection sight distance, vehicle turning paths, and the need for signing or geometric measures to deter wrong-way movements.



TYPICAL RCUT LAYOUT INCLUDING SIGNAL LOCATIONS

Figure 36-11.E



EXAMPLE RCUT GEOMETRICS

Figure 36-11.F

36-11.01(b) Signalization

Expressways and four-lane divided arterials typically move large volumes of through traffic as a primary function. Signals that provide a high percentage of mainline green promote progression and improve operations over a wide range of traffic demands. Because RCUTs can require only two phases instead of the four (or more) phases needed at conventional intersections, and because the two mainline directions will operate independently, opportunities to optimize primary route progression is a primary advantage for RCUT corridors. Select cycle lengths that provide for effective mainline flows while not unduly delaying side road vehicles (and pedestrians where present). The timing offset for crossover signals (where needed) will typically fit within a progression band on the primary route regardless of offset distance. Guidance on signal operations at RCUTs and superstreet corridors is provided in the FHWA's *Restricted Crossing U-Turn Intersection Informational Guide*.

36-11.01(c) Safety

Safety benefits typically result from the redirection of the minor road through and left-turning movements. The number of vehicle-vehicle conflict points is reduced and the modified movements tend to result in less severe crashes. Compare the crash history of each existing intersection with statewide peer group intersections as a starting point in assessing the potential safety benefits of an RCUT design. Focus on assessment of crash types. RCUTs typically experience fewer angle and turning crashes than do conventional 4-legged intersections; however, increases in less-severe same-direction sideswipe and rear end crashes may be seen. Consider using Crash Modification Factors (CMFs) from the FHWA CMF Clearinghouse for converting unsignalized conventional intersections to unsignalized RCUTs; such assessment can be a primary justification for RCUT implementation.

36-11.01(d) Signing

Driver unfamiliarity can be a concern at RCUTs immediately after implementation, since some movements do not meet the expectations of drivers unfamiliar with this intersection type. However, experience in other states has indicated that drivers adapt fairly quickly to RCUT operations. Proper signing at an RCUT will typically lead to good operational and safety performance. Diagrammatic guide signs may be considered to aid drivers on the minor road approaches. Prominent "Right Turn Only" regulatory signs are required facing the side road approaches. Utilize "One Way" and "No Left Turn" signs strategically in accordance with the ILMUTCD. Signing can generally be ground-mounted rather than overhead. The Central Bureau of Operations can assist by providing a typical design; statewide consistency is sought.

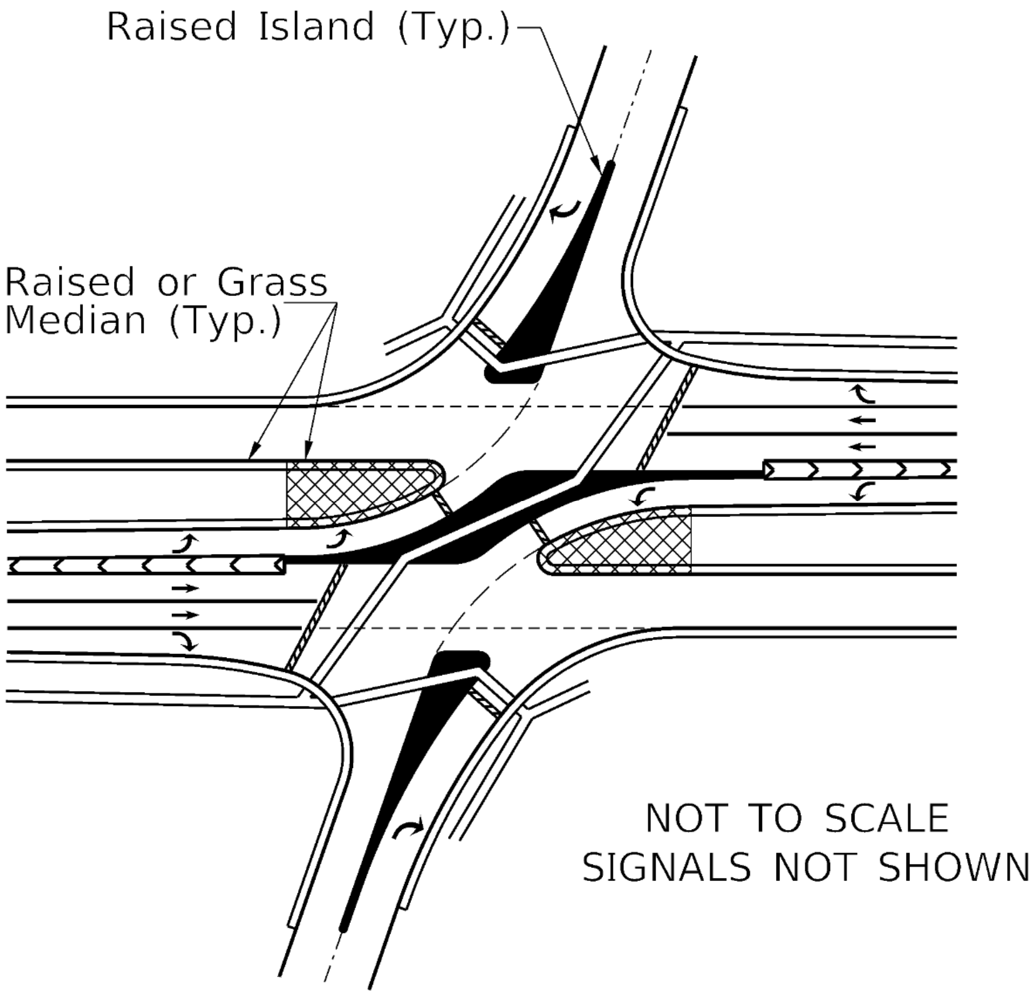
36-11.01(e) Access Management and Right of way Considerations

Driveway access should be limited to the extent possible in close proximity to the main RCUT intersection. Because of access restrictions RCUTs can be perceived as adversely affecting businesses located near intersection or at the corners. Inferences can be drawn from the *NCHRP Report 420,* which indicates that some land uses suffer economic losses with wide median installations. Businesses that rely on pass-by traffic, such as gas stations and convenience stores, may be affected by the less-direct access typically provided with an RCUT. Manage access in consideration of safety and efficiency. Discuss required access restrictions with potentially-affected property owners and local agency officials.

The combined median and loon area width needed to accommodate large vehicle U-turns at crossovers can sometimes result in ROW acquisition and/or spot location impacts. Given inherent flexibility, seek to locate crossovers and loons to minimize impacts while satisfying operational requirements. The potential for oversize loads should be discussed with the Bureau of Operations, as there may need to be restrictions placed on routing.

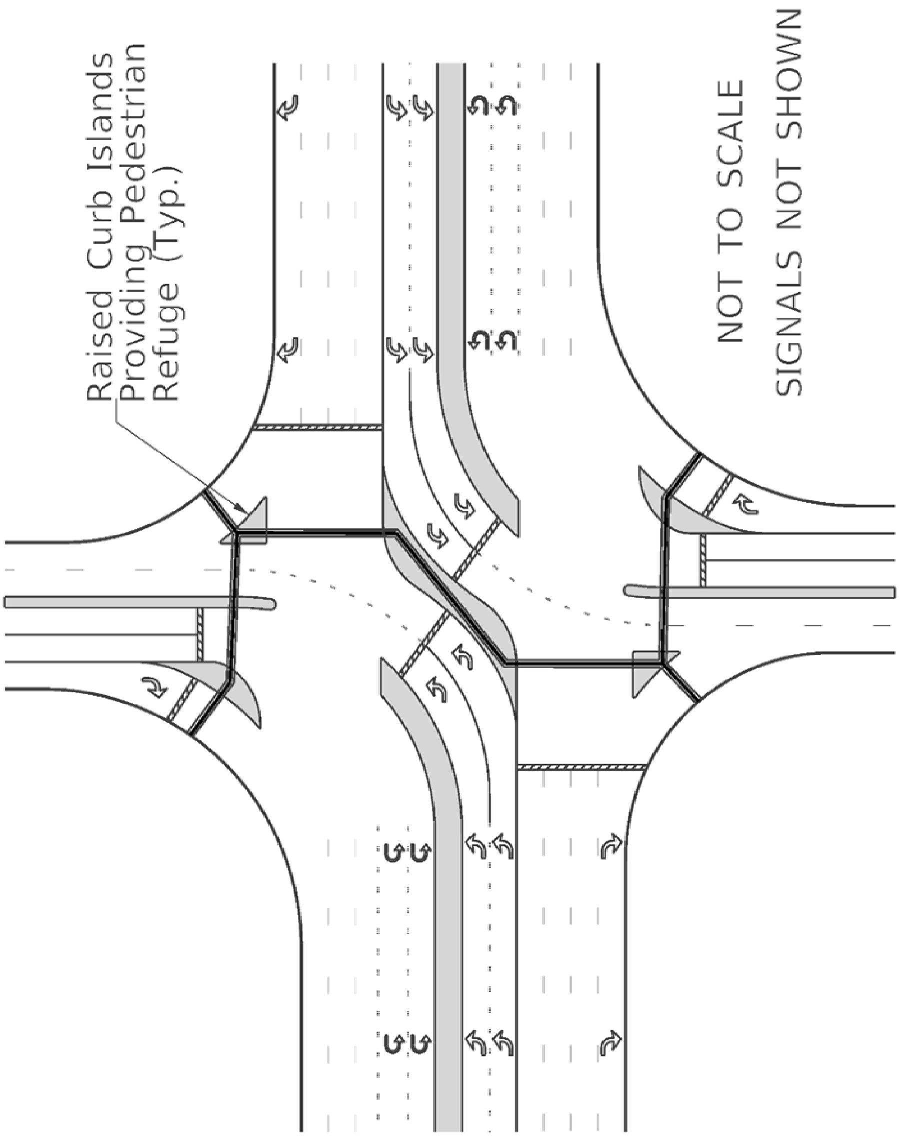
36-11.01(f) Pedestrian Accommodations

Figure 36-11.G shows typical pedestrian accommodations for a signalized RCUT at a minor side road; Figure 36-11.H depicts an accommodation scenario at a major side road. A raised median area is needed to establish refuge, and pedestrian signal heads and pushbuttons are required for the multi-stage crossings. Wayfinding signing may sometimes be helpful in guiding pedestrians. Offset sideroads, as illustrated schematically in Figure 36-11.I, would further simplify pedestrian movements where such a configuration is possible.



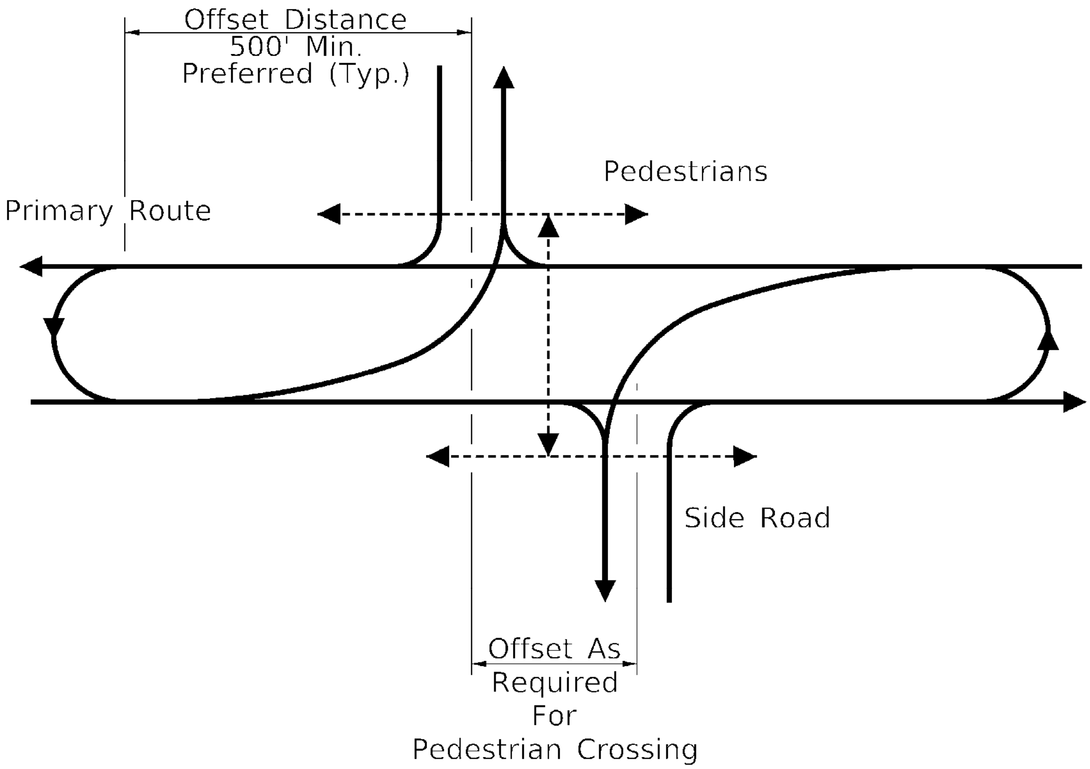
SIGNALIZED RCUT WITH MINOR SIDEROAD, INCLUDING PEDESTRIAN MOVEMENTS

Figure 36-11.G



SIGNALIZED RCUT WITH MAJOR SIDEROAD, INCLUDING PEDESTRIAN MOVEMENTS

Figure 36-11.H



OFFSET RCUT SCHEMATIC

Figure 36-11.I

36-11.01(g) <u>Stakeholder Outreach</u>

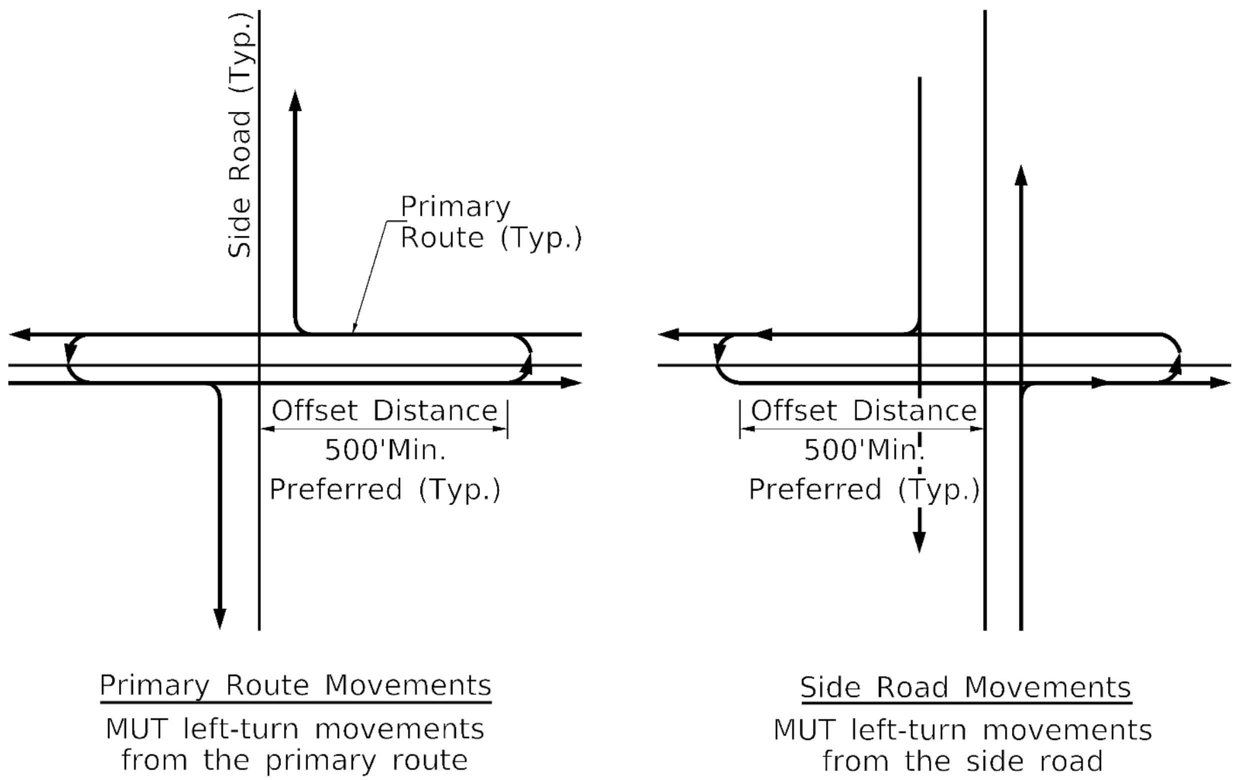
When RCUTs are considered it is important to provide effective outreach with communities and roadway users. Multiple forums can be used, including public informational meetings, local agency council meetings, and media campaigns. Highlight safety analyses that show a likely reduction in serious crashes. Investigate and report on the performance of similar RCUT locations already in service. Driver education can be important in reducing the potential for driver confusion; potentially coordinate with the Illinois Secretary of State’s office on a local education program.

36-11.02 Median U-Turn Intersections

Median U-Turn (MUT) intersections are at-grade signalized intersections where all left turns are indirect. U-turn movements occur at adjacent crossovers that are usually but not always also signalized. MUTs are very similar in many respects to signalized RCUTs but allow the minor road through movements. MUTs must always be signalized to handle those movements. They may be an effective design option for existing intersections with either operational and/or safety concerns along urban and suburban multi-lane arterials, and in series along corridors where the higher-volume cross streets warrant signals.

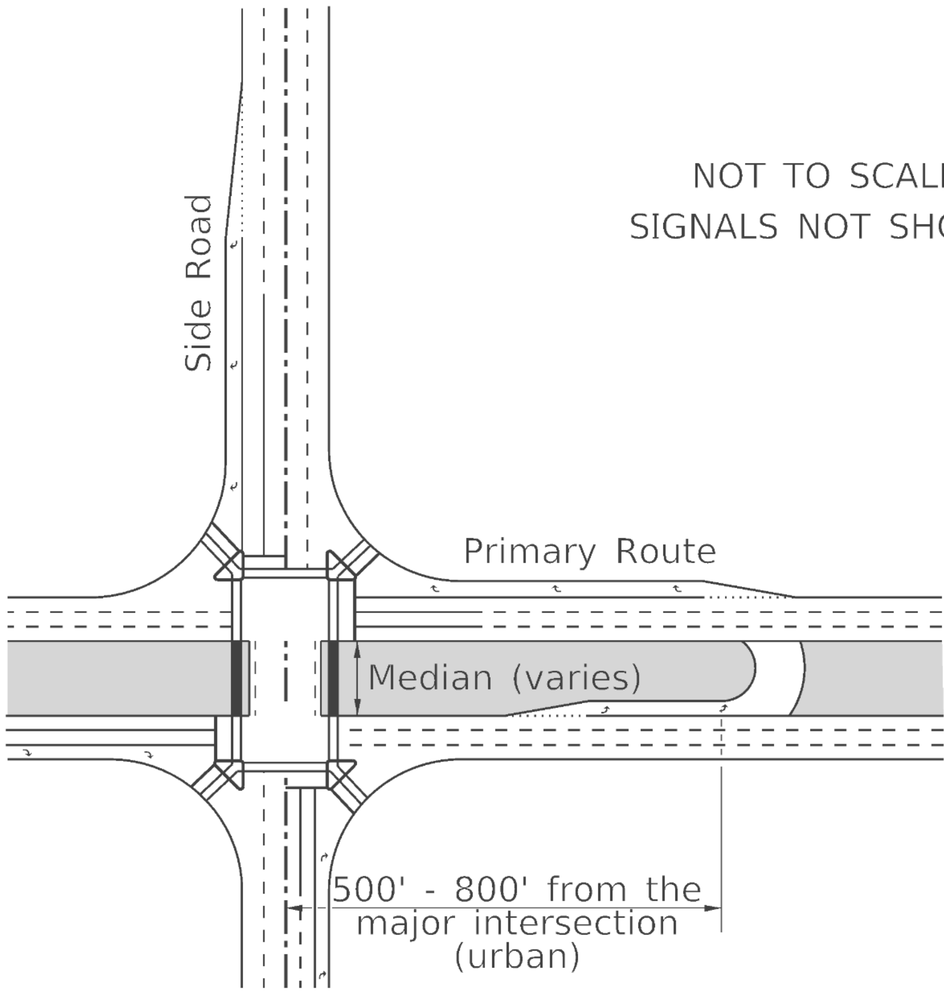
In almost all cases the MUT will redirect left-turning traffic from both primary and minor road approaches. Mainline drivers intending to turn left will continue beyond the main intersection, complete a U-turn maneuver at a downstream median opening, and then turn right to continue along the minor road. Sideroad traffic intending to turn left instead turns right and performs a U-turn at a crossover.

A schematic view of the MUT design movements is provided in Figure 36-11.J. An example layout of an overall MUT design is shown in Figure 36-11.K. The details of a typical U-turn intersection, incorporating a loon, are consistent with RCUT layouts shown in Section 36-11.1.



MUT SCHEMATICS BY MOVEMENT

Figure 36-11.J



TYPICAL MUT LAYOUT

Figure 36-11.K

MUTs typically improve safety performance by causing drivers to make a series of low-complexity decisions and allowing them to find adequate gaps more easily. Based on the changes in movement types, crashes that do occur at MUTs tend to be less severe than those that occur at traditional full-access signalized intersections. The total number of vehicular conflict points is reduced by approximately fifty percent.

Multiple MUTs can be installed along high-ADT primary routes as a signalized corridor treatment. This will typically improve traffic flow efficiency and improve safety performance compared to corridors with conventionally-designed intersections. Medians at MUTs can be very narrow; side road through vehicles are typically not allowed to store in the median. Wider open medians could be designed to allow for occasional vehicle storage in the median; however, clearing all median queues will improve efficiency and eliminate potential conflicts.

With maximum posted mainline speed limits of 45 mph (70 km/hr), median openings (crossovers) for U-turns are typically located 500 ft to 800 ft (150 m to 240 m) downstream of the main intersection, with locations dependent on speed and geometric factors. Two-phase signals are typically used. If traffic volumes are expected to grow substantially after initial opening, a MUT design can provide for expansion through a phased implementation. At least one ILMUTCD signal warrant must be met when MUTs are installed. The two mainline directions will not operate independently with MUTs; optimization of corridor progression bands is critical.

MUT intersections and corridors may be especially suitable where:

- There is heavy through and/or heavy left-turn volumes on primary route approaches;
- The ratio of the minor road approach volume to the total intersection approach volume is less than 0.40;
- The intersection is heavily-congested and signal phase failures (LOS F) occur for through and/or left-turn traffic on the primary route;
- Corridor access management is desirable;
- The history of intersection crashes, both overall and for turning and angle crashes, shows rates above the statewide average for peer group locations; and
- Sight distance constraints for left turns onto or off of the primary route seem to have led to crashes or documented near-misses.

36-11.02(a) General Design Considerations

The design spacing from the main intersection to the U-turn crossover, the “offset distance”, is guided by geometric limitations such as turn lane lengths and adjacent access points; 500 ft to 800 ft (150 m to 240 m) being the typical design range. Signals for the U-turn locations may be included where warranted and needed operationally. Pedestrians (usually present) are accommodated with crosswalks at each of the signalized intersections; see Section 36-10.2(e).

The crossover intersection must incorporate sufficient space for the design vehicle(s) to make the required U-turn movements. This typically requires widening pavement for a “loon” area along the far side of the mainline. It is possible to incorporate existing or relocated access points into a crossover intersection. If the crossover is signalized an additional phase will be required. Consider intersection sight distance, design vehicle turning paths, and the need for signing or geometric measures to deter wrong-way movements. Other potential design considerations are covered in Section 36-11.1(a).

36-11.02(b) Safety

Safety benefits typically result from the redirection of all left-turning movements at MUTs. The number of vehicle-vehicle conflict points is reduced and the conflict types are modified to be typically less severe than those at conventional intersections. Compare the crash history of each existing intersection with statewide peer group intersections as a starting point in assessing potential safety benefits of MUT.

36-11.02(c) Signing

Driver confusion can be a concern at MUTs immediately upon implementation, but experience in other states has indicated that drivers adapt fairly quickly to MUT operations. Proper signing at a MUT is critical to operational and safety performance, because some movements do not meet the expectations of drivers unfamiliar with this intersection type. Diagrammatic guide signs may be considered to aid drivers on all approaches. Prominent “No Left Turn” regulatory signs are needed facing each of the approaches. Most or all of the signing can be ground-mounted signs rather than overhead; signing design involves unique considerations at each location. The Central Bureau of Operations can assist by providing a typical design; statewide consistency is sought.

36-11.02(d) Access Management and Right of way Considerations

Driveways should not typically be allowed in close proximity to the main MUT intersection. MUTs can be perceived as adversely affecting businesses located near intersection or at the corners. Inferences can be drawn from the *NCHRP Report 420,* which indicates that some land uses suffer economic losses with wide median installations. Businesses that rely on pass-by traffic, such as gas stations and convenience stores, may be affected by less-direct access provided with a MUT. Designers should manage access in light of both safety and efficiency. Discuss issues with potentially-affected property owners and local agency officials.

Another concern with MUT designs is that the combined median and loon area width needed to accommodate large vehicles making U-turns at crossovers can result in ROW acquisition and/or impacts. Designers should seek to locate the loons to minimize impacts while satisfying operational requirements.

36-11.02(e) Pedestrian Accommodations

The two-phase signal at a MUT typically allows for a shorter cycle length than with a conventional intersection. Along the primary route a central raised median area is typically used, but suburban roadways may have wide medians. Based on these conditions, pedestrian crossings will often occur in two stages, with use of a median refuge. Typically include pedestrian signal heads and push buttons in the median to allow for two-stage crossings. For shorter crossings it may be possible for pedestrians to cross during a single phase. As always, it is important that all pedestrians follow the marked crosswalks; additional guidance may be provided to help ensure safe operations.

36-11.02(f) Stakeholder Outreach

When MUTs are considered it is important to provide effective outreach with communities and roadway users. Multiple forums can be used, including public informational meetings, local agency council meetings, and media campaigns. Highlight the potential safety benefits of the design. Driver education can be important in reducing any initial driver confusion; potentially coordinate with the Illinois Secretary of State’s office on a local education program.

36-11.03 Displaced Left-Turn Intersections

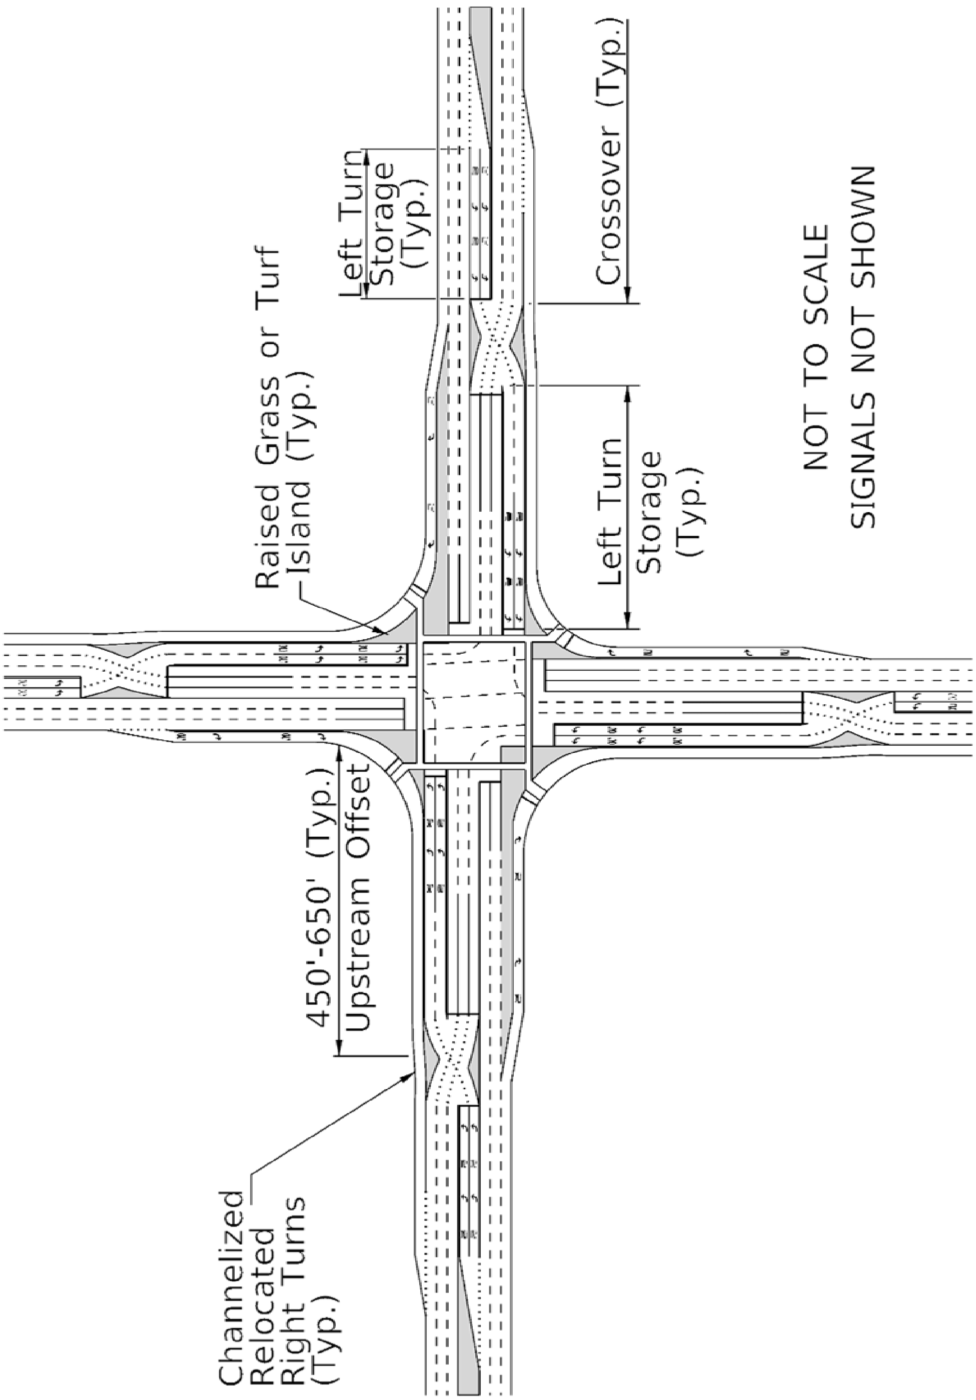
Displaced Left Turn Intersections (DLTs), also known as a Continuous Flow Intersections (CFIs), have been implemented nationally as high-volume operational improvements. Compared to traditional signalized intersections, a DLT's reduced traffic signal phases and fewer conflict points will improve traffic operations and safety performance under a range of relative-volume conditions. They may provide an effective design option for existing high-volume intersections along either multi-lane urban arterials with medians as narrow as 30 ft (9.0 m), and for rural multi-lane expressways with wide medians.

DLTs relocate, or displace, a left-turn movement to the other side of the opposing directional roadway in advance of the main intersection. This eliminates the separate left-turn phase at the main intersection since all through-movements and left turns from the main route proceed concurrently. The removal of high-volume conflicts from the main intersection to a preceding crossover often leads to both operational and safety-performance improvements. Coordinated traffic signals are required at the main intersection and each of the new crossover intersections. Figure 36-11.L illustrates a full DLT.

Designers must carefully consider each individual lane group volume in developing proposed geometry and selecting signal timings that accomplish the following goals:

- Reduce delay for the through vehicles,
- Reduce delay for left turning vehicles,
- Reduce the number of stops for all vehicles, and
- Increase the efficiency of pedestrian crossings (for relevant intersection legs).

Full interchanges are often the only effective alternative for handling the higher-end traffic volumes that can be processed at a DLT. A DLT design has a potential to reduce right-of-way acquisition and costs substantially when volumes are projected such that an interchange is under consideration. Specific safety concerns can also be successfully addressed as part of DLT designs, especially those related to left turns. Safety analyses will be an important part of alternatives evaluations.



TYPICAL PLAN VIEW WITH DISPLACED LEFT TURNS ON ALL APPROACHES

Figure 36-11.L

36-11.03(a) General Design Considerations

Figure 36-11.M shows typical DLT geometrics along one leg of a DLT intersection. Primary route left turning vehicles should typically cross the opposing through traffic lanes 450 ft to 650 ft (140 m to 200 m) upstream of the main intersection. This ‘upstream offset’ distance depends on the signal design and anticipated queuing under the coordinated system; offsets may need to be greater in some cases. Dual left-turn lanes are typically required based on the high-volumes of left turns at intersections where this design type is implemented. The signal control at the main intersection can often operate with two-phases and opposing mainline traffic lanes moving together. DLTs allow for a wide range of cycle lengths to be tested to optimize progression along a corridor.

Radii leading to the crossover movements will typically range from 90 ft to 200 ft (27 m to 60 m). The radii of the left-turn movements at each intersection depend on the dual turning movements of the design vehicle combination; refer to Section 36-3.05 for design guidance on dual turn lanes. Lane widths at the crossover reverse curves should typically be 13 ft to 14 ft (4.0 m to 4.3 m) wide and must accommodate the selected design vehicles side-by-side.

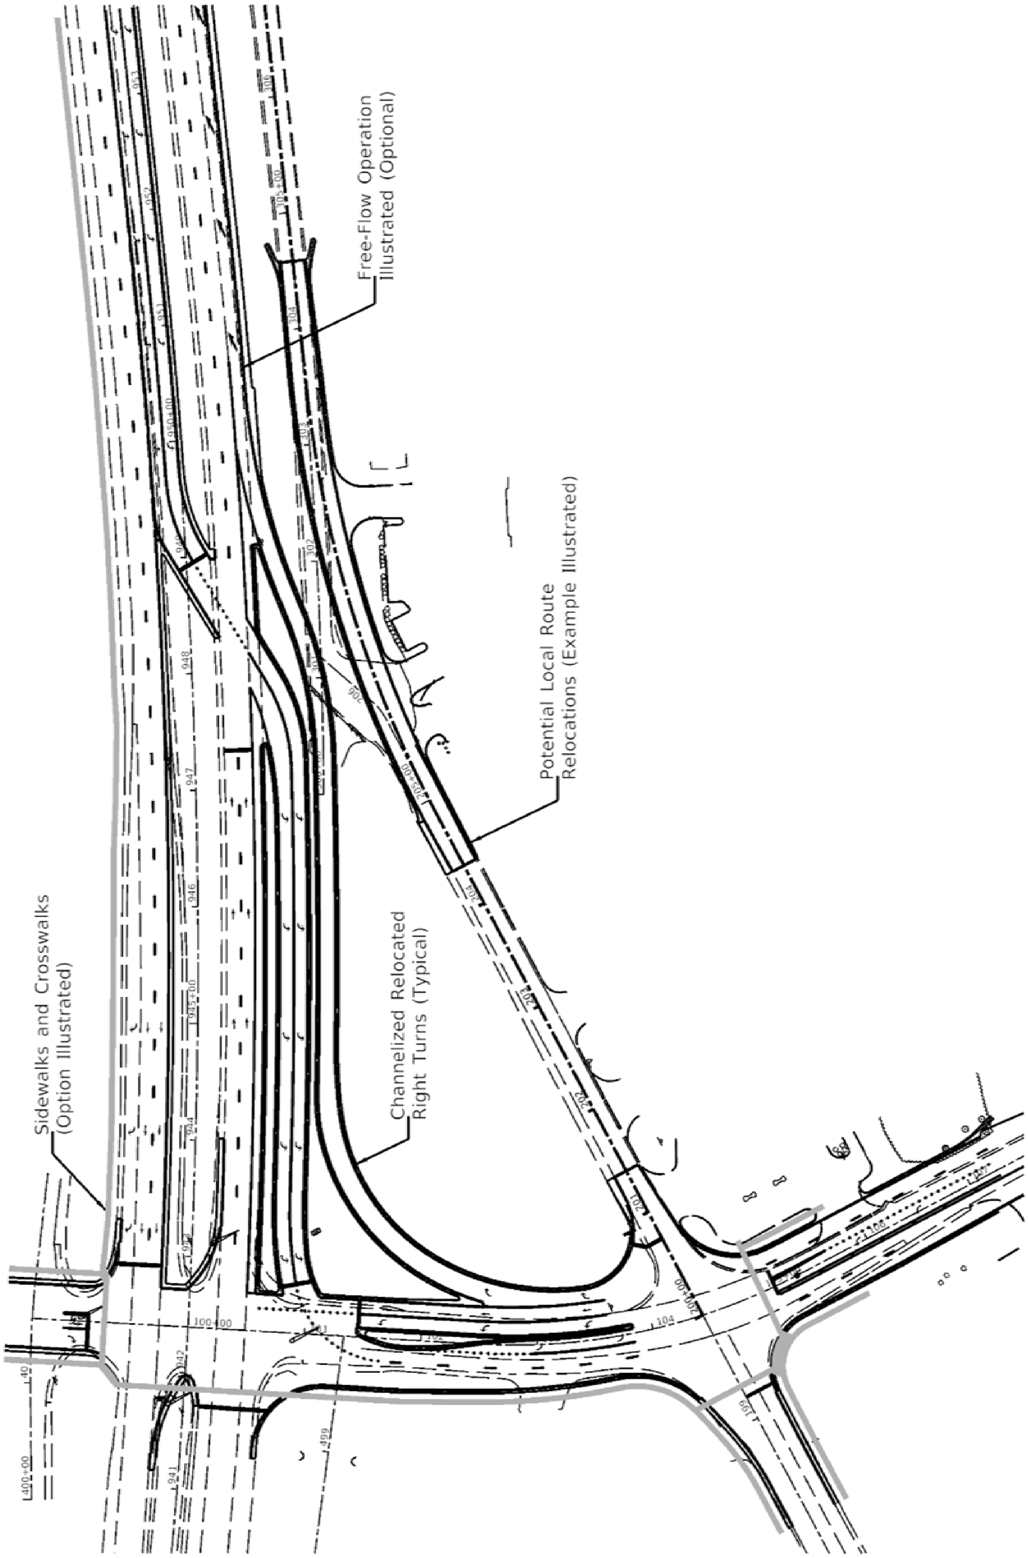
A full DLT with left-turn crossovers on all approaches would have five signalized junctions. Signal coordination with adjacent upstream and downstream intersections is very important to proper DLT operations. The location illustrated in Figure 36-11.M shows that the DLT concept can be implemented on a single mainline leg without changing operations on other legs. In this case, at a minimum a third signal phase would be required to handle the opposing mainline left turns.

The provision of separate right-turning lanes and channelized right-turn paths up to the crossover intersection is a typical feature of the DLT. Most but not all DLTs will relocate right turns in this way to improve overall LOS. Two options are then available for the right-turning traffic entering the primary route flow:

1. provide a non-stop merge condition (appropriate for single right-turn lanes with substantial mainline intersection spacing), or
2. stop traffic at the crossover intersection and allow it to proceed concurrently with the left turn crossing movement (required with dual right-turn lanes and/or with constrained mainline intersection spacing).

The upstream offset distance is primarily dependent on the expected queuing of through and left-turning vehicles from the main intersection. Greater offsets can substantially increase costs given the need to construct the left-turn storage area (for the crossed-over traffic) and often the right-turning pavement for the opposite movement traffic. Typically the offset distance should be minimized within operational constraints.

DLTs are usually retrofit designs. If the existing arterial has a wide median that is no longer needed for left-turn storage designers may consider narrowing the median by using transition curves on the approaches. Refer to Figure 36-11.L for an example of such median use. Balance operations with impacts and overall construction costs.



PARTIAL PLAN VIEW, DLT ON ONE MAJOR ROAD APPROACH

Figure 36-11.M

36-11.03(b) Safety

The DLT has marginally fewer conflict points compared to a conventional intersection. At this time, no direct Crash Modification Factors (CMFs) are available from the FHWA CMF Clearinghouse for assessing the safety benefits of converting a traditional signalized intersection to a DLT. However, individual movements with crash history may be considered in order to estimate a potential change in safety performance. Compare the crash history of an existing intersection with statewide peer group intersections as a starting point in assessing the potential benefits of a DLT. Measures to increase non-motorized user safety should also be considered, as discussed in Chapter 17 and earlier in this chapter.

36-11.03(c) Operations and Signing

Operational benefits of a DLT are most evident with high left-turning and overall traffic volumes. Simultaneous movement of the left-turn and through traffic improves progression of traffic platoons and increases overall vehicular throughput. As part of an alternatives analysis designers should investigate and consider the value of vehicle delay reduction, queue length reduction, and overall capacity changes with a DLT.

Signing and marking of a DLT involve unique considerations. Emphasis should be given to ‘wrong-way’ pavement markings and signing to warn drivers of restrictions that they might not immediately recognize. Overhead and/or post-mounted guide signing should be placed at the left-turn crossover intersections. Since some movements can initially be counterintuitive to unfamiliar drivers unambiguous signing is critical. Consider providing ‘No Left Turn’ signs facing through traffic at the main intersection. Provide notification of lane assignments in advance of the intersection. Through-arrow pavement marking may be considered at locations such as those shown on Figure 36-11.M in order to reinforce required driving patterns. Other design features to improve effectiveness and safety at DLTs include channelizing islands, right-in-right-out driveways (rather than full access), high-visibility pedestrian refuge areas and crosswalks, raised pavement markers for lane delineation, and traffic flow separation using raised medians. Experience in other states has indicated that any initial driver confusion is quickly reduced as these intersections are opened and driver experience levels increase.

36-11.03(d) Pedestrian and Bicyclist Accommodations

For accommodating bicycle left turns at DLT intersections it may be appropriate to guide riders to the intersection proper, to proceed as would a pedestrian, rather than following the left turning paths of vehicles. Alternatively, adding a two-stage bicycle turning box encourages left-turning bicyclists to store at an appropriate location within the intersection before completing the second stage of their intended left turn.

Pedestrians are required to cross DLTs in multiple stages. Existing literature describes alternative pedestrian signal strategies including clockwise and counterclockwise optimization of pedestrian flows at a DLT intersection. Figure 36-11.M shows an accommodation example. There are situations where accommodating pedestrians on only one side of the minor road crossing may provide overall operational advantages.

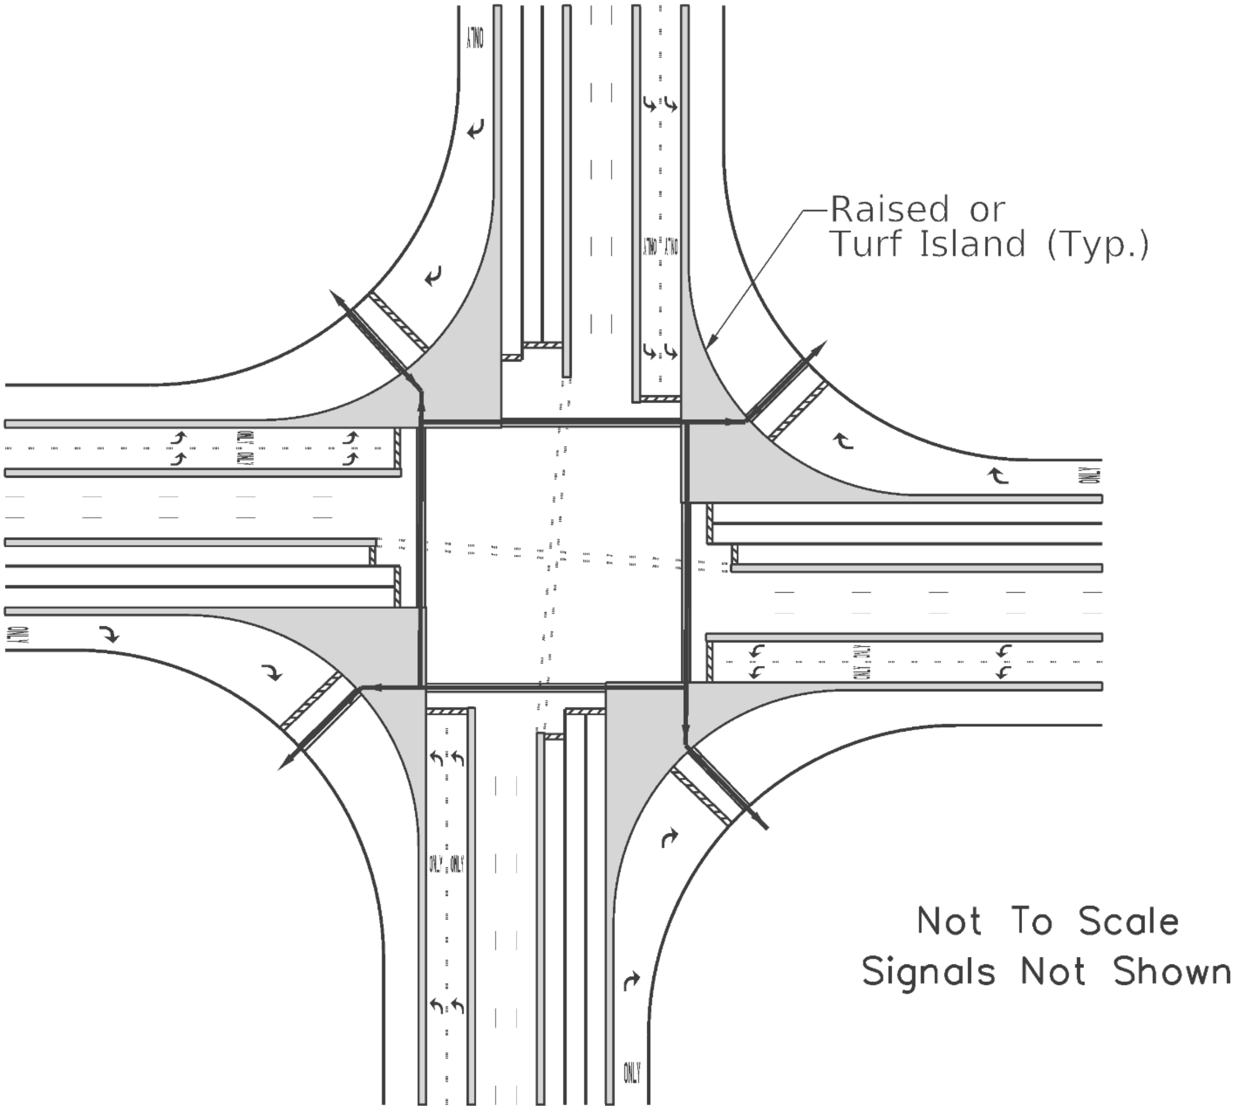
The position of intersection approach lanes can be counter-intuitive to pedestrians. The wide geometric footprint of the DLT, often combined with shorter signal cycle lengths, make pedestrian crossings a critical part of system optimization. Medians and corner islands must provide adequate pedestrian refuge. Refer to Section 36-4.03(b) for pedestrian refuge requirements.

Pedestrian time and distance considerations are less important than pedestrian safety. Figure 36-11.N shows typical pedestrian crossing paths among the four quadrants. Crossing the street diagonally typically requires the following procedure, following pedestrian signal heads:

1. Cross a channelized right-turn roadway to a pedestrian refuge island. Crosswalks for single-lane right-turning roadways may be provided with or without pedestrian pushbuttons at designer discretion (they are advisable for some wider crossings). Pedestrian pushbuttons are required for crossings of dual right turn lanes.
2. Cross all lanes of the first street that offers a “Walk” signal to reach the pedestrian refuge island on the opposite side.
3. Cross all lanes of the second street by crossing with a “Walk” signal to the diagonally opposite pedestrian refuge island.
4. Complete the crossing procedure by crossing a right-turn roadway; see #1 above.

The push-buttons for crossing the major legs of the intersection are located on the channelizing corner islands which serve as pedestrian refuge areas and must be sized for storage of the expected pedestrian streams at all locations.

Lighting designs may involve unique considerations at a DLT, particularly if pedestrian crosswalks will be part of the design; refer to Chapter 56.



PEDESTRIAN MOVEMENTS AT A DLT

Figure 36-11.N

36-11.03(e) Access Issues

It is advisable to evaluate with the Central Bureau of Operations emergency vehicle access for addressing crashes or disabled vehicle situations. The use of mountable curbs in the crossover area helps facilitate emergency vehicle access to the crossover and adjacent areas. Where present, the use of frontage roads may be part of an overall emergency access plan. Consider appropriate response procedures for the removal of disabled vehicles or a signal malfunction event.

Restriction of access to parcels located close to the main intersection is typically necessary. Locate driveways as far from the signalized intersections as possible. Approaches that have left-turn crossovers cannot accommodate median breaks within the distance of the new right-turn lanes (i.e., up to the crossover intersections). If any driveways on the approaches to the main intersection are allowed to remain, they must be right-in-right-out (RIRO) only.

36-11.03(f) Stakeholder Outreach

When a DLT is considered it is important to provide effective outreach with communities and roadway users. Multiple forums can be used, including public informational meetings, local agency council meetings, and media campaigns of various types. The results of the analysis related to vehicle delay and LOS may be an important area of discussion during local agency and public coordination. Public information and educational campaigns prior to opening a DLT can help mitigate local concerns. Driver education can be important to help minimize any initial driver confusion.

36-11.04 Continuous Green T Intersections

The continuous green T intersection, or CGT, is a 3-legged signalized intersection that allows for one of the mainline through movement (opposite the sideroad) to flow freely with a continuous green indication. CGTs have the potential to simultaneously address safety and operational concerns at existing T intersections, especially in suburban and rural locations that have higher than average crash rates, specific over-represented crash types, excessive delay, or high tractor-trailer truck traffic.

CGTs are typically used in locations where safety or operational concerns make a traditional 3-legged signalized intersection less effective. Example concerns could include low LOS for minor road movements during peak periods or rear-end crash patterns along the mainline. For locations currently unsignalized yet meeting at least one signal warrant, a CGT may provide a way to minimize disruption and address both increasing congestion and safety concerns related to inserting a new signal along rural or suburban roadways.

CGTs are most often appropriate in locations with design and posted speeds of 40 mph to 55 mph (60 km/hr to 90 km/hr). In lower speed urban locations with pedestrian presence the potential conflicts created by the preferential mainline vehicle flows can run counter to the safety and accommodation goals common to urban and urban core contexts.

36-11.04(a) General Design Considerations

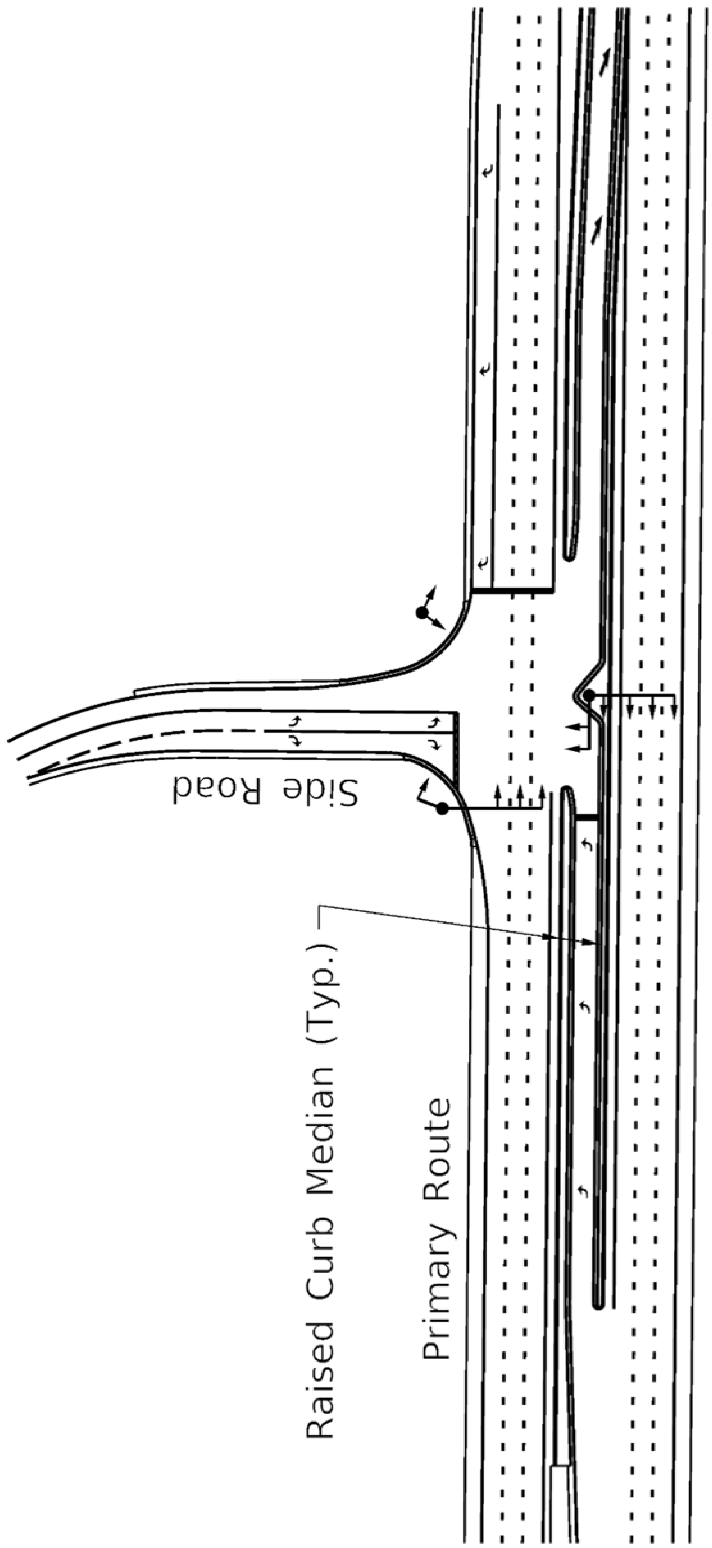
Figure 36-11.O shows a typical CGT layout. CGTs are signalized intersections. It may be possible, however, to incorporate CGT geometric design features into an unsignalized T intersection location, with a plan to add signals later as traffic demand grows.

CGTs require that adequate median width is available to develop channelization. A raised curb or barrier median is included along the mainline to provide channelized left-turning movements, physically separate median left turn (diverging) traffic, and allow accelerating traffic to reach appropriate speeds before merging with mainline flows.

Raised curb islands are most commonly used for the channelization, but at high speeds concrete median barriers may be used. In either case, offset the face of curb/barrier by a full shoulder width when the posted speed is greater than 45 mph (70 km/hr). An advantage of a raised curb treatment is that the better visibility provided between vehicles allows drivers to react appropriately to adjacent traffic.

36-11.04(b) Signalization

The traffic signal at a CGT operates with three phases, with left turns from the mainline usually having protected-only phasing. The far-side mainline through movement is typically free-flow, and green arrow signal faces are provided to inform drivers of that condition. The provision of a typically free-flow movement means that CGTs will have limited applications in urban areas.



TYPICAL CGT LAYOUT

Figure 36-11.O

36-11.04(c) Access

In some cases, one or more mainline access point may need to be located within or immediately adjacent to the intersection. However, the number of driveways should be limited and those present should be offset from the signal location to the extent possible. Busier commercial entrances and sideroads should preferably be located completely outside of the intersection (channelization) area. Major driveways may require both STOP and RIGHT TURN ONLY signs. Consider ONE WAY signs in the median facing private entrances.

36-11.04(d) Safety

CGT intersections address safety primarily by improving the operational characteristics of the intersection, channelizing the left turn movements, and providing for protected left-turn movements.

36-11.04(e) Pedestrian Accommodations

With any level of pedestrian activity, the free-flow movement will need to be stopped whenever pedestrians activate a pushbutton or are passively detected. Due to this additional phase, and the potential for safety issues, pedestrian presence at an intersection may be of sufficient concern that CGTs not be considered. If implemented in areas with pedestrian presence, signalization and high-visibility pedestrian crossings will be needed. In urban locations, overall operational advantages in comparison to a more traditional design could be justification for CGT implementation. However, stress high-visibility crossings and added safety features as part of CGT designs in urban and suburban locations.

Chapter Thirty-seven
INTERCHANGES

AASHTO defines an interchange as a system of interconnecting roadways in conjunction with one or more grade separations that provide for the movement of traffic between two or more roadways on different levels. The operational efficiency, capacity, safety, and cost of the highway facility are largely dependent upon its design. Chapter 37 provides guidance in the design of interchanges including interchange types, selection, layout, operations, spacing, freeway ramp terminals, ramps, and ramp/crossroad terminals. Information that is also applicable to interchanges is included in the following chapters:

- Chapter 15 discusses the procedures and content for interchange type and design studies.
- The application of bicycle lanes through interchanges is discussed in Chapter 17.
- Chapter 35 discusses access control along interchange crossroads.
- Chapter 36 discusses intersection designs, including left and right-turn lanes, channelizing islands, turning radii, design vehicles, sight distance requirements, etc.
- Chapter 44 discusses freeway new construction and reconstruction design criteria, lane drops, frontage roads, grade separations, and access control along the freeway.
- Chapter 50 discusses freeway 3R design criteria.
- The warrants and design criteria for interchange lighting are discussed in Chapter 56.
- Guidance on interchange and/or ramp/crossroad terminal intersection traffic control devices, including striping, signing, and traffic signals is discussed in Chapter 57.
- Accessibility for persons with disabilities, including the design of compliant curb ramps, crosswalks, and roadway approach grades at interchange ramp/crossroad terminals is discussed in Chapter 58.

37-1 GENERAL

37-1.01 Responsibilities

The district is responsible for determining the need for, location of, type of, and design of interchanges. For interchange types other than the conventional diamond and parclo Type C, BDE involvement in type studies is recommended because of the larger number of alternatives requiring analysis and the typically higher costs; see Chapter 15.

37-1.02 Guidelines

The need for an interchange will vary based on site-specific conditions. Consider the following guidelines when determining the need for and practicality of an interchange:

1. Access Control. The following will apply:

    a. Full Access Control. On all fully access-controlled facilities, intersecting crossroads must be terminated, rerouted, provided a grade separation, or provided an interchange. The importance of the continuity of the crossroad, the feasibility of an alternative route, traffic volumes, construction costs, environmental impacts, etc., are evaluated in order to determine which option is most practical. Interchanges generally are provided at:

        - all freeway-to-freeway crossings;
        - all major highways, unless determined inappropriate; and
        - other highways based on the anticipated demand for regional access.

    b. Partial Access Control. On facilities with partial access control (expressways), intersections with public roads will be accommodated by an interchange, an intersection, and occasionally a grade separation. Refer to Section 45-1.03 for the decision-making process for the treatment of crossroads at expressways.

    c. No Access Control. On a facility with no access control, the need for an interchange will be determined on a case-by-case basis emphasizing cost effectiveness, safety, and operations. A road-user benefit analysis will generally be required to determine the economic feasibility of an interchange. See Item 5. However, this analysis alone is not sufficient justification for the provision of an interchange.

2. Congestion. Consider providing an interchange where the level of service (LOS) at an intersection is unacceptable, and the intersection cannot be redesigned to operate at an acceptable LOS.

3. Safety. In special cases, consider the crash reduction benefits of an interchange at an existing intersection that exhibits extremely high-crash frequencies and rates.

4. Site Topography. Where access is necessary, the topography may dictate an interchange or a grade separation rather than an intersection.

5. Road-User Benefits. If an analysis reveals that road-user benefits over the service life of the interchange will exceed costs, then an interchange may be considered. The designer must consider all costs including right-of-way, construction, maintenance, and user costs in the analysis. For additional guidance, the designer may refer to the AASHTO publication, *A Manual on User Benefit Analysis of Highway and Bus-Transit Improvements*.

6. Access. An interchange may be required in an area where access availability from other sources is not practical, and the freeway is the only facility that serves the area.

7. Traffic Volumes. Although there are no specific traffic volumes that warrant an interchange, consider providing an interchange where the traffic volumes at an intersection are at or near capacity and where other improvements are not practical.

37-1.03 New or Revised Interstate Access Approval

37-1.03(a) FHWA Regulations

The FHWA states, in their current *Policy on Access to the Interstate System* that it is in the national interest to preserve and enhance the Interstate System to meet the needs of the 21st Century by assuring that it provides the highest level of service in terms of safety and mobility. Full control of access along the mainline and ramps, along with control of access on the crossroad at interchanges, is critical to providing such service. Therefore, an FHWA decision to approve new or revised access points to the Interstate System under Title 23, United States Code (U.S.C.), Section 111, must be supported by substantiated information justifying and documenting that decision.

Section 111 of Title 23, *United States Code* (23 U.S.C. 111) identifies that all agreements between FHWA and IDOT for the construction of projects on the Interstate System must contain a clause that IDOT will not add any points of access to, or exit from, the project in addition to those approved by FHWA in the plans for the project, without the prior approval of FHWA. 23 CFR 625 designates those criteria and policies that are acceptable to FHWA for the geometric and structural design of highways, including Interstate facilities.

The original FHWA policy regarding new or revised access points to existing Interstate facilities was first published in the *Federal Register (55 Fed. Reg. 42670)* on October 22, 1990, revised in the February 11, 1998 *Federal Register (63 Fed. Reg. 7045)*, and then revised again in the August 27, 2009 *Federal Register (74 Fed. Reg. 43743)*. The February 1998 revision incorporates the planning requirements of the *1991 Intermodal Surface Transportation and Efficiency Act*, clarifies the coordination between the access request and environmental procedures, and updates the policy language at various locations. The August 2009 revisions were made to reflect the direction provided in the *Safe, Accountable, Flexible, Efficient Transportation Equity Act: A Legacy for Users* (SAFETEA–LU), to clarify the operational and safety analysis and assessment of impacts that provides the basis for proposed changes in access to the Interstate System, and to update language at various locations to reference Federal laws, regulations, and FHWA policies. Additional guidance from FHWA Headquarters office was established in 1996 and 1997. This guidance allowed FHWA Division Offices to approve more Interstate revisions in access and established a two-step process for approving these changes. Finally, on May 22, 2017, FHWA clarified its policy for documenting new or revised access points on the Interstate system, including separation of issues related to engineering, operations, and safety (to be included within Illinois as part of an Access

Justification Report) from other issues such as planning requirements and land use (to be included in NEPA documents).New or revised access points to the existing Interstate System will be reviewed against the criteria in Section 37-1.03(b). Sections 37-1.03(d) and 37-1.03(e) define the information required to be included in final submittals to FHWA when requesting approval for revisions in Interstate access. Section 37-1.03(c) provides the procedures for obtaining approvals from IDOT and/or FHWA.

37-1.03(b) Applicability

New and/or revised access points that degrade mainline operations or safety should be minimized on existing fully access-controlled facilities. Avoiding such degradation is the primary focus of FHWA and BDE reviews and approval.

Each entrance and exit point on the mainline, including "locked gate" access (e.g., utility opening), is defined as an access point. For example, a standard diamond interchange configuration has four access points. Revised access is considered to be a change in the existing interchange configuration although the number of access points may not change. For example, replacing one of the direct ramps of a diamond interchange with a loop or changing a cloverleaf interchange into a fully directional interchange is considered to be a revised access.

The criteria in Section 37-1.03 is applicable to new or revised access points to existing fully access-controlled facilities (Interstate and non-Interstate facilities) regardless of the funding source. Consequently, it applies to private developers, and any changes to an access-controlled facility, which may be required of the private developer by IDOT or a local agency.

Each access revision will need to be analyzed on a case-by-case basis. Consider the following:

1. Revisions Requiring BDE/FHWA Access Approval. The following revisions to access-controlled facilities are considered changes in access and will require BDE/FHWA access approval:

    - new freeway-to-freeway interchange;
    - major modification of freeway-to-freeway interchange configuration (e.g., adding new ramp(s), abandoning/removing ramp(s), completing basic movements);
    - new partial interchange or new ramps to-from a continuous frontage road that creates a partial interchange (e.g., slip ramps);
    - new freeway-to-crossroad interchange (e.g., addition of a combination of on-ramps and off-ramps);
    - modification of existing freeway-to-crossroad interchange configuration (e.g., replacing one of the direct ramps of a diamond interchange with a loop);
    - completion of basic movements at a partial interchange (e.g., completing a partial diamond interchange by adding a ramp, the addition of any on- or off-ramp to the mainline);

- locked gate access (e.g., access via locked gates by privately employed personnel); and
- abandonment of ramps or interchanges.

2. Revisions Requiring BDE Access Approval. The following revisions to, and immediately-adjacent to, access-controlled facilities are not considered a change in access and do not require FHWA access approval; however, these typically do require BDE approval:

   a. Ramp/Crossroad Improvements. This includes the addition of left-turn storage lanes, right-turn storage lanes, and/or through travel lanes at the local road end of exit ramps. These additions will inherently and expeditiously increase ramp safety for ramps that chronically back-up onto the mainline travel lanes, by shortening the queue lengths and minimizing the occurrence of high-speed, rear-end collisions. Ensure that adequate stopping sight distance, decision sight distance, geometrics, etc., are provided. Any ramp/ crossroad intersection improvements (e.g., constructing roundabouts) should be assessed regarding both capacity and safety performance.

   b. Ramp Relocation. This includes relocation or shifting of existing crossroad/ramp termini (i.e., moving the ramp end that connects with the local road). The designer must ensure that adequate stopping sight and decision sight distance are provided at the ramp terminals.

   c. Services Ramps. Ramps providing access to rest areas, information centers, and weigh stations within the Interstate controlled access are not considered access points requiring FHWA approval. These facilities can only be accessible to vehicles to and from the Interstate System. Access between these facilities and local roads or adjoining property is prohibited. The only allowed exception is for access to adjacent publicly owned conservation and recreation areas, if access to these areas is only available through the rest area, as allowed under 23 CFR 752.5(d).

   d. Auxiliary Lanes. This includes the addition of a single auxiliary lane between two adjacent interchange ramps. The single auxiliary lane should not function as a mainline travel lane and must be shown to provide both operational and safety benefits.

   e. Acceleration and Deceleration Lanes.

      i. Decreasing the Length. Prior to decreasing the length of these types of lanes, conduct an HSM safety analysis by analyzing the crash history and future crash potential. Also review sight distance and ensure appropriate signing revisions are provided.

      ii. Increasing the Length. f the adjacent upstream on-ramp or adjacent downstream off-ramp exists at a distance equal to or less than the criteria in Section 37-2.16 (i.e., measured between physical gore areas), conduct an operational analysis (e.g., weaving, capacity, signing). The spacing between interchanges should safely accommodate weaving, diverging, merging maneuvers, and provide for good directional signing.

iii. Design Exceptions. If design criteria cannot be met, request a design exception for the improvement. See Section 31-7 for the procedures for obtaining a design exception.

f. Addition of On-Ramp Lanes. This consists of adding a lane to a single lane on-ramp, resulting in a two-lane on-ramp. Conduct an operational analysis (e.g., weaving, capacity, signing) to show operational and safety benefits.

g. Traffic Signals. This includes traffic signalization improvements at ramp termini with local roads. Improvements in the level-of-service for the ramp leg traffic at the exit ramp terminal must be shown.

h. Signing and Pavement Markings. This includes new signing, striping, and/or resurfacing of an on-ramp or off-ramp where geometric features are not changed.

i. Roadside Safety. Installation of roadside guardrail or barriers (e.g., for resurfacing and safety projects) will not require access approval.

37-1.03(c) Processing Procedures

BDE and FHWA must approve all proposed changes in access, in accordance with the list in Section 37-1.03(b), along the Interstate System. For proposed changes in access on non-Interstate freeways, BDE and/or the Bureau of Operations will review and approve any access changes; FHWA will not be regularly involved for these facilities.

The following procedures are applicable where 1) the highway is on the State highway system and Federal funds were used for right-of-way and/or construction costs of the roadway segment; and 2) the highway is access controlled and the proposed access revisions will modify previous commitments made in environmental documents:

1. Environmental Procedures. The FHWA revised access approval constitutes a Federal action and, as such, requires that the transportation planning, conformity, congestion management process, and the *National Environmental Policy Act* (NEPA) procedures be followed and their requirements satisfied. NEPA procedures also apply even when changes to an Interstate facility are being financed completely by the State, local municipality, or a private developer. The NEPA procedures will be accomplished as part of the normal project development process and as a condition of the access approval. The district will determine the type and scope of the necessary environmental process in cooperation with FHWA; see Chapter 22. Generally, this will occur at scheduled district coordination meetings. Compliance with the NEPA procedures should proceed concurrently with the analyses to determine engineering acceptability and feasibility.

Although compliance with the NEPA procedures need not precede the determination of engineering acceptability and feasibility, the FHWA Illinois Division Office will not give final access approval before the completion of the NEPA process.

2. Secondary Impacts. Determine the secondary impacts associated with the proposed access revisions based on traffic-induced impacts on the State highway facility and on the potential environmental impacts on the surrounding area. Because the area of influence on the highway facilities and surrounding land use will vary, describe the limits of influence for each case prior to determining impacts.

3. Outside Agency Proposals. The district will recommend whether IDOT or the agency requesting the revision will conduct the studies. BDE will review and approve Phase I reports.

4. FHWA Coordination. BDE usually will review and approve the interchange type and interchange design studies (IDS) using the Department's Certification Acceptance procedures except where the action is proposed on the Interstate system. For Interstates, FHWA must also agree on the type and the design details, see Sections 37-1.03(d) and 37-1.03(e). IDOT must discuss with FHWA any proposed access control revisions on the NHS at scheduled district coordination meetings.

5. Central Office Processing. Access control revisions along a freeway will be processed by the Central Office in the following manner:

   a. Bureau of Operations. In general, proposed revisions in the access control along freeways and along interchange crossroads on the State highway system will be reviewed and processed by the Bureau of Operations except where location/design studies are necessary and/or where IDOT construction funds are used in the action.

   b. BDE. Where design studies and/or construction funds are used in the proposed action requiring access control revisions, BDE will review and process the proposed action.

   c. Freeway Orders. Projects involving a revision to an existing Freeway Order will be handled by either BDE or the Bureau of Operations up to the stage where a Freeway Order revision is filed for approval. After this stage, BDE will process the revision of the Freeway Order.

   d. Impact Assessments. Where assessments of the impacts of proposed access control revisions are required, BDE will determine what elements should be considered in the review and processing of the assessment. Proposed access changes should be discussed at district coordination meetings and then submitted for review early in the NEPA process. This procedure will allow for a timely determination of engineering and operational acceptability and will ensure that the proposed design is acceptable for inclusion as an alternative in the environmental process.

e. Overlapping. Where the criteria are overlapping, unclear, or there is uncertainty about who is responsible for conducting the review and processing of the request, BDE and the Bureau of Operations will coordinate to determine which Bureau will take responsibility for the request.

f. FHWA Approval. BDE will work with the district to submit an Access Justification Report (AJR) to the FHWA Division Office for review, comment and approval. This submission will be a "stand-alone" document that will show reasonable care has been performed and confirm future safety and traffic operations along the Interstate corridor will not be adversely affected by the proposed new or revised Interstate access. Section 37-1.03(d) further discusses FHWA approvals.

g. Filing. BDE will retain on file the approved revision in access submittal.

6. Coordination Meetings. The agendas for scheduled district coordination meetings should clearly distinguish projects involving proposed access control revisions from other projects. Furnish this information in adequate time to allow either BDE or Bureau of Operations to facilitate their attendance.

37-1.03(d) FHWA Approvals

FHWA approval is required where there are new or revised access points to the Interstate System. The following will apply to Interstate routes:

1. Design Criteria. All FHWA approvals for new, added or revised access are conditioned upon IDOT complying with all applicable Federal rules and regulations. For Illinois, the design criteria are contained in the *BDE Manual* and the *Illinois Highway Standards* which meet or exceed the criteria presented in the AASHTO publications, *A Policy on Geometric Design of Highways and Streets* and *A Policy on Design Standards - Interstate System*.

2. FHWA Concept Approval. Concept approval is the first step in the FHWA approval process and involves a determination of safety, engineering, and operational acceptability. Ideally, it should be done as soon as the Department has a good understanding of the proposed scope of the improvement. The FHWA Division Office and IDOT will develop a consensus on proposed access concepts at coordination meetings. FHWA concept approval will need to be received from either the FHWA Headquarters Office or from the FHWA Illinois Division Office as in accordance with the following:

   a. FHWA Headquarters Concept Approval. Concept review and approval is required from the FHWA Headquarters (HQ) Office for the specific major Interstate access requests that are listed below. IDOT will send three copies of the official transmittals requesting FHWA HQ concept approval, and local FHWA Division Office final approval, will need to be sent to the FHWA Division Office. Note that advance coordination with the FHWA HQ Office may be necessary, and appropriate, on certain complex and/or controversial projects that will require FHWA HQ concept review and approval during the project's environmental process. In these cases, IDOT should coordinate directly with the local FHWA Division Office. The FHWA HQ Office concept approval is required for the following types of Interstate revised access:

- new freeway-to-freeway interchange,
- major modification of freeway-to-freeway interchange configuration,
- new partial interchange or new ramps to/from continuous frontage road that create a partial interchange, and
- new freeway-to-crossroad interchange located in a Transportation Management Area (TMA).

b. FHWA Illinois Division Office Concept Approval. The FHWA Division Office and the Department will develop a consensus on proposed access concepts at coordination meetings, which are subsequently documented in the Access Justification Report (AJR); see Section 37-1.03(e). FHWA Division Office concept approval will be given by the FHWA Division Administrator. IDOT will send the AJR to the FHWA Division Office with signature lines for the FHWA Division Office Field Engineering Manager (FEM) (recommend approval) and for the FHWA Division Office Division Administrator (for approval). The signed AJR will document FHWA concept approval. Once signed, the AJR will be sent back to IDOT. The FHWA Division Office gives concept approval for the following types of Interstate revised access:

- new freeway-to-crossroad interchange not located in a TMA,
- modification of existing freeway-to-crossroad interchange configuration,
- completion of basic movements at partial interchange,
- locked gate access, and
- abandonment of ramps or interchanges.

3. FHWA Final Approval. The FHWA Division Administrator gives final approval for all types of Interstate access changes. Concept Approval and completion of the NEPA process are needed for the Final Approval of Access Revision. No additional information is required for the final approval request unless any conditions previously noted in the AJR have changed substantially.

4. Reevaluation. An affirmative determination by FHWA of engineering and operational acceptability for proposals for new or revised access points to the Interstate System should be reevaluated whenever a significant change in conditions occurs (e.g., land use, traffic volumes, roadway configuration or design, environmental commitments). Proposals must be reevaluated if the project has not progressed to construction within

eight years of receiving an affirmative determination of engineering and operational acceptability (23 CFR 625.2(a)). If the project is not constructed within this time period, an updated Access Justification Report based on current and projected future conditions must be submitted to FHWA to receive either an affirmative determination of engineering and operational acceptability, or final approval if all other requirements have been satisfied.

37-1.03(e) Access Justification Report Contents

All requests for new or revised access points on completed Interstate highways must closely adhere to the planning and environmental review processes as required in 23 CFR 450 and 771. As part of their May 22, 2017, Policy on Access to the Interstate System, the FHWA moved documentation for issues not directly related to engineering, operations, and safety of Interstate access changes (all but two points, numbered 13 and 18 in the list below) out of the AJR and solely into other required NEPA documentation. Refer also to Section 37-1.03(c). The final FHWA approval of requests for new or revised access, the *acceptability determination*, cannot precede the completion of NEPA processes. The AJR provides a primary basis for a timely approval decision by the FHWA and IDOT on new or revised access.

To provide for an efficient review IDOT continues to require that a wide range of information be included within the AJR, although many points may be briefly summarized. The AJR must include the information described below in 20 points:

1. <u>Description</u>. Provide a description of the proposed new or revised access. It is acceptable to present more than one alternative, with identification of a preferred design.

2. <u>Purpose</u>. Describe the purpose and need specifically related to the new or revised access point. Project purpose and need is typically a product derived from discussions by the project scoping team and with input from an array of project stakeholders. The new or revised access point may be one element of an overall project.

3. <u>Cost</u>. Include the estimated total cost of the overall project and the new or revised access point.

4. <u>Background Information</u>. Provide any additional background support information to explain and/or support the access proposal (e.g., developer input, known public opposition, status of the NEPA process, summary of input received from public meetings, sources of project funding, and implementation schedule).

5. <u>Concerns</u>. List any known areas of concern (e.g., operational, environmental, safety) in the direct vicinity of the access change. Always include a crash history summary for all new or revised access requests. The project must include proposed mitigation measures to improve the safety issues identified here. FHWA and IDOT must be convinced that there will be steps taken to improve safety and operations of the Interstate facility itself.

6. Communities. Note the distances to and size of communities or facilities directly served.

7. Connections. Describe the relationship and distance of the interchange to adjacent interchanges, the adequacy of acceleration, deceleration and weaving lengths, and the ability to provide adequate signing.

8. Design Exceptions. Clearly identify any necessary design exceptions from current BDE design criteria; see Section 31-7.

9. Traffic Signals/Signing. Include a conceptual plan of the type and location of the signs proposed to support the preferred alternative. Identify locations of additional proposed traffic signalization, if applicable.

10. Lane Balance. Describe how the interchange will provide lane balance with a consistent basic number of lanes.

11. Alternative Existing Facility Improvements. Show that all reasonable alternatives, including improvements to the existing local roads and streets in lieu of new freeway access, have been properly considered. Could streets generally parallel to the Interstate facility be used as connections to existing adjacent interchange ramps in lieu of adding a new interchange or ramps? Could improvements such as access control along surface streets, improving traffic control, modifying ramp terminals and intersections, adding turn bays or lengthening storage satisfactorily accommodate the design-year traffic demands? Diagrammatic figures may be helpful in describing the alternatives assessed. Designers must demonstrate that an access point is needed for regional traffic needs and not to solve local system problems. The freeway facility must primarily serve regional traffic.

12. Alternative Mainline or Transportation System Management Improvements. Explain whether transportation system management type improvements (such as ramp metering, mass transit, and HOV facilities), and/or geometric design improvements to the Interstate, could address existing issues without the proposed change in access.

13. Access Connections and Design. FHWA policy states: “The proposed access connects to a public road only and will provide for all traffic movements. Less than “full interchanges” may be considered on a case-by-case basis for applications requiring special access, such as managed lanes (e.g., transit or high occupancy vehicle and high occupancy toll lanes) or park and ride lots. The proposed access will be designed to meet or exceed current standards (23 CFR 625.2(a), 625.4(a)(2), and 655.603(d)). In rare instances where all basic movements are not provided by the proposed design, the report should include a full interchange option with a comparison of the operational and safety analyses to the partial interchange option. The report should also include the mitigation proposed to compensate for the missing movements, including wayfinding signage, impacts on local intersections, mitigation of driver expectation leading to wrong-way movements on ramps, etc. The report shall describe whether future provision of a

full interchange is precluded by the proposed design." Partial interchanges usually have undesirable operational characteristics. If circumstances exist where a partial interchange is considered appropriate, then commitments to the FHWA, possibly even purchase of necessary right-of-way during the initial project stage for future completion, must be made by IDOT. Special purpose access for HOV's, for transit vehicles, or for park and ride lots should be treated as special cases and the movements to be provided decided on a case-by-case basis.

14. Transportation Land Use Plans. Show that the proposal considers and is consistent with local and regional land use and transportation plans and that necessary coordination has begun. Prior to Phase I approval, new or revised access must be included in a Metropolitan Transportation Plan, a Statewide or Metropolitan Transportation Plan (STIP or TIP), and a Congestion Management Process(as applicable).

15. Comprehensive Interstate Network Study. If applicable, analyze and consider all proposed changes in access for an area at the same time. If a new or revised interchange is being proposed and another new or revised adjacent interchange is being planned and programmed by IDOT then analyze both changes together.

16. Coordination with Transportation System Improvements. If the new or revised access point is in part due to a new, expanded, or substantial change in current or planned future development or land use, demonstrate coordination has occurred with the property developers. Describe the commitments agreed upon to assure adequate collection and dispersion of the traffic resulting from the development with the adjoining local street network and Interstate access point. It is incumbent upon IDOT to ensure that highway facilities are developed in an orderly and coordinated manner to serve the public. The developer might, for example, be required to have certain parts of the local circulation system ready before ramps can be constructed or opened to traffic.

17. Status of Planning and NEPA. Confirm and report information relative to the status of the planning and NEPA processes.

18. Operational and Safety Analyses. FHWA policy states: "An operational and safety analysis has concluded that the proposed change in access does not have a significant adverse impact on the safety and operation of the Interstate facility (which includes mainline lanes, existing, new, or modified ramps, and ramp intersections with crossroad) or on the local street network based both the current and the planned future traffic projections. The analysis should, particularly in urbanized areas, include at least the first adjacent existing or proposed interchange on either side of the proposed change in access (23 CFR 625.2(a), 655.603(d) and 771.111(f)). The crossroads and the local street network, to at least the first major intersection on either side of the proposed change in access, should be included in this analysis to the extent necessary to fully evaluate the safety and operational impacts that the proposed change in access and other transportation improvements may have on the local street network (23 CFR 625.2(a) and 655.603(d)). Requests for a proposed change in access should include a description and assessment of the impacts and ability of the proposed changes to safely

and efficiently collect, distribute and accommodate traffic on the Interstate facility, ramps, intersection of ramps with crossroad, and local street network (23 CFR 625.2(a) and 655.603(d)). Each request should also include a conceptual plan of the type and location of the signs proposed to support each design alternative (23 U.S.C. 109(d) and 23 CFR 655.603(d))."

Highway Safety Manual methods, or other approved safety analysis methodologies, will be used to present a robust assessment of the potential safety effects of the changes in access. Typically, the current *Highway Capacity Manual* analysis procedures will be used for the operational analyses. Refer to #20 below for the specific tables, maps, and outputs required to summarize the operational analyses.

Analyze safety and operations on the mainline between the proposed new/revised access and the adjacent existing interchanges on either side. Extend the analyses as far along the mainline as is necessary to establish the extent and scope of the impacts. In urban areas with several relatively closely-spaced interchanges more than three locations may need to be included.

The safety and operational analyses must use current traffic data and extend to a design year that is 20 years after the date when the construction is scheduled to be complete.

Include the following in the analyses:

- Summarize the crash history of the affected Interstate segment, provide a comparison of this history with statewide averages for comparable facilities, and identify any over-represented crash types on the affected Interstate segment.
- Identify the anticipated safety implications of the proposed access point on mainline Interstate traffic, and at applicable nearby interchanges. Of critical importance are the geometrics associated with the proposal and shifts in nearby traffic patterns. Include a brief concluding statement summarizing the level of impact the proposed access point change is expected to have on safety performance of the mainline Interstate facility.
- Summarize the level of impact the proposed access point change is expected to have on traffic flow performance of the mainline Interstate facility.

The safety and operational analyses should typically include or directly refer to some or all of the information in Items 19 and 20.

19. Interchange Drawing. For the preferred and analyzed alternative, provide a dimensioned, detailed drawing of the design elements and a comparison to existing conditions. Include, as applicable:

- project limits,
- adjacent interchange(s),
- ramp to be added and removed,

- relocation of ramp gores,
- travel lanes and shoulder widths,
- ramp radii,
- ramp grades,
- acceleration lane lengths,
- deceleration lane lengths,
- taper lengths,
- auxiliary lane lengths,
- auxiliary/operational lane(s), and
- collector/distributor road(s).

Together, the drawing and report should identify all presently known pertinent engineering design details of the proposed change. Clearly identify any design exceptions and compare them with the latest BDE and AASHTO criteria.

Include a separate drawing showing the traffic volumes for all turning movements as well as mainline, ramp, and local road traffic volumes. Include current and design year ADTs and DHVs (Refer to the following section for details).

20. Highway Capacity Analysis. Use the current version of the *Highway Capacity Software* (HCS), for the operational analyses, supplemented by modeling as agreed by BDE and FHWA. Include all the following information and engineering analyses unless otherwise agreed to by BDE and FHWA:

    a. Existing Peak Hour Volumes. Provide a plan view map, with ramps and mainline through lanes labeled with Existing “AM Peak Hour” and “PM Peak Hour” volumes.

    b. Design Year No-Build Peak Hour Volumes. Provide a plan view map, with ramps and mainline through lanes labeled with the Design Year No-Build “AM Peak Hour” and “PM Peak Hour” volumes.

    c. Design Year Build Peak Hour Volumes. Provide a plan view map, with ramps and mainline through lanes labeled with the Design Year Build “AM Peak Hour” and “PM Peak Hour” volumes.

    d. Summary of Operational Analysis. As applicable, provide a table listing the “Freeway LOS”, “Ramp LOS”, “Weave LOS”, and “Non-Weave LOS” for the corresponding Existing AM/PM, Design Year “No-Build” AM/PM, and Design Year “Build” AM/PM for on-ramps, off-ramps, and through lanes.

    e. Existing Peak Hour Levels of Service. Provide a plan view map, with ramps, mainline through lanes, and crossroads labeled with calculated Existing “AM Peak Hour Level of Service” values and “PM Peak Hour Level of Service” values.

f. Design Year No-Build Peak Hour Levels of Service. Provide a plan view map, with ramps, mainline through lanes, and crossroads labeled with calculated Design Year No-Build “AM Peak Hour Level of Service” values and “PM Peak Hour Level of Service” values.

g. Design Year Build Peak Hour Levels of Service. Provide a plan view map, with ramps, mainline through lanes, and crossroads labeled with calculated Design Year Build “AM Peak Hour Level of Service” values and “PM Peak Hour Level of Service” values.

h. Basic Freeway Segments Analyses of Existing Conditions. Provide program outputs for adjacent freeway segments.

i. Basic Freeway Segments Analyses of the Design Year “No-Build” Conditions. Provide program outputs for all adjacent freeway segments.

j. Basic Freeway Segments Analyses of the Design Year “Build” Conditions. Provide program outputs for all adjacent freeway segments.

k. Ramp Junction Analyses of the Existing Conditions. Provide program outputs for all ramp junctions.

l. Ramp Junction Analyses of the Design Year “No-Build” Conditions. Provide program outputs, including queue analysis, for all ramp junctions.

m. Ramp Junction Analyses of the Design Year “Build” Conditions. Provide program outputs, including queue analysis, for all ramp junctions.

n. Weave Area Analyses of the Existing Conditions. Provide program outputs for all weaving areas.

o. Weave Area Analyses of the Design Year “No-Build” Conditions. Provide program outputs for all weaving areas.

p. Weave Area Analyses of the Design Year “Build” Conditions. Provide program outputs for all weaving areas.

37-2 GENERAL DESIGN CONSIDERATIONS

37-2.01 Interchange Spacing

Where interchanges are spaced farther apart, freeway operations, level of service, and safety between connecting facilities are improved. Desirably, the spacing between interchanges on the average should not be less than 2 miles (3 km) in urban areas, 4 miles (6 km) in suburban areas, and 7.5 miles (12 km) in rural areas. These values allow adequate distances for an entering driver to adjust to the freeway environment, for proper weaving maneuvers between entrance and exit ramps, and for adequate signing distances. However, considering the effects of existing streets and highways, traffic operations, and social considerations, the spacing between adjacent interchanges may vary considerably. The minimum distance between adjacent interchanges should not be less than 1 mile (1.5 km) in urban areas, 2 miles (3 km) in suburban areas, and 3 miles (5 km) in rural areas. In urban areas, a spacing of less than 1 mile (1.5 km) may be developed by using grade-separated ramps or collector-distributor roads.

37-2.02 Basic Number of Lanes

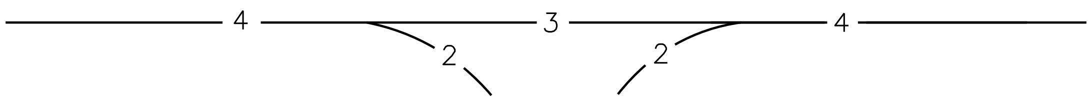
The basic number of lanes is the minimum number of lanes designated and maintained over a significant length of a route based on the overall operational needs of that section. The number of lanes should remain constant over short distances. For example, do not drop a lane at the exit of a diamond interchange and then add it at the downstream entrance simply because the traffic volume decreases between the exit and entrance ramps. Likewise, do not drop a basic lane between closely spaced interchanges simply because the estimated traffic volume does not warrant the higher number of lanes. Lane drops should only occur where there is general lowering of the traffic volumes on the freeway route as a whole.

37-2.03 Lane Balance

Lane balance refers to certain principles that apply at freeway exits and entrances:

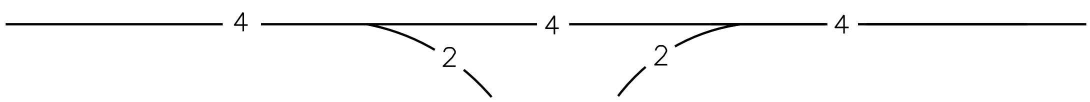
1. Exits. The number of approach lanes on the highway should equal the sum of the number of mainline lanes beyond the exit plus the number of exiting lanes minus one; see Figure 37-2.A. An exception to this principle would be at cloverleaf loop ramp exits that follow a loop ramp entrance or at exits between closely spaced interchanges (e.g., interchanges where the distance between the taper end of the entrance terminal (1 ft (300 mm) stub) and the beginning taper (1 ft (300 mm) stub) of the exit terminal is less than 1500 ft (450 m) and a continuous auxiliary lane is used between the terminals). In these cases, the auxiliary lane may be dropped at a single-lane exit with the number of lanes on the approach roadway being equal to the number of through lanes beyond the exit plus the lane on the exit.

2. Entrances. At entrances, the number of lanes beyond the merging of the two traffic streams should be not less than the sum of the approaching lanes minus one; see Figure 37-2.A.



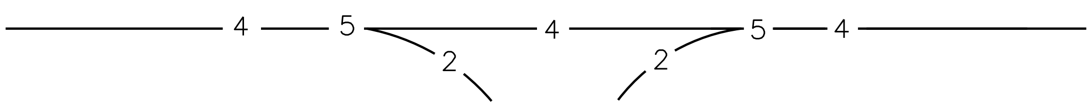
LANE BALANCE BUT NO COMPLIANCE WITH BASIC NUMBER OF LANES

-A-



NO LANE BALANCE BUT COMPLIANCE WITH BASIC NUMBER OF LANES

-B-



COMPLIANCE WITH BOTH LANE BALANCE AND BASIC NUMBER OF LANES

-C-

$N_C = N_F + N_E - 1$

Max: $N_C = N_F + N_E$

Min: $N_C = N_F + N_E - 1$

Where:

N_C =Number of Lanes for Combined Traffic

N_F =Number of Lanes on Freeway

N_E =Number of Lanes on Exit or Entrance Ramp

LANE BALANCE EQUATIONS

-D-

COORDINATION OF LANE BALANCE AND BASIC NUMBER OF LANES

Figure 37-2.A

3. Travel Lanes. Reduce the number of travel lanes on the freeway only one lane at a time.

For example, dropping two mainline lanes at a two-lane exit ramp would violate the principle of lane balance. One lane should provide the option of remaining on the freeway. Lane balance would also prohibit immediately merging both lanes of a two-lane entrance ramp into a highway mainline without the addition of at least one additional lane beyond the entrance ramp. Figure 37-2.A illustrates how to coordinate lane balance and the basic number of lanes at an interchange. Figure 37-2.A also illustrates how to achieve lane balance at the merging and diverging points of branch connections.

37-2.04 Capacity and Level of Service

The capacity of an interchange will depend upon the operation of its individual elements that include:

- basic freeway section where interchanges are not present,
- freeway ramp terminals,
- weaving areas,
- ramp proper,
- collector-distributor roadways, and
- ramp/crossroad intersections.

The basic capacity reference is the *Highway Capacity Manual* (HCM). The HCM and the *Highway Capacity Software* (HCS) provide the analytical tools required to analyze the level of service for each element listed above. Other capacity analysis programs and techniques may be used provided they are approved by BDE. To be eligible for approval, the output results of other programs and techniques must compare closely with the HCS.

Level of service values presented in Chapter 44 for freeways will also apply to interchanges. Desirably, the level of service of each interchange element should be equal to the level of service provided on the basic freeway section. Individual elements should not operate at more than one level of service below that of the basic freeway section. In addition, the operation of the ramp/crossroad intersection in urban areas should not impair the operation of the mainline. This will likely involve a consideration of the operational characteristics on the minor road for some distance in either direction from the interchange. For most projects, the district geometrics engineer will be responsible for conducting or reviewing the capacity analysis at interchanges.

37-2.05 Auxiliary Lanes

As applied to interchange design, auxiliary lanes are most often used to comply with the principle of lane balance, to increase capacity, to accommodate weaving, or to accommodate entering and exiting vehicles. Operational efficiency of the freeway may be improved if a continuous auxiliary lane is provided between entrance and exit terminals where interchanges are closely spaced. An auxiliary lane may be dropped at an exit if properly signed and designed. The following statements apply to the use of an auxiliary lane within or between interchanges:

1. Within Interchange. Figure 37-2.B provides the basic schematics of alternative designs for adding and dropping auxiliary lanes within interchanges. The selected design will depend upon traffic volumes for the exiting, entering, and through movements.

2. Between Interchanges. Where interchanges are closely spaced, the designer should provide an auxiliary lane where the distance between the taper end of the entrance terminal and beginning taper of the exit taper is less than 1500 ft (450 m). Figure 37-2.C illustrates where an auxiliary lane is used between two closely spaced interchanges.

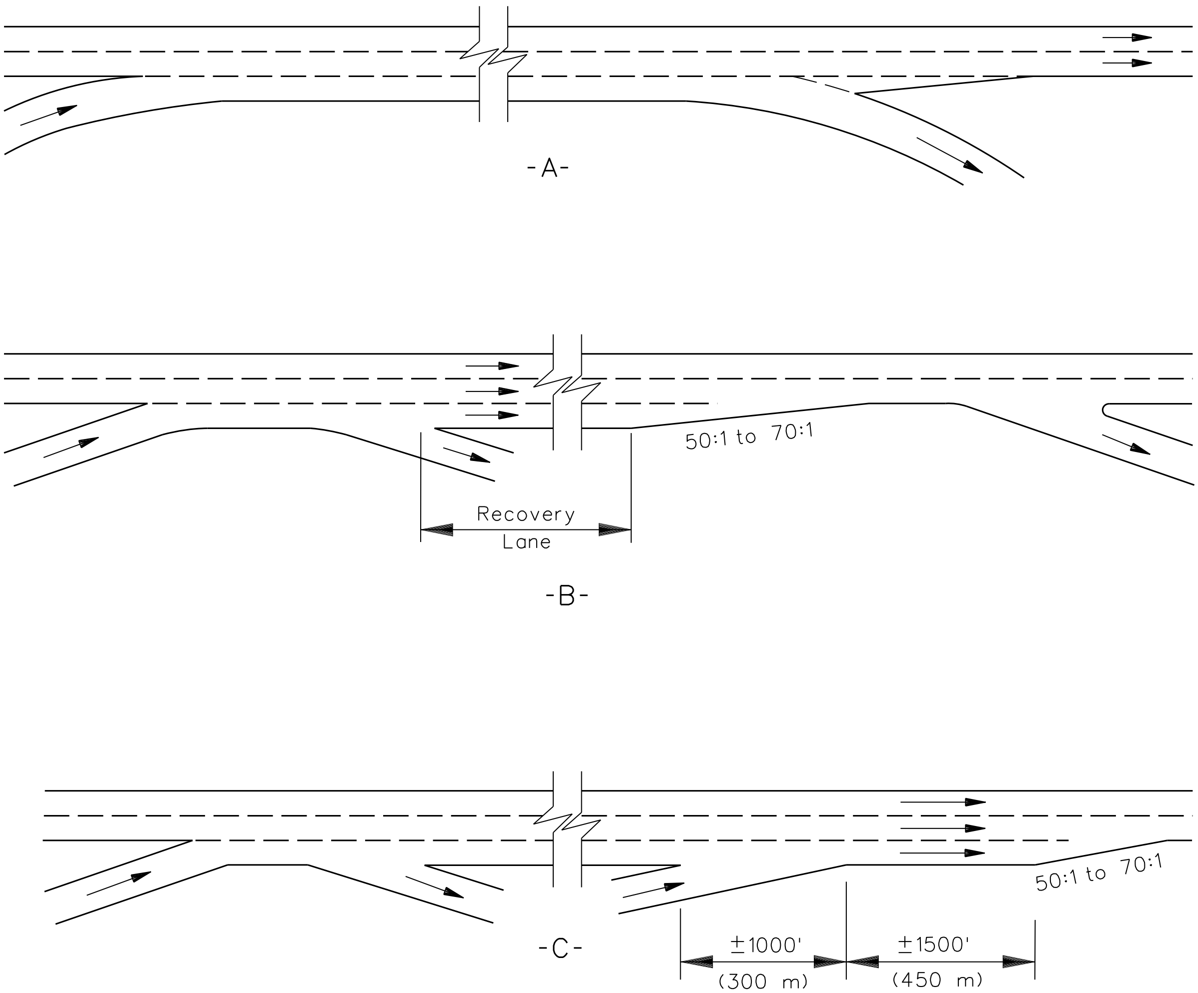
Auxiliary lane drops beyond the interchange may be merged approximately 2500 ft (750 m) beyond the influence of the last interchange. Design details for auxiliary lane drops beyond an interchange are provided in Chapter 44. Design details for dropping auxiliary lanes at exits or adding them at entrances are provided in Section 37-6. If the auxiliary lane is dropped at a single lane exit, a recovery area beyond the gore should be provided as shown in Figure 37-2.B. Where certain sight distance restrictions are unavoidable (e.g., on structures), the recovery area should be extended 500 ft to 1000 ft (150 m to 300 m) downstream from the exit. This distance should be increased to 1500 ft (450 m) or more with complex designs.

37-2.06 Route Continuity

The major route should flow continuously through an interchange. For freeway and expressway routes that change direction, the driver should not be required to change lanes or exit to remain on the major route. Route continuity without a change in the basic number of lanes is consistent with driver expectancy, simplifies signing, and reduces the decision demands on the driver. Interchange configurations should not necessarily favor the heavier traffic movement. Other marked routes that turn or exit at an interchange can be accomplished by a single-lane ramp if capacity is adequate. If these ramps are longer than ½ mile (800 m), consider providing a two-lane ramp for better traffic operations.

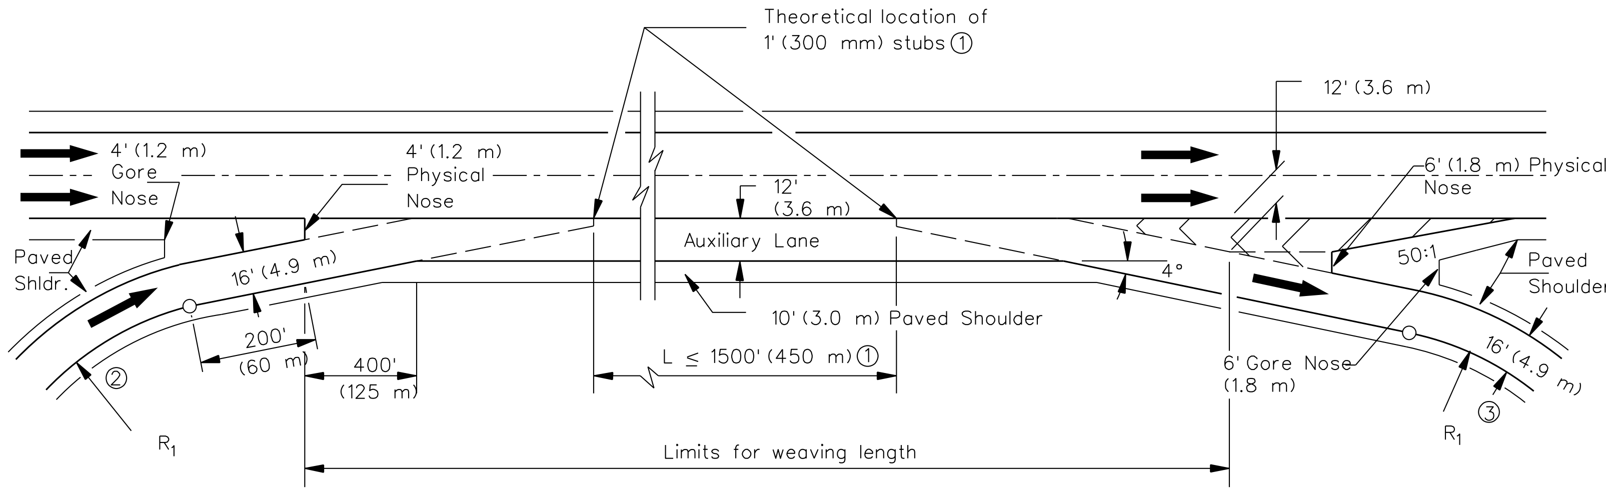
37-2.07 Uniformity

Interchange configurations should be uniform from one interchange to another. All ramps should exit and enter on the right except under highly unusual conditions. Dissimilar arrangements between interchanges can cause confusion resulting in undesirable lane switches, reduced speeds, etc., especially in urban areas where interchanges are closely spaced.



AUXILIARY LANES WITHIN AN INTERCHANGE

Figure 37-2.B



Notes:

1. *If the distance between the theoretical 1 ft (300 mm) stubs is less than or equal to 1500 ft (450 m), provide an auxiliary lane connecting the entrance terminal to the exit terminal even if the auxiliary lane would not be required by a weaving analysis.*

2. *See Figure 37-6.L for Entrance Ramp Terminal with auxiliary lane.*

3. *See Figure 37-6.B for Exit Terminal with auxiliary lane.*

AUXILIARY LANE BETWEEN TWO INTERCHANGES

Figure 37-2.C

37-2.08 Left-Hand Ramps

Avoid the use of left-hand exit and entrance ramps. They are less efficient operationally than right-hand ramps and may present a serious crash potential. They also introduce an undesirable element of non-uniformity into the design of a freeway system that leads to confusion and, in some cases, hazardous behavior by drivers. The disadvantages of left-hand ramps greatly outweigh the potential for directional turning movements and the increased flexibility of design. Therefore, where a left-hand ramp is being considered, approval of the design and analysis must be obtained from BDE for the Interchange Design Study (IDS).

37-2.09 Signing and Marking

Proper interchange operations depend partially on the compatibility between its geometric design and the traffic control devices at the interchange. The proper application of signs and pavement markings will increase the clarity of paths to be followed, safety, and operational efficiency. The logistics of signing along a highway segment will also impact the minimum acceptable spacing between adjacent interchanges. See the Bureau of Operations Departmental Policy TRA-14, and use the current edition of the Bureau of Operation's *Traffic Policies and Procedures Manual*, the *Pavement Marking Selection, Installation, and Inspection Manual*, the *Manual on Uniform Traffic Control Devices,* and the *Illinois Highway Standards* to select and design the appropriate pavement markings and crosswalks at interchanges. Chapter 57 provides general guidelines for the placement of pavement markings and reflectorized markers. For complex interchanges and location/design studies involving closely spaced interchanges, include a preliminary signing plan with the IDS.

37-2.10 Ramp Metering

Ramp metering may be used to improve freeway operations. Ramp metering consists of traffic signals installed on entrance ramps before the entrance terminal to control the number of vehicles entering the freeway. The Bureau of Operations will determine the need for ramp metering. If ramp metering is used, the designer will need to coordinate with the Bureau of Operations to determine the placement of the ramp signal to ensure that there is sufficient storage area before the ramp signal and that sufficient acceleration distance is available beyond the signal to allow a vehicle to reach the freeway operating speed.

37-2.11 Weaving Sections

Weaving sections are highway segments where the pattern of traffic entering and exiting at contiguous points of access results in vehicular paths crossing each other. The turbulent effect of weaving operations can result in reduced operating speeds and levels of service for the through traffic. Weaving sections may be eliminated at an interchange between two major highways by using directional or semi-directional connections or by using collector-distributor roadways.

Consider the following for weaving sections:

1. Weave Length. Weaving sections on freeways other than cloverleafs should be at least 1000 ft (300 m) or the length determined using the *Highway Capacity Manual* (HCM), whichever is greater. Section 37-3.06(b) discusses the minimum design criteria for one-sided weaving sections at cloverleaf interchanges.

2. Level of Service. The level of service of a weaving section should be the same as the adjacent mainline; however, at a minimum, it can be one level lower. A higher volume in weaving sections may be accommodated and their adverse impact on through traffic minimized by providing the weaving section on collector-distributor roadways. Section 37-4.02 discusses the use and design of collector-distributor roadways.

37-2.12 Grading and Landscaping

Consider the grading around an interchange early in the design process. Alignment, fill and cut sections, median widths, lane widths, drainage, structural design, and infield contour grading, all affect the aesthetics of the interchange. Properly graded interchanges allow the overpassing structure to blend naturally into the terrain. In addition, ensure that the crossroad and ramp slopes are not too steep to compromise safety and that they can support plantings that prevent erosion and enhance the appearance of the area. Flatter slopes also allow easier maintenance. Transitional grading between cut and fill slopes should be long and natural in appearance. The designer must ensure that plantings will not affect the sight distance within the interchange and that larger plantings are a significant distance from the traveled way. See Chapter 59 for additional guidelines.

37-2.13 Review for Ease of Operation

Review the proposed design from the driver's perspective. Examine all possible movements that a motorist might encounter. Several computer programs are available that allow a designer to test drive the design. Review the plans for areas of possible confusion, sufficient weaving and sight distances, proper signing, and ease of operation.

37-2.14 Geometric Design Criteria

Design all roadways through an interchange with the same criteria as used for the approaches including design speed, sight distance, horizontal and vertical alignment, cross section, and roadside safety elements. The applicable chapters in Parts IV, Roadway Design Elements, and V, Design of Highway Types, present the geometric design criteria that apply to the roadways through interchanges. In addition, consider the following:

1. Functional Classification. Determine the crossroad functional classification using the criteria in Chapter 43.

2. Design Year. Typically, use a 20-year design period based on the anticipated opening date of the facility.

3. Design Speed. The crossroad design speed will be based on its functional classification and its urban or rural classification; see the geometric design tables in Part V, Design of Highway Types. For rural crossroads (e.g., county highways, township roads), the minimum design speed of the crossroad through the interchange should be 55 mph (90 km/hr).

4. Horizontal Alignment. In general, lay out the alignment of the freeway/expressway and crossroad through the interchange on a tangent. Where this is not practical, consider the following:

   a. Freeway Mainline. Avoid curves to the left.

   b. Freeway Ramp Terminals. Lay out the freeway alignment so that only one exit terminal departs from the mainline curving to the right, or design the mainline curve to lie entirely within the limits of the interchange and away from the exit and entrance terminals.

   c. Superelevation. Desirably, lay out the horizontal alignment so that superelevation and superelevation transitions will not be required through the freeway ramp terminals or through the ramp/crossroad intersection.

   d. Crossroad. Where a curve is necessary, provide a significantly large horizontal curve so that superelevation is not required on the crossroad.

   e. Structures. For a freeway or expressway over a crossroad, place the PC or PT of the horizontal curve 400 ft (120 m) or more from the back of the bridge abutment.

5. Vertical Alignment. Vertical profiles for both roadways through the interchange should be as flat as practical. Where compromises are necessary, use the flatter grade on the major facility. In addition, the designer should consider the following:

   a. Sight Distance. To improve the sight distance to exit gores, locate exit ramp terminals and major divergences where the mainline is on an upgrade.

   b. Ramps. Avoid creating a hidden ramp roadway in the vertical plane. Also, provide flat approach grades adjacent to the crossroad. For additional information on storage platforms at the ramp/crossroad intersection, see Sections 36-1.06 and 37-5.01.

   c. Exit Ramp Terminals. Where a freeway or expressway is proposed to cross over the crossroad, locate the exit ramp terminals on the mainline no closer than 1000 ft (300 m) from the high point of a crest vertical curve on the mainline. This will ensure that no hidden ramps exist and will provide for safer operations at the exit ramp terminal.

   d. Turning Trucks. Large trucks may become unstable when executing a nonstop, left turn from a crossroad on a downgrade. The combination of a downgrade, sharp turning maneuvers into a ramp, and reverse superelevation may produce instability in large trucks. Therefore, the maximum grade for all crossroads associated with these conditions is desirably 2% through the ramp/crossroad terminal. For existing crossroads to remain in place, limit the downgrade to 3%. At a maximum, limit the up and downgrades to 4%.

6. Cross Sections. When designing the crossroad through the interchange, consider the following:

   a. Widths. In general, carry the approach cross section of the major facility through the interchange. See Sections 37-5.01 and 37-5.02 for typical cross sections of a crossroad through an interchange.

   b. Raised-Curb Medians. Raised-curb medians are used throughout the limits of the interchange. This facilitates the construction of separate left-turn lanes and promotes the proper use of the ramp/crossroad intersections. To determine the crossroad channelized approach in conjunction with the crossroad design speed and number of lanes on the crossroad, see the IDOT publication *Transitional Approaches to Channelized Intersections* for additional information. Chapter 36 also provides guidance on the design of channelized left-turn lanes and islands.

   c. Side Slopes. Side slopes on the crossroad through the interchange area should be 1V:4H or flatter. Chapter 34 and Part V further discuss roadway side slopes.

7. Sight Distance. Because of the additional demand placed on the driver at an interchange, the designer should consider the following sight distance elements:

   a. Stopping Sight Distance. Provide adequate stopping sight distance on both intersecting highways throughout the interchange and on all ramps. Check both the vertical and horizontal alignment to ensure that the location of piers, abutments, structures, bridge rails, vertical curves, etc., will not restrict sight distance. Chapter 32 discusses the application of horizontal sight distance. Chapter 33 discusses the application of vertical sight distance.

   b. Decision Sight Distance. Desirably, provide decision sight distance to all decision points (e.g., exit and entrance terminals). Driver expectancy should not be violated; see Chapter 31.

   c. Intersection Sight Distance. Section 36-6 discusses intersection sight distance (ISD), which is also applicable at ramp/crossroad intersections (non-merging sites). Section 37-5.01 provides additional ISD guidance that should be considered at ramp/crossroad intersections that are stop controlled.

8. Ramp/Crossroad Intersections. When designing the ramp/crossroad intersection, consider the following:

    a. Angle of Ramp Intersection. To determine the appropriate angle for the ramp/crossroad intersection, see Section 37-5.

    b. Access Control. To determine the required length of access control along the crossroad at the interchange, see Chapter 35.

    c. Left-Turn Lanes. Select the appropriate left-turn lane lengths based on the design speed of the crossroad and/or the required storage lengths; see Section 36-3.02. For guidance on the design of left-turn lanes across or under a structure, see Section 37-5.

    d. Design Vehicle. Check the ramp/crossroad intersection with the applicable design vehicle turning template or use a computer-simulated turning template program. As discussed in Section 36-1.08, use the WB-67 (WB-20) design vehicle at all ramp/crossroad intersections.

    e. Design Users. Where present and permitted users along the crossroad, pedestrians and bicyclists should be treated as design users of the facility and given the same consideration as the design vehicle.

    f. Corner Islands. See Section 36-2.02 when designing or modifying corner islands at ramp/crossroad intersections.

9. Mainline/Crossroad Point of Intersection. Once Items 1 through 8 above have been determined, the designer must decide where the mainline alignment best intersects with the crossroad. The overall size of the interchange, crossroad gradelines, required length of access control along the crossroad, access to property at the ends of access control on the crossroad, and topography are the most influential factors in this determination. Complete this investigation before the detailed design of an interchange is initiated.

10. Structures. Chapter 39 provides the geometric design criteria for structures designed in conjunction with interchanges.

11. Trucks. Check truck merging speeds at entrance terminals. This typically is only critical where the:

    - mainline profile is on an upgrade of 3% or greater,
    - the ramp profile is on a steep upgrade, and/or
    - the mainline volume is heavy.

37-2.15 Operational/Safety Considerations

Operations and safety are important considerations in interchange design. The following summarizes several major considerations:

1. Exit Ramps. For exit ramps, consider the following:

    - Provide decision sight distance, where practical, to the freeway exit; see Chapter 31. Desirably, use the pavement surface for the height of object (i.e., 0.0 inches (0.0 mm)).

    - Ramps should depart from the mainline where there will be no vertical curvature to restrict visibility along the ramp. Avoid ramp designs that drop out of sight.

    - Avoid locating exit terminals where the mainline curves to the left.

    - Proper advance signing of exits is essential to allow necessary lane changes before the exit.

    - Provide sufficient distance to allow safe deceleration from the freeway design speed to the design speed of the first governing geometric feature on the ramp, typically a horizontal curve.

2. Entrance Ramps. Provide an acceleration distance of sufficient length to allow a vehicle to attain an appropriate speed for merging. Where entrance ramps enter the mainline on an upgrade, the acceleration distance may need to be lengthened, or an auxiliary lane may be required to allow vehicles to reach a safe speed prior to merging.

3. Driver Expectancy. Ensure that the interchange is designed to conform to the principles of driver expectation. These may include the following:

    - Avoid left-hand exit or entrance terminals. Drivers expect single-lane exit and entrance terminals to be located on the right side of the freeway.

    - Do not locate exit ramps so that it gives the appearance of a continuing mainline tangent as the mainline curves to the left.

    - Do not mix operational patterns between interchanges, lane continuity, or interchange types.

    - Provide lane balance and basic number of lanes on the freeway.

    - Provide sufficient spacing between interchanges to allow proper signing distances to decision points.

4. Fixed Objects. Because of traffic operations at interchanges, many fixed objects may be located within interchanges (e.g., signs at exit gores, bridge piers, rails). Avoid locating these objects near decision points, make them breakaway, or shield them with barriers or impact attenuators. Make any concrete footings flush with the ground line. See Chapter 38 for additional guidance on roadside safety.

5. Controlled Ramp Terminals. The designer must ensure that ramp/crossroad intersections have sufficient capacity so that the queuing traffic at the crossroad

intersection does not backup onto the freeway. Also, sufficient access control and intersection sight distance must be maintained along the crossroad to allow the ramp intersection to work properly.

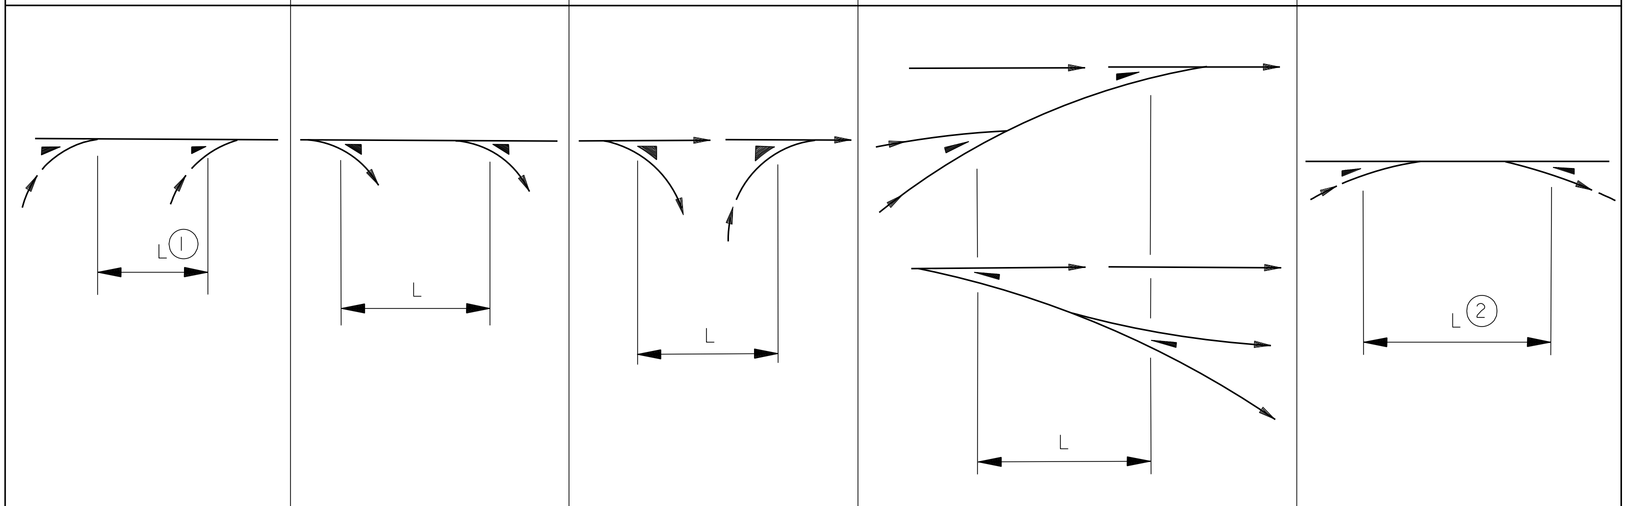
6. Wrong-Way Maneuvers. Provide channelized medians, islands, and adequate signing to minimize wrong-way possibilities. Avoid designs that may result in poor visibility, confusing ramp arrangements, or inadequate signing.

7. Weaving. Areas of vehicular weaving may create a high demand on driver skills and attentiveness. Where practical, design interchanges without weaving areas by changing the sequence of ramps, increasing the spacing between ramps, or removing the weaving areas from the highway mainline by using collector-distributor roads.

8. Pedestrians and Bicyclists. Use signing and lane markings to increase awareness of pedestrians and bicyclists. Signing, crosswalks, barriers, over and underpasses, bridge sidewalks, and other traffic control devices may be required to manage traffic movements and to control pedestrian and bicycle movements.

37-2.16 Distance Between Successive Freeway Ramp Terminals

Successive freeway ramp terminals may be placed relatively close to each other especially in urban areas. The distance between the terminals should provide for vehicular maneuvering, signing, and capacity. Figure 37-2.D provides recommended guidelines for spacing distances of various freeway ramp terminals. The criteria in Figure 37-2.D should be considered for the initial planning stages of interchange location. The final decision on the spacing between freeway ramp terminals must satisfy the level-of-service criteria. This will be determined by conducting a detailed capacity analysis using the *Highway Capacity Manual*. Where the distance between the tapers of successive entrance and exit terminals is less than 1500 ft (450 m), connect the two terminals with an auxiliary lane and provide a recovery area beyond the exit terminal as illustrated in Figure 37-6.B.



EN-EN	EX-EX		EX-EN		Directional Ramps		EN-EX (Weaving)

FDR - Freeway Distributor Road CDR - Collector-Distributor Road EN - Entrance EX - Exit

Notes:

1. *Distance is measured from the end of taper (1 ft (300 mm) stub) to the gore nose and desirably should be 400 ft (120 m) or more; see Figure 37-6.K.*
2. *For cloverleaf loop ramps, this distance is determined from Figure 37-3.N and a weaving analysis.*
3. *The lengths are based on operational experience and the need for flexibility and adequate signing. They should be checked according to the procedure in the* Highway Capacity Manual. *The larger of the values is suggested for use. Also, a procedure for measuring the length of the weaving section is given in the* Highway Capacity Manual.

RAMP TERMINAL SPACING GUIDELINES

Figure 37-2.D

37-3 INTERCHANGE TYPES AND LAYOUTS

37-3.01 General

In Illinois, there are six basic interchange types — the diamond, the cloverleaf, the partial cloverleaf, the trumpet, the directional, and the semi-directional. These interchange types, and variations within each type, permit adaptation to traffic needs, available right-of-way, terrain, and cultural features. The following sections discuss these basic interchange types and the design elements for laying out the interchange. The FHWA publication *Alternative Intersection/Interchange: Informational Report (AIIR)* discusses alternative interchange designs (e.g., diverging diamond interchange, displaced left-turn interchange). Each interchange must be designed to fit the individual site considerations. The final design may be a minor or major modification of one of the basic types or may be a combination of two or more basic types. Sections 37-2, 37-4, 37-5, and 37-6 provide the general design criteria for the individual elements of the interchange.

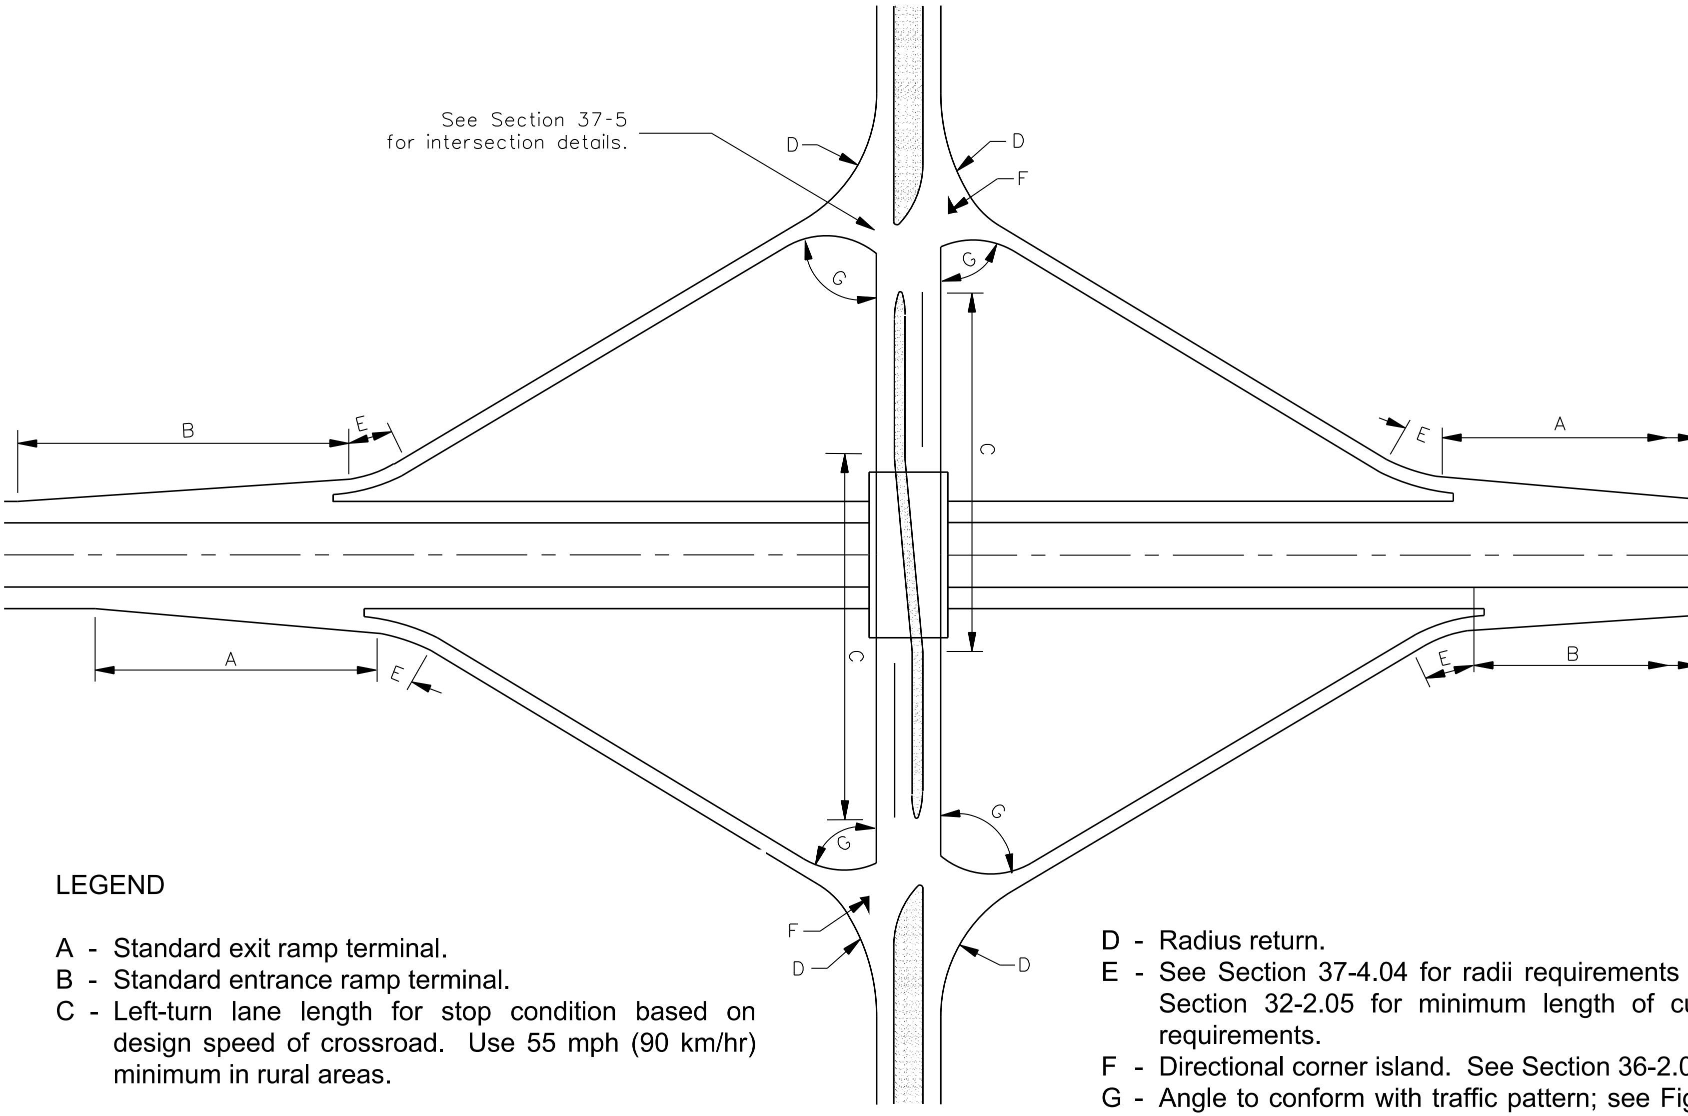
37-3.02 Conventional Diamond

37-3.02(a) General

The conventional diamond is the simplest and most common interchange type. Diamonds include one-way diagonal ramps in each quadrant and two intersections at the crossroad. With proper treatments at the crossroad, the diamond interchange can accommodate a wide variety of circumstances in suburban and urban areas where the crossroad operating speeds are 45 mph (70 km/hr) or less. The diamond is usually the best interchange choice where the intersecting road is not access controlled. Figures 37-3.A and 37-3.B illustrate typical diamond interchanges. Some of its advantages and disadvantages include:

Advantages

- All exits from the mainline occur before reaching the crossroad structure and entrances occur after the structure. This conforms to driver expectancy and therefore minimizes confusion.
- All traffic can enter and exit the mainline at relatively high speeds.
- At the crossroad, adequate sight distance can usually be provided, and the operational maneuvers are consistent with other intersections on the crossroad.
- They require less right-of-way than other interchange types.
- The diamond configuration easily allows modifications to provide greater ramp capacity, if needed in the future.
- Their common usage has resulted in a high level of driver familiarity.
- Typically, it is the least expensive of all interchange types.



LEGEND

A - Standard exit ramp terminal.
B - Standard entrance ramp terminal.
C - Left-turn lane length for stop condition based on design speed of crossroad. Use 55 mph (90 km/hr) minimum in rural areas.
D - Radius return.
E - See Section 37-4.04 for radii requirements and Section 32-2.05 for minimum length of curve requirements.
F - Directional corner island. See Section 36-2.02.
G - Angle to conform with traffic pattern; see Figure 37-3.C.

I - Minimum tangent distance between curves.
J - Minimum 67% length of superelevation runoff. Tangent length must not overlap into radius return.

DIAMOND INTERCHANGE LAYOUT
(75 Degree 0R 90 Degree Design)

Figure 37-3.B

Disadvantages

- Traffic is subject to stop-and-go operations rather than free flow.
- In suburban and urban areas, signalization is generally required at the crossroad intersections. These signals should be interconnected for progression.
- They require right-of-way in all four quadrants of the interchange.
- A diamond has a greater potential for wrong-way entry onto the ramps than, for example, a full cloverleaf. Raised-curb channelization is used on the crossroad to minimize the likelihood of driver confusion and wrong-way maneuvers.

37-3.02(b) Left-Turn Lanes

The first step in laying out diamond interchange ramps is to determine the location of the ramp/crossroad intersections. The length of the overlapping left-turn lanes generally will determine the location of these intersections; see Figure 37-5.A. Section 36-3.02 provides the criteria for determining the length for these separate left-turn lanes. Once the lengths are determined and located away from the grade separation, set the left-turn control radii and establish the baseline control; see Figures 37-5.D through 37-5.G.

37-3.02(c) Ramp/Crossroad Intersections

Figures 37-5.D through 37-5.G illustrate typical diamond ramp/crossroad intersections. Figure 37-3.C provides guidelines for determining allowable ramp/crossroad intersection angles where the crossroad is approximately perpendicular to the freeway. The preferred ramp/crossroad intersection angle is 90 degrees, but if avoidance of agricultural property or other adjacent right-of-way is desired, other angles are permitted according to Figure 37-3.C. The ramp angles in Figure 37-3.C are based on the volume of left-turning vehicles from either the crossroad or the ramp.

Left-Turn DHV at Ramp/Crossroad Intersection	Allowable Ramp/Crossroad Intersection Angles
125 or less	60°- 90°
125 - 250	75° - 90°
250 or more	90°

Note: This figure assumes the freeway and crossroad intersect at approximately 90°.

RAMP/CROSSROAD INTERSECTION ANGLES

Figure 37-3.C

37-3.02(d) Ramp Layout

Although the angle of ramp intersection with the crossroad is important, the complete development of ramp geometry may be influenced by a combination of other factors (e.g., conservation of agricultural land, avoiding existing development, angle of intersection of the crossroad with the freeway). Because the angle of the crossroad with the freeway is a major factor in determining the ramp alignment and length, the following design considerations are provided:

1. Freeway and Crossroad — Perpendicular. Where the crossroad is approximately perpendicular to the freeway, consider the following guidelines:

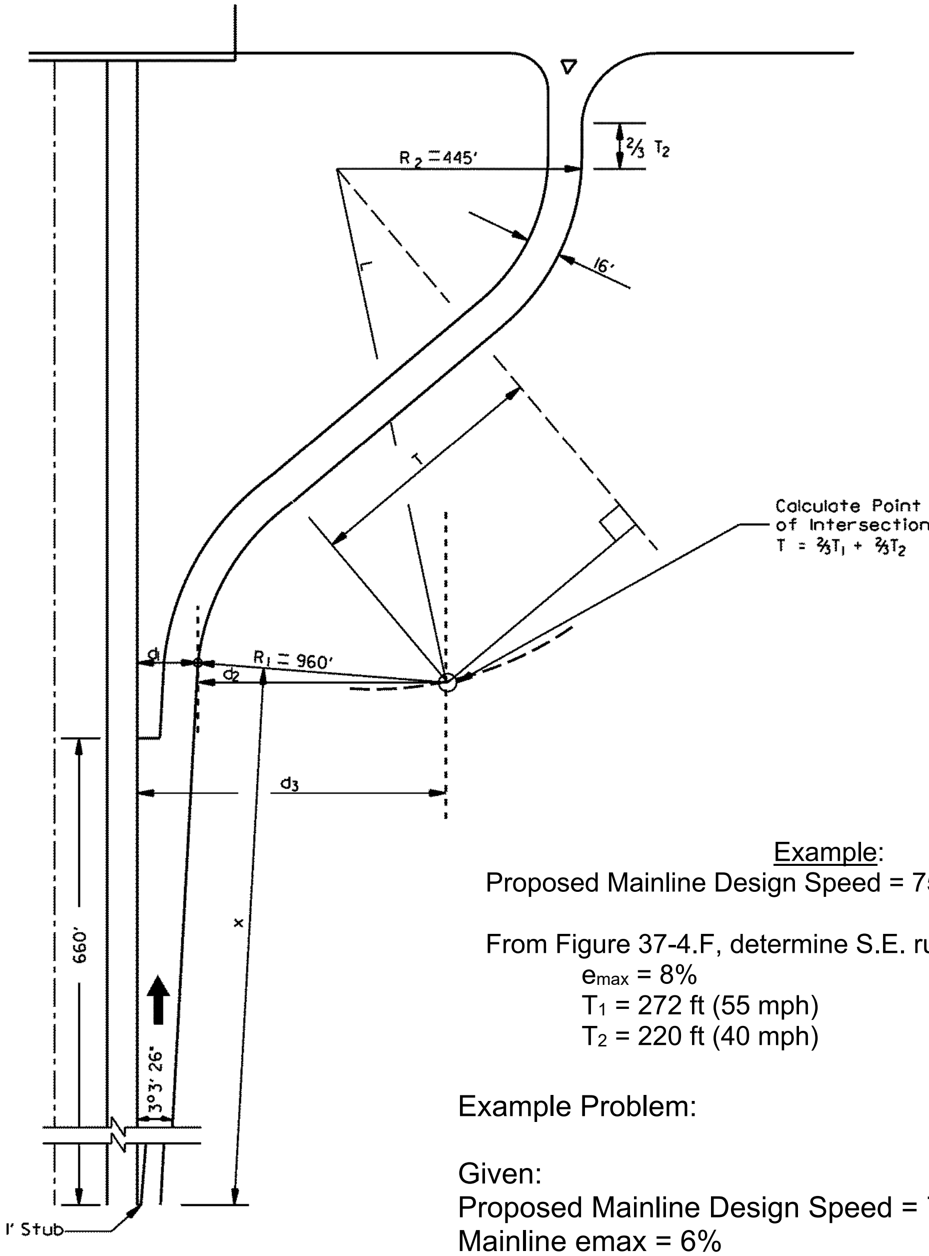
   a. Angle of Intersection. Figure 37-3.C provides the preferred ramp intersection angles with the crossroad. These angles are based on the number of left-turning vehicles on either the crossroad or the exit ramp.

   b. Number of Curves. With a 60° intersection angle, only one curve is required on the ramp; see Figure 37-3.A. For other angles of intersection, a second curve adjacent to the crossroad will generally be required. For rural ramps with a 75 degree intersection angle with the crossroad, design the ramp curve nearest to the crossroad with a minimum 30 mph (50 km/hr) design speed and, desirably, with a 40 mph (60 km/hr) design speed. In urban areas, the design speed should be at least 25 mph (40 km/hr) unless available right-of-way is highly restricted by existing development; see Figure 37-3.B.

   c. Minimum Tangent Length. The minimum tangent length between two reverse curves should be ($2/3T_1 + 2/3T_2$). T_1 and T_2 are the individual superelevation runoff lengths for each curve. See Figure 37-4.F for the applicable runoff lengths.

   d. Curve Locations. Where two curves are designed on an exit ramp, the curve nearest the freeway ramp terminal may be located by computing the center-to-center distance of the two curves. This center-to-center distance, "L," passes through a point of intersection with a line drawn parallel to the edge of the freeway and passing through the center of the curve located next to the freeway. This procedure is illustrated in Figure 37-3.D.

2. Freeway and Crossroad — Skewed. If the crossroad is skewed, in either direction, strict adherence to the guidelines for perpendicular intersections in Item 1 can result in unacceptable design features (e.g., excessive ramp lengths, short curve lengths, steep grades, indirect alignment). Therefore, design modifications are generally necessary. Under these conditions, give primary consideration to the ramp alignment rather than the intersection angle as determined from Figure 37-3.C. With skewed crossroads, the ramp alignment should be, in order of preference, one of the following:



<u>Example</u>:
Proposed Mainline Design Speed = 75 mph

From Figure 37-4.F, determine S.E. runoff length.

e_{max} = 8%

T_1 = 272 ft (55 mph)

T_2 = 220 ft (40 mph)

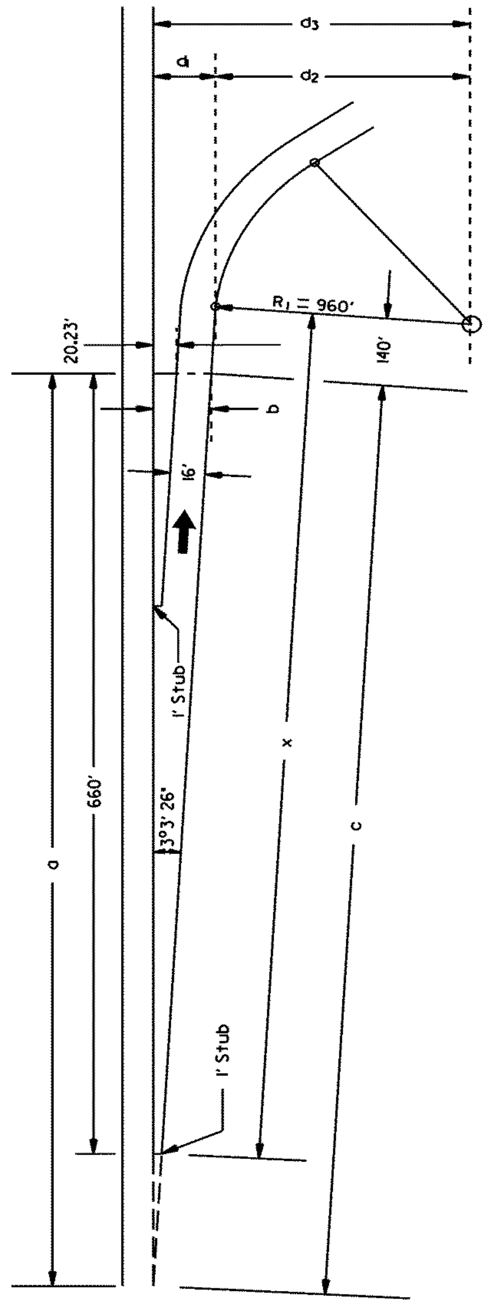
Example Problem:

Given:
Proposed Mainline Design Speed = 75 mph
Mainline emax = 6%
Ramp emax = 8%

Determine:
Values for x, T, L, d1, d2, and d3.

LOCATION OF INITIAL CURVE FOR AN EXIT RAMP
(Diamond Interchange)

Figure 37-3.D
(1 of 3)



LOCATION OF INITIAL CURVE FOR AN EXIT RAMP
(Diamond Interchange)

Figure 37-3.D
(2 of 3)

Solution:
From Figure 37-4.F, determine S.E. runoff length for R_1 and R_2:

T_1 = 272 ft (55 mph)
T_2 = 220 ft (40 mph)

$T = (2/3)\ T_1 + (2/3)\ T_2$
$T = (2/3)\ 272 + (2/3)\ 220$
T = 328.00 ft

From the law of triangles:

$a^2 + b^2 = c^2$

$c = \sqrt{a^2 + b^2}$

$b = \sqrt{c^2 - a^2}$

Using dimensions from *Highway Standard* 406101:

a = 660 + 1/Tan 3°3'26"
a = 678.72 ft

b = 20.23 + 16/Cos 3°3'26"
b = 36.25 ft

$c = \sqrt{(678.72)^2 + (36.25))^2}$

c = 679.69 ft

Calculate x, the length along the ramp alignment from the 1 foot stub to the point of curvature of the ramp:

x = 679.69 + 140 – 16 Tan 3°3'26" – (1/Sin 3°3'26")
x = 800.09 ft

$L = \sqrt{(960+445)^2 + (328)^2}$

L = 1442.78 ft

d_1 = (800.09 Sin 3°3'26") + 1
d_1 = 43.67 ft

d_2 = 960 Cos 3° 3′ 26″
d_2 = 958.63 ft

$d_3 = d_1 + d_2$
d_3 = 43.67 ft + 958.63 ft
d_3 = 1002.30 ft

LOCATION OF INITIAL CURVE FOR AN EXIT RAMP
(Diamond Interchange)
Figure 37-3.D
(3 of 3)

- a tangent ramp with a single curve adjacent to the freeway;
- reverse curves with radii connected by a tangent length greater than the minimum required for superelevation runoff lengths, see Item 1c above; or
- reverse curves with radii connected by a tangent equal to the minimum superelevation runoff needs, see Item 1c above.

In the design of the preferred alignment, the designer must also control the overall ramp length. Normally, the gore nose of a ramp should be located about 1250 ft (375 m) from the crossroad structure. If the first preference alignment cannot be developed with a gore within 1250 ft to 1400 ft (375 m to 425 m) of the structure, the second preference should be investigated and the third, if necessary, until an acceptable ramp length is achieved for both grade and directness.

37-3.03 Modified Diamond

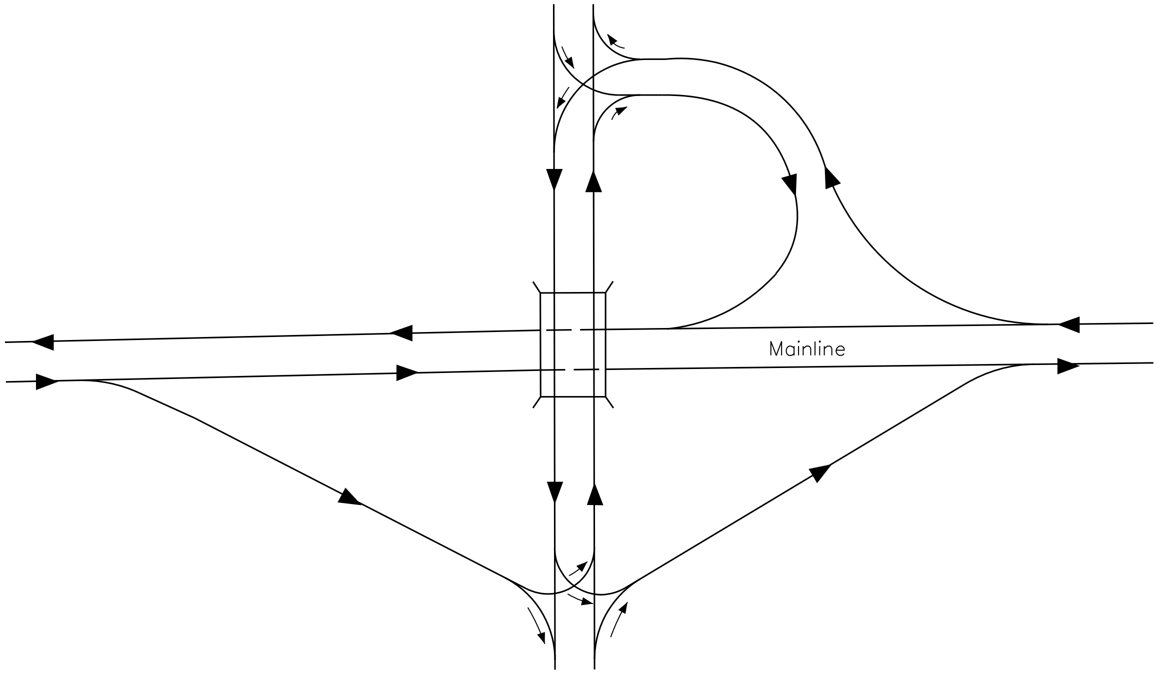
The modified diamond interchange is a combination of the diamond interchange and partial cloverleaf. Figure 37-3.E illustrates typical schematics of a modified diamond interchange. This design type is typically used where subdivisions, extensive commercial or industrial development, lakes, ponds, or other adverse topography and/or soil conditions are located in one of the interchange quadrants, making right-of-way acquisition, design, or construction unusually expensive. Some of the advantages and disadvantages of the modified diamond include:

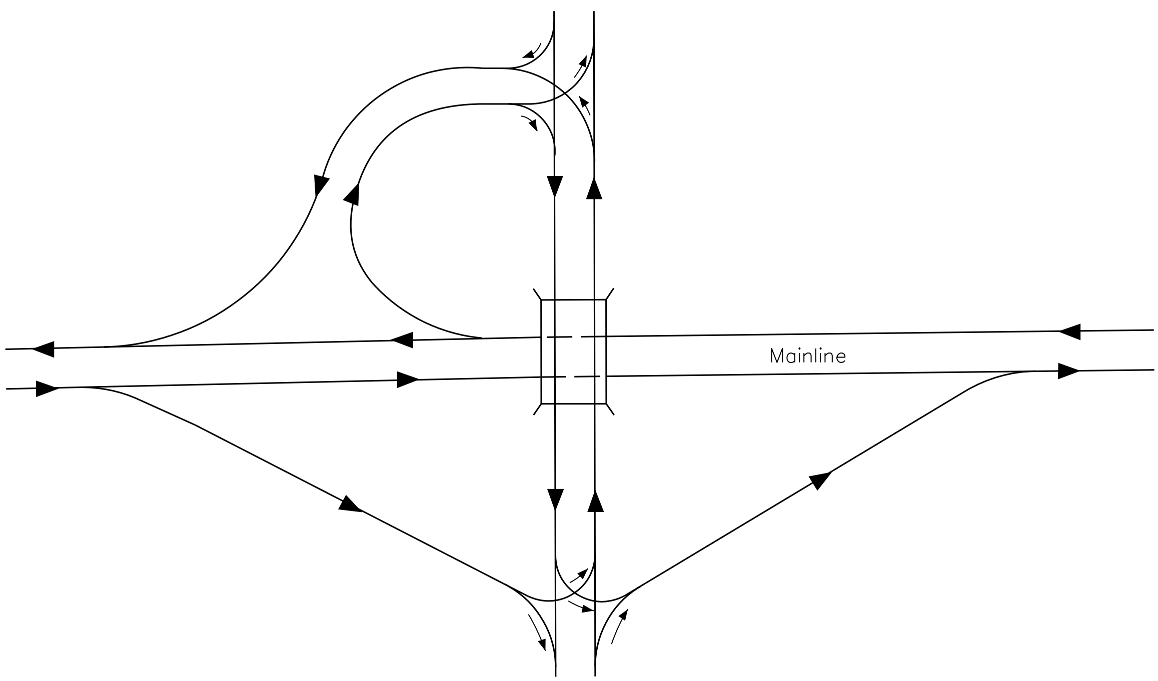
Advantages

- Depending upon site conditions, modified diamonds may offer the opportunity to increase weaving distances.
- It allows access where one of the quadrants presents adverse right-of-way, topography, or environmental constraints.
- It can be used where a full parclo is not desirable.

Disadvantages

- Modified diamonds may be more expensive than a conventional diamond interchange due to longer ramp lengths and wider structures.
- The loop results in a longer travel distance for the turning vehicle than for a conventional diamond, and the operating speeds on the loop ramp are generally slower.
- The exit or entrance terminal is located before or after the crossroad structure that may require additional signing to guide the motorist.





MODIFIED DIAMOND INTERCHANGE

Figure 37-3.E

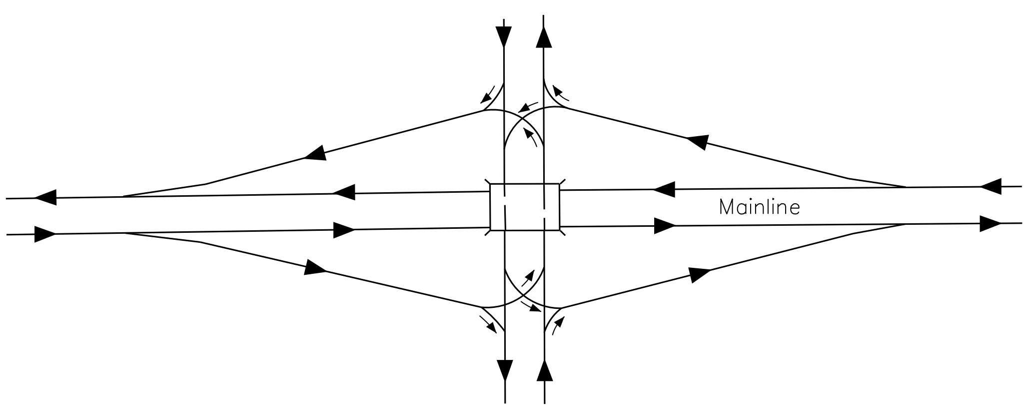
37-3.04 <u>Compressed Diamond</u>

37-3.04(a) General

A compressed diamond, also called a tight diamond interchange, is similar to the conventional diamond except that the ramp termini on the crossroad are located near the structure. Figure 37-3.F presents a schematic of a compressed diamond interchange without frontage roads. This design type is generally only used in urban areas where a diamond interchange is appropriate, but right-of-way or other environmental features preclude the use of the conventional diamond. Although operationally a compressed diamond is similar to a single-point diamond discussed in Section 37-3.05, they have significant differences. Some of the advantages and disadvantages of the compressed diamond include:

<u>Advantages</u>

- Less right-of-way is required than that for a conventional diamond.
- The open pavement area at the intersection is significantly less than that for a single point diamond.
- The grade separation structure is significantly smaller than that for a single-point diamond, retaining walls and/or embankments are less expensive, and construction costs are lower.
- The ramp/crossroads intersections operate as two typical intersections, similar to a conventional diamond and, therefore, are less confusing to drivers.
- Slip ramps for one-way frontage roads can be easily incorporated into the design.



COMPRESSED DIAMOND INTERCHANGE

Figure 37-3.F

Disadvantages

- Left-turn lanes between the ramp termini usually need to be overlapped (i.e., side-by-side opposing left-turn lanes). Consequently, the cross section of the crossroad is generally wider than a conventional diamond.
- Signal timing and interconnection are necessary in order to eliminate left-turn queues from overlapping each other and causing gridlock.
- Due to the close proximity of the two intersections, the compressed diamond typically will need to operate as a six-phase overlap signal system. Consequently, longer clearance times are required.
- Length of access control on the crossroad may be more extensive than that for a conventional diamond.

37-3.04(b) Ramp/Crossroad Intersections

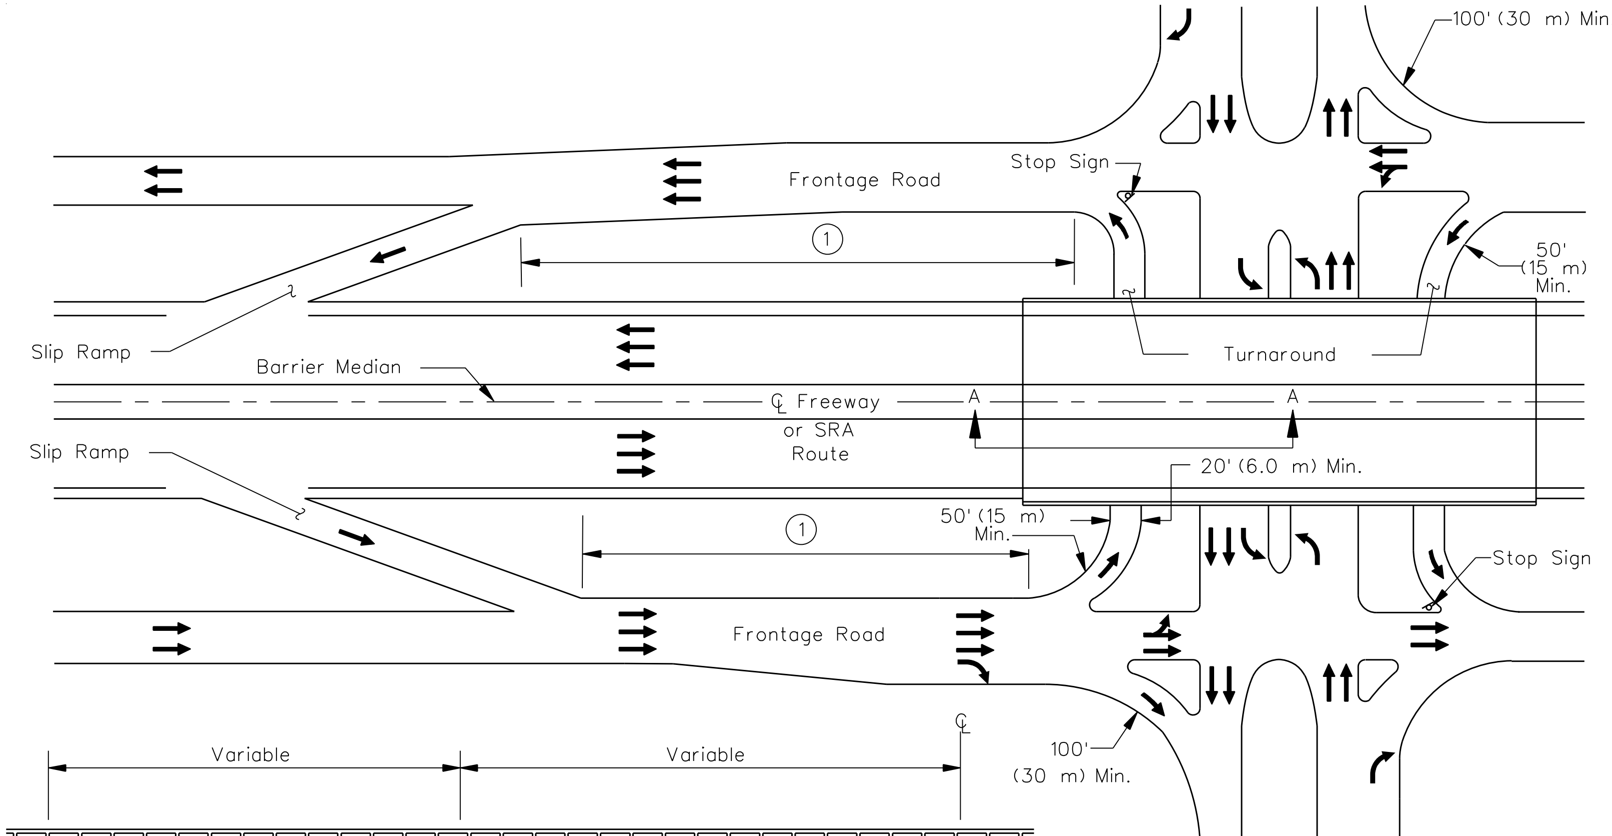
Section 37-5 presents the criteria for ramp/crossroad intersections, which is also applicable to compressed diamonds. However, the minimum length for left-turn lanes is based on the storage length and not on the deceleration distance. See Section 36-3.02 to determine the minimum storage length. If there is insignificant space for storage, the designer will need to consider optimizing the traffic signals.

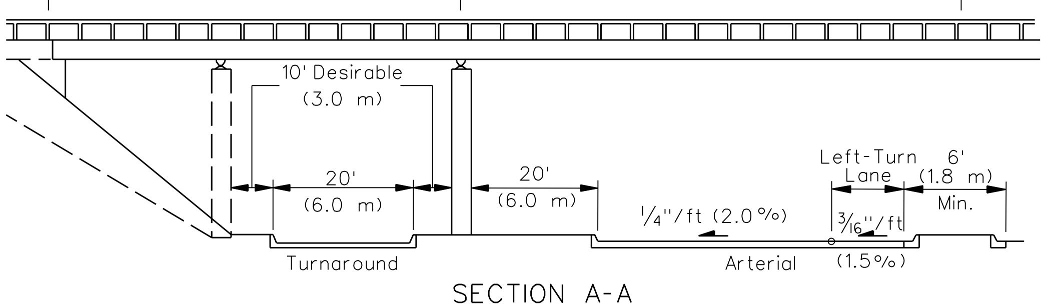
Figure 37-3.F illustrates a schematic of a compressed diamond without frontage roads. Figure 37-5.M presents the criteria for a compressed diamond with one-way frontage roads and slip ramps. Where there are one-way frontage roads and where there is significant U-turn traffic to the opposite frontage road, the designer may want to consider using a turnaround design. Figure 37-3.G illustrates the general layout and cross section for a turnaround design. Depending upon specific site conditions, this arrangement may significantly improve traffic operations at the interchange. The major operational feature of the turnaround is to provide access for traffic on the freeway to the one-way frontage road in the opposite direction without passing through the two intersections on the crossroad. If U-turn movements are considered to be significant, prepare an origin and destination study to determine the need for a turnaround prior to the development of IDS.

Some advantages and disadvantages of the turnaround design are as follows:

Advantages

- It preserves and enhances the accessibility to property abutting one-way frontage roads.
- U-turning vehicles do not have to pass through the two intersections on the crossroad.
- The capacity of the crossroad intersections is improved.





Notes:

1. *Use a weaving analysis to determine this distance. See Figure 37-5.M for minimum distances.*
2. *See Chapter 35 for length of access control along the frontage roads and crossroad.*
3. See Section 36-2.02 for corner island design.

COMPRESSED DIAMOND WITH TURNAROUND

Figure 37-3.G

Disadvantages

- It is more costly than a typical compressed diamond due to the longer structure.
- It may be confusing to non-repeat drivers because it violates driver expectancy (i.e., driving to the left of the oncoming traffic).
- Longer distances are required between the slip ramp frontage road merge point and the crossroad.

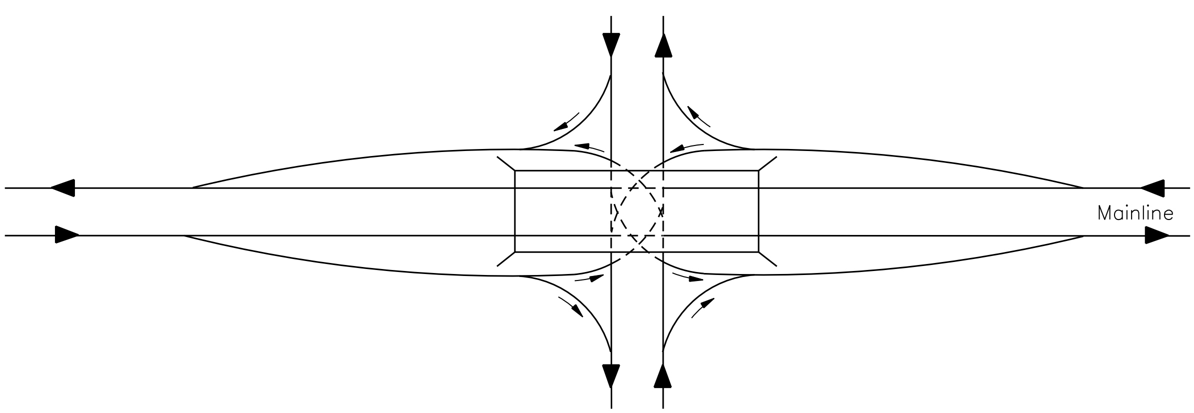
37-3.05 Single-Point Urban Diamond

37-3.05(a) General

The single-point urban diamond interchange (SPUI) offers improved traffic-carrying capabilities, safer operations, and reduced right-of-way needs under certain conditions when compared with other interchange configurations. The distinguishing feature of this interchange is the convergence of all through and left-turning movements into a single, large signalized intersection area. Figure 37-3.H illustrates a schematic of a SPUI. Some of its advantages and disadvantages include:

Advantages

- Only requires one intersection instead of two intersections at a typical diamond.
- Allows for better traffic signal progression on the crossroad.
- It can increase interchange capacity and alleviate storage problems from two closely spaced intersections on the crossroad.



SINGLE-POINT URBAN DIAMOND INTERCHANGE

Figure 37-3.H

- Opposing left turns operate to the left of each other so that their paths do not cross each other.

- Less right-of-way is required than any other interchange type.

- At the intersection of the ramps with the crossroad, the design typically includes flatter curves for turning radii, which allows left turns to be completed at higher speeds.

Disadvantages

- Special pavement markings and a centrally located diamond-shaped island are required to guide the left-turning drivers through the intersection.

- There is a significantly wider pavement area for pedestrians to cross and may create greater delays in traffic when compared to the conventional diamond.

- Because of wide pavement areas, it requires longer signal clearance times.

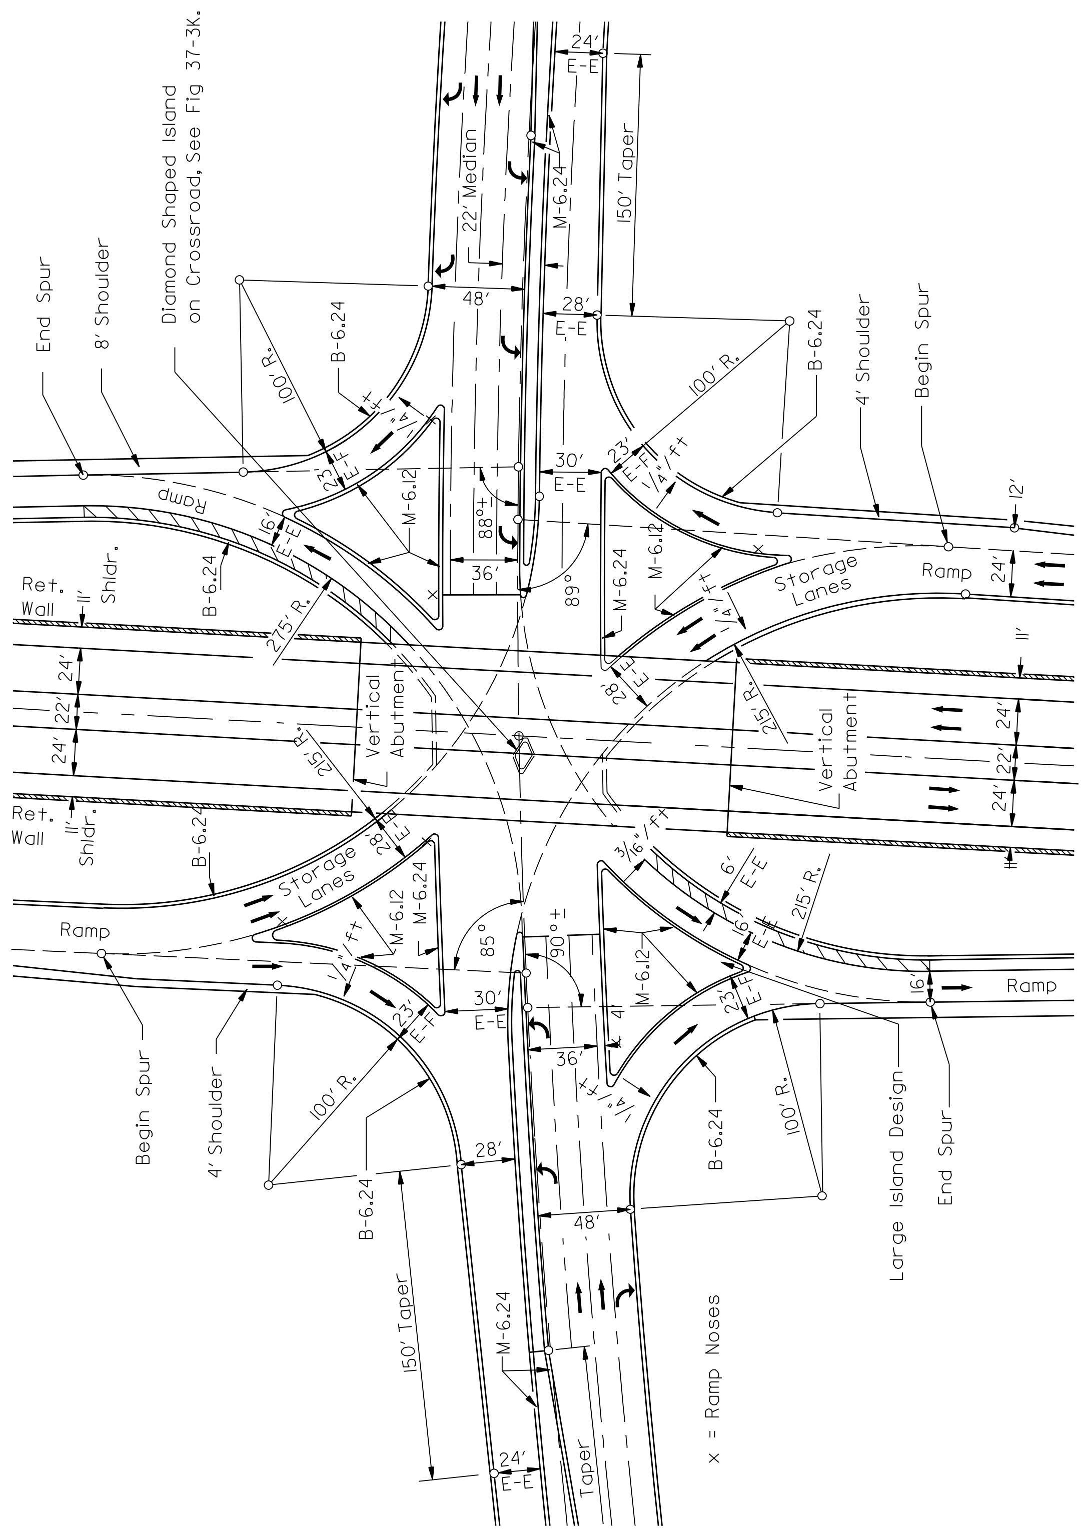
- It has a higher cost than the conventional or compressed diamond because of the need for a long, single-span structure and the need for retaining walls or reinforced earth walls along the mainline.

- In the case of the mainline over a crossroad, lighting is required under the structure.

37-3.05(b) Design Considerations

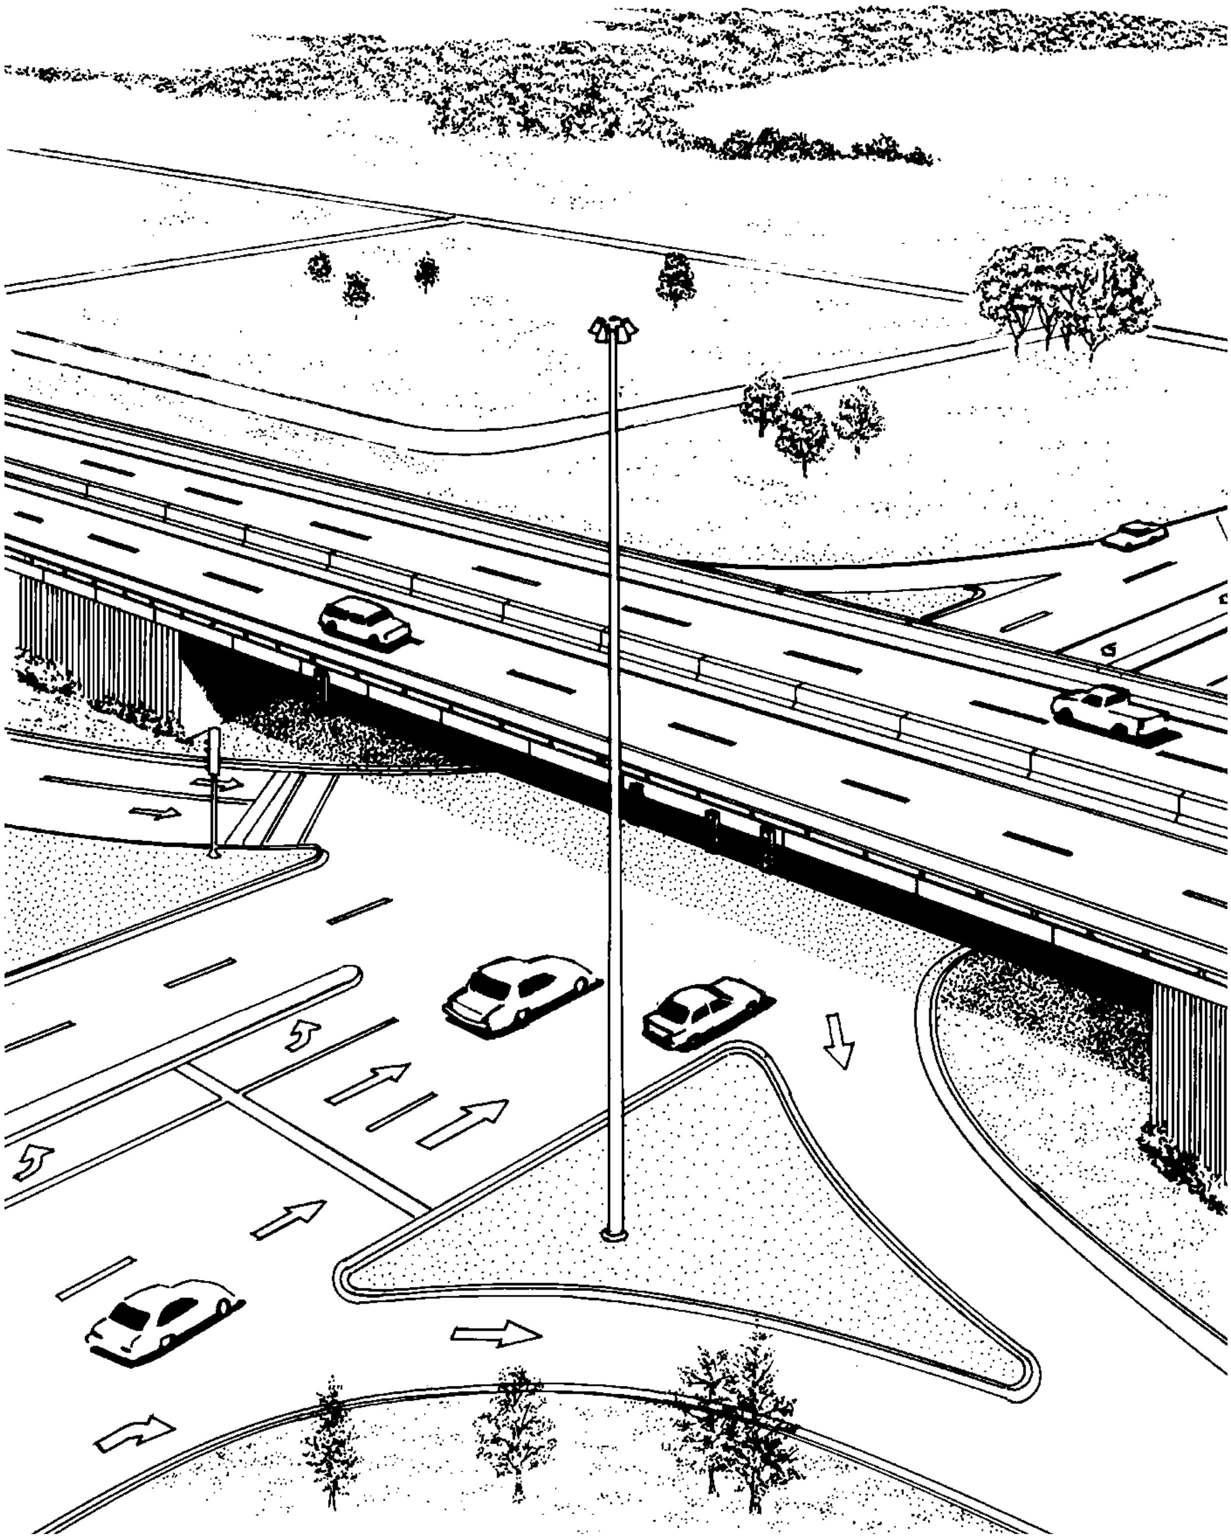
The interrelationship of the design elements is extremely important in the design of single-point diamond interchanges (SPUI). Therefore, make every effort to use the desirable values for all design features of the interchange. See NCHRP 345 *Single-Point Urban Interchange Design and Operational Analysis* for complete design details. Figures 37-3.I and 37-3.J illustrate the typical layout for a SPUI. In addition, consider the following:

1. Over versus Under. One of the first things the designer must address is whether to place the freeway or expressway over or under the crossroad. The overpass SPUI, illustrated in Figure 37-3.I, typically includes a conventional, single-span structure 220 ft (67 m) in length with a depth of 8 ft to 9 ft (2.4 m to 2.7 m). The underpass design (freeway over) typically includes two spans of approximately 65 ft (20 m) in length and a depth of 3 ft to 4 ft (1.0 m to 1.2 m). The underpass design tends to provide a more open and less restrictive feeling as the driver approaches the intersection area. For both designs, the crossroad profile should be as flat as practical. Section 44-4.02 discusses additional considerations when determining whether to place the crossroad over or under the freeway.



SINGLE-POINT URBAN DIAMOND INTERCHANGE
(Example of Central Intersection Details)

Figure 37-3.I



PERSPECTIVE VIEW OF SINGLE-POINT URBAN DIAMOND INTERCHANGE

Figure 37-3.J

2. Sight Distance. Sight distance along the exit ramp to the crossroad intersection is especially critical with the SPUI because the decision point to turn left or right generally will occur sooner at a SPUI than at other diamond type interchanges. The point of initial driver perception of the large triangular intersection island and the point for the left- or right-turn decision should occur at or just beyond the gore nose of the off ramp. At a minimum, provide the stopping sight distance as discussed in Section 31-3.01 and, desirably, decision sight distance wherever practical (Section 31-3.02). The designer must also check the horizontal sight distance to ensure that the structure abutments or parapet walls do not block the sight distance.

3. Intersection Sight Distance. Provide adequate intersection sight distance as discussed in Section 36-6. The designer must check both the vertical and horizontal planes to ensure that adequate intersection sight distance is available. The profile of the crossroad should be flat to allow motorists to see the entire crossroad surface and all ramps in one view.

4. Design Speed. Desirably, the design speed for the turns should be 30 mph to 40 mph (50 km/hr to 60 km/hr). In highly restricted ROW areas, the left-turning roadway from the exit ramp onto the crossroad may be designed with a 25 mph (40 km/hr) design speed.

5. Horizontal Alignment. One benefit of the SPUI is it provides high-speed, left-turning roadways in comparison to the compressed diamond interchange design. Design the left-turning roadways with 2% superelevation and radii between 200 ft and 400 ft (60 m and 120 m). See Figure 48-5.B to determine radii for other design speeds.

6. Number of Lanes. A capacity analysis is required to determine the number of turn lanes for the overall intersection design. At a minimum, provide sufficient space to allow two through lanes for each direction on the crossroad, one left-turn lane on the crossroad, dual-turn lanes on the exit ramp for left-turning movements, and one right-turn lane from the exit ramp onto the crossroad.

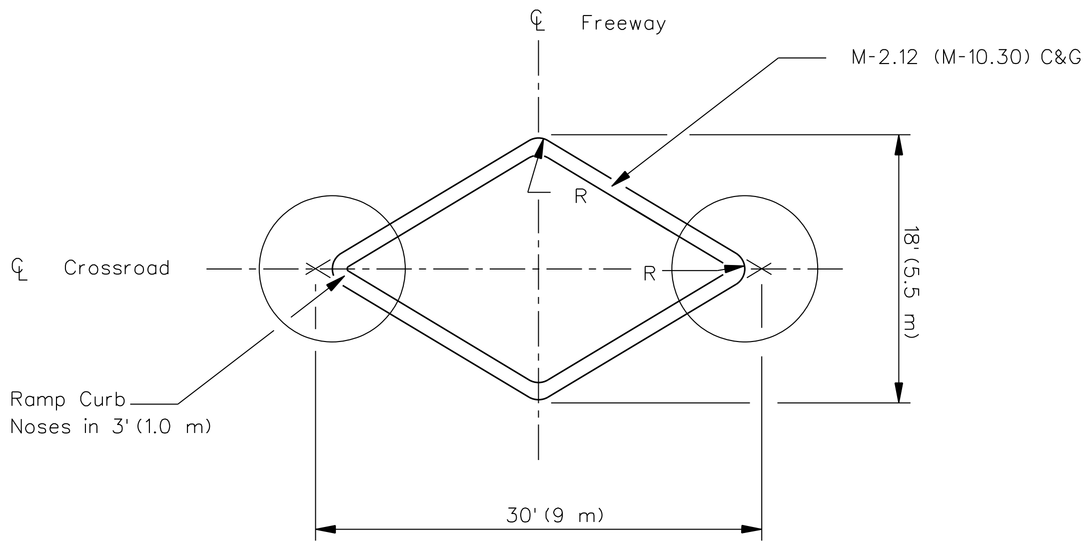
7. Intersection Angle. The intersection angle should be approximately 90 degrees.

8. Median Design. Crossroad medians should be in the range of 18 ft to 30 ft (5.5 m to 9.5 m) wide and with sufficient distance provided for left-turn storage in the median.

9. Central Island. Figure 37-3.K illustrates the central island that should be used on the crossroad.

10. Offset Turning Movements. To allow ease of movements for left-turns, the separation between opposing left-turning vehicles on the crossroad should be at least 10 ft (3.0 m).

11. Right-Turn Lanes. Ensure the right-turn lanes on the exit ramps are of sufficient length to allow right-turning vehicles to bypass the queue of left-turning vehicles on the ramp.



Note: R = 3 ft (1.0 m) to edge of pavement.

DIAMOND ISLAND ON CROSSROAD
(Single-Point Urban Diamond Interchange)

Figure 37-3.K

12. Traffic Control Devices. To eliminate confusion at the SPUI, proper exit ramp guide signing, pavement markings, and lane-use signing must be included to provide the necessary positive guidance through the intersection. Contact the Bureau of Operations for the applicable signing and pavement marking criteria.

13. Traffic Signal Placement. When determining signal locations, consider the following:

    - Due to possible lane confusion, mount signal heads directly over the travel lanes.
    - For overpass SPUI's, mount vertical signal heads outside the structure; see Figure 37-3.J.
    - The visibility of the signal heads controlling the exit-ramp left-turning movements is critical. An additional signal for advance notice may be required within the large triangular island.
    - A "pull-through" signal on the opposite island may be required where travel distances through the intersection are relatively long.
    - Contact the Bureau of Operations for the design of all signal installations.

37-3.06 Full Cloverleafs

37-3.06(a) General

Cloverleaf interchanges are used at four-leg intersections and employ loop ramps to accommodate left-turn movements. Full cloverleaf interchanges are those with loops in all four quadrants; all others are partial cloverleafs and are discussed in Section 37-3.07.

Where two access-controlled highways intersect, a full cloverleaf is the minimum type of interchange design that will suffice. In addition, they also may be used at the intersection of other multilane arterials to accommodate large volumes of traffic.

The operation of a cloverleaf with high weaving volumes is greatly improved through the addition of collector-distributor (C-D) roadways; see Section 37-4.02. The C-D roadways may be advantageous in suburban areas because of the need for smaller loops. This may reduce the amount of right-of-way acquisition necessary for the development of the interchange. Although right-of-way requirements may be reduced, overall costs usually increase due to longer and wider structures and additional pavement costs.

Figure 37-3.L provides typical examples of full cloverleafs with and without C-D roads.

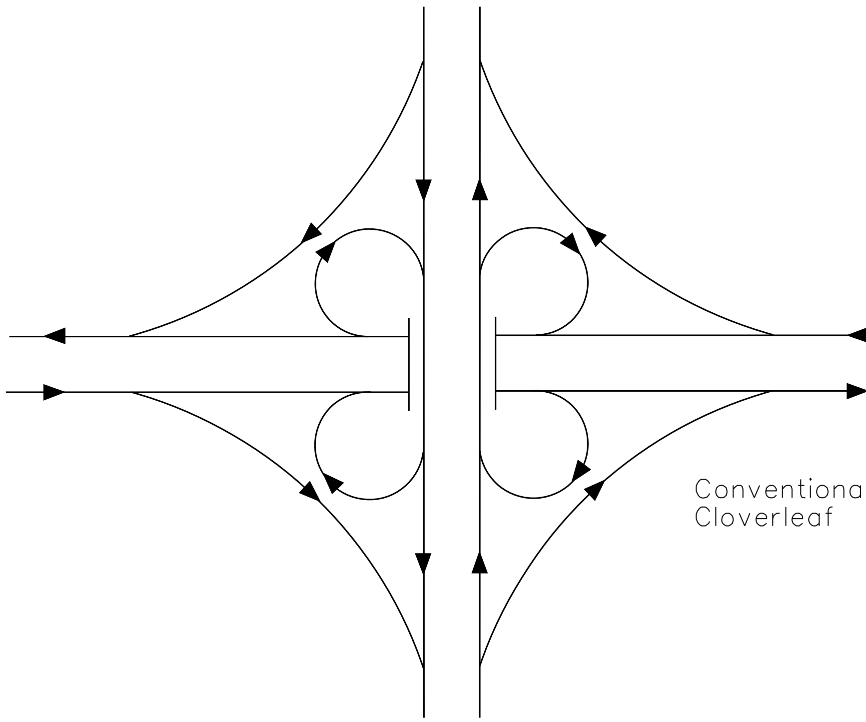
Some of the advantages and disadvantages of full cloverleafs include:

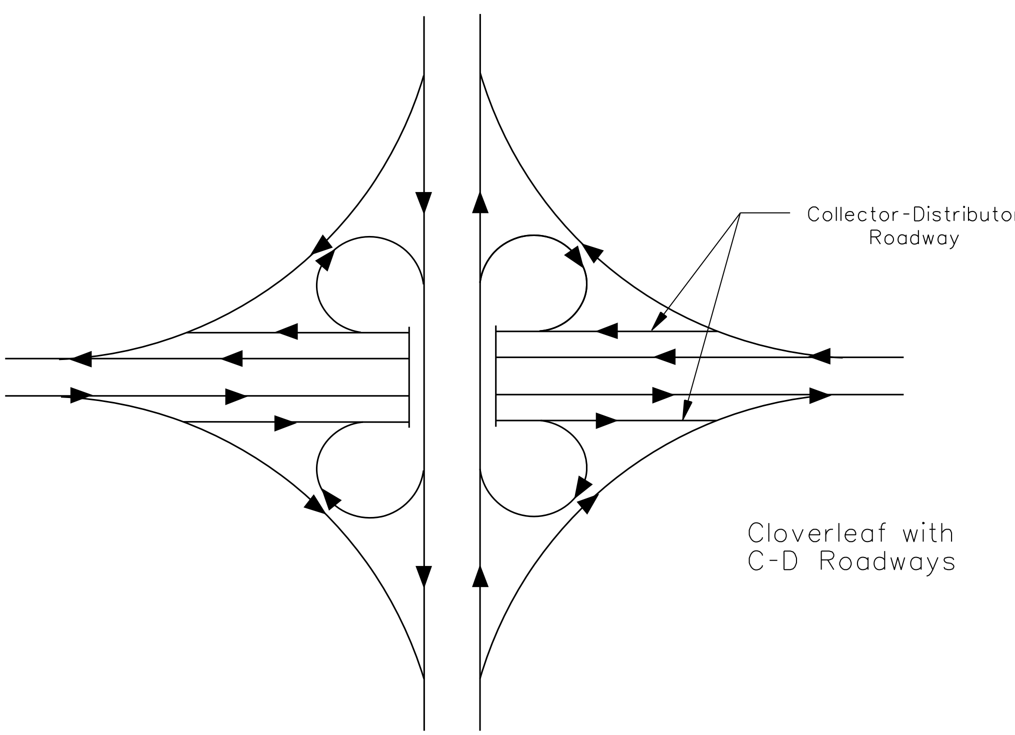
Advantages

- Full cloverleafs eliminate all vehicular stops through the use of free-flow terminals and they provide continuous free-flow operation on both intersecting highways.
- Full cloverleafs eliminate all at-grade intersections, eliminate left turns across traffic and, therefore, eliminate the need for traffic signals.

Disadvantages

- Because of the geometric design of loops, full cloverleafs require large amounts of right-of-way.
- They are typically more expensive than diamond interchanges due to considerably more lengths of ramps, wider structures, and the desirability of providing C-D roads.
- The loops in cloverleafs result in a greater travel distance for left-turning vehicles than do diamonds and the speeds on the ramps are generally slower.
- Exit and entrance terminals are located before and after the crossroad structure, which require additional signing to guide motorists.
- Weaving sections between loop ramps must be made long enough to provide for satisfactory traffic operations.
- Where the crossroad is an expressway or other multilane highway, considerable length of access control distance is needed along the crossroad to the first point of access.





CLOVERLEAF INTERCHANGES

Figure 37-3.L

37-3.06(b) Design Considerations

Figure 37-3.M illustrates the design and layout of a typical cloverleaf interchange. In developing the cloverleaf interchange, consider the following steps:

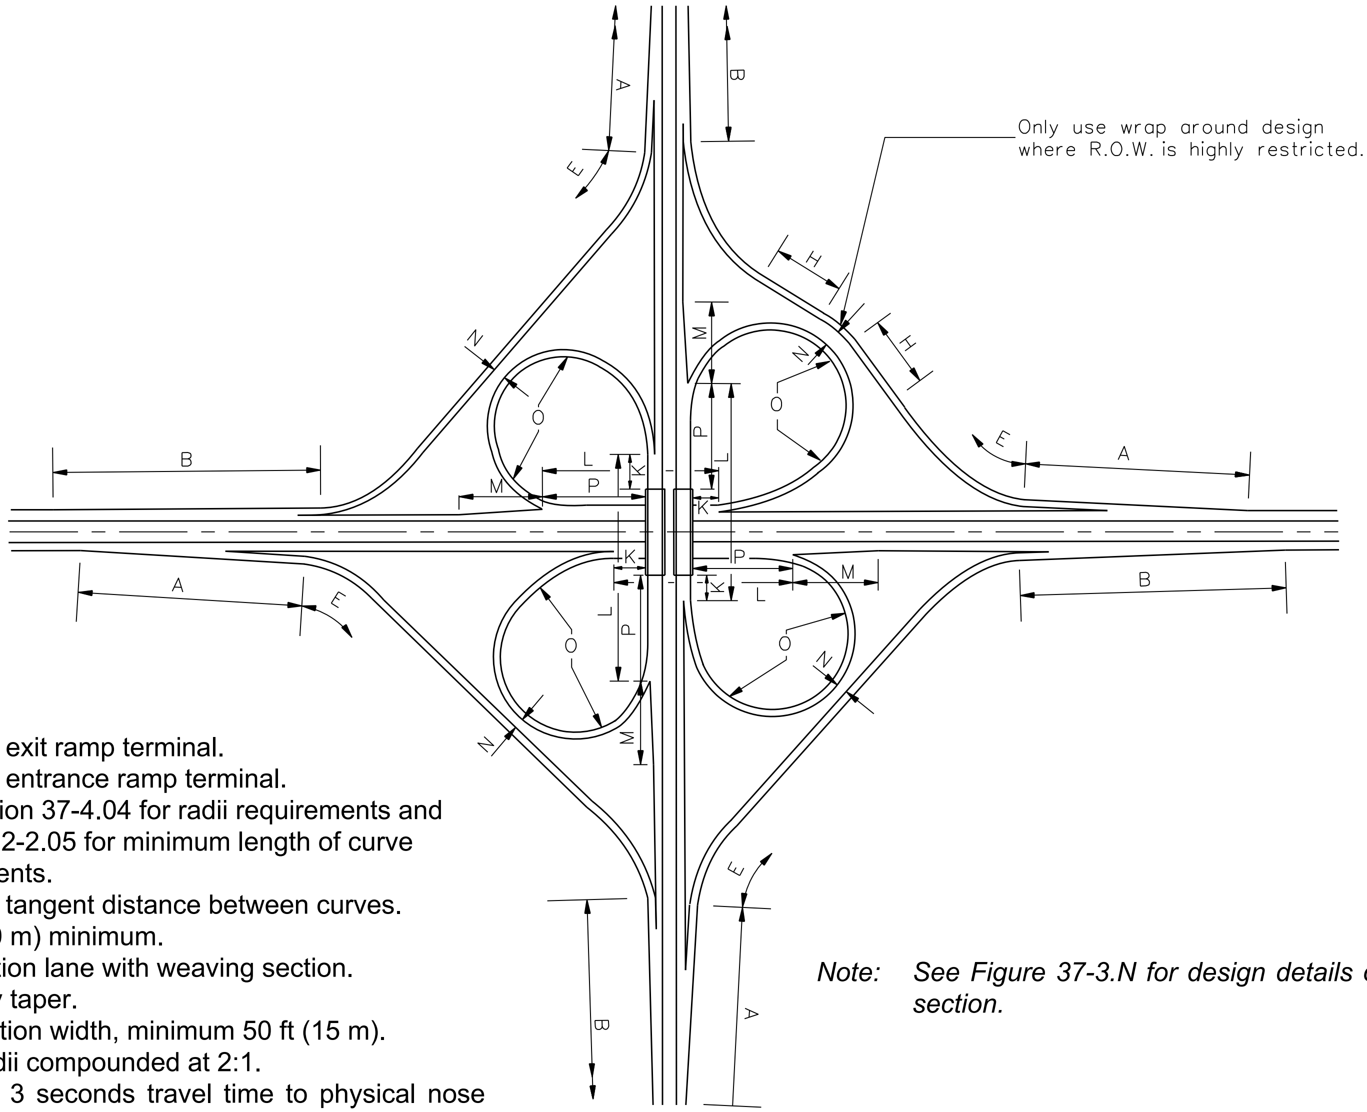
1. Exit Gore. The first step is to locate the physical nose of the exit gore of the weaving section a minimum of three seconds of travel time at the design speed beyond the structure on each of the four interchange legs; see Figures 37-3.N.

2. Weaving Section. The second step is to determine the minimum lengths required for the weaving sections. The following will apply:

   a. Length. Figure 37-3.N illustrates various weaving lengths based on the design speed of the highway and ramp curvature of the preceding entrance ramp and the following exit ramp. The length of the weaving section also must be determined using the *Highway Capacity Manual* (HCM) and the appropriate level of service; see Item 2b below. The minimum weaving section length will be based on the greater value from the HCM or Figure 37-3.N.

   b. Capacity. At a minimum, the level of service of the weaving sections may be one level lower than the adjacent freeway. Desirably, the level of service should be the same as the adjacent mainline. When the total volume on the two successive ramps reaches approximately 1000 vph, interference increases rapidly with a resulting reduction of the through traffic speed. At these weaving volume levels, consider using a collector-distributor road. Section 37-4.02 discusses the use and design of collector-distributor roadways. Expected design capacities for single-lane loops range from 800 to 1200 vph. The higher figures are generally only achievable where the design speed is 30 mph (50 km/hr) or higher and few trucks use the loop.

   c. Superelevation. Figure 37-3.N provides the superelevation criteria for a weaving section adjacent to the tangent mainline. The cross slope of the auxiliary lane between control point(s) c should not be flatter than 1/4″/ft (2%) draining toward the right edge. For mainline alignments curving to the right, control points a, b, and e are maintained as shown in Figure 37-3.N. The cross slope of the auxiliary lane between the two points labeled c should be congruent with the cross slope of the traveled way, but not greater than 5%. For alignments curving to the left, control points a and e are maintained according to Figure 37-3.N. The superelevation rate at control point b is 6%. Where the mainline is curving to the left, the crossover crown between the two points labeled c should not exceed 5%. In all cases where weaving sections are located on a curved horizontal alignment, engineering judgment will be required where the above criteria cannot be maintained.



LEGEND

A - Standard exit ramp terminal.
B - Standard entrance ramp terminal.
E - See Section 37-4.04 for radii requirements and Section 32-2.05 for minimum length of curve requirements.
H - Minimum tangent distance between curves.
K - 100 ft (30 m) minimum.
L - Acceleration lane with weaving section.
M - Recovery taper.
N - Ditch section width, minimum 50 ft (15 m).
O - Ramp radii compounded at 2:1.
P - Minimum 3 seconds travel time to physical nose of exit gore.

Note: *See Figure 37-3.N for design details of weaving section.*

ⓔ	- 464 mm	- 72 mm	(8 %)

CLOVERLEAF INTERCHANGE
(Weaving Section) (Metric)

Figure 37-3.N

3. Entrance Gore. The location of the entrance gore is determined by adding the minimum weaving length to the exit gore nose location determined in Step 1. At a minimum, place the entrance gore 100 ft (30 m) before the structure and, desirably, 200 ft (60 m) before the structure; see Figure 37-3.N.

4. Inner Loops. Once the physical noses of the exit and entrance gores have been determined, the horizontal alignment between the corresponding exit and entrance gores must be determined. Circular curve loop ramps are the most desirable geometrically because speeds and travel paths tend to be more uniform. However, this is often impractical and compound curvature is generally required. The initial and final arcs of the loops may preclude using the specified radii for the design speed of the respective highways and length of the weaving sections. A third intermediate arc is then compounded with initial and final arcs. If necessary, in obtuse quadrants, two arcs may be compounded between the initial and final curves. If the intermediate arc cannot be compounded with the minimum arc lengths provided in Section 37-4.07, one or both of the adjacent weaving sections containing the loop terminals must be adjusted and the process repeated.

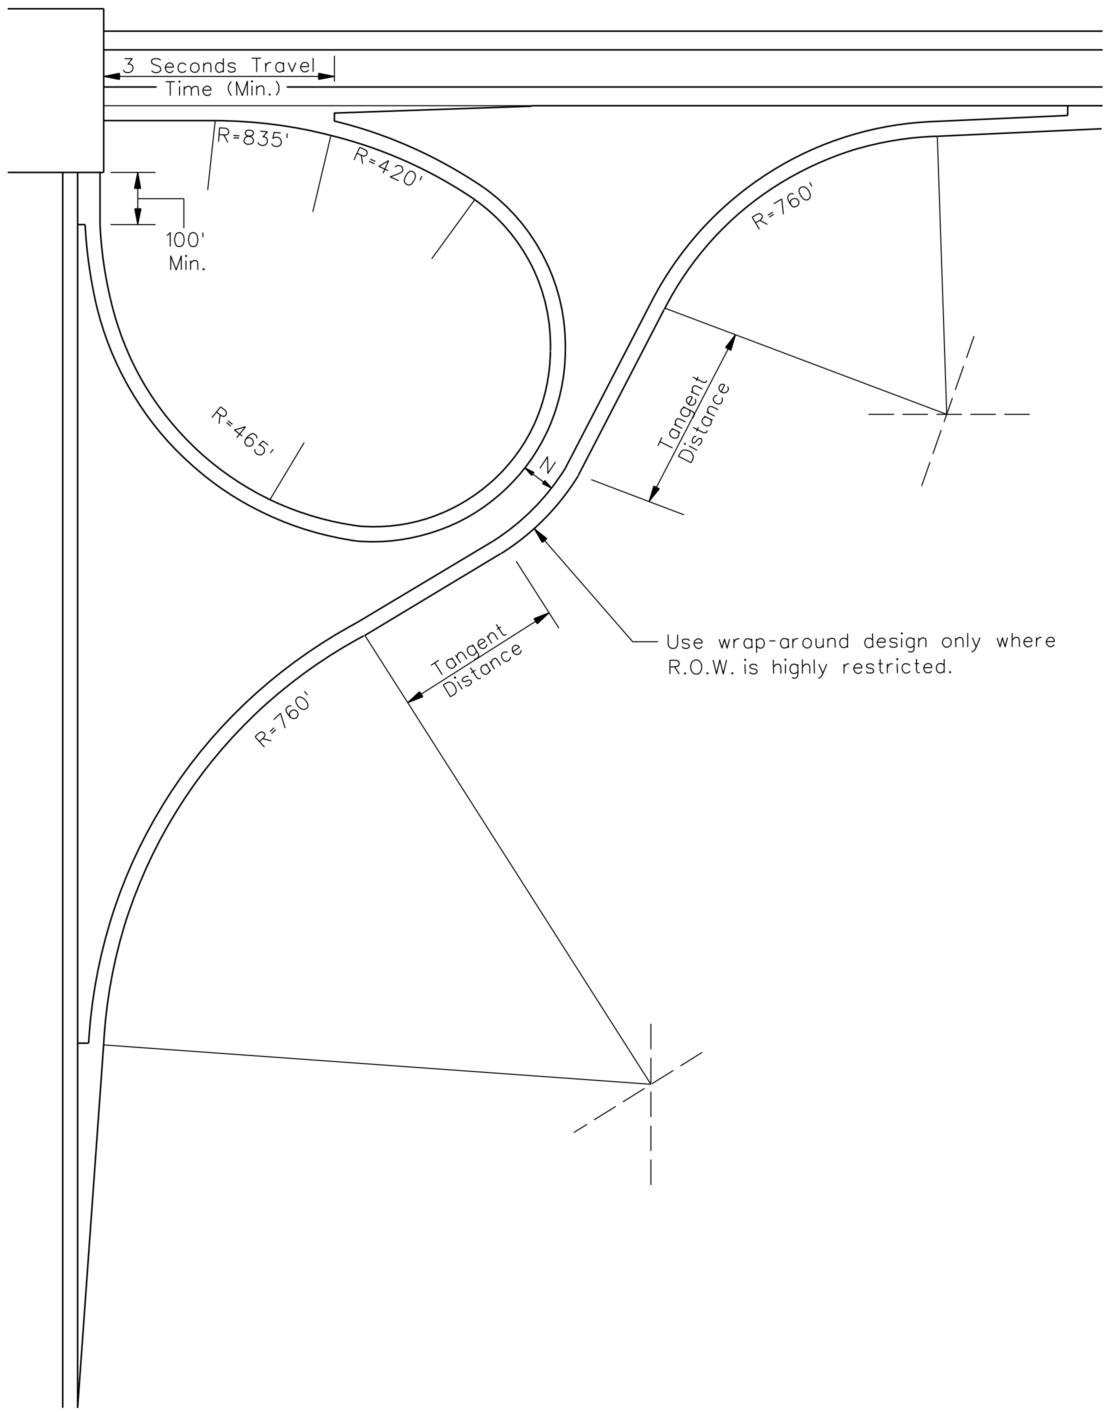
5. Outer Connections. Once a satisfactory inner loop design has been developed, the designer must select the appropriate outer connection design. Desirably, this will be a tangent section connected by radii at the exit and entrance terminals. In place of the tangent section, compound curves having a radius greater than the radius preceding the exit terminal may be used. In urbanized areas where right-of-way may be restricted, a "wrap around" design may be used. In this situation, the central curve of the outer connector is normally made concentric to the arc at the center of the inner loop and the selected radius should provide a minimum design speed of 40 mph (60 km/hr). Set the outer connector to provide a common drainage section between the inner loop and the outer connection. Figure 37-3.O illustrates a typical layout with a wrap-around design.

37-3.07 Partial Cloverleafs

37-3.07(a) General

Partial cloverleaf (parclo) interchanges are those with loops in one, two, or three quadrants. Several of the disadvantages listed for full cloverleafs also apply to partial cloverleafs (e.g., geometric restriction of loops). However, some specific advantages of partial cloverleafs include:

- Partial cloverleafs provide access where one or more quadrants present adverse right-of-way and/or topographic problems that preclude a typical diamond interchange.
- Partial cloverleafs may accommodate heavy left-turn traffic by means of a loop and thereby improve capacity, operations, and safety.
- Depending upon site conditions, partial cloverleafs may offer the opportunity to increase weaving distances.



Note: Where the two ramps parallel each other, the elevations of the left edge of the outer ramp should approximately match the elevation of the inner loop ramp.

EXAMPLE OF CLOVERLEAF QUADRANT DESIGN
(Wrap-Around Outer Ramp)

Figure 37-3.O

Partial cloverleaf designs can be segregated into the two-quadrant and four-quadrant partial cloverleaf. These are further explained as follows:

1. Two-Quadrant Partial Cloverleaf Interchanges. The two-quadrant partial cloverleaf interchange is normally used at those locations where cultural or natural features restrict the development of the diamond interchange. The two-quadrant parclo interchanges Type A (Figure 37-3.P) and Type B (Figure 37-3.Q) are used where right-of-way and/or construction is precluded in opposite quadrants of the interchange. The two-quadrant parclo interchange Type C (Figure 37-3.R) is used at intersections where additional structures or extensive relocation of the crossroad would be required to develop the diamond interchange (e.g., adjacent to rivers, railroads).

   The operations of the two-quadrant parclo interchanges can be further defined as follows:

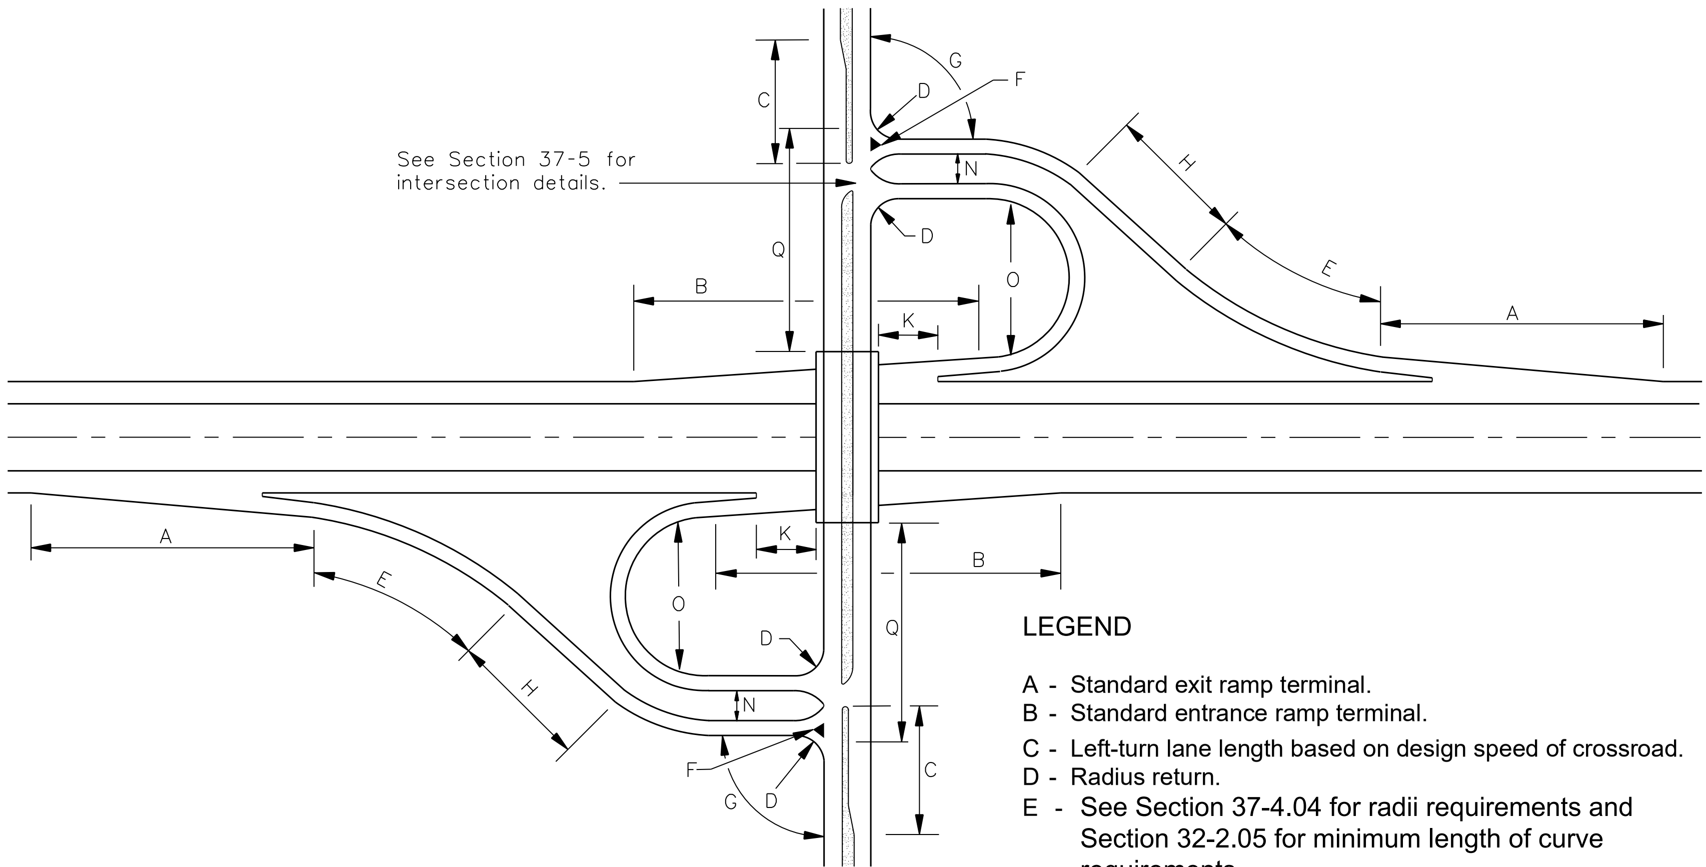
   a. Type A. Both the exit and entrance terminals are located in advance of the structure and two channelized "T" intersections are formed on the crossroad. This arrangement reduces the probability of wrong-way movements. However, all turning movements from the crossroad must undergo a "reverse" operation; i.e., drivers traveling to the right must turn left and those traveling to the left must turn right.

   b. Type B. Because the "T" intersections allow normal operations for turning movements from the crossroad, the probability of wrong-way movements are greatly reduced. The exit terminals are located beyond the structure and, due to the lower design speed on the loop ramp, drivers tend to decelerate more on the mainline through lanes in advance of the exit.

   c. Type C. No uniform pattern of operation is realized because traffic on the freeway exits in advance of the structure in one direction and beyond the structure in the other. Movements to the right or left from the crossroad are made by turning to the right for one direction and by turning left for the opposite direction. Consequently, channelization of the crossroad, with separate left-turn lanes is essential for proper operation.

2. Four-Quadrant Partial Cloverleaf Interchange. Figures 37-3.S and 37-3.T illustrate the Type A and Type B four-quadrant parclo interchanges, respectively. The four-quadrant parclo interchange is used to provide for higher traffic volumes than the conventional diamond through the elimination of left-turning traffic at the crossroad ramp terminals.

   Although there is a mixture of free-flowing and controlled terminals on the crossroad, there is little operational difficulty because the relative turning volumes and the arrangement of the ramp designs are compatible. Of the two types, Type A is probably more desirable, because it eliminates all conflicting left-turns from the crossroad.



LEGEND

A - Standard exit ramp terminal.
B - Standard entrance ramp terminal.
C - Left-turn lane length based on design speed of crossroad.
D - Radius return.

PARTIAL CLOVERLEAF INTERCHANGE LAYOUT
(Four-Quadrant – Type B)

Figure 37-3.T

37-3.07(b) Two-Quadrant Parclo Interchange

Figures 37-3.P, 37-3.Q, and 37-3.R provide the general design and layout criteria for Type A, Type B, and Type C parclo cloverleafs, respectively. During the layout and design of the two-quadrant partial cloverleaf, consider the following steps:

3. Ramp/Crossroad Intersection Location:

    a. Type A. Place the physical nose of the standard entrance terminal a minimum of 100 ft (30 m) upstream from the structure. Design the smallest loop radius with a 30 mph or 40 mph (50 km/hr or 60 km/hr) design speed in rural areas and 25 mph or 30 mph (40 km/hr or 50 km/hr) design speed in urban areas. Project a tangent line from the loop radius to intersect with the crossroad at approximately 90 degrees. This procedure sets the location of both ramps and the location for the beginning of the left-turn lane on the crossroad. Check the intersection sight distance at the intersection of the exit ramp with the crossroad back to the left along the crossroad; see Section 36-6.

    b. Type B. Place the physical nose of the exit terminal three seconds of travel time beyond the structure. Design the smallest loop radius with a 30 mph to 40 mph (50 km/hr or 60 km/hr) design speed in rural areas and 25 mph or 30 mph (40 km/hr or 50 km/hr) design speed in urban areas. Project a tangent line from the loop radius to intersect with the crossroad at approximately 90 degrees. Layout the location of the left-turn lane on the crossroad to fit into the intersection of the entrance ramp. Check the intersection sight distance at the intersection of the exit ramp with the crossroad back to the right along the crossroad; see Section 36-6.

    c. Type C. The ramp/crossroad intersections for a Type C parclo are located in the same manner as the respective terminals for Types A and B.

4. Loop Ramps. For Type A parclos, the radii of succeeding arcs should increase in the direction of travel so that the traffic may enter the mainline highway at a reasonably high operating speed. For Type B parclos, the radii of succeeding arcs should decrease at a ratio of 2:1, with the arc of the sharpest curve being located immediately before the tangent section of the ramp.

5. Outer Connections. The tangent portions of the outer connectors are set parallel to the tangent portions of the loop ramps and are separated by a 50 ft (15 m) median. This width provides for a suitable common drainage section and minimizes headlight glare from opposing traffic. The remaining portion of the outer connection is developed concentric with the loop ramp and then follows a line approximately 45 degrees in relationship to the mainline. The intervening tangent length between the reverse curves should be no less than the sum of 67% of the two superelevation runoff lengths.

37-3.07(c) Four-Quadrant Parclo Interchange

Figures 37-3.S and 37-3.T illustrate the typical design and layout criteria for four-quadrant partial cloverleaf interchange Types A and B. The design procedures for the four-quadrant parclo are similar to those for the cloverleaf and the corresponding two-quadrant parclo. The loop ramps are designed in the same manner as those of the cloverleaf. However, because they use the standard entrance and exit terminals rather than the weaving section terminals, the loops are smaller than the conventional cloverleaf loops. The outer connectors are designed in the same manner as those of the two-quadrant parclo interchange.

Provide a common drainage section between the outer connectors and the free-flow loops and set the tangent approach to the crossroad to intersect the crossroad at approximately 90 degrees. The right-turn free-flow directional ramps located in opposite quadrants consist of compound circular arcs where the adjacent radii should not exceed a ratio of 2:1. The standard exit and entrance terminals of the directional ramps are located a certain minimum distance from the intersection of the outer connections with the crossroad. These features are illustrated in Figures 37-5.K and 37-5.L.

37-3.08 <u>Trumpet Interchange</u>

37-3.08(a) General

The trumpet type interchanges, illustrated in Figures 37-3.U and 37-3.V, are examples of three-leg interchanges where three of the turning movements are accommodated with directional or semi-directional ramps and one movement by a loop ramp.

Trumpet Types A and B are used primarily:

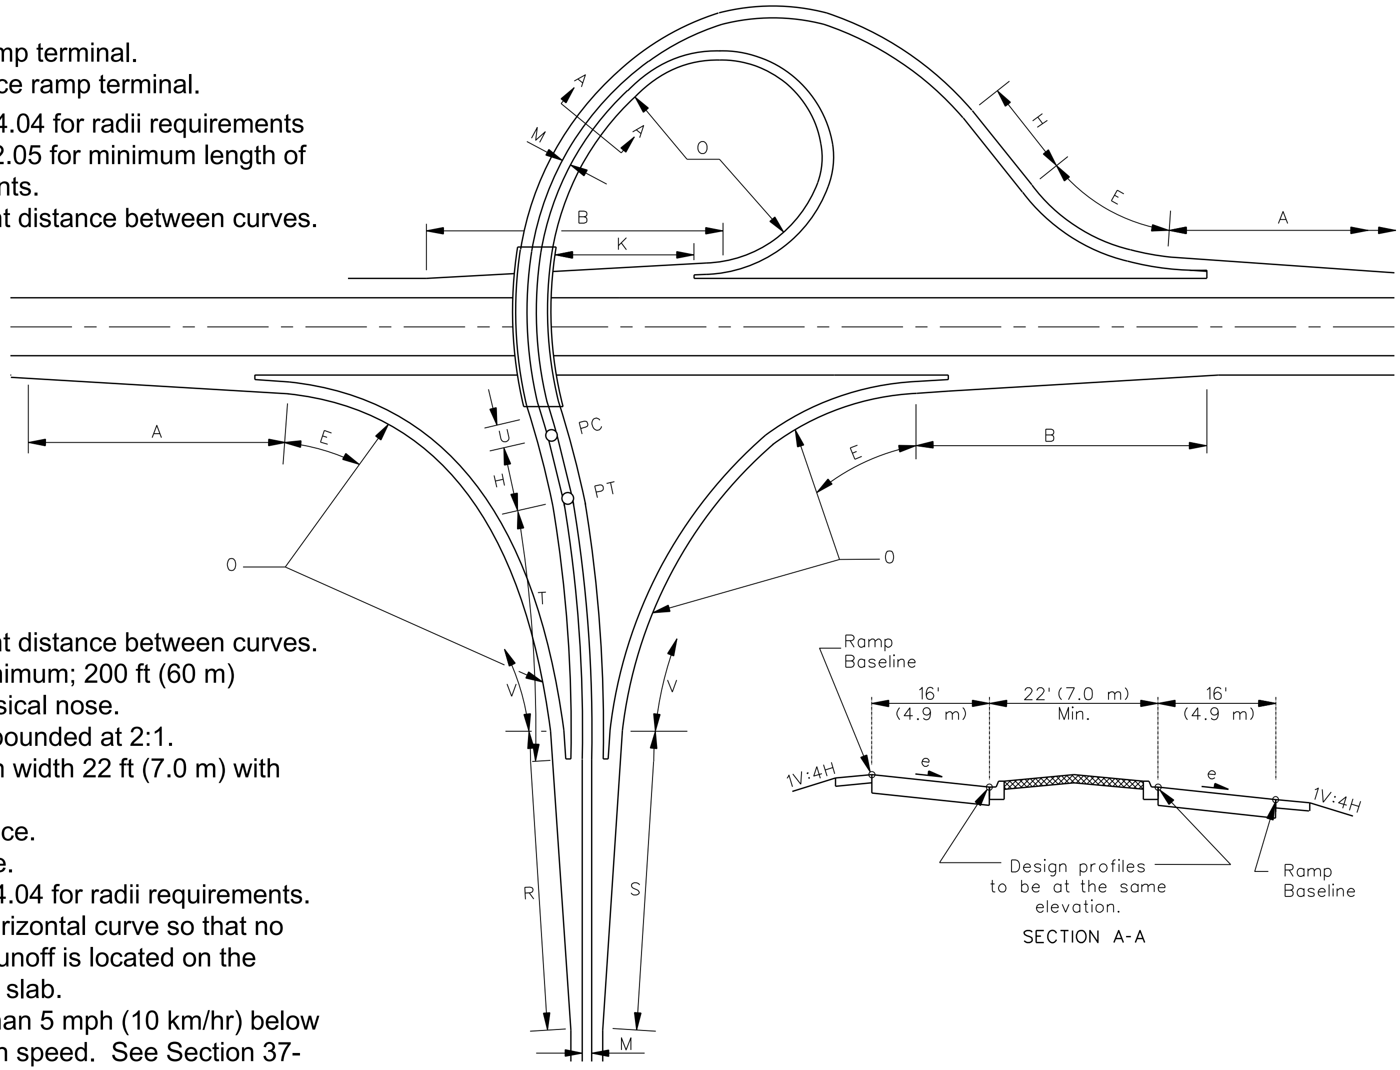
- at intersections with non-freeway spur connections or routes which are terminated at the freeway,
- at intersections with other highways which are contiguous with the freeway for a short distance and then diverge on their own alignment, or
- where future expansion to the unused quadrant is not practical or likely.

They are typically limited to intermediate traffic volumes that can be accommodated by single-lane ramps.

The “bell” of the trumpet is normally oriented to favor the predominant turning movements. Where the volume of traffic exiting from the freeway exceeds the volume entering from the minor highway, use the trumpet Type A. Where the volume entering from the minor highway exceeds the volume exiting from the freeway, use the trumpet Type B. Where the entering and exiting volumes are comparable, the trumpet Type A is preferred due to its better operational characteristics.

LEGEND

A - Standard exit ramp terminal.
B - Standard entrance ramp terminal.
E - See Section 37-4.04 for radii requirements and Section 32-2.05 for minimum length of curve requirements.
H - Minimum tangent distance between curves.



H - Minimum tangent distance between curves.
K - 100 ft (30 m) minimum; 200 ft (60 m) desirable to physical nose.
O - Ramp radii compounded at 2:1.
M - Minimum median width 22 ft (7.0 m) with C&G.
R - Minor convergence.
S - Minor divergence.
T - See Section 37-4.04 for radii requirements.
U - Locate end of horizontal curve so that no superelevation runoff is located on the bridge approach slab.
V - Curve not less than 5 mph (10 km/hr) below crossroad design speed. See Section 37-4.04 for radii requirements and Section 32-2.05 for minimum length of curve requirements.

TRUMPET INTERCHANGE LAYOUT (Type B)

Figure 37-3.V

37-3.08(b) Design Considerations

Figures 37-3.U and 37-3.V illustrate the design and layout criteria for Type A and Type B trumpet interchanges. Use Type A configuration where the predominate movement is left-turns from the freeway to the minor road. Use Type B configuration where the predominant movement is right turns from the freeway to the minor road.

In designing the trumpet interchange, first develop the location of the loop ramp and structure. This requires a certain amount of trial and error because the loop is a continuation of the minor highway rather than a connection to a standard entrance and exit terminal. The loop and the outer connection are placed on curved alignment as they pass over the major highway. Reverse curvature is used before the structure for operational purposes. Because the minor highway is typically carried over, full superelevation should be attained before the structure approach slab so that the structure and approach slabs may be designed with a constant superelevation rate.

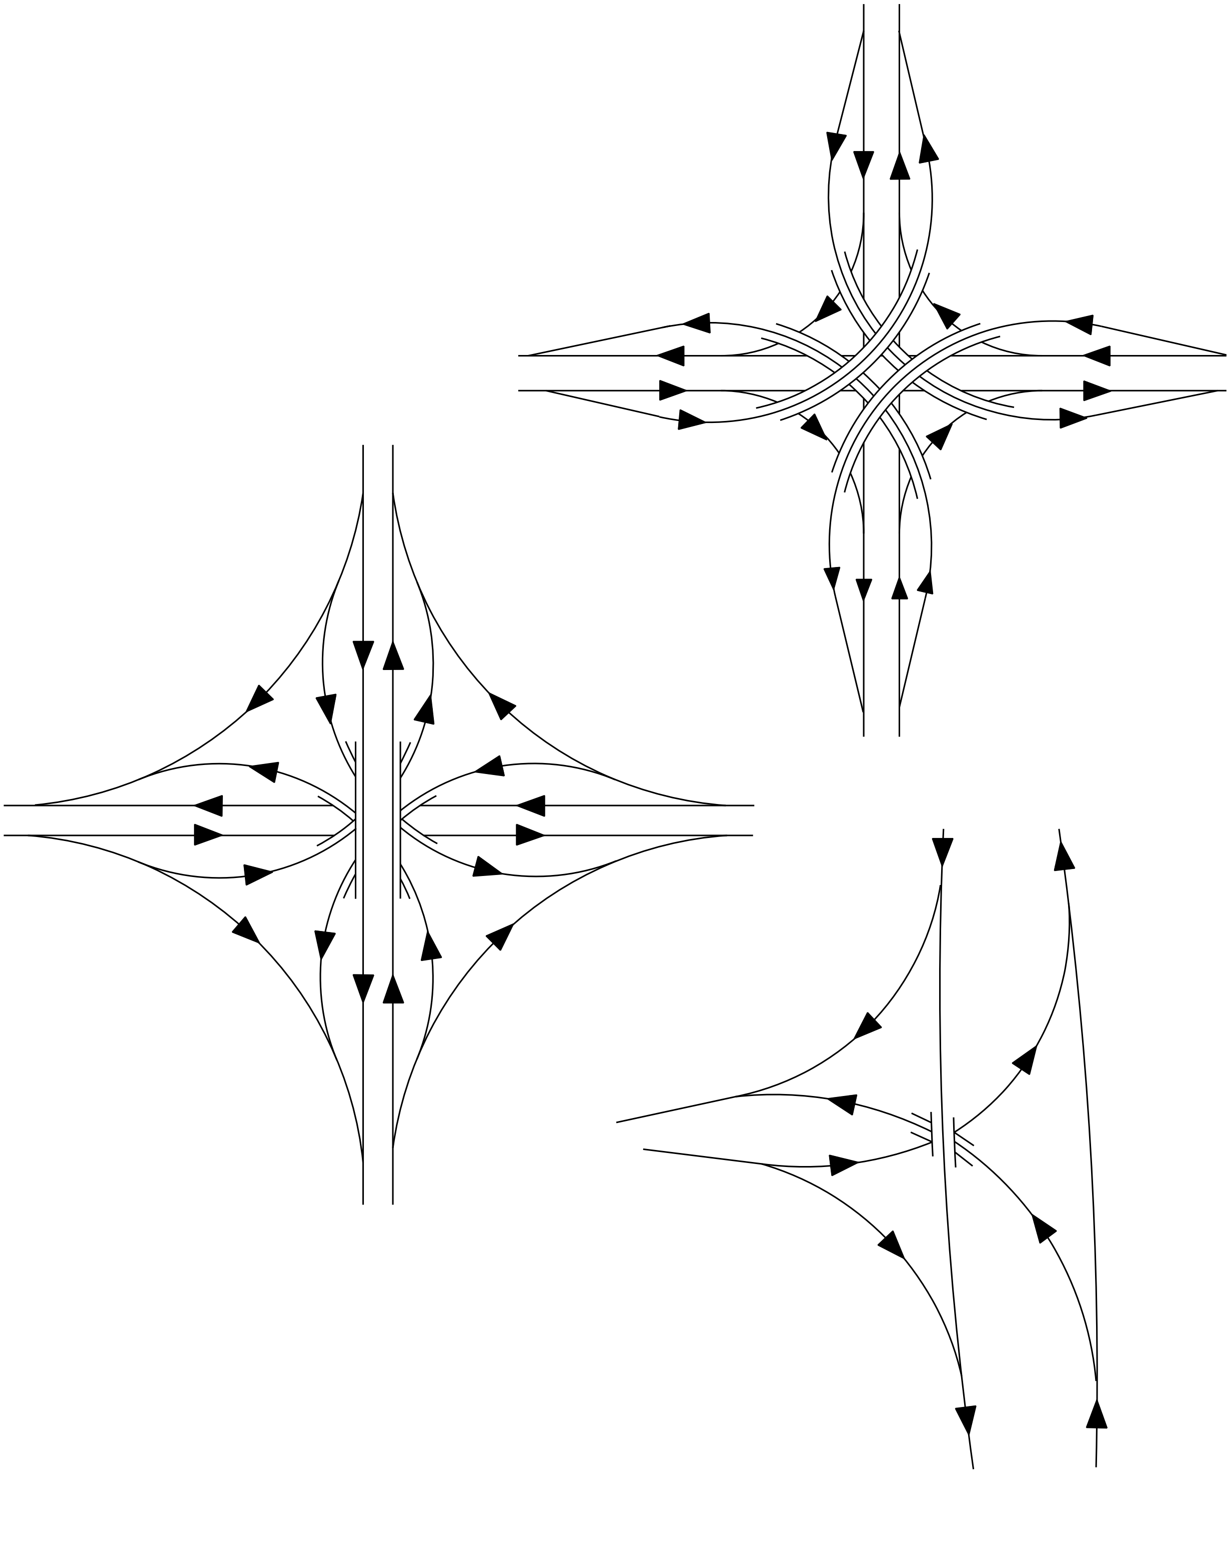
The outer connector is located adjacent and parallel to the roadway of the loop ramp and the rest of the ramp is located based on the selected design speed. These directional ramps provide turning movements to and from the minor highway through the use of standard entrance and exit terminals on the freeway and minor convergence and divergence terminals on the minor highway. Design the directional ramps for right turns to and from the minor highway using compound curves and a minimum design speed of 50 mph (80 km/hr).

As shown in Figures 37-3.U and 37-3.V, the loop ramps or outer connectors do not exit from the minor highway with the standard terminals, but are a continuation of the single-lane roadways formed by the minor divergence and convergence terminals; see Figures 37-6.R and 37-6.T. Because of sight distance restrictions, due to the presence of the structure or piers and higher possible speeds on the stem approach, motorists may be confronted with an abrupt transition in speed and alignment immediately beyond the structure. To minimize these operational difficulties, place the ramps on curved alignment before passing over or under the freeway with larger radii.

37-3.09 <u>Directional and Semi-Directional Interchanges</u>

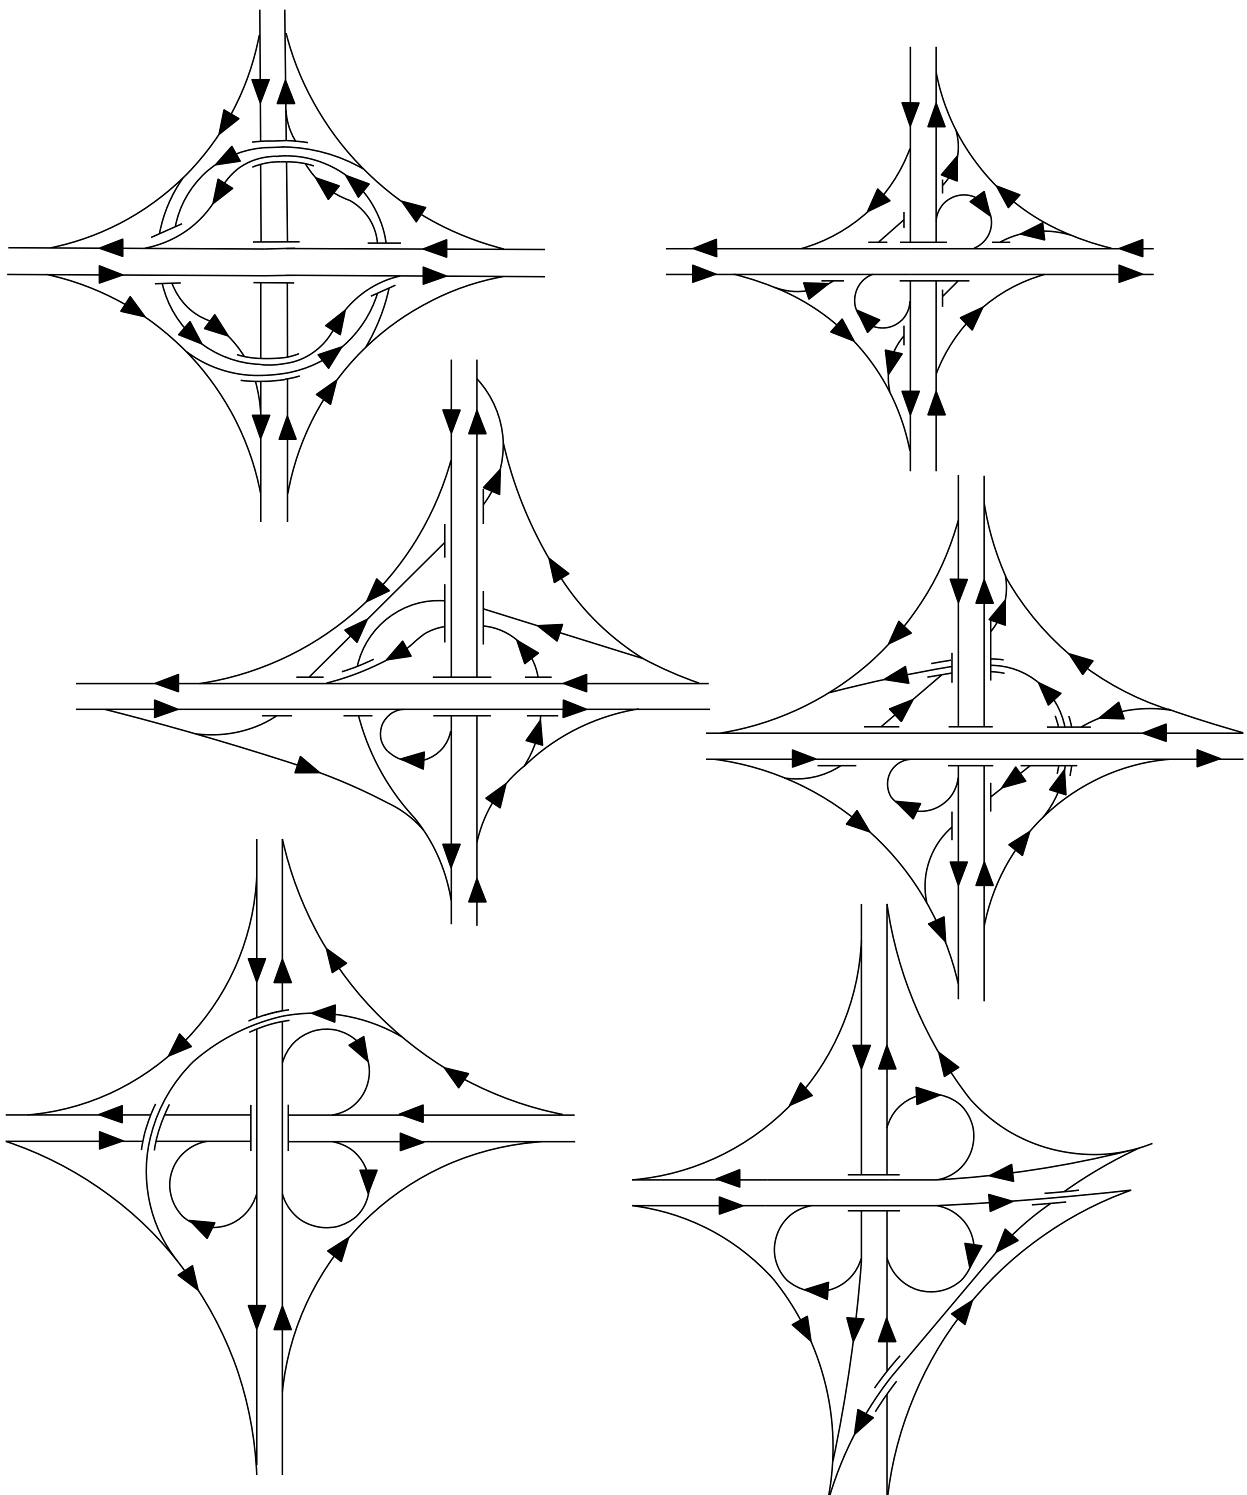
Directional or semi-directional ramps are used for heavy left-turn movements, to reduce travel distance, to increase speed and capacity, and to eliminate weaving. These types of connections allow an interchange to operate at a better level of service than is possible with loops. Figures 37-3.W and 37-3.X illustrate common directional and semi-directional ramps and/or roadways. Left-hand exits and entrances should be avoided.

Directional or semi-directional interchanges are most often provided in urban or suburban areas at freeway-to-freeway or freeway-to-arterial intersections. In rural areas, there is generally an insufficient traffic volume to justify the use of directional or semi-directional ramps in all quadrants. A directional interchange provides the highest possible capacity and level of service, but it is often costly to construct due to the number of structures required and amount of embankment.



DIRECTIONAL INTERCHANGES

Figure 37-3.W



SEMI-DIRECTIONAL INTERCHANGES

Figure 37-3.X

No uniform design procedures can be established for directional or semi-directional ramps at interchanges due to the great variety of configurations. Loop ramps and weaving sections, where used, are designed as discussed in Sections 37-3.06 and 37-3.07. Because motorists perceive that higher operating speeds are possible on directional and semi-directional roadways, the alignment of these facilities should be as free flowing as practical.

37-3.10 Diverging Diamond Interchange (Double Crossover Diamond Interchange)

A diverging diamond interchange (DDI) has the basic form of a standard diamond interchange but incorporates directional crossover intersections that transpose traffic along the crossroad between the ramp terminals. DDIs thereby typically accommodate left-turning onto the on-ramps as free-flow movements and eliminate the need for left-turn signal phasing. This helps reduce overall interchange delay in comparison to other interchange types. Figure 37-3.Y shows a schematic layout of a typical DDI. Figure 37-3.Z provides more detailed information on geometry, signing, and striping of a typical DDI, and identifies some issues to consider in the design of a DDI. For additional guidance see the FHWA Report “Diverging Diamond Interchange Informational Guide” (2014) and other resources at the following FHWA website: https://safety.fhwa.dot.gov/intersection/innovative/crossover/.

37-3.10(a) General

Within certain contexts and project constraints DDIs can offer improved traffic-carrying capabilities, safer operations, and reduced right-of-way needs in comparison to other interchange designs. Some DDI advantages and disadvantages include:

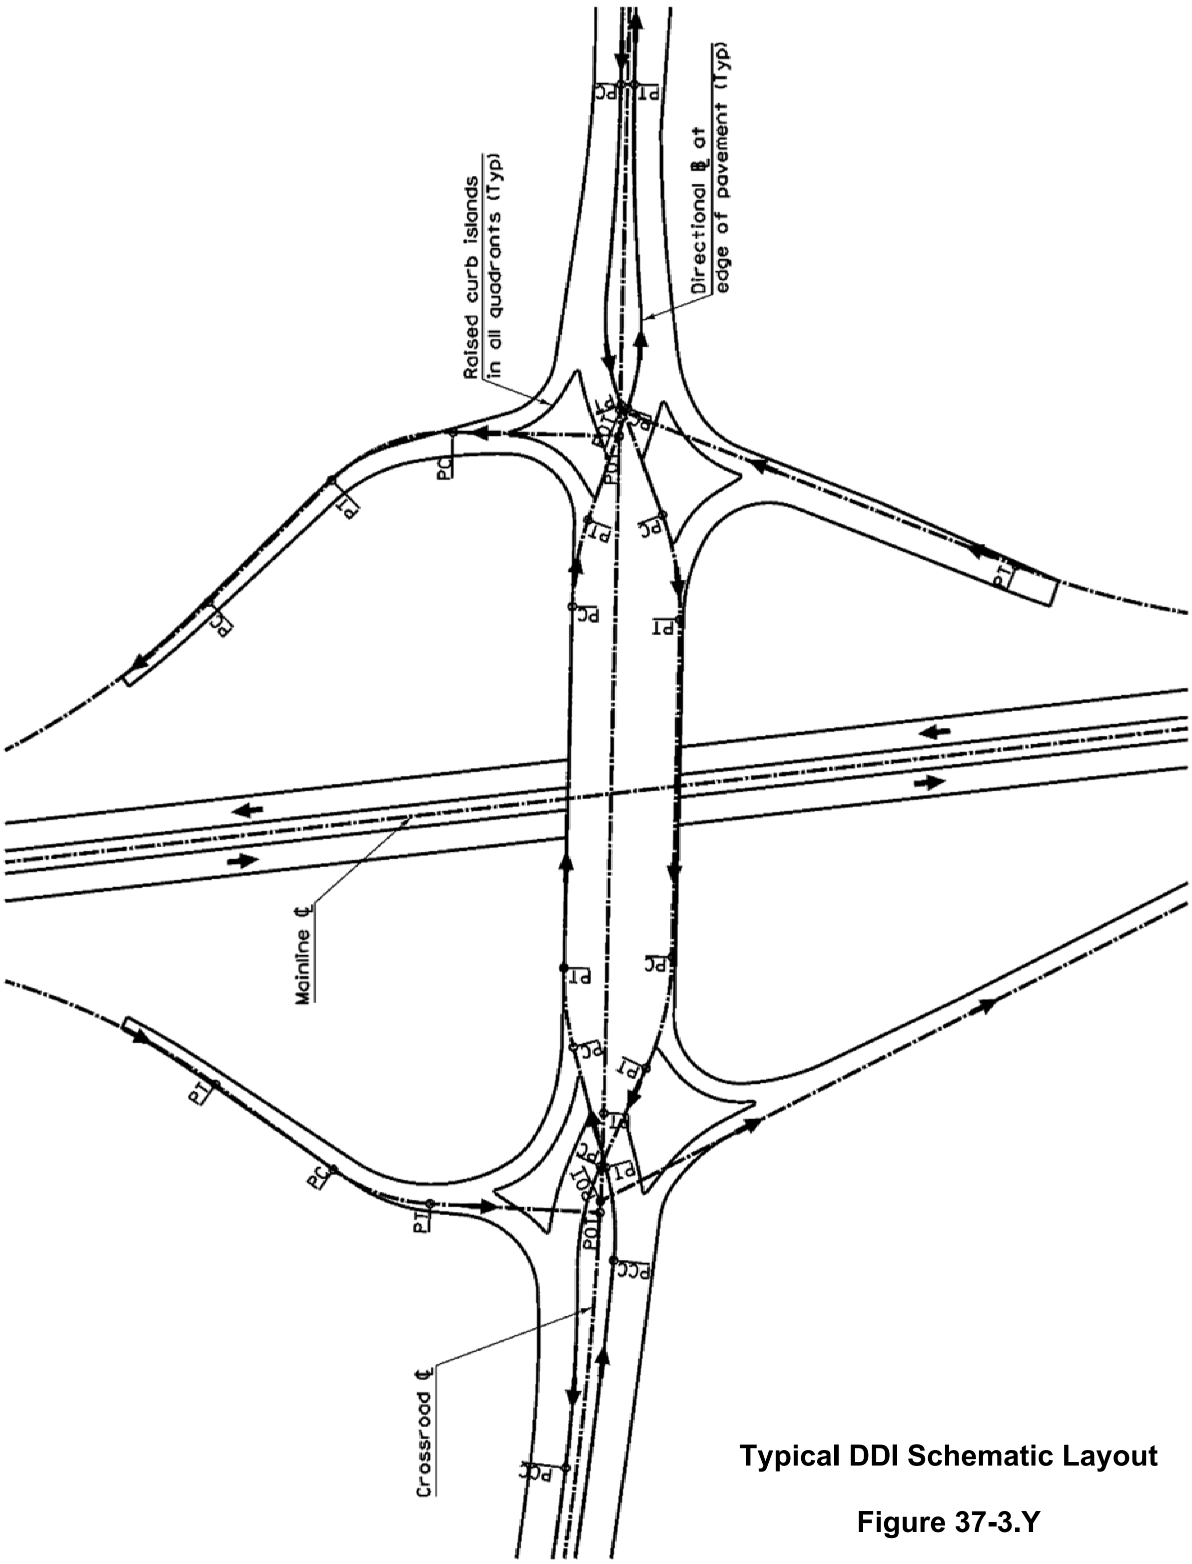
Advantages:

- By separating the crossroad left-turn movements from the signalized intersection operations overall delay can be reduced, since the two-phase signal operations can minimize lost time per cycle. Where left-turning movements are high the operational advantages can be very significant.

- Safety performance is generally improved since there are fewer conflicts points at the signalized intersections, and specific conflicts typically involved with serious crashes are eliminated, e.g. crossing movements from the off ramps. National crash modification factors (CMFs) are available through the online CMF Clearinghouse to aid in predicting DDI safety performance.

- Where shared use paths and/or sidewalks are included along the crossroad the number of conflict points between motor vehicles and non-motorized users can be reduced. Non-motorized users can also use median refuge areas to cross one direction of traffic at a time.

- The geometrics along the crossroad encourage lower traffic speeds, typically 35 mph (55 km/hr) or less, and therefore can reduce the severity of crashes that may occur.



Typical DDI Schematic Layout

Figure 37-3.Y

- Intersection spacing can better allow for traffic signal progression along the crossroad due to the reduced speeds.

- Because left-turning vehicles need not be queued in the median it may be possible to substantially reduce total bridge deck area, typically a major element of interchange cost.

- The flexibility in alignment options can reduce cost, allow for continued use of an existing structure, and create advantageous staging options.

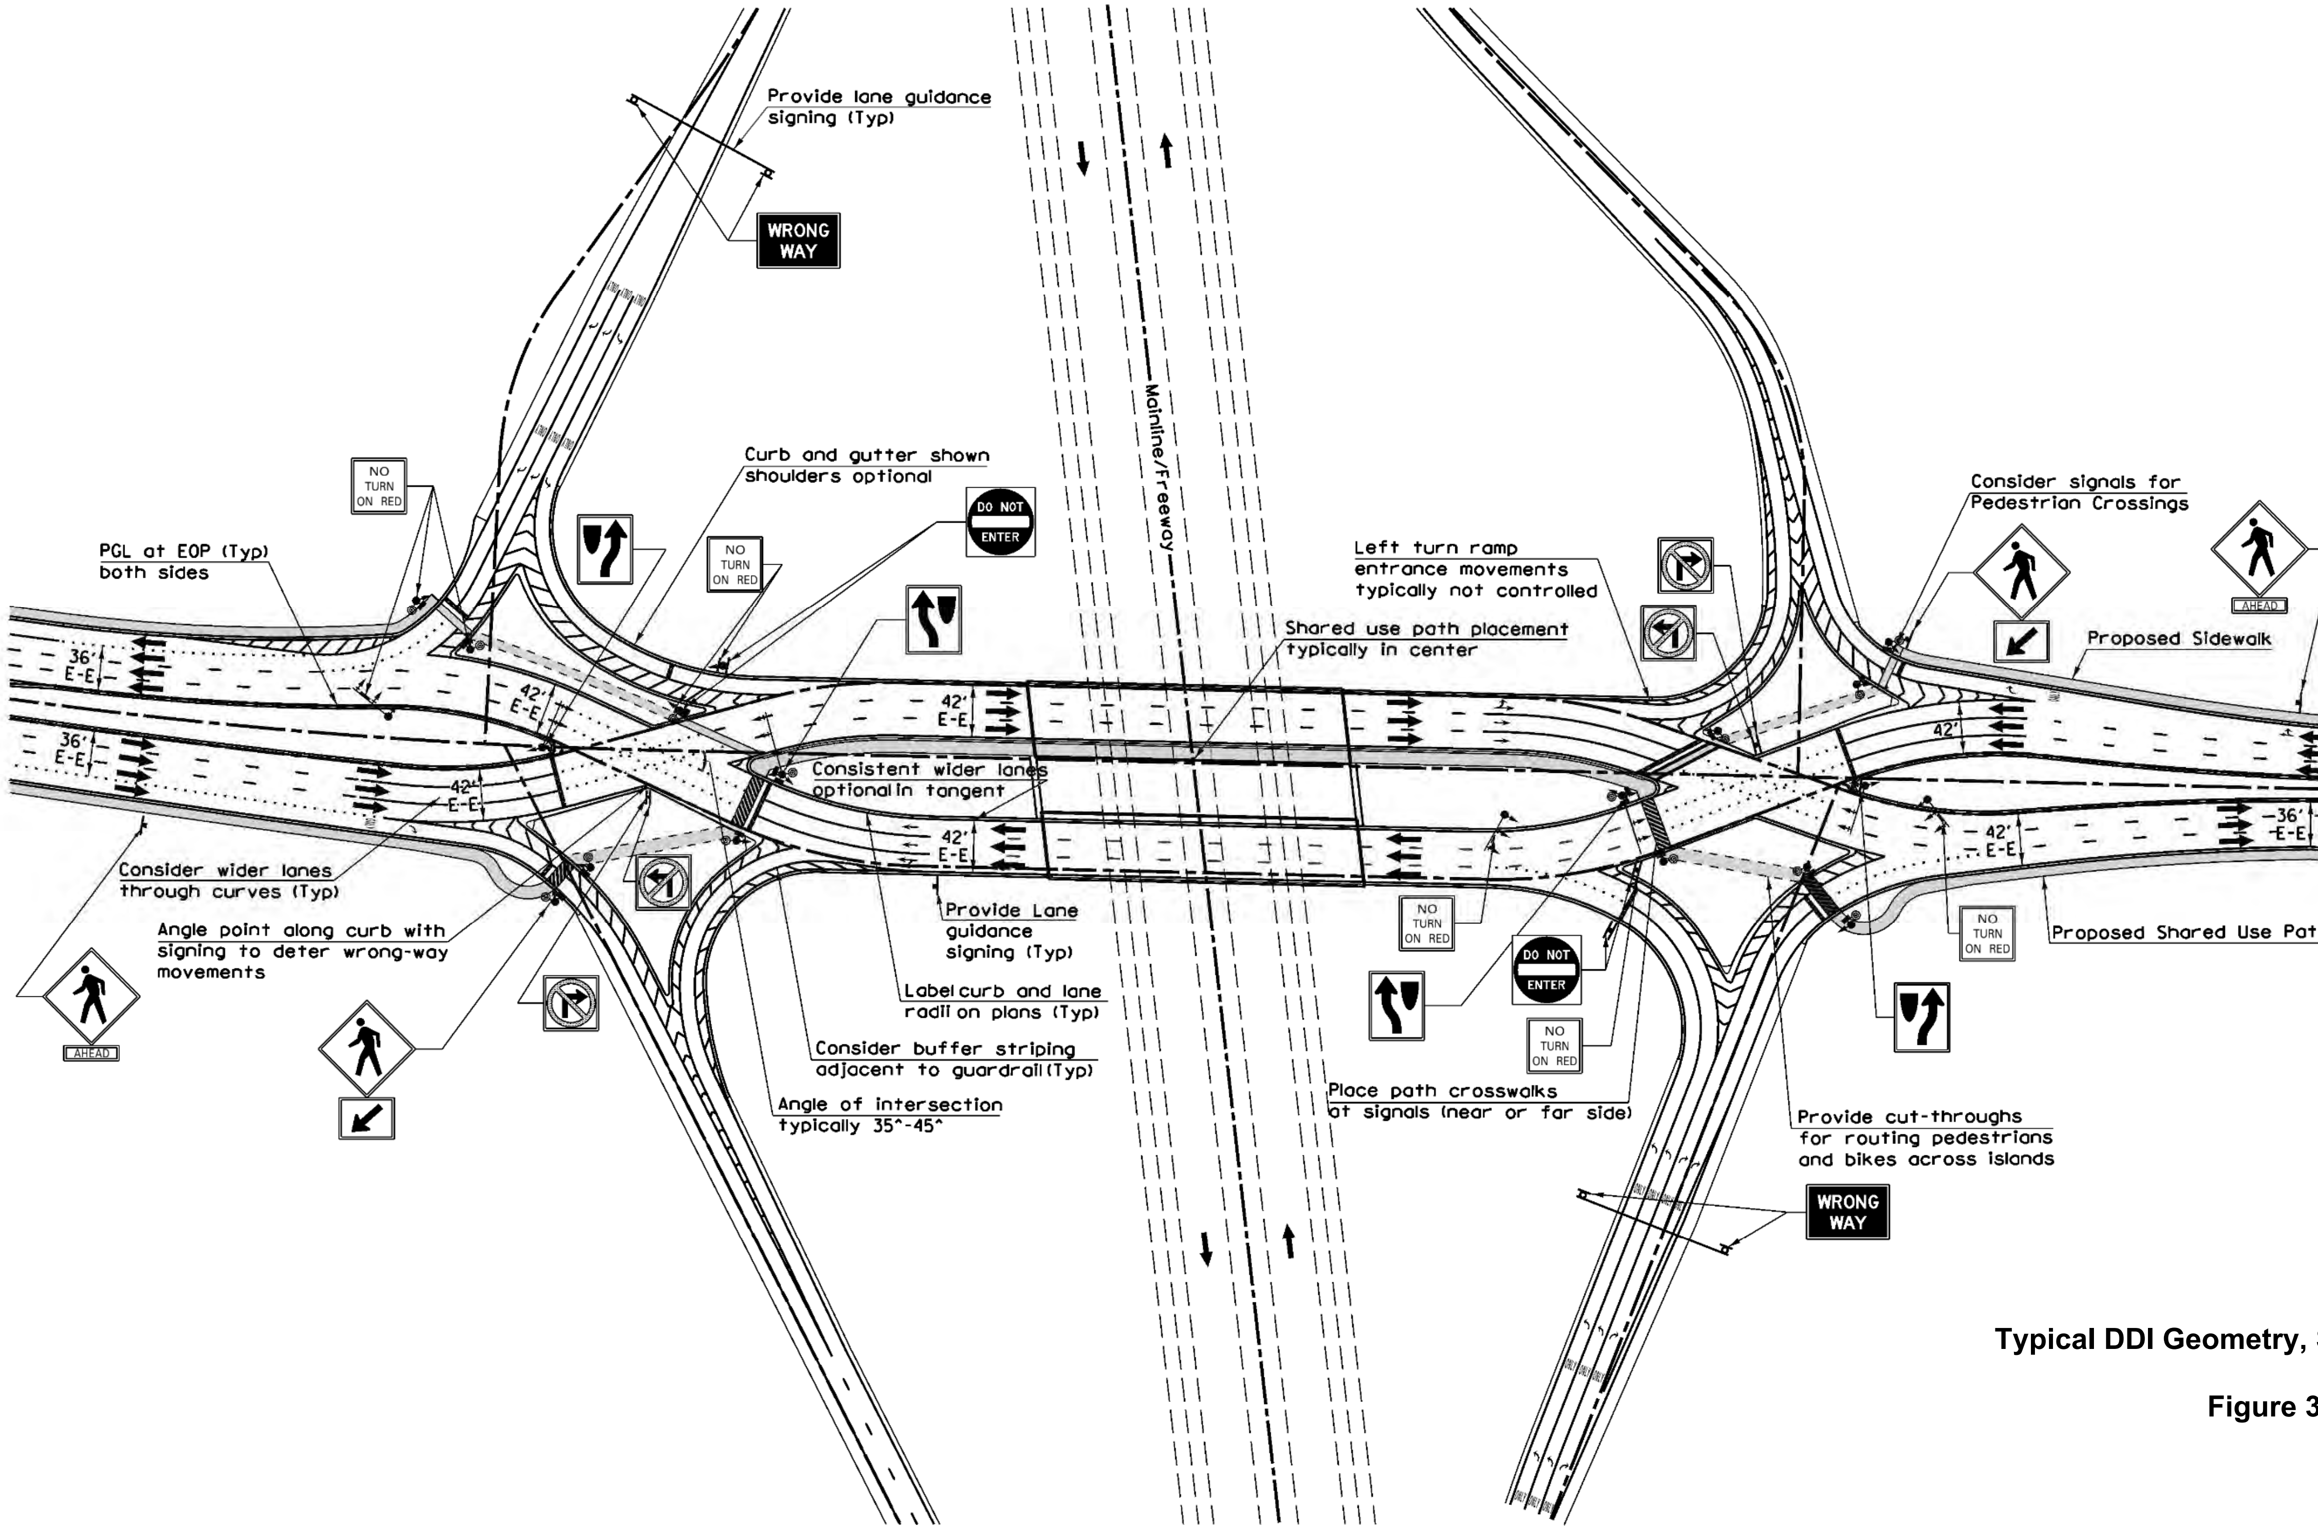
Disadvantages:

- Operational concerns must be considered for unfamiliar drivers. For example, it has been observed that some drivers may look along the wrong set of lanes for approaching traffic when turning from an exit ramp. Signing and pavement marking are critical and different than for other interchange forms.

- The DDI design removes the opportunity to directly route traffic (or operational equipment) along an exit-ramp-to-entrance-ramp path. This may be considered a relevant movement for traffic incident management or the movement of permit loads.

- For lower volume locations in rural contexts, especially where there are low left-turning volumes from the crossroad, DDIs may not provide any operational or safety benefits over traditional diamond configurations.

- Where signals would not otherwise be warranted the crossings of the two directions of through traffic along the crossroad would likely create additional conflicts and delay.



Typical DDI Geometry, Signing and Striping

Figure 37-3.Z

37-3.10(b) Design Considerations

DDI design requires consideration of issues unique to this interchange type. Consider the following when designing a DDI:

1. Over versus Under. One of the first things the designer must address is whether to place the crossroad over or under the freeway or expressway. Especially on retrofit projects, this decision is usually dictated by existing conditions. Either option is possible for a DDI. Section 44-4.02 discusses additional considerations when determining whether to place the crossroad over or under the freeway.

2. Design Speed. Design speeds for the through movements along the crossroad will typically be 35 mph (55 km/hr) or lower. Desirably, the design speed along the crossroad should be 25 mph to 35 mph (40 km/hr to 55 km/hr). The primary goal is to promote a consistent and moderate speed through the crossover intersections while reinforcing the intended movements through geometric design, signing, and pavement marking. The free-flowing left-turn movements onto the ramps may be designed for speeds of 10 mph to 20 mph (15 km/hr to 30 km/hr), with the lower end of this range being advisable for unsignalized ramp movements where pedestrian crossings may be present. The design speed of the crossroad outside of the area of influence of the interchange will typically be higher than that within the interchange, but the regulatory speed limit need not typically be lowered for the short section of roadway, and the geometry of the roadway will work to control travel speeds. Utilize W3-3 signal ahead warning signs to identify the traffic signal and, if there is a 10 mph or greater difference versus the approach, also identify the lower advisory speed.

3. Continued Use of an Existing Structure. Either a single bridge or dual bridges could be utilized for a crossroad passing over a freeway. Utilizing an existing bridge structure in the ultimate condition usually offers substantial cost advantages in comparison to a new larger structure. At retrofit locations DDIs provide inherent flexibility of alignments at lower design speeds and can provide opportunities to utilize existing structures and minimize staging and construction costs.

6. Roadway Alignment and Superelevation. Design the curves for the crossroad through movements using AASHTO Method 2 to distribute superelevation and side friction. Refer to Section 48-5.02. Open Roadway conditions (using AASHTO Method 5) may exist along the crossroad adjacent to the interchange, but drivers are expected to accept a higher driving demand through the lower-speed crossover curves. Typically limit the design superelevation rate to 2.0 percent maximum. Adverse crown slopes may be necessary at some locations due to the interactions of the two directions of travel through the intersection. It is of great importance to maintain positive drainage throughout all parts of the intersection.

   Curve radii approaching the crossover intersections will usually range between 250 ft (75 m) and 600 ft (180 m). Avoid abrupt reverse curvature (i.e. a point of reverse curvature - PRC) since such designs can make it difficult for drivers of larger vehicles to stay within their lanes. Instead, provide tangent sections through the intersections where possible, and preferably extend the tangent onto the entry approach by 15 to 25 ft (5 to 8 m). Providing a Point of Curvature (PC) immediately on the departure side of the intersection creates little concern operationally.

In retrofit projects it may be appropriate to shift the alignment of only one of the two directional travelled ways and provide an asymmetrical design. Issues to consider related to alignment include: minimizing the cross section under or over a bridge, reducing ROW requirements, meeting necessary spacing of the ramp terminals, and providing staging flexibility. The vertical alignment of the crossroad should be assessed to ensure adequate sight lines approaching the signalized crossover intersections. Refer to further discussion of Traffic Signal Placement below.

7. Intersection Crossing Angle. At each intersection, the crossover intersection angle is an important design criterion that can affect both operational and safety performance. The crossing angle is the acute angle between the two directional travelled ways, based on the tangent sections or the lines perpendicular to the radii at points of reverse curvature. Although at most traditional intersections the goal is to provide 75 to 90-degree angles, such angles are not feasible or desirable at DDI crossover intersections. This is primarily due to the large footprint and overly sharp reverse curves that would likely be required with larger angles. The preferred range for the intersection angle is 35 to 45 degrees. Lower/shallower angles may increase the risk of wrong-way movements, compromise sight lines, and require greater driver head-turn. Shallow angles also tend to make intersections overly expansive, hamper operations and make crosswalk design more challenging. Note that as the number of lanes increases beyond two each way a crossover angle of 40 to 45 degrees may be appropriate to introduce adequate median width for the shared use path.

8. Intersection Sight Distance. Provide intersection sight distance as discussed in Section 36-6, checking both the vertical and horizontal planes. The profile of the crossroad should be relatively flat to allow motorists to see the entire crossroad surface and approaches in one view. The extent of head-turn required by drivers at any proposed right-turn-on-red locations is a key consideration if such movements will be allowed. Left-turn-on-red opportunities can be unique to DDIs and require similar assessment.

9. Pedestrian and Bicycle Accommodation. DDIs often provide good opportunities for separated and comfortable pedestrian accommodations. Shared use paths are usually the best way to optimize safety and accommodate less confident bicyclists along the crossroad at minimum cost. A sidewalk and/or a shared-use path will typically be incorporated within the median between the two directions of traffic. This center location allows for crosswalks to be placed where most or all traffic can be controlled by a signal. Crossings of right-turning entrance ramp traffic will require signalization or clearly-visible uncontrolled crossing safety countermeasures.

   The two-phase DDI signal operations can better serve pedestrians by providing more crossing time per phase and/or shorter cycle lengths that can reduce wait times. Crossing distances are usually shorter and pedestrians can deal with one direction of vehicle traffic at a time. Barrier walls are typically incorporated along both sides of a median path but may not be required away from structures depending on speeds and offsets. Cut-through islands are used to provide clear and positive guidance to pedestrians near crosswalks. Bicyclists may also be accommodated directly on the roadway in the traffic lane or by provision of a bicycle lane or paved shoulder in each direction.

10. Lane Widths. Design lane widths for the crossroad through movements at DDIs based on speed, project context, and the need to accommodate the design vehicle either side-by side or in one lane. This choice can depend on the truck volumes at the site. It is usually impractical to apply the turning roadway design criteria in Section 36-2.03 to develop the lane widths for curved crossroad through movements. Review truck and other vehicle templates with the goal of providing lanes that are adequate, yet not excessively wide. Modest curvatures may allow lane widths of 12 to 14 ft (3.6 to 4.3 m). Tighter curves, especially when heavy truck volumes are high, could warrant through lane widths of up to 15 ft (4.6 m). Lanes wider than 15 ft (4.6 m) should be avoided since they may unduly increase intersection size and could create operational issues in tangent sections. As an alternative where truck templates indicate that additional operational width may be appropriate in urban cross sections, consider adding narrow shoulders of 2 to 3 ft (600 to 900 mm) along the crossroad. Also consider providing hatched buffers along guardrail locations to help reduce nuisance hits by trucks. Section 36-2.03 and vehicle turning software may be used for ramp approach and departure design. Include hatched or chevron striping to properly guide passenger cars along ramp movements while accommodating trucks.

11. Median Width and Design. DDI median width can vary with the independent directional crossroad alignments. Since left-turn storage is not required within the median, the minimum median width between the crossovers may be based on the width of a shared use path plus barrier walls, the proposed single or twin structures (when located over the freeway or expressway), or the proposed piers (when located under the freeway or expressway). Experience in other states has indicated that the use of colored/stamped median surfaces can improve driver understanding within DDIs. It seems that the median color change leading into a DDI helps drivers perceive the unique design and better follow the provided signing and marking guidance. When a paved median surface will be used within the limits of a DDI appropriately colored/stamped median surfaces should be included in the design. Maintenance is also reduced in comparison to grass medians.

12. Shoulders and Lane Striping. Shoulder considerations are different at DDIs than at other locations because of the reversal of the two directional pavements. Because the right-side shoulder is typically considered by motorists to be the most appropriate refuge location, the median is the better side to maintain wider shoulders on rural crossroads. Such right-side shoulders would also provide continuity for bicyclists using a shoulder (or bike lane) through the interchange.

13. Traffic Control Devices. Signals will normally be warranted at DDI intersections. Installation of signals is limited to locations meeting ILMUTCD warrants. No special traffic control devices, beyond those included in the ILMUTCD, are necessary or appropriate at a DDI.

    Some early national experience found that over-signing or over-marking DDIs to clarify the unusual traffic pattern could result in driver overload. Minimize potential driver confusion at a DDI by providing positive guidance to drivers in the form of exit ramp guide signing, lane use signing, and pavement markings. Consider guide and lane use signs to position drivers in appropriate lanes before entry into the interchange area. Warning signs should only be used to call driver attention to potential hazards that would be otherwise difficult to perceive. Where present, white edge lines are typically maintained on the right (median) side between intersections, based on driver familiarity. Contact the Bureau of Operations with any specific questions regarding proposed signing and pavement marking.

14. Traffic Signal Placement and Design. When determining signal head locations, proactively address the potential of lane confusion for some drivers. Mount a signal head directly over each travel lane. Consider providing supplemental near-side signal heads to reinforce the intersection traffic control, especially where alignment issues may restrict sight lines and where the maximum allowable distance from a stop line to a signal is approached. Refer to the ILMUTCD for signal head location requirements. Green arrow displays are typically recommended in lieu of circular green signal indications to further enhance directional guidance at DDI intersections. Contact the Bureau of Operations with any specific questions regarding the design of signal installations.

15. Operational Analysis. Use the *Highway Capacity Manual* (HCM) and *Highway Capacity Software* (HCS) to perform a detailed operational analysis of a DDI. Given the crossover geometry and documented DDI driver behavior, operational analysis for DDI interchanges includes several unique inputs, including those for lane utilization, saturation flow rate, lost time, and capacity of yield-controlled turns (where present). The procedures are documented in the HCM and applied in the current HCS. Note that off-ramp left- and right-turn movements may be a significant distance from the crossover, requiring longer intersection clearance (i.e. all-red) time.

    Where there are existing and adjacent signals, consideration of a DDI design alternative may dictate that a comparative analysis be completed for the alternatives under consideration. Synchro or VISSIM software may be used to model corridor traffic operations for alternatives. First perform location-specific calibration of the model for the existing corridor and then compare future no-build and build alternative conditions. Default settings in the software may be used, but analysts can and should apply local adjustments based on professional judgement. Such operational analysis should include any signalized intersections within one-half mile (800 m) of the interchange.

The typical split-phasing of the signals can allow the two crossover movements to operate independently. Traffic progression along the crossroad can be favored in some periods, while prioritizing the turning movements from the ramps may sometimes be necessary to avoid queue build-up on the ramps. Corridor modeling will help identify the potential for unique issues that can occur with DDIs, such as demand starvation due to the increased efficiency of the two-phase signals.

37-3.11 Selection

Typically, several interchange types will be evaluated for potential application considering the following:

- compatibility with the highway system and functional classification of the intersecting highway;
- route continuity and uniformity with adjacent interchanges;
- level of service for each interchange element (e.g., freeway ramp terminal, ramp proper, ramp/crossroad terminal);
- operational and safety considerations (e.g., signing);
- availability of access control along the crossroad;
- road-user impacts (e.g., travel distance and time, convenience, comfort);
- driver expectancy;
- topography and geometric design;
- right-of-way impacts and availability, construction and maintenance costs, and potential for stage construction;
- accommodation of pedestrians and bicyclists on crossroad;
- environmental impacts; and
- potential growth of surrounding area.

In addition, consider the following, which will influence the selection of an interchange type:

1. Basic Types. A freeway interchange will be one of two basic types. A "systems" interchange will connect a freeway to a freeway; a "service" interchange will connect a freeway to a lesser facility.

2. Urban/Rural. In rural areas where interchanges occur relatively infrequently, the type selected is normally influenced by existing topography and environmental factors. In urban areas where restricted right-of-way and close spacing of interchanges are common, the type selection and design of the interchange may become more complex.

The operational characteristics of the crossroad and proximity of nearby interchanges must be considered when selecting and designing an urban interchange.

3. Capacity. The need for loop ramps or other free-flowing ramps may depend upon the capacity of the ramp termini to adequately accommodate the turning traffic. Conduct a capacity analysis to determine if the ramp termini will be adequate and to determine the appropriate number of approach lanes on the crossroad and ramps.

4. Movements. All interchanges should provide for all movements, even when the anticipated turning volume is low.

For certain projects it may be appropriate to evaluate alternative interchange design types by applying an Intersection Control Evaluation (ICE) analysis. ICE tools set up a performance-based framework in order to more objectively analyze alternatives while considering all users. Factors considered in ICE analyses include safety, traffic operations, non-motorized accommodations, environmental impacts, right-of-way, stakeholder and political considerations, and life-cycle costs. The ICE process can begin by assessing a wide range of alternate designs in a preliminary screening. This is followed by a secondary analysis for a short list of the best-performing alternatives. Those could, for example, be presented to project stakeholders leading to a preferred/selected design. The ICE process includes steps to define the issues (based on the project purpose and need), establish project objectives and constraints, screen and analyze alternatives for performance, and select one (or more) best-performing alternative(s). The FHWA has developed the CAP-X and SPICE tools for use by transportation agencies in performing ICE analyses. Contact the Bureau of Design and Environment when considering such an analysis for a project. Project design teams are in the end responsible for type selection and design based on the factors unique to their specific location and should use the tools that best allow them to make an effective project-specific interchange type selection.

37-4 RAMP DESIGN

37-4.01 Ramp Types

The components of a ramp include the freeway ramp terminal, the ramp proper, and a free-flow or controlled ramp terminal at the crossroad. Although ramps have varying shapes, each can be classified into one or more of the types illustrated in Figure 37-4.A and discussed in the following sections.

37-4.01(a) Loop Ramps

There are two types of loop ramps:

1. Free-Flow. The free-flow loop, Figure 37-4.A(a), consists of compounded circular arcs which turn through approximately 270 degrees. The initial and final curves of the loop are tangent to the standard exit or entrance terminal or to a weaving section, depending upon the interchange type. The free-flow loop is a standard component of the cloverleaf interchange, the four-quadrant partial cloverleaf interchange, and the trumpet interchange. Free-flow loops are designed so that the central arc is a sharper radius than that of either the initial or final arcs, or the central arc is intermediate between the two. Motorists decelerate from the speed of the through highway over the initial portion of the ramp and accelerate uniformly over the final portion of the ramp.

   Avoid flatback loops or loop ramps where the central arc has a greater radius than either the initial or final arcs.

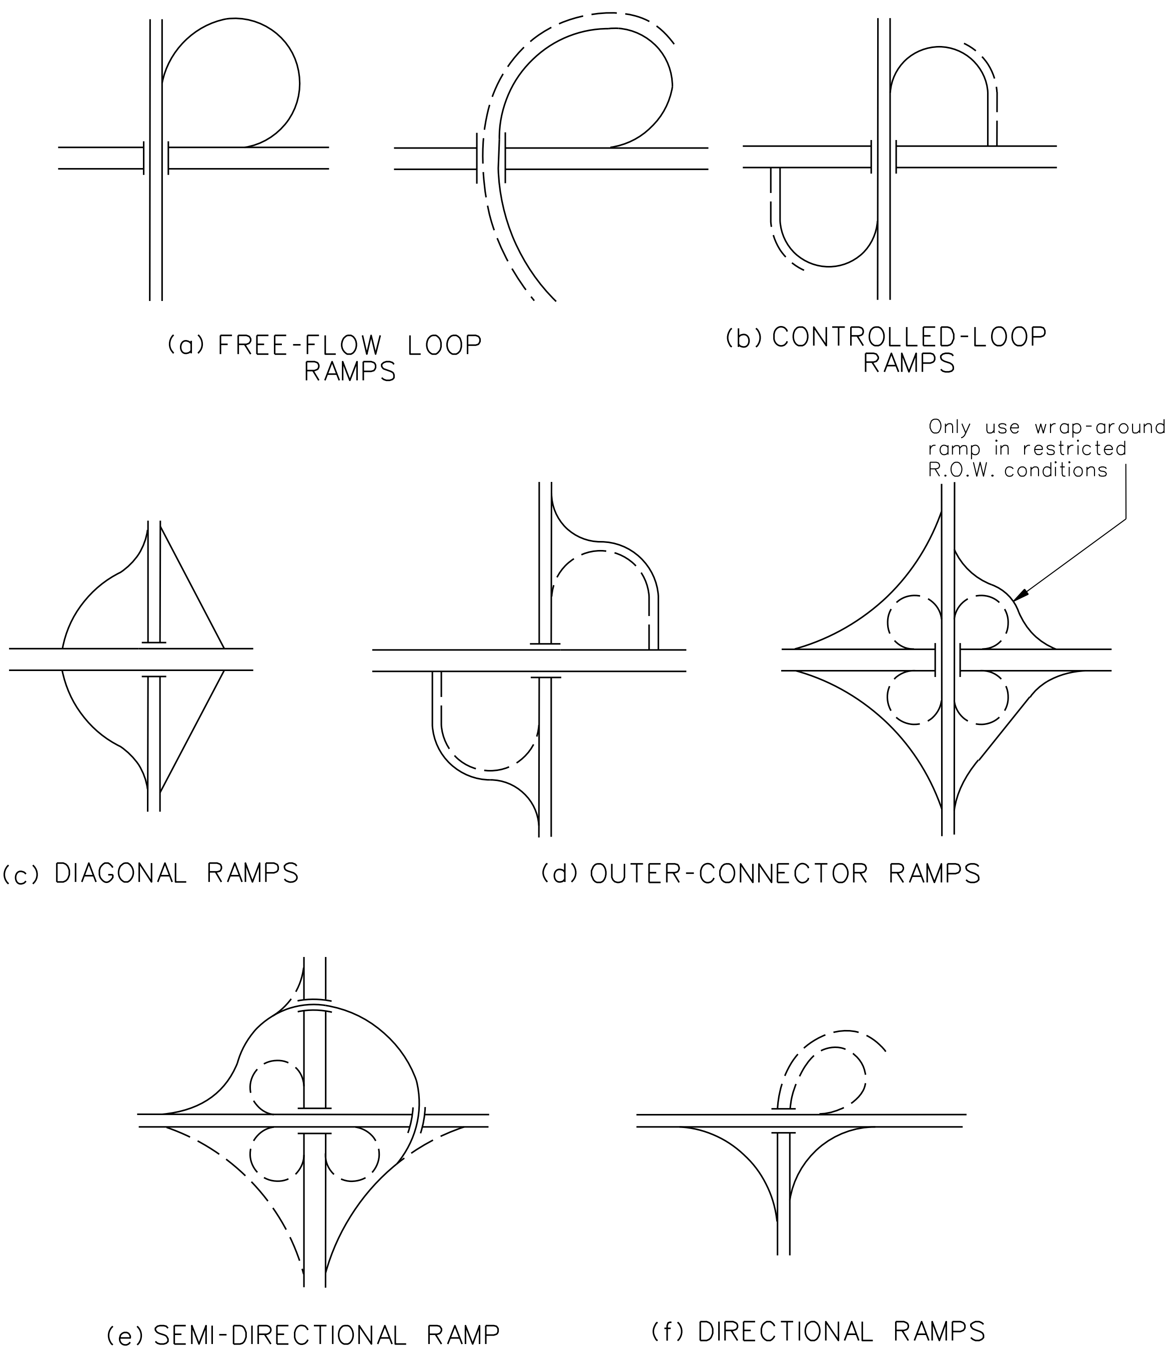
2. Controlled Terminal. Controlled terminal loops, Figure 37-4.A(b), are a component of the two-quadrant partial cloverleaf interchange. They are used most often with the standard entrance and exit terminals. Controlled terminals are provided at the intersections with the crossroad and permit both right- and left-turning movements. Wherever practical, design the angle of intersection for 90 degrees.

37-4.01(b) Diagonal Ramps

Diagonal ramps, Figure 37-4.A(c), are a component of the diamond interchange. Standard entrance and exit terminals are used on the major road, and controlled terminals are provided on the crossroad. The angle of intersection with the crossroad varies between 60 and 90 degrees; see Section 37-3.02(d).

37-4.01(c) Outer-Connector Ramps

Outer-connector ramps are in the same quadrant and to the outside of loop ramps; see Figure 37-4.A(d). They may have free-flow operation (e.g., at cloverleaf or trumpet interchanges) or have controlled operations (e.g., at partial cloverleaf interchanges).



RAMP TYPES

Figure 37-4.A

37-4.01(d) Semi-Directional Ramps

Semi-directional ramps are indirect in alignment, yet more direct than a loop ramp. These ramps are illustrated in Figure 37-4.A(e). Motorists making a left turn normally exit to the right and initially turn to the right, reversing direction before entering the intersecting highway. The outer connection of the trumpet interchange is also a semi-directional ramp.

37-4.01(e) Directional Ramps

Directional ramps do not deviate greatly from the intended direction of travel. These are illustrated in Figure 37-4.A(f) as an element of a trumpet interchange. They are also used to accommodate single lane, right-turning traffic on four-quadrant partial cloverleafs, semi-directional, and directional interchanges.

37-4.02 Collector-Distributor Roadways

37-4.02(a) Usage

A collector-distributor (C-D) roadway is an auxiliary roadway parallel to and separated from the main traveled way which serves to collect and distribute traffic from several access points. It provides greater capacity and permits higher operating speeds to be maintained on the main traveled way. C-D roadways may be provided at single interchanges, through two adjacent interchanges or, in urban areas, continuously through several interchanges. Figure 37-3.L illustrates a schematic of a C-D roadway within a full cloverleaf interchange.

Usually, interchanges designed with single exits are superior to those with two exits, especially if one exit is a loop ramp or the second exit is a loop ramp preceded by a loop entrance ramp. Whether used in conjunction with a full cloverleaf or with a partial cloverleaf interchange, the single-exit design may improve the operational efficiency of the entire interchange. C-D roadways use the single exit approach to improve the interchange operational characteristics. C-D roadways will:

- remove weaving maneuvers from the mainline and transfer them to the slower speed C-D roadways,
- provide high-speed single exits and entrances from and onto the mainline,
- satisfy driver expectancy by placing the exit before the grade separation structure,
- simplify signing and the driver decision-making process, and
- provide uniformity of exit patterns.

C-D roadways are most often warranted when traffic volumes (especially in weaving sections) are so high that the interchange cannot operate at an acceptable level of service. They also may be warranted where the speed relationship between weaving and non-weaving vehicles is significant.

37-4.02(b) Design

When designing C-D roadways, consider the following:

1. Design Speed. The design speed of a C-D roadway usually ranges from 40 to 55 mph (60 to 90 km/hr). Typically, use a design speed within 20 mph (30 km/hr) of the mainline design speed, but not exceeding 55 mph.

2. Lane Balance. Maintain lane balance at the exit and entrance points of the C-D roadways; see Section 37-2.03.

3. Width. C-D roadways may be one or two lanes, depending upon the traffic volumes and weaving conditions. C-D roadways are designed similar to ramps with traveled way widths of either 16 ft or 24 ft (4.9 m or 7.2 m).

4. Separations. The separation between the C-D roadway and mainline should be as wide as practical. Figure 37-4.B provides the minimum separation that should be provided with and without a median barrier.

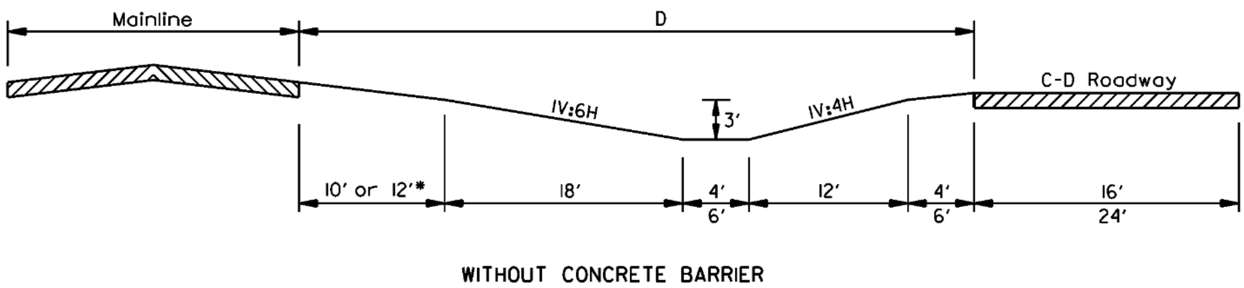
5. Terminal Designs. Figure 37-4.C illustrates typical entrance terminal designs for C-D roadways. Figure 37-4.D illustrates typical exit terminal designs.

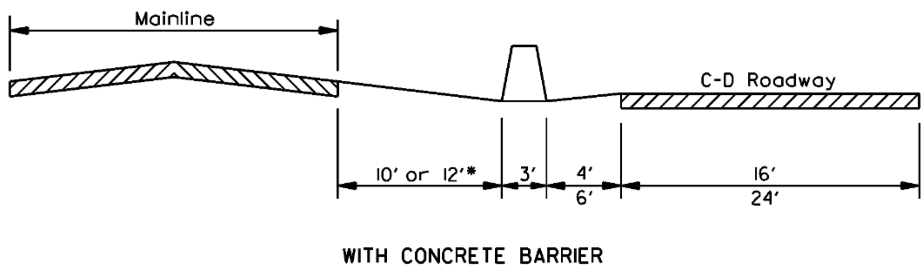
37-4.03 High-Speed Directional/Semi-Directional Roadways

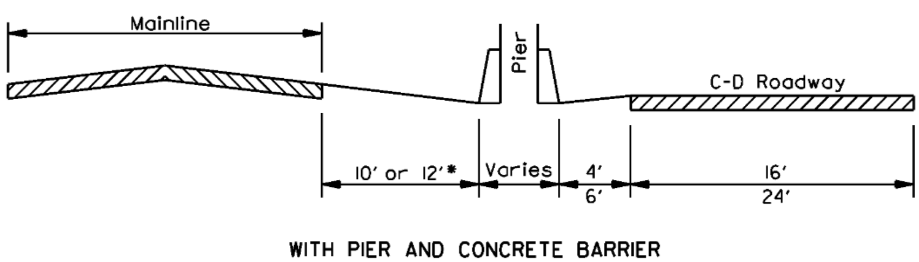
High-speed directional or semi-directional roadways, like ramps, accommodate turning movements at interchange facilities, but they are distinguished from ramps in that they provide two-lane, one-way operations. These roadways are provided for large traffic movements that exceed the capacity of a one-lane ramp, for route continuity, or for improved traffic operations. For route continuity purposes, directional roadways may carry any route including expressways and freeways. These roadways are directional or semi-directional in alignment and generally have major divergence and convergence at their terminals. Design criteria for these roadways are:

1. Directional Roadways. The design speed of directional roadways, in rural areas may be 60 mph or 70 mph (100 km/hr or 110 km/hr). In urban areas, directional roadways may be designed for 50 mph, 55 mph, or 60 mph (80 km/hr, 90 km/hr, or 100 km/hr) depending on traffic volumes, right-of-way, motorist expectations, and importance of route. In all cases, the maximum superelevation rate is 6%. Shoulder widths are the same as the mainline roadway.

2. Semi-Directional Roadways. Desirably, use the criteria for directional roadways. However, use minimum design speeds, 55 mph (90 km/hr) in rural areas and 50 mph (80 km/hr) in urban areas. Where two-lane roadways are required for capacity or route continuity, the maximum superelevation rate is 6%. However, where a two-lane roadway is desirable because of the long design length of a single-lane ramp, a maximum superelevation rate of 8% may be used.







* 12 ft. paved shoulders should be considered where the directional distribution of trucks exceeds 250 DDHV.

37-4.04 Design Speed

Figure 37-4.E provides the AASHTO recommended ranges of ramp design speeds based on the design speed of the mainline. IDOT targets the middle range and the values apply to the entire ramp (i.e., ramp terminal and ramp proper). In addition to Figure 37-4.E, consider the following when selecting the ramp design speed:

1. Loop Ramps. Design speeds in the middle and high range are generally not attainable for loop ramps. The following apply to loop ramps:

    - For loop ramps on collector-distributor roadways or in restricted urban conditions, the minimum design speed for loops should be 25 mph (40 km/hr).
    - Where the truck ADT is greater than 15%, use a minimum design speed of 30 mph (50 km/hr) for the initial curve after the exit curve; see Figure 37-3.N.
    - For rural loop ramps, a 30 mph (50 km/hr) design speed is preferred.
    - Use a design speed of 35 mph (60 km/hr) for cloverleaf interchange loop ramps between freeways.

Mainline Design Speed	US Customary						Metric				
	50 mph	55 mph	60 mph	65 mph	70 mph	75 mph	80 km/hr	90 km/hr	100 km/hr	110 km/hr	120 km/hr
	Ramp Design Speed (mph)						Ramp Design Speed (km/hr)				
High Range	45	45	50	55	60	65	70	80	90	100	110
Middle Range	35	40	45	45	50	55	60	60	70	80	90
Low Range	25	30	30	30	35	40	40	50	50	60	70

RAMP DESIGN SPEEDS

Figure 37-4.E

2. Outer Connector Ramps. The design speed for the outer connector ramp of a rural cloverleaf interchange should be in the middle range however, where a wrap-around type ramp is used, a design speed 5 mph (10 km/hr) less than the middle range may be used for the center curve.

3. Semi-Directional Ramps. Use design speeds in the middle range for semi-directional ramps. In restricted urban conditions do not use a design speed less than 40 mph (60 km/hr).

4. Directional Ramps. These include both diagonal ramps at a diamond interchange and ramps at a directional interchange. The design speed shall be in the middle range.

5. Directional Roadways. Two-lane directional roadways within an interchange shall be designed in the middle range.

6. Controlled Terminals. If a ramp is terminated at an intersection with a stop or signal control, the design speeds in Figure 37-4.E are not applicable to a portion of the ramp near the intersection. The design speed on the ramp near the crossroad intersection is usually assumed to be 40 mph (60 km/hr) but can be a minimum of 25 mph (40 km/hr) in restricted areas.

7. Variable Speeds. The ramp design speed may vary based on the two design speeds of the intersecting roadways. Use a higher design speed on the portion of the ramp near the higher speed facility and a lower design speed near the lower speed facility. When using variable design speeds, the maximum speed differential between controlling design elements (e.g., horizontal curves, vertical curves) should not be greater than 10 mph (20 km/hr). The designer must ensure that sufficient deceleration distance is available between design elements with varying design speeds (e.g., two horizontal curves).

Figure 37-4.F presents geometric design criteria for interchange ramps based on the selected design speed (e.g., sight distance, horizontal alignment and vertical alignment). These are discussed in detail in the following sections.

37-4.05 Sight Distance

The designer should review the ramp cross-section, horizontal alignment, and vertical alignment to ensure that stopping sight distance is continuously provided along the interchange ramp. Because ramps are composed of curves of various radii and design speeds, sight distance requirements may vary over the length of the ramp. Figure 37-4.F provides a summary of the geometric criteria for ramps, including stopping sight distance.

GEOMETRIC REQUIREMENTS								
Ramp Design Speed at R_1 (mph)		55	50	45	40	35	30	25
Stopping Sight Distance (ft)		495	425	360	305	250	200	155
HORIZONTAL ALIGNMENT								
Minimum Radius (ft) for R_1 for $e = e_{max}$ (Entrance and Exit Ramps)	8%	960	758	587	444	314	214	134
	6%	1060	833	643	485	340	231	144
Minimum Length of Arc (ft)		See Figure 37-4.H						
Superelevation Runoff Length for One Lane Ramp (ft) (adjusted for 16 ft width)	8%	272	255	235	220	205	195	185
	6%	204	190	180	165	155	145	135
VERTICAL ALIGNMENT								
Maximum Grades		+4% and -6%						
Crest Vertical Curves K-values		114	84	61	44	29	19	12
Sag Vertical Curves K-values		115	96	79	64	49	37	26

GENERAL NOTES:

- Where radii greater than R_1 are used, determine the ramp superelevation rate according to Section 32-3.
- e_{max} = 6% values are applicable to areas with snow and ice conditions and/or highly congested traffic operations.

SUMMARY OF ROADWAY DESIGN CRITERIA FOR INTERCHANGE RAMPS (US Customary)

Figure 37-4.F

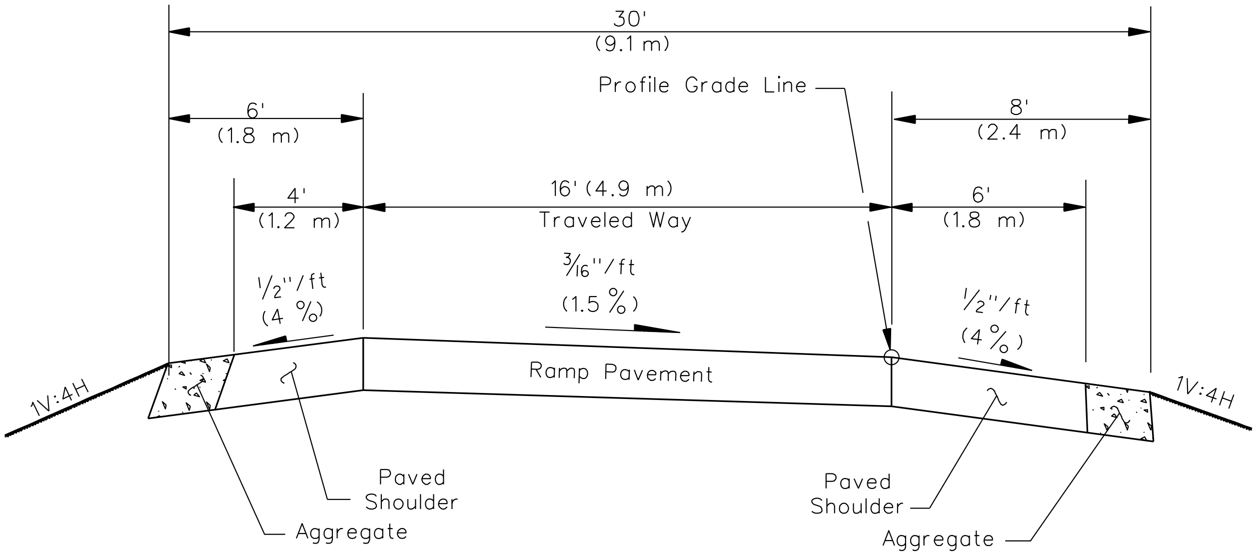
GEOMETRIC REQUIREMENTS							
Ramp Design Speed at R_1 (km/hr)		90	80	70	60	50	40
Stopping Sight Distance (m)		160	130	105	85	65	50
HORIZONTAL ALIGNMENT							
Minimum Radius (m) for R_1 for $e = e_{max}$ (Entrance and Exit Ramps)	8%	304	229	168	113	73	41
	6%	336	252	184	123	79	43
Minimum Length of Arc (m)		See Figure 37-4.H					
Superelevation Runoff Length for One Lane Ramp (m) (adjusted for 4.9 m width)	8%	83	78	71	65	60	55
	6%	63	58	53	49	45	42
VERTICAL ALIGNMENT							
Maximum Grades		+4% and -6%					
Crest Vertical Curves K-values		39	26	17	11	7	4
Sag Vertical Curves K-values		38	30	23	17	12	8

GENERAL NOTES:

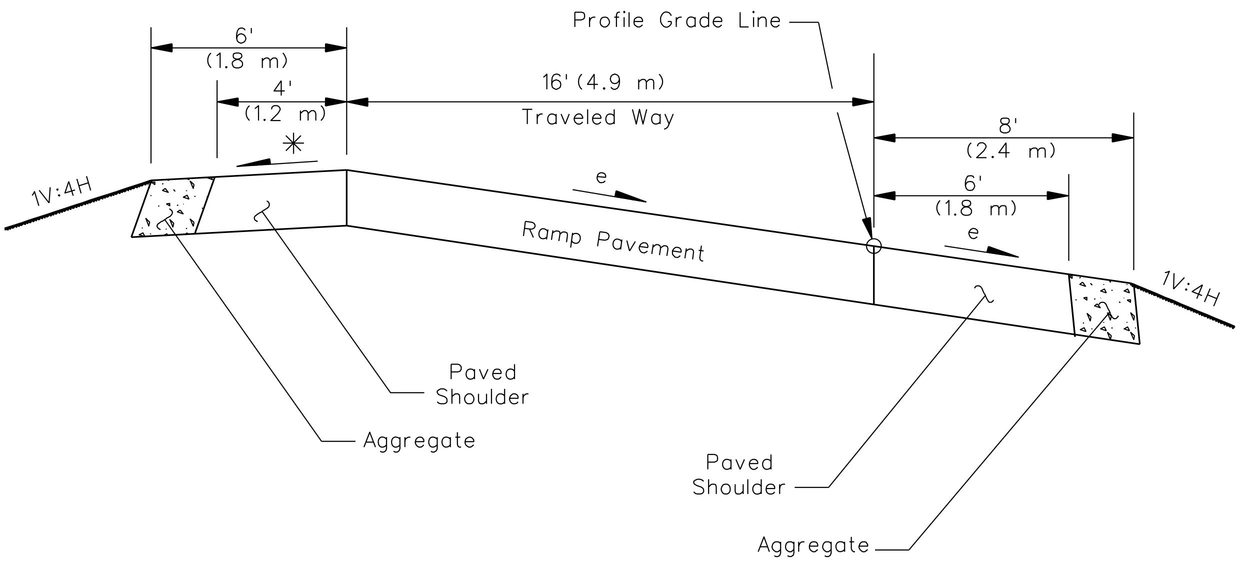
- Where radii greater than R_1 are used, determine the ramp superelevation rate according to Section 32-3.
- e_{max} = 6% values are applicable to areas with snow and ice conditions and/or highly congested traffic operations.

SUMMARY OF ROADWAY DESIGN CRITERIA FOR INTERCHANGE RAMPS (Metric)

Figure 37-4.F



TANGENT SECTION



SUPERELEVATED SECTION

TYPICAL RAMP CROSS SECTIONS

Figure 37-4.G

37-4.06 Cross Section Elements

Figure 37-4.G presents the typical cross section criteria for tangent and superelevated portions of ramps. The following also applies to the ramp cross section:

1. Width. The minimum width of a one-way, one-lane ramp is 30 ft (9.1 m). The 30 ft (9.1 m) width includes a 6 ft (1.8 m) left shoulder (4 ft (1.2 m) paved), an 8 ft (2.4 m) right shoulder (6 ft (1.8 m) paved), and a 16 ft (4.9 m) paved traveled way. This arrangement is illustrated in the ramp cross sections in Figure 37-4.G. For multilane directional roadways, the cross sectional width is the same as the freeway design (e.g., 24-ft (7.2-m) traveled way width plus shoulders); see Chapter 44.

2. Pavement Design. For pavement design information that is also applicable to ramps, see Chapter 54.

3. Cross Slope. For tangent sections, the 16 ft (4.9 m) traveled way is sloped unidirectionally at 3/16″/ft (1.5%) towards the right shoulder. Shoulder cross slopes, for both the paved and unpaved portions, are typically 1/2″/ft (4%). The left shoulder is typically sloped away from the traveled way. For all superelevated ramps, the ramp traveled way and shoulders are sloped as discussed for open roadways conditions in Section 32-3.

4. Curbs. If curb and gutter is required, place it on the outside edge of the full-width paved shoulders. See Chapters 34 and 38 for information on the use of curbs.

5. Bridges and Underpasses. Carry the full paved width of the ramp, including the paved shoulders over a bridge. See Chapters 38 and 39 when determining the clear ramp width for an underpass.

6. Side Slopes/Ditches. For the ramp proper, use a side slope of 1V:4H or flatter. Chapters 34 and 38 provide the applicable design information for side slopes and ditches.

7. Clear Zones. Measure the clear zone from the edge of the traveled way on both sides of the ramp using the criteria in Section 38-3.

8. Right-of-Way. The right-of-way adjacent to the ramp is fully access controlled and the right-of-way is fenced.

37-4.07 Horizontal Alignment

37-4.07(a) Theoretical Basis

Establishing horizontal alignment criteria for any highway element requires a determination of the theoretical basis for the various alignment factors. These include the side-friction factor (f), the distribution method between side friction and superelevation, the relative longitudinal gradients, and the distribution of the superelevation runoff length between the tangent and horizontal curve. For horizontal alignment on the ramp proper, the theoretical basis will be open-roadway conditions as discussed in Chapter 32. In summary, this includes:

- relatively low side-friction factors (i.e., a relatively small level of driver discomfort);
- the use of AASHTO Method 5 to distribute side friction and superelevation;
- relatively flat longitudinal gradients for superelevation runoff lengths; and
- distributing 67% of the superelevation runoff length on the tangent and the remainder on the horizontal curve.

The following sections discuss the specific horizontal alignment criteria for ramps.

37-4.07(b) Design Controls

The following will apply to the horizontal alignment of ramps:

1. Minimum Curve Radii. Figure 37-4.F provides the minimum curve radii based on ramp design speed, open-roadway conditions, and e_{max}.

2. Superelevation Rates. For most areas, the maximum superelevation rate on the ramp is e_{max} = 8%. For areas with snow and ice conditions and/or areas with high congestion, the maximum superelevation rate is e_{max} = 6%. For two-lane directional roadways within an interchange, use an e_{max} = 6% throughout the State.

   Because of the typically restricted site conditions for interchanges (e.g., the need to minimize right-of-way), the majority of horizontal curves on ramps will be superelevated at e_{max}. Where practical, use curves flatter than R_{min}. For these curves, the design superelevation rate will be determined from the applicable e_{max} figure in Section 32-3 for open roadways.

3. Trucks. Where there are a significant number of trucks on loop ramps, the designer may need to consider how the design may increase the rollover potential for large trucks. To reduce this potential, consider using flatter curve radii on the second curve. Modified radii can be obtained by reducing the superelevation rates and/or lowering the side-friction factors. For additional guidance on modified truck friction factors, see the article in Transportation Research Record No. 1385 entitled “Interchange Ramp Geometrics — Alignment and Superelevation Design.”

4. Superelevation Runoff Lengths. Open-roadway conditions, as discussed in Section 32-3, apply to transitioning the ramp from its normal cross slope on tangent to the needed superelevation on curves. The relative longitudinal slopes in Figure 32-3.F apply to ramps. Based on these gradients, $e = e_{max}$, and a 16 ft (4.9 m) ramp traveled way, Figure 37-4.F presents the superelevation runoff lengths for horizontal curves on ramps.

5. Ramp Baseline. Typically, the right edge of the ramp traveled way is used for horizontal and vertical control, and the control point for the axis of rotation.

6. Shoulder Superelevation. The criteria presented in Section 32-3 for superelevating the high and low side of shoulders for open roadways will apply to superelevated curves on ramps.

7. Reverse Curves. Reverse curves may be required to:

   - meet restrictive right-of-way conditions,
   - provide for a better location of the intersection on the crossroad, and/or
   - provide a preferred angle of intersection with the crossroad.

   Design the reverse curves with a minimum tangent section consisting of a continuously rotating plane between the curves. This continuously rotating plane will determine the necessary distance between the PT and the succeeding PC and is based on the 67% superelevation runoff lengths for each curve. See Section 32-3 for more information on superelevating reverse curves.

8. Sight Distance. Section 32-4 presents the criteria for sight distance around horizontal curves based on the curve radii and design speed. These criteria also apply to curves on ramps.

9. Controlled Ramp Termini. Exit ramps may end at a controlled intersection — stop control or signal control. If horizontal curves on the ramps are near the intersection, a design speed for the curve should be selected which is appropriate for expected operations at the curve. See Section 36-1.05(b) for more information.

37-4.07(c) Length of Arc

Where compound arcs of decreasing radius are used on exit ramps, the arcs should have sufficient length to enable motorists to decelerate at a reasonable rate over the range of design speeds; see Figure 37-4.H. The radii of the flatter arc compared to the radii of the sharper arc should not exceed a ratio of 2:1 to prevent abruptness in operation and appearance.

Comparable radii and length controls may be used on entrance ramps with compound arcs of increasing radii. However, for entrance ramps, the 2:1 ratio of compound curves is not critical because the vehicle is accelerating into a curve with a larger radius or into a tangent section.

US Customary							
Radius (ft)	**100**	**150**	**200**	**250**	**300**	**400**	**500 or more**
Minimum (ft)	40	50	60	80	100	120	140
Desirable (ft)	60	70	90	120	140	180	200
Metric							
Radius (m)	**30**	**50**	**60**	**75**	**100**	**125**	**150 or more**
Minimum (m)	12	15	20	25	30	35	45
Desirable (m)	20	20	30	35	45	55	60

Note: These lengths are applicable where the ramp curve is followed by a curve 1/2 the radius or preceded by a curve of double radius.

ARC LENGTHS FOR COMPOUND CURVES

Figure 37-4.H

37-4.08 Vertical Alignment

37-4.08(a) Grades

Values of limiting gradients are +4% to -6% regardless of the design speed but, for any one ramp, the selected gradient is dependent upon several factors. These include:

- Where steep grades are required, locate them within the center portion of the ramp.
- Locate freeway ramp terminals and approach areas near intersections on as flat a grade as practical; see Section 37-5 for grades near ramp/crossroad intersections and Section 37-6 for freeway ramp terminal grades.
- Ramp grades may affect the location of ramp termini. This may be a concern where the ramp intersects the crossroad at an angle of 70 degrees or less. Section 37-5.01 further discusses the location of ramp/crossroad intersections.

37-4.08(b) Vertical Curvature

Design vertical curves on ramps to meet the stopping sight distance criteria based on the ramp design as presented in Chapter 33. Figure 37-4.F provides the K-values for both crest and sag vertical curves. The ramp profile often assumes the shape of the letter S with a sag vertical curve at one end and a crest vertical curve at the other. In addition, design the vertical curvature adjacent to the standard exit and entrance terminals using a design speed of 50 mph (80 km/hr) or greater.

37-4.08(c) Cross Sections Between Adjacent Ramps

Where the horizontal alignment of a ramp is designed to be parallel to an adjacent ramp (e.g., parclo, cloverleaf, trumpet interchanges), first establish the profile of the loop ramp and then set the profile of the outer ramp to be approximately parallel to the inner-loop ramp profile. This is accomplished by calculating the left-edge elevations of the loop ramp and matching those elevations for the left-edge elevations of the outer ramp. To ensure the median edges between the two ramps are approximately level, develop a typical cross section during the preparation of the IDS.

37-4.09 Roadside Safety

The criteria in Chapter 38 (e.g., clear zones, barrier warrants, length of need) will apply to the roadside safety design of interchange ramps.

37-5 RAMP/CROSSROAD INTERSECTIONS

37-5.01 General Design Criteria

At diamond and partial cloverleaf interchanges, the ramp will terminate or begin at a controlled intersection on the crossroad, either with a stop sign or traffic signal. In general, the intersection should be designed as described in Chapter 36. Consider the following in the design of ramp/crossroad intersections:

1. Length of Left-Turn Lanes. For diamond interchanges, typically the minimum distance between ramp/crossroad intersections is set by the length of overlapping left-turn lanes. Note that in rural areas, the minimum design speed for determining the length of left-turn lanes on the crossroad is 55 mph (90 km/hr). Left-turn lanes are usually designed with straight-line tapers when the crossroad goes over the freeway and with reverse curves when the crossroad goes underneath the freeway; see Figure 37-5.A. For compressed diamond interchanges, the length of the left-turn lanes will be determined based on left-turn storage requirements, see Section 36-3.02 and Figure 37-5.B. The left-turn control radii into the ramps are set at the ends of the left-turn lanes. This also determines the location of the ramp baselines.

2. Turn Lanes on Ramps. Exclusive turn lanes are often required at the end of an exit ramp. Chapter 36 provides information on the design of turn lanes at intersections, which are also applicable for ramps.

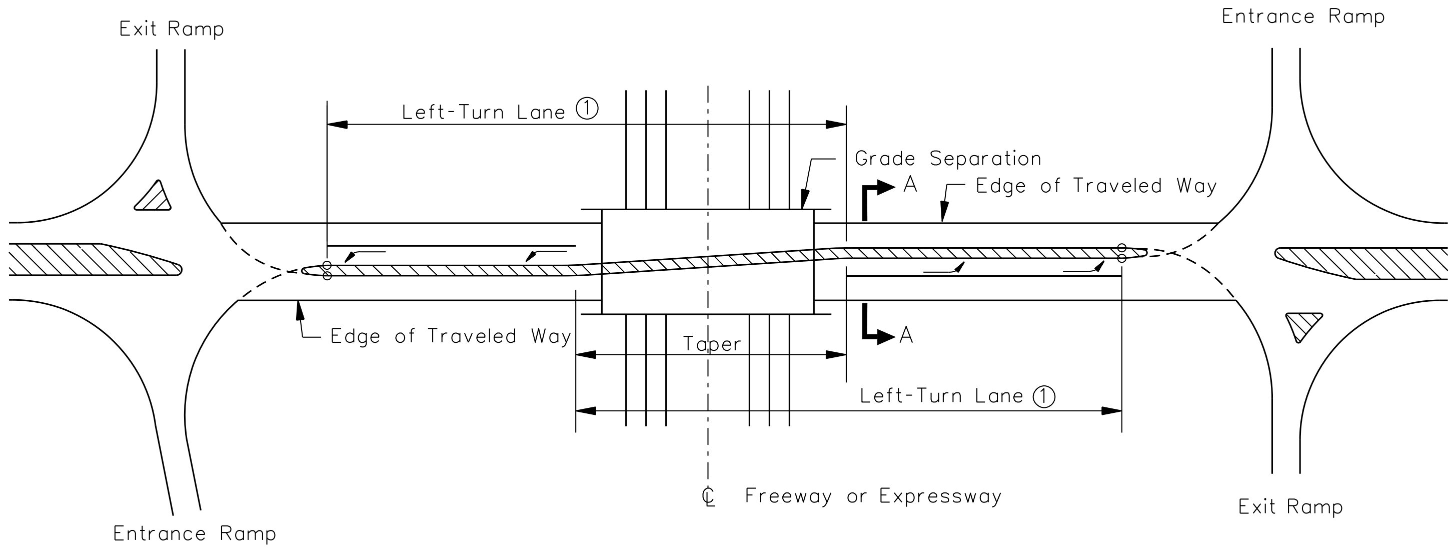
3. Signalization. Where queuing at one intersection is long enough to effect operations at another, the two intersections may need a larger separation, interconnected signals, or a six-phase overlap signal design.

4. Ramp Grades. Where the exit and entrance ramps intersect with the crossroad, design the first 150 ft to 200 ft (45 m to 60 m) of the ramp with a profile grade of 1.5% to 2%.

5. Crossroad Grades. Design the crossroad grades for a maximum of 2% through the ramp/ crossroad intersection.

6. Capacity. Ensure that sufficient capacity and storage for the ramp/crossroad intersection is available. This may require adding lanes at the intersection or on the ramp proper. The analysis must also consider the operational impacts of the traffic characteristics in either direction on the crossroad.

7. Sight Distance. Section 36-6 discusses the criteria for intersection sight distance. These criteria also apply to the ramp/crossroad intersection. Give special attention to the location of the bridge piers, abutments, sidewalks, bridge railing, roadside barrier, etc.; these elements may present major sight distance obstacles. The bridge obstruction and the required intersection sight distance may result in the relocation of the ramp/crossroad intersection further from the structure. In addition, the crest vertical curve on the crossroad may need to be lengthened to provide adequate sight distance in the vertical plane.

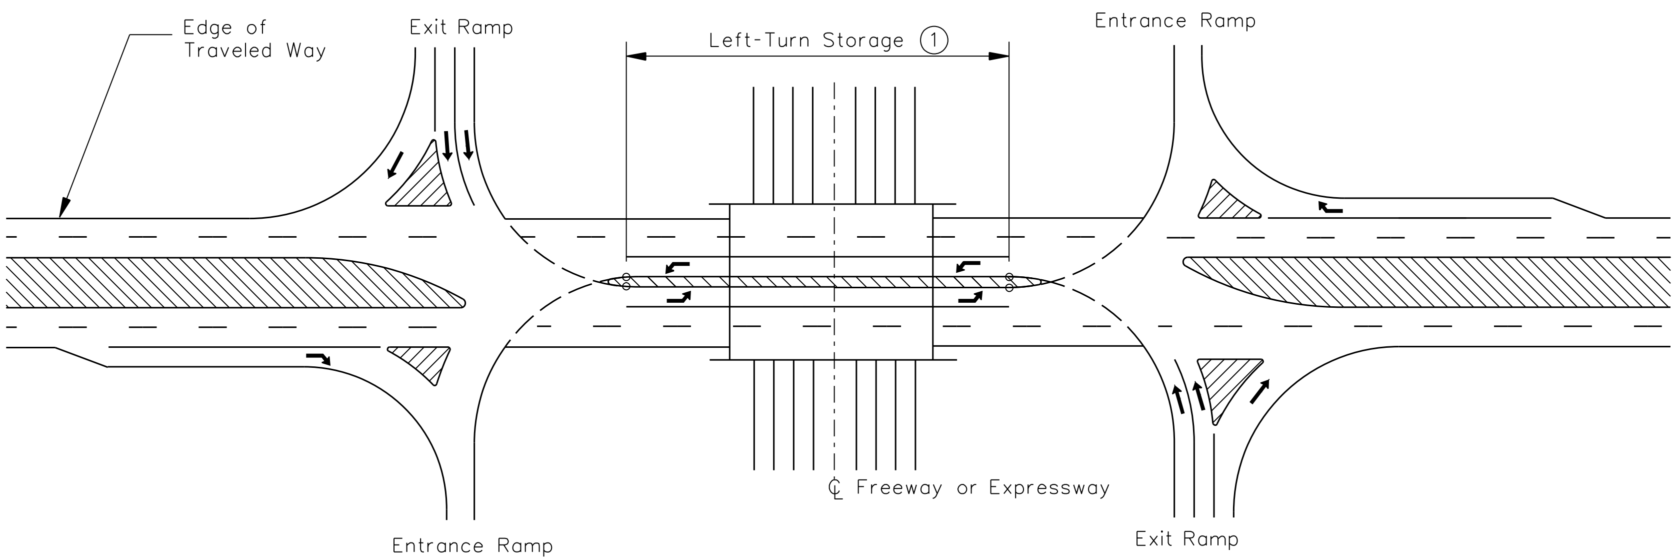


Notes:

1. *Determine the left-turn length on the crossroad using Section 36-3.02 and by assuming the distance needed for a stop condition.*
2. *Set the location of left-turn control radii to and from the crossroad at the same crossroad station.*
3. *See Figure 37-5.C for Section A-A.*

LEFT-TURN LANES ON CROSSROADS
(Diamond Interchanges)

Figure 37-5.A



Notes:

1. *Determine the left-turn length on the crossroad using Section 36-3.02. For this design, the storage requirements will govern.*
2. *Set the location of left-turn control radii to and from the crossroad at the same crossroad station.*
3. *For new construction, use a 30 ft (9.0 m) minimum median width on the crossroad.*

LEFT-TURN LANES ON CROSSROADS
(Compressed Diamond Interchange)

Figure 37-5.B

8. Wrong-Way Movements. Wrong-way movements may originate at the ramp/crossroad intersection onto an exit ramp. To minimize the probability of these movements, provide a raised-curb median on the crossroad and sign the ramp according to the *ILMUTCD*.

9. Crossroad Cross Section. For safety and capacity, the crossroad through an interchange should be as wide as practical. The minimum cross section is an 18 ft (5.5 m) raised-curb median separating two 14 ft (4.2 m) lanes and 8 ft (2.4 m) outside shoulders. See Figure 37-5.C and Section 37-2.14 for additional information on the crossroad dimensions.

10. Design Vehicle. Radius returns and left-turn control radii for ramp/crossroad intersections should be designed using a WB-67 (WB-20) design vehicle; see Section 36-1.08.

11. Design Users. Where present and a permitted user of the crossroad, pedestrians and bicyclists should be treated as design users of the facility and given the same consideration as the design vehicle.

12. Corner Islands. The approach angle for right-turning vehicles is critical in the design of new corner islands or the modification of existing corner islands. If designed without the approach angle in mind, corner island design may impose challenges to the motorist regarding excessive head-turn and reduced sight distance. These challenges in the driving task are further amplified at intersection approaches on heavy skew angles. Figure 36-2.F depicts two options for a standard corner island design that will minimize potentially adverse operating characteristics. In the design of a corner island, seek to meet or approach a head-turn angle goal of 115 degrees for the line of sight as shown for drivers at the stop bar. See Section 36-2.02 for more information when designing or modifying corner islands at ramp/crossroad intersections.

13. Stop Bar Locations. See the *Illinois Supplement to the Manual on Uniform Traffic Control Devices (ILMUTCD)* regarding stop bar placement at intersections. On multilane approaches or approaches with corner islands, care should be taken in design to ensure the proposed stop bar placement of one lane does not create a line of sight restriction for the adjacent stopping maneuver. See Section 36-2.02(a) and (c) for more information on stop bar placement when using a corner island.

37-5.02 Typical Intersection Designs

37-5.02(a) Diamond Interchange

Typical ramp/crossroad intersections at a diamond interchange are shown in Figures 37-5.D, 37-5.E, 37-5.F, and 37-5.G. The appropriate radius returns, based on the WB-67 (WB-20) design vehicle, are used to delineate the right-turning paths for the corner island design. For left turns from an exit ramp onto a 14 ft (4.2 m) traveled way, offset the median nose as shown in Figure 37-5.H.

37-5.02(b) Two-Quadrant Partial Cloverleaf Interchange

The ramp/crossroad intersections with a two-quadrant partial cloverleaf interchange are similar in design to a channelized “T” intersection; see Figure 37-5.I. To discourage wrong-way movements into the exit ramp, use a maximum left-turn control radius of 80 ft (24 m) from the crossroad into the entrance ramp and a 100 ft (30 m) left-turn control radius from the exit ramp onto the crossroad.

Figure 37-5.J illustrates a typical median design on the crossroad for a parclo type interchange.

TYPICAL CROSSROAD MEDIAN DETAIL
(Diamond Interchange)

Figure 37-5.J

37-5.02(c) Four-Quadrant Partial Cloverleaf Interchange

The controlled ramp terminals of a four-quadrant partial cloverleaf interchange are similar in design to the ramp/crossroad intersections of a diamond interchange; however, they must be located to minimize any adverse operational effects on the directional ramps in the opposite quadrants. The left-turning path from the controlled ramp terminal of the four-quadrant partial cloverleaf Type A must intersect the crossroad downstream from the gore of the exit terminal, as illustrated in Figure 37-5.K. The minimum distance of 200 ft (60 m) discourages wrong-way movements and allows for stored vehicles on the crossroad when signalized.

For the four-quadrant partial cloverleaf Type B, illustrated in Figure 37-5.L, terminate the left-turn lane from the crossroad into the controlled entrance ramp in advance of the merging nose of the entrance terminal. Providing this separation minimizes confusion between two decision points on the crossroad and provides better traffic operations when signalized.

37-5.02(d) Compressed Diamond with Slip Ramps

The designer must consider the impact of frontage roads, where present, on interchange design. At some urban interchanges, separating the intersection of the ramp and frontage road with the crossroad may be impractical. In these cases, the only alternative is to provide a slip ramp to a one-way frontage road before the intersection with the crossroad. This can apply to either an exit or entrance ramp. Sufficient distance must then be provided between the freeway ramp terminal and the ramp/frontage road terminal to provide the necessary acceleration or deceleration distance and weaving distance.

Figure 37-5.M provides the basic schematic for this design. The critical design element is the distance “A” between the ramp/frontage road merge and the crossroad. This distance must be sufficient to allow traffic weaving, vehicular deceleration and stopping, and vehicular storage to avoid interference with the merge point. Figure 37-5.M presents general guidelines that may be used to estimate this distance during the preliminary design phase. A number of assumptions have been made including weaving volume, operating speeds, and intersection queue distance. Therefore, a detailed analysis will be necessary to firmly establish the needed distance to properly accommodate vehicular operations. Additional information can be found in a Transportation Research Record 682 article entitled, “Distance Requirements for Frontage-Road Ramps to Cross Streets: Urban Freeway Design” or in the Texas Transportation Institute publication *Procedures to Determine Frontage Road Level of Service and Ramp Spacing*.

Distance “B” in Figure 37-5.M is determined on a case-by-case basis. It should be determined based on the number of frontage road lanes and the intersection design. This distance is typically determined by the necessary weave distance from the intersection to the ramp entrance. For capacity analysis of the weave section, see the *Highway Capacity Manual*.

① *Assumes the total volume of traffic on the frontage road including the merged exit-ramp volume.*
② *Assumed to be 70% of total volume in first column.*

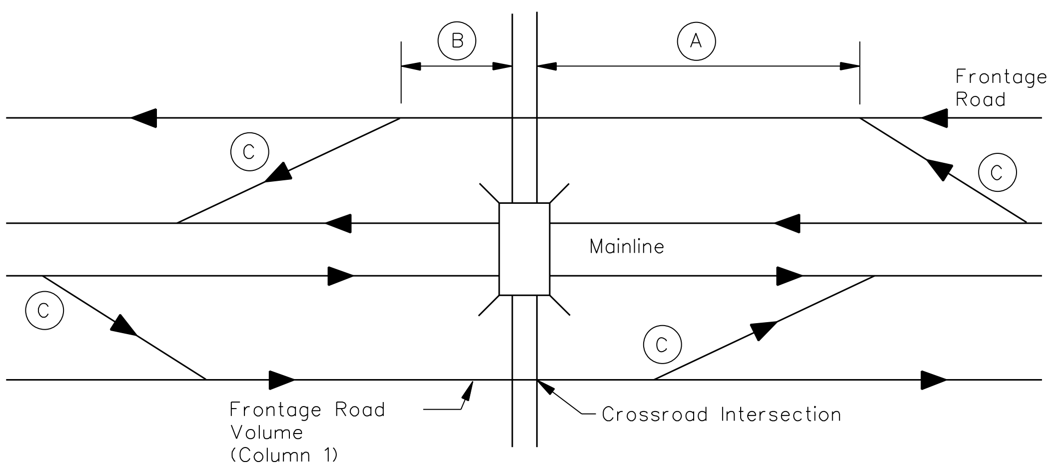
Notes:

1. *Table values are acceptable for planning purposes only. Final lengths will be based on a detailed operational analysis. This design may be used only in restricted urban areas.*

2. *Distance "B" is determined on a case-by-case basis.*

3. *"C" is a slip ramp.*

4. *See Chapter 35 for access control design along frontage road and crossroad.*



RAMP/CONTINUOUS FRONTAGE ROAD INTERSECTION

Figure 37-5.M

37-5.03 Crossroad Access Control

Providing access control along the crossroad of an interchange is an important design feature for both the safety and efficient operation of an interchange. The access control line is defined as a line established by the Department that restricts direct access to property abutting a highway. See Chapter 35 for additional details on access control limits.

37-6 FREEWAY RAMP TERMINALS

37-6.01 Exit Ramp Terminals

37-6.01(a) Types

The exit ramp terminal is a speed-change lane that permits high-speed traffic to exit from the through lane of the highway and enter the ramp proper. The exit terminal must be visible to the approaching motorist and provide a clear indication for the point of departure from the traveled way. When designing the interchange, consider the following exit ramp types:

1. Standard Exit Terminal. There are two basic types of exit freeway ramp terminals — the parallel design and the taper design. For all new and reconstructed ramps, use the taper design. Figure 37-6.A and the *Illinois Highway Standards* illustrate the Department's standard exit ramp terminal design. Exit ramp terminals may carry a marked route provided the marked route is not a freeway or expressway. Where a freeway or expressway turns through an interchange, use the major divergence design as discussed in Section 37-6.03.

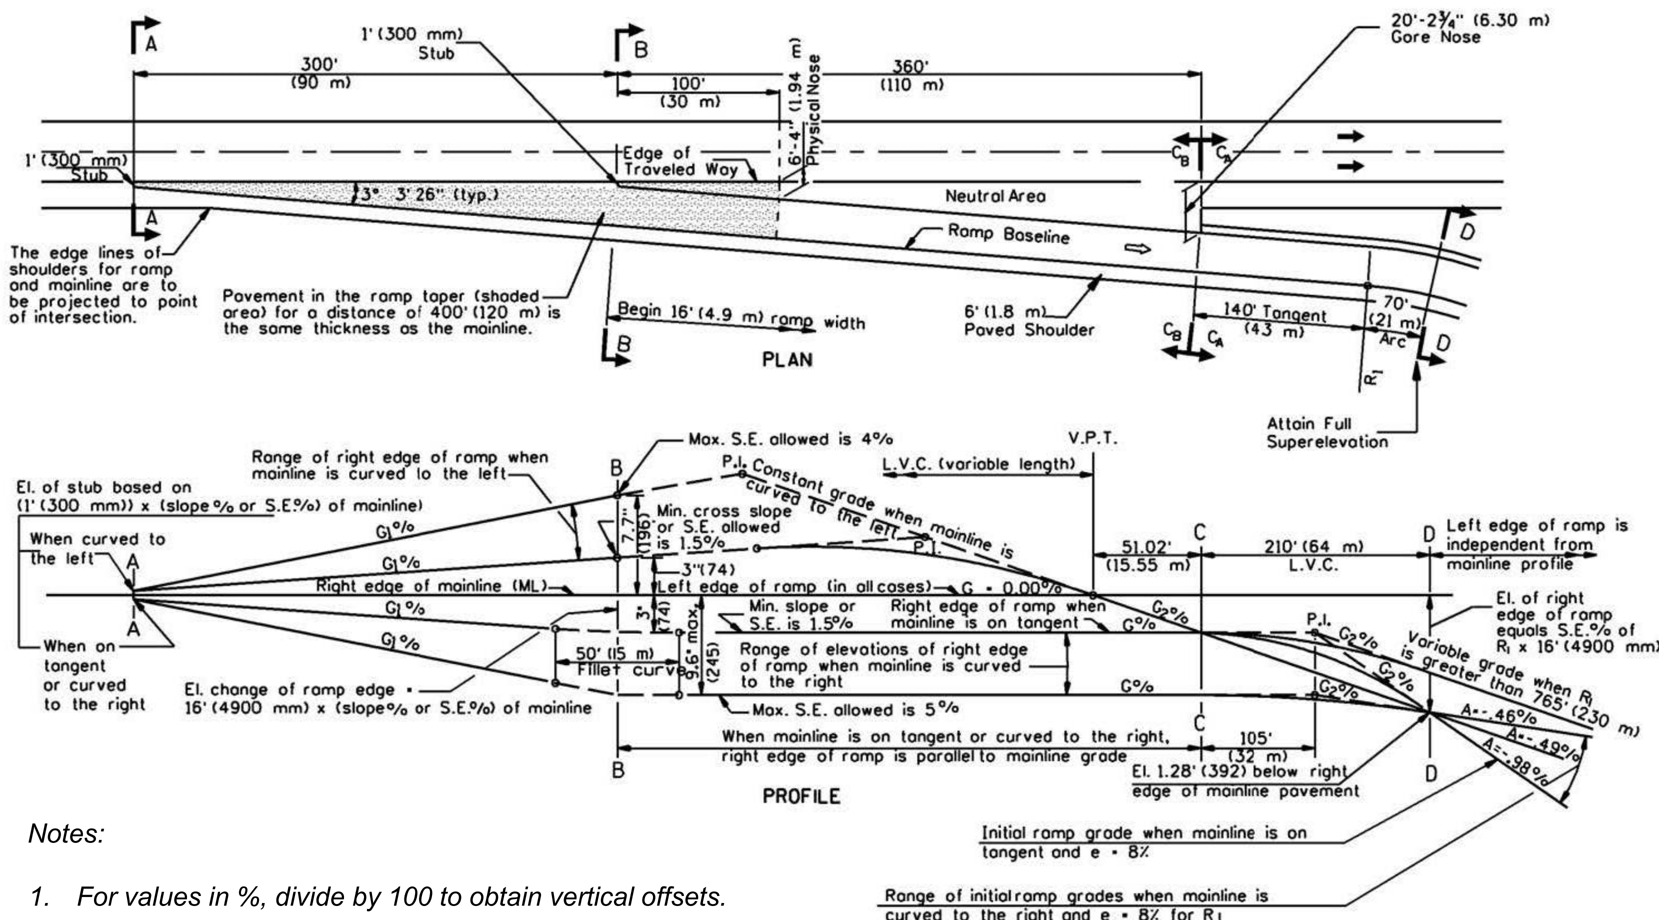
2. Exit Terminal With an Auxiliary Lane. An auxiliary lane may be required prior to the exit terminal:

   - to meet the guidelines discussed in Section 37-2.05,
   - where the exiting design traffic exceeds the appropriate service volume of a standard exit terminal design but does not require a two-lane exit, and/or
   - proceeding a left-hand exit terminal. Note that interchange designs should not use left-hand exit terminals. However, where necessary, left-hand exits must be first approved by BDE before the interchange type approval.

   Figure 37-6.B illustrates the design criteria for an exit terminal preceded by an auxiliary lane. Extend the pavement markings on the left edge of the ramp to the right edge of the mainline traveled way. Provide transverse pavement markings in the recovery area to discourage the use of the auxiliary lane beyond the exit gore. Pavement markings in the recovery area should be according to the Bureau of Operations' *Policies and Procedures Manual*.

3. Two-Lane Exits. These terminals are typically required where the traffic volumes on the ramp exceed the capacity of a single-lane exit ramp. The following lists several elements the designer should consider for two-lane exit terminals:

   a. Lane Balance. For consistent freeway operations, maintain lane balance at the freeway ramp terminal; see Section 37-2.03.

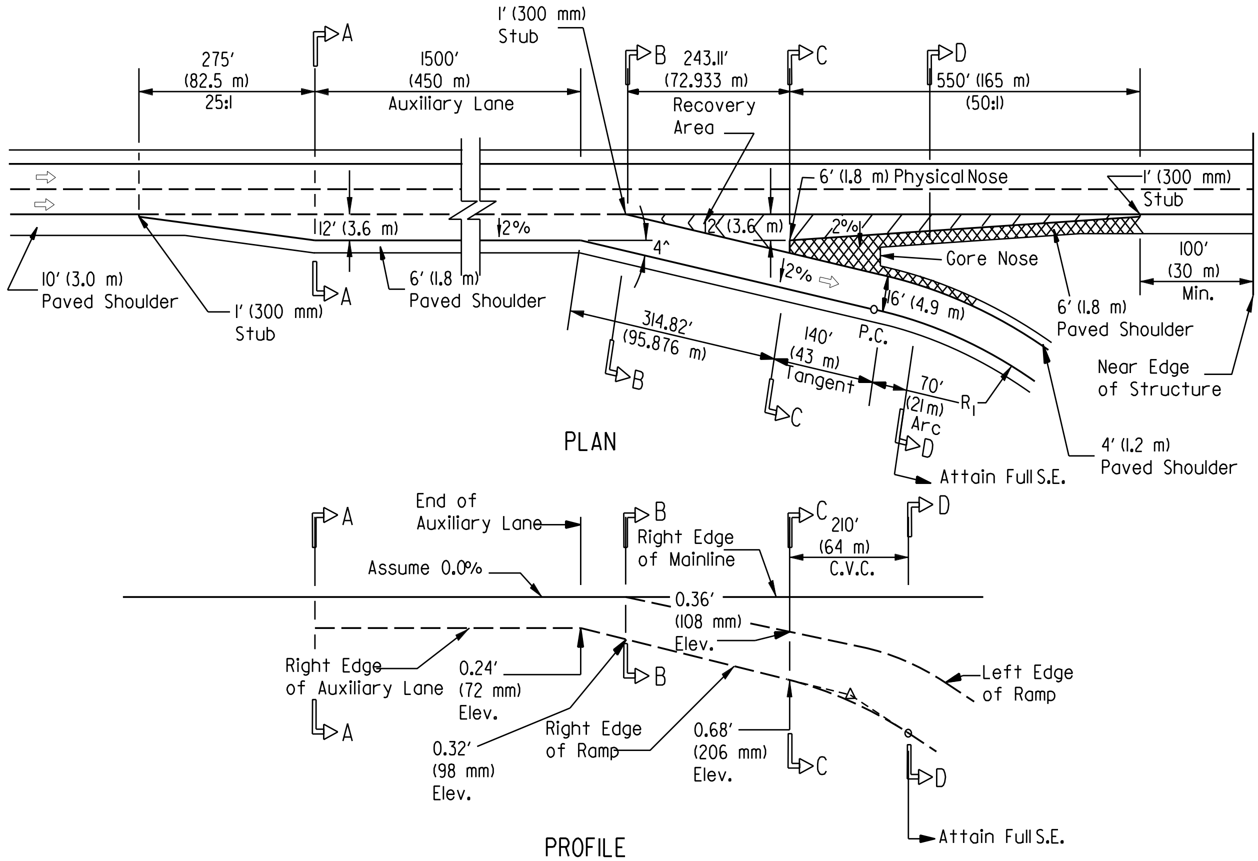


Notes:

1. *For values in %, divide by 100 to obtain vertical offsets. Vertical differences are in inches (mm).*
2. *C_A = Cross section ahead*
3. *C_B = Cross section back*
4. *Mainline grade is assumed to be 0%.*
5. *See Highway Standards for Sections B-B and C-C.*

STANDARD EXIT RAMP TERMINAL

Figure 37-6.A



Notes:

1. *Where the mainline is superelevated to the left or right, the terminal elevations and grades must be adjusted.*
2. *A 50 ft (15 m) vertical curve may be used for comfort and aesthetics along the right edge of the ramp at the grade changes.*
3. *Include cross sections A-A, B-B, C-C, and D-D with the IDS.*
4. *Regardless of the % S.E. at D-D, the % cross slope at the PC is always ⅔ the difference between C-C and D-D.*

EXIT RAMP TERMINAL WITH AUXILIARY LANE

Figure 37-6.B

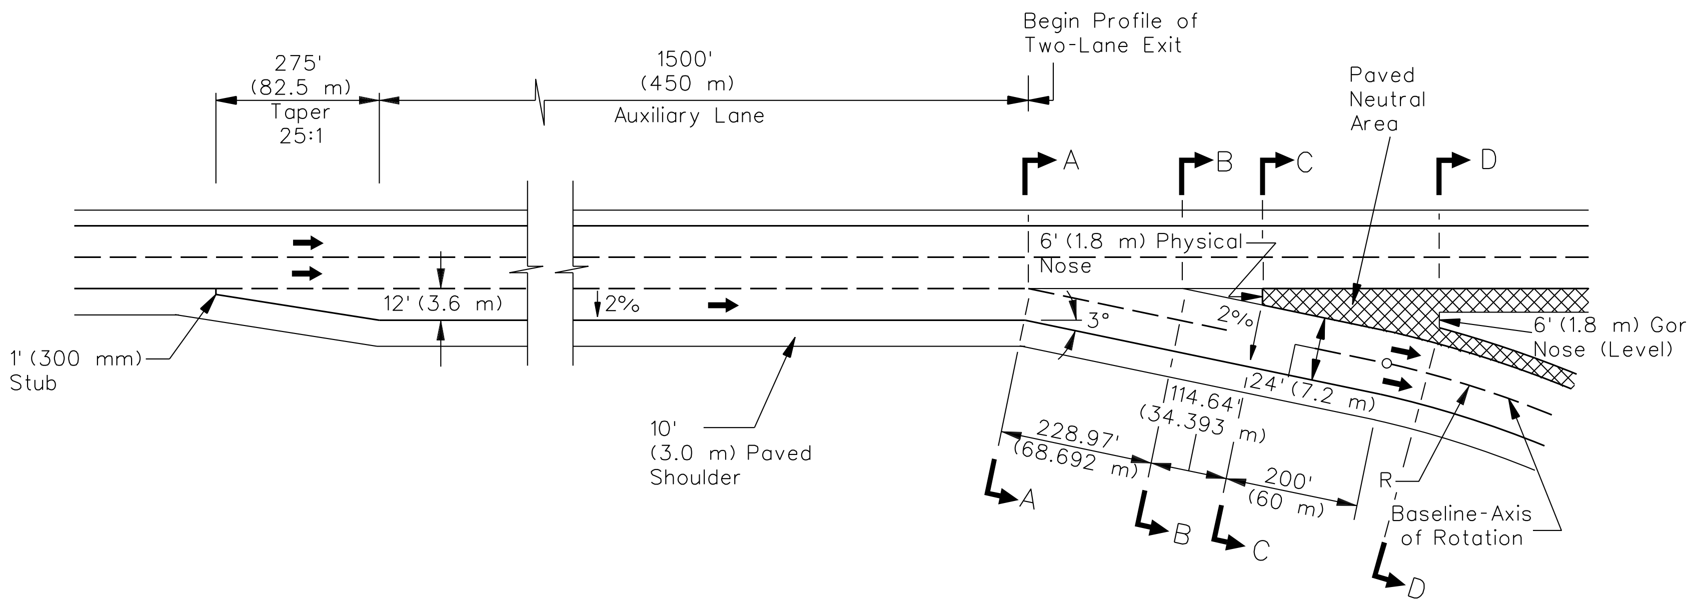
b. Design. A typical two-lane exit terminal design is illustrated in Figure 37-6.C. To develop the proper level of service at a two-lane exit facility and provide proper lane balance, add a minimum 1500 ft (450 m) long auxiliary lane prior to the exit terminal. The concepts for controlling gradelines and pavement cross slopes on two-lane exit terminals are generally the same as those described for major divergences. Prepare detailed cross sections for critical locations on the two-lane exit ramp and present them in the Interchange Design Study (IDS).

37-6.01(b) Sight Distance

The sight distance approaching the gore nose should exceed the stopping sight distance for the through traffic, desirably by 25% or more. Where there are unusual conditions, consider providing decision sight distance to the exit terminal. Extra sight distance is particularly important for exit loops immediately beyond a structure. When measuring for adequate sight distance, ensure that the motorist can see the pavement surface at and beyond the gore nose. Locating the exit terminal and gore nose where the mainline is on an upgrade provides the best design condition. Do not locate exit terminals near mainline crest vertical curves where the ramp pavement may disappear from the driver's view.

37-6.01(c) Alignment

Figures 37-6.D through 37-6.F illustrate methods to determine the grades along sections of typical exit ramp terminals where the mainline is on tangent, curving to the right, and curving to the left. The Department's preferred practice is to locate exit terminals on tangent sections or on mainline curves to the right. However, this may not be practical in highly restricted areas. Section 37-4.07 discusses the minimum alignment criteria for the ramp proper, including the minimum radii for the initial ramp curve (R_1).



Notes:

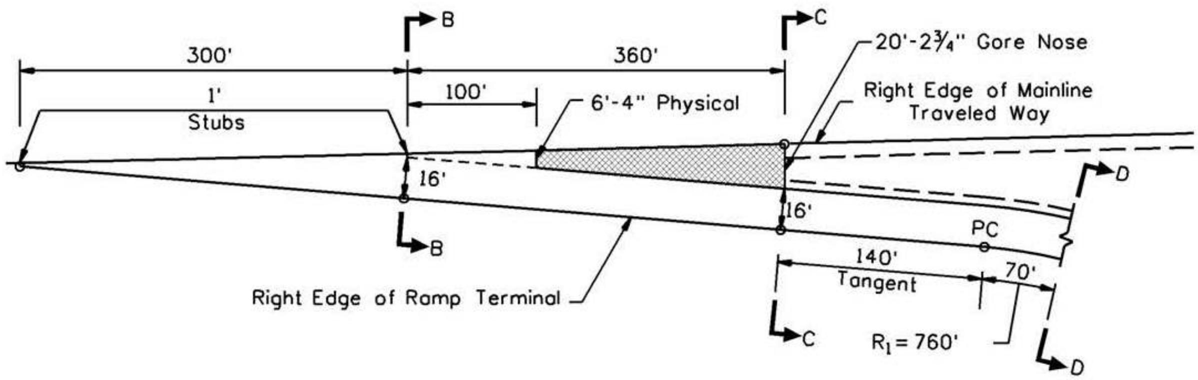
1. *Attain full superelevation at Section D-D.*
2. *Include cross sections A-A, B-B, C-C, and D-D with the IDS.*

TWO-LANE EXIT RAMP TERMINAL

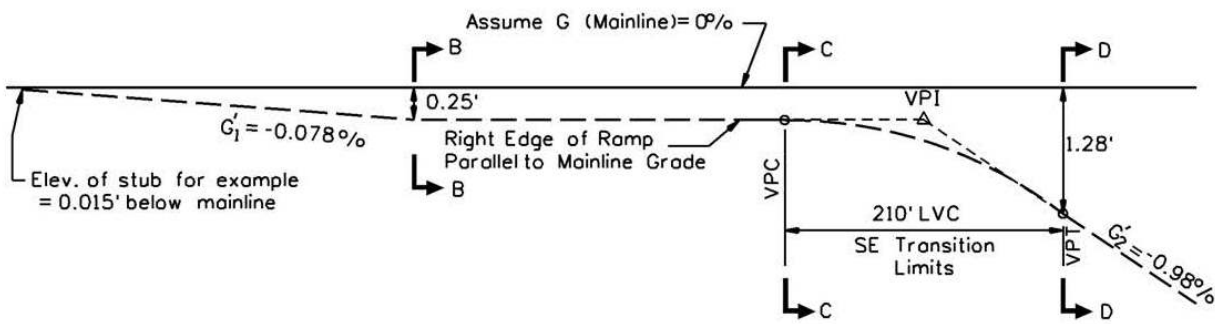
Figure 37-6.C

Example 37-6.1

Given: Freeway design speed = 70 mph
Freeway is on tangent
Freeway grade, G = +2.00%
Initial ramp curve radius, R_1 = 760 ft
Ramp e_{max} = 8%



PLAN VIEW FOR BASE CONDITIONS



PROFILE FOR BASE CONDITIONS

APPLICATION: See Figure 37-6.A.

Problem: Find G_1 and G_2, where G_1 and G_2 are the actual design grades.

EXAMPLE EXIT RAMP TERMINAL
(Mainline on Tangent)

Figure 37-6.D(1)
(1 of 2)

Solution:

1. Determine G_1.

$G_1 = G + G_1'$

Use the profile equation for base conditions for the mainline:
Mainline profile = 0.0%
Mainline on tangent

$$G_1' = \left[\frac{(e/100 \times 16) - (e/100 \times 1)}{300}\right] \text{ x } 100$$

Where: e = superelevation of the mainline (maximum 5% for G_1').

Determine actual G_1

$$G_1 = 2.00 + \left[\frac{(-1.56/100 \times 16) - (-1.56/100 \times 1)}{300}\right] \text{ x } 100$$

$G_1 = 2.00\% + (-0.078\%) = +1.922\%$

2. Determine G_2.

$G_2 = G + G_2'$

Use the profile equation for base conditions for the ramp:
Mainline profile = 0.0%
R_1 = 760 ft

$$G_2' = \left[\frac{(e/100 \times 16) - (\text{Elev. Of VPI})}{105}\right] \text{ x } 100$$

Where: 105 ft = half of LVC
And e = superelevation for the radius R_1
From Figure 32-3.B, ramp superelevation: e = 8.0% for R_1 of 760 ft.

Determine actual G_2

$$G_2 = 2.00 + \left[\frac{(-8.0/100 \times 16) - (-0.25)}{105}\right] \text{ x } 100$$

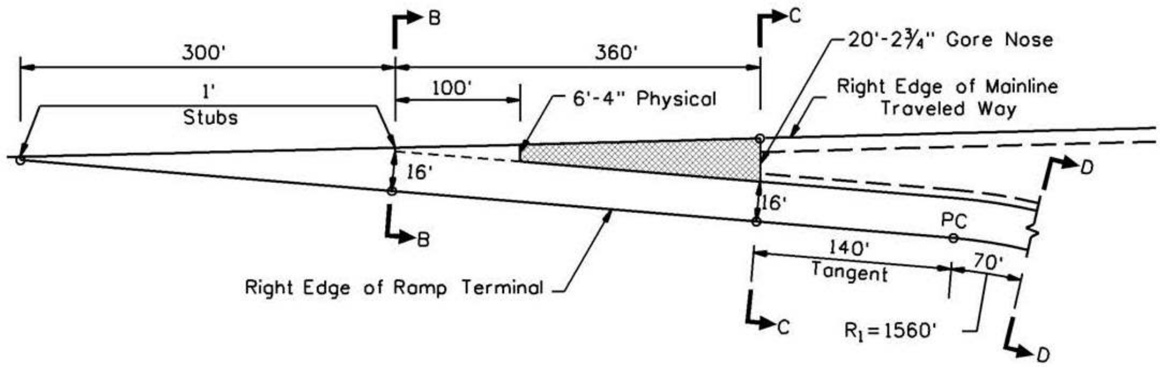
$G_2 = 2.00\% + (-0.98\%) = +1.02$

EXAMPLE EXIT RAMP TERMINAL
(Mainline on Tangent)

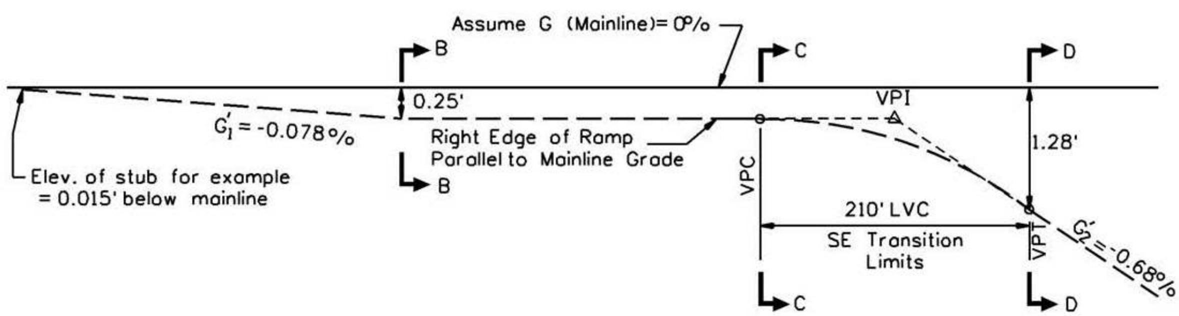
Figure 37-6.D(1)
(2 of 2)

Example 37-6.2

Given: Freeway design speed = 70 mph
Freeway is on tangent
Ramp design speed = 50 mph
Freeway grade, G = +2.00%
Initial ramp curve radius, R_1 = 1560 ft
Ramp e_{max} = 8%



PLAN VIEW FOR BASE CONDITIONS



PROFILE FOR BASE CONDITIONS

APPLICATION: See Figure 37-6.A.

Problem: Find G_1 and G_2, where G_1 and G_2 are the actual design grades.

EXAMPLE EXIT RAMP TERMINAL
(Mainline on Tangent)

Figure 37-6.D(2)
(1 of 2)

Solution:

1. Determine G_1.

   G_1 = +1.922%

   (See Example Problem 37-6.1 for G_1 calculations.)

2. Determine G_2.

   $G_2 = G + G_2'$

   Use the profile equation for base conditions for the ramp except for R_1:
   Mainline profile = 0.0%
   R_1 = 1560 ft

   $$G_2' = \left[\frac{(e/100 \times 16) - (\text{Elev. Of VPI})}{105}\right] \times 100$$

   Where: 105 ft = half of LVC
   And e = superelevation for the radius R_1
   From Figure 32-3.B, ramp superelevation: e = 6.0% for R_1 of 1560 ft.

   Determine actual G_2

   $$G_2 = 2.00 + \left[\frac{(-6.0/100 \times 16) - (-0.25)}{105}\right] \times 100$$

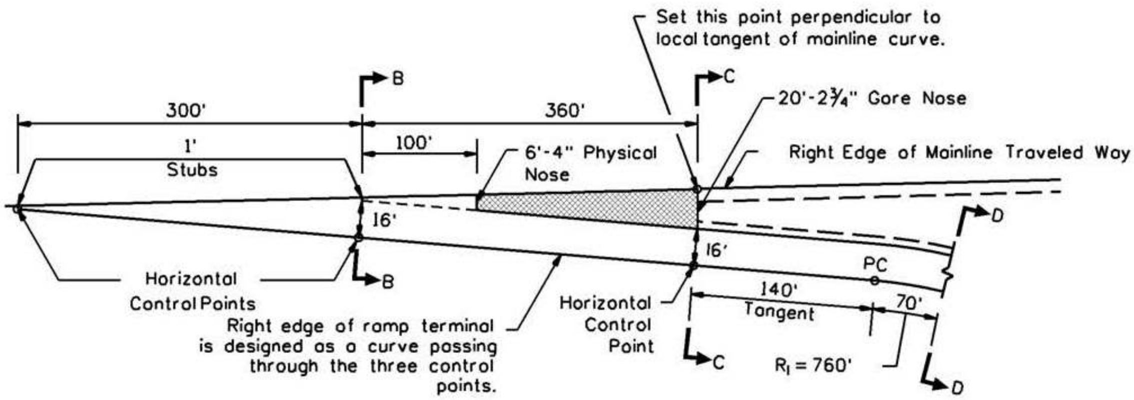
   G_2 = 2.00% + (– 0.68%) = +1.32%

EXAMPLE EXIT RAMP TERMINAL
(Mainline on Tangent)

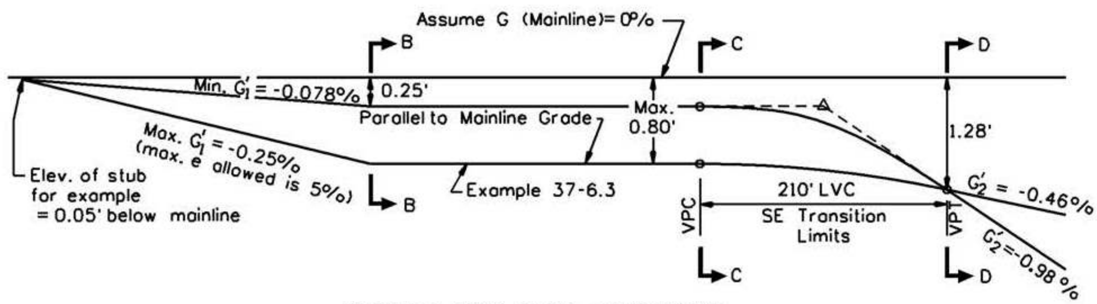
Figure 37-6.D(2)
(2 of 2)

Example 37-6.3

Given: Freeway Design Speed = 70 mph
Freeway curves to the right, R = 3330 ft
Initial Ramp Radius, R_1 = 760 ft
Freeway Grade, G = – 1.80%
Freeway e_{max} = 6%
Ramp e_{max} = 8%



PLAN VIEW FOR BASE CONDITIONS



PROFILE FOR BASE CONDITIONS

APPLICATION: See Figure 37-6.A.

Problem: Find G_1 and G_2, where G_1 and G_2 are the actual design grades.

EXAMPLE EXIT RAMP TERMINAL
(Mainline Curving to the Right)

Figure 37-6.E(1)
(1 of 2)

Solution:

1. Determine G_1.

$G_1 = G + G_1'$

Use the profile equation for base conditions for the mainline except mainline is on curve:
Mainline profile = 0.0%
From Figure 32-3.C, the freeway superelevation, e = 5.0%.
5% is the maximum superelevation of the ramp terminal when the mainline is curved to the right.

$$G_1' = \left[\frac{(e/100 \times 16) - (e/100 \times 1)}{300}\right] \text{ x } 100$$

Where: e = superelevation of the mainline (maximum SE is 5% for G_1').

Determine actual G_1

$$G_1 = -1.80 + \left[\frac{(-5.0/100 \times 16) - (-5.0/100 \times 1)}{300}\right] \text{ x } 100$$

$G_1 = -1.80\% + (-0.25\%) = -2.05\%$

2. Determine G_2.

$G_2 = G + G_2'$

Use the profile equation for base conditions for the ramp.
Mainline profile = 0.0%
R_1 = 760 ft

$$G_2' = \left[\frac{(e/100 \times 16) - (\text{Elev. of VPI})}{105}\right] \text{ x } 100$$

Where: 105 ft = half of LVC
And e = superelevation for the radius R_1
From Figure 32-3.B, ramp superelevation: e = 8.0% for R_1 of 760 ft.

Determine actual G_2

$$G_2 = -1.80 + \left[\frac{(-8.0/100 \times 16) - (-0.80)}{105}\right] \text{ x } 100$$

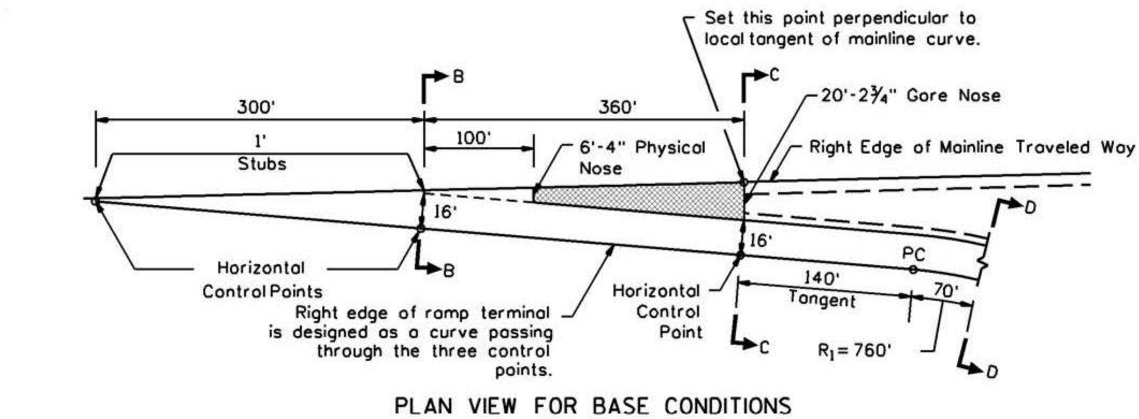
$G_2 = -1.80\% + (-0.46\%) = -2.26\%$

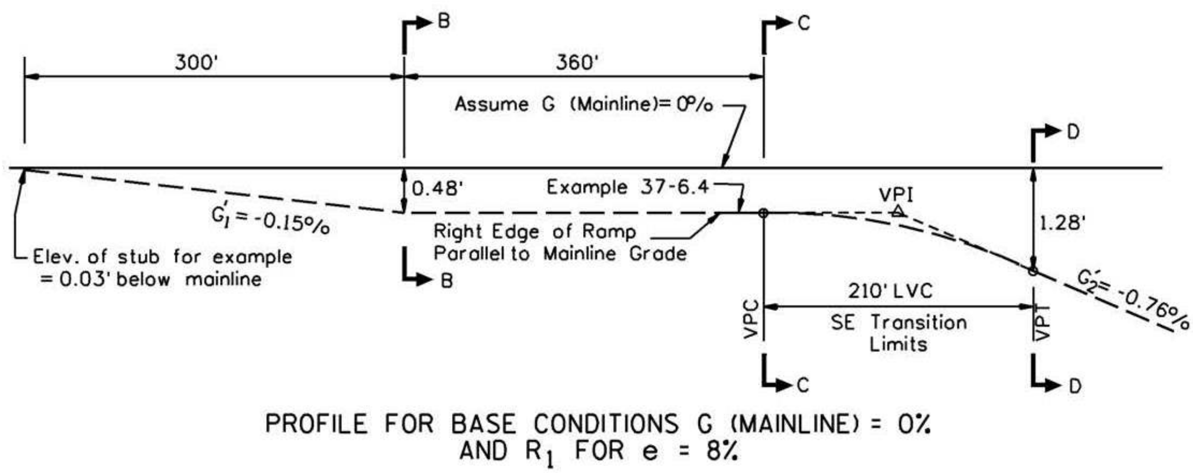
EXAMPLE EXIT RAMP TERMINAL
(Mainline Curving to the Right)

Figure 37-6.E(1)
(2 of 2)

Example 37-6.4

Given: Freeway Design Speed = 70 mph
Freeway curves to the right, R = 6490 ft
Initial Ramp Radius, R_1 = 760 ft
Freeway grade, G = +2.50%
Freeway e_{max} = 6%
Ramp e_{max} = 8%





APPLICATION: See Figure 37-6.A.

Problem: Find G_1 and G_2.

EXAMPLE EXIT RAMP TERMINAL
(Mainline Curving to the Right)

Figure 37-6.E(2)

(1 of 2)

Solution:

1. Determine G_1.

$G_1 = G + G_1'$

Use the profile equation for base conditions for the mainline except mainline is on curve:
Mainline profile = 0.0%
From Figure 32-3.C, the freeway superelevation, e = 3.0%.
5% is the maximum superelevation of the ramp terminal when the mainline is curved to the right.

$$G_1' = \left[\frac{(e/100 \times 16) - (e/100 \times 1)}{300}\right] \text{ x } 100$$

Where: e = superelevation of the mainline (maximum SE is 5% for G_1').

Determine actual G_1

$$G_1 = +2.50 + \left[\frac{(-3.0/100 \times 16) - (-3.0/100 \times 1)}{300}\right] \text{ x } 100$$

G_1 = +2.50 % + (–0.15%) = +2.35%

2. Determine G_2.

$G_2 = G + G_2'$

Use the profile equation for base conditions for the ramp.
Mainline profile = 0.0%
R_1 = 760 ft

$$G_2' = \left[\frac{(e/100 \times 16) - (\text{Elev. of VPI})}{105}\right] \text{ x } 100$$

Where: 105 ft = half of LVC
And e = superelevation for the radius R_1
From Figure 32-3.B, ramp superelevation: e = 8.0% for R_1 of 760 ft.

Determine actual G_2

$$G_2 = +2.50 + \left[\frac{(-8.0/100 \times 16) - (-0.48)}{105}\right] \text{ x } 100$$

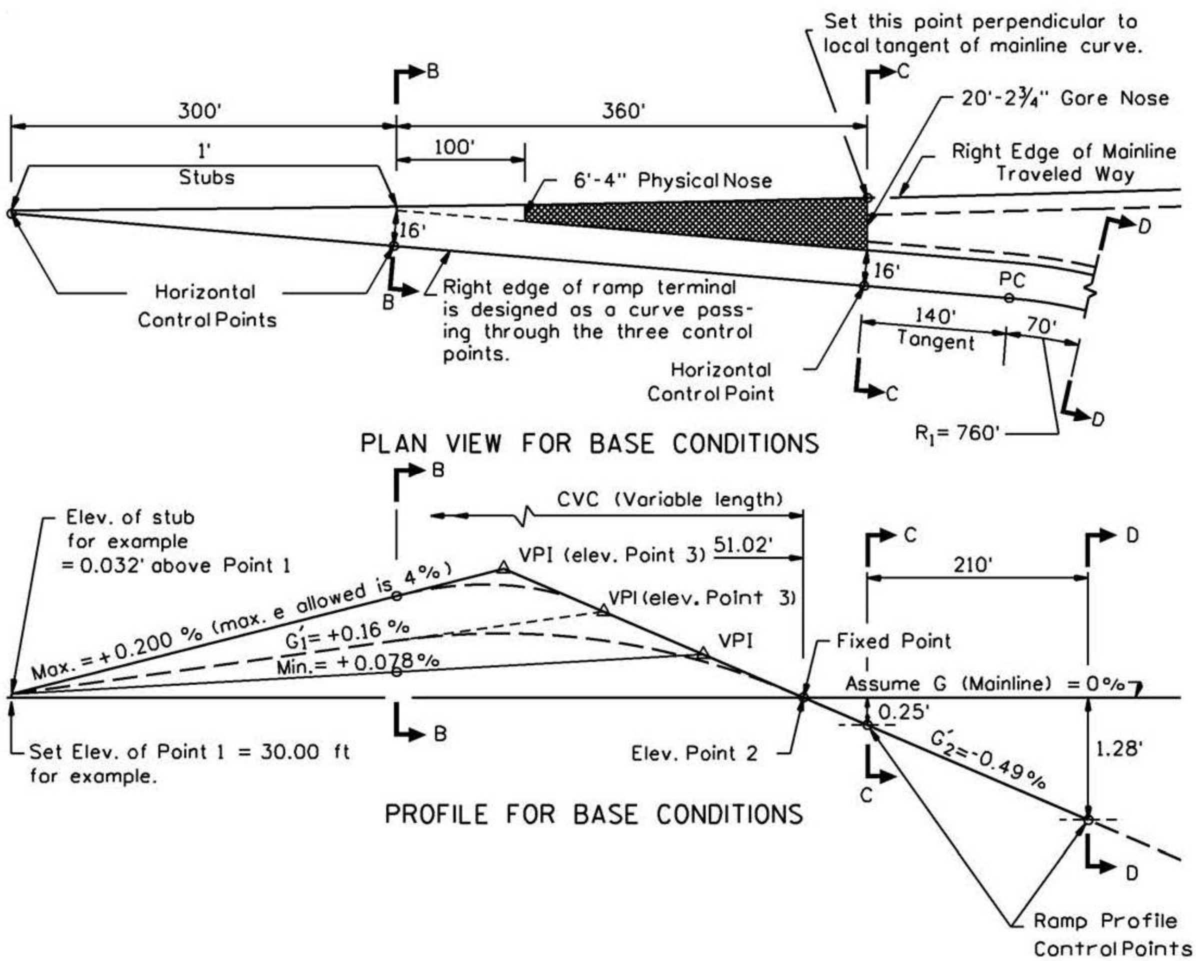
G_2 = +2.50 % + (– 0.76%) = +1.74%

EXAMPLE EXIT RAMP TERMINAL
(Mainline Curving to the Right)

Figure 37-6.E(2)
(2 of 2)

Example 37-6.5

Given: Freeway Design Speed = 70 mph
Freeway curves to the left, R = 6010 ft
Initial Ramp Radius, R_1 = 760 ft (curved to the right)
Freeway Grade, G = + 2.00%
Freeway e_{max} = 6%
Ramp e_{max} = 8%



APPLICATION: See Figure 37-6.A.

Problem: Find G_1 and G_2.
Find the location and the elevation of the VPI along the right edge of the ramp.

EXAMPLE EXIT RAMP TERMINAL
(Mainline Curving to the Left)
Figure 37-6.F(1)
(1 of 3)

Solution:

1. Determine G_1.

$G_1 = G + G_1'$

Use the profile equation for base conditions for the mainline except mainline is on curve:
Mainline profile = 0.0%
From Figure 32-3.C, the freeway superelevation, e = 3.2%.
4% is the maximum superelevation of the ramp terminal when the mainline is curved to the left.

$$G_1' = \left[\frac{(e/100 \times 16) - (e/100 \times 1)}{300}\right] \text{ x } 100$$

Where: e = superelevation of the mainline (maximum SE is 4% for G_1').

Determine actual G_1

$$G_1 = +2.00 + \left[\frac{(3.2/100 \times 16) - (3.2/100 \times 1)}{300}\right] \text{ x } 100$$

$G_1 = +2.00\ \% + (0.16\%) = +2.16\%$

2. Determine G_2.

$G_2 = G + G_2'$

Use the profile equation for base conditions for the ramp.
Mainline profile = 0.0%
R_1 = 760 ft

$$G_2' = \left[\frac{(e/100 \times 16) - (-0.25)}{210}\right] \text{ x } 100$$

Where: 210 ft is the distance between the points in the numerator.
- 0.25 is the fixed elevation of the right edge of the ramp at C-C relative to the right edge of the mainline
and e = superelevation for the radius R_1
From Figure 32-3.B, ramp superelevation: e = 8.0% for R_1 of 760 ft.

Determine actual G_2

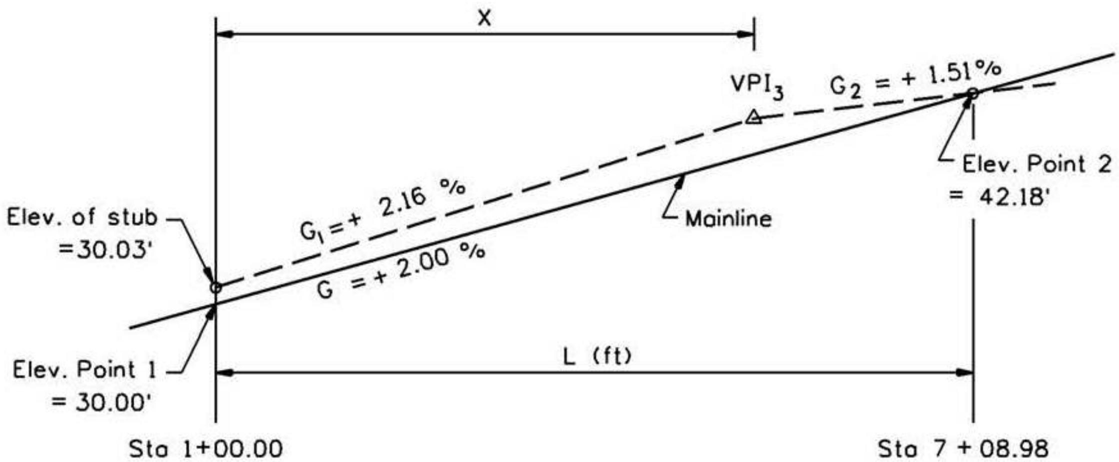
$$G_2 = +2.00 + \left[\frac{(-8.0/100 \times 16) - (-0.25)}{210}\right] \text{ x } 100$$

$G_2 = +2.00\ \% + (-0.49\%) = +1.51\%$

EXAMPLE EXIT RAMP TERMINAL
(Mainline Curving to the Left)

Figure 37-6.F(1)
(2 of 3)

3. Find the location and elevation of the VPI where the two design grades, G_1 and G_2, intersect:



See Chapter 33 for basic equation of two lines intersecting:

$$x = \frac{(\text{Elev. of Pt. 2} - \text{Elev. of Stub}) - G_2/100 \times L}{(G_1 - G_2)/100}$$

$$x = \frac{(42.18 - 30.03) - (1.51/100 \text{ x } 608.98)}{(2.16 - 1.51)/100}$$

x = 454.52 ft

Elev. of VPI_3 = G_1X + Elev. Stub

$$\text{Elev. of } VPI_3 = \frac{2.16}{100}\,(454.52) + 30.03$$

Elev. VPI_3 = 39.84 ft

EXAMPLE EXIT RAMP TERMINAL
(Mainline Curving to the Left)

Figure 37-6.F(1)
(3 of 3)

Example 37-6.6

A high speed freeway with a mainline curve to the left may have certain situations where the typical profile design shown in Example 37-6.5 does not provide the best fit for an exit terminal. In these cases, extend the 140 ft tangent section of the standard exit terminal ahead on tangent before an initial ramp curve to the right is designed into the ramp alignment. The cross slope of the ramp at Section C-C and beyond should be set at 3/16″/ft. Near the end of the tangent section, the ramp is then rotated to transition into the superelevation runoff length.

EXAMPLE EXIT RAMP TERMINAL
(Mainline Curving to the Left)

Figure 37-6.F(2)

37-6.01(d) Superelevation and Cross Slopes

Ramp cross slopes and superelevation rates for horizontal curves on ramps near the freeway ramp terminal must be developed to properly transition the driver from the mainline to the first curve on the exit ramp. The following will apply:

1. Cross Slope. The cross slope of the initial segment of the ramp departure from the through lane, or an auxiliary lane preceding the exit ramp is usually sloped at the same rate as the mainline. However, if the mainline has a flat longitudinal grade (i.e., less than 0.35%), consider increasing the cross slope rate on an auxiliary lane and the exit terminal to 2%. Where the mainline is curving to the right, the maximum cross slope on the exit terminal is 5%. Where the mainline is curving to the left, the maximum cross slope on the terminal is 4%.

2. Maximum Ramp Superelevation. In general, use an e_{max} of 8%. However, in highly congested areas with snow and ice conditions, use an e_{max} of 6%.

3. Radius/Superelevation Rate. Section 32-3 discusses the use of Method 5 for open roadway conditions to distribute superelevation and side friction. This theoretical basis also applies to the ramp portion of freeway exit terminals. Therefore, Figure 32-3.B (e_{max} = 8%) and Figure 32-3.C (e_{max} = 6%) are used to determine the proper radius and superelevation rate for horizontal curves on exit ramps. Also, see Figure 37-4.F. To determine the applicable design speed to use, see Figure 37-6.G.

US Customary		**Metric**	
Mainline Design Speed (mph)	**Minimum Design Speed (mph)of Initial Curve (R_1)**	**Mainline Design Speed (km/hr)**	**Minimum Design Speed (km/hr)of Initial Curve (R_1)**
75	55	120	90
70	50	110	80
60	45	100	70
50	40	80	60
40*	30	60*	50

**C-D roads only*

MINIMUM DESIGN SPEED FOR INITIAL EXIT CURVE

Figure 37-6.G

37-6.01(e) Gore Area

The gore area is normally considered both the paved triangular area between the through lane and the exit ramp, plus the graded area that extends a significant distance downstream beyond the gore nose; see Figure 37-6.H. The following definitions will apply:

1. Physical Nose. This is a point 100 ft (30 m) downstream of Section B-B from where the 16 ft (4.9 m) ramp width begins. As illustrated in Figure 37-6.H, the physical nose has a dimensional width of 6 ft 4 in. (1.94 m).

2. Gore Nose. This is the point where the paved shoulders separate from each other and the sodded area begins as the ramp and mainline diverge. As illustrated in Figure 37-6.H, the gore nose has a dimensional width of 20 ft 2¾ in. (6.3 m), which includes the 10 ft (3.0 m) right shoulder of the freeway and the 4 ft (1.2 m) paved left shoulder of the ramp.

Consider the following when designing the gore area:

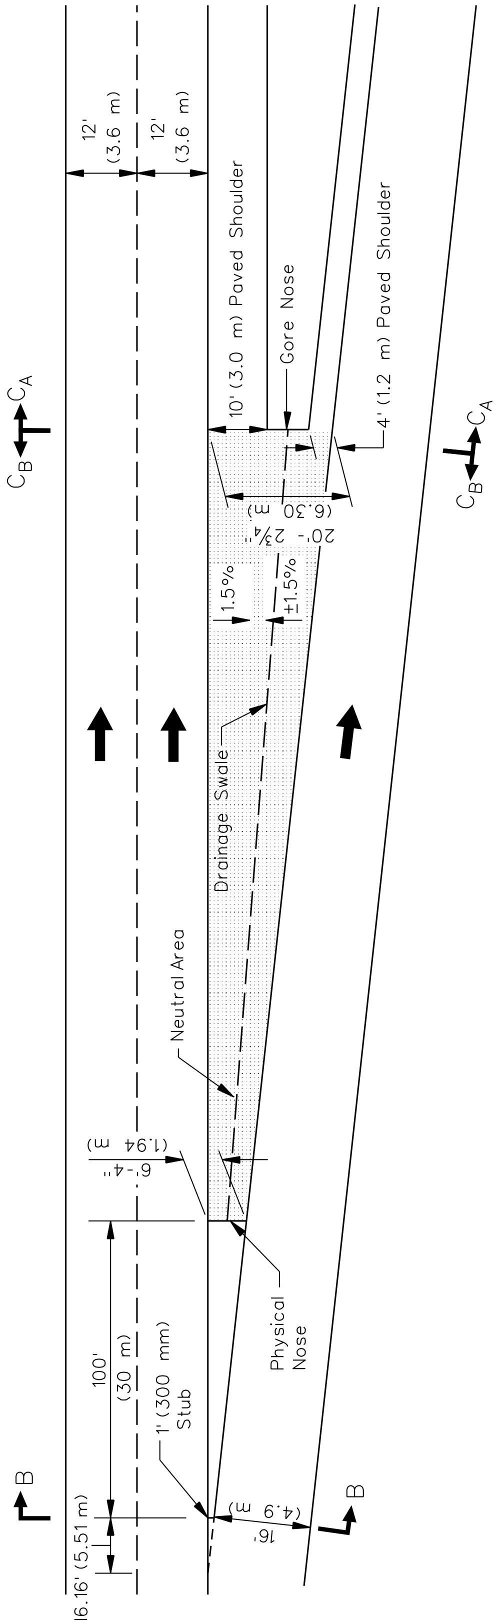
1. Roadside Obstacles. Desirably, the area beyond the gore nose should be free of all obstacles (except the ramp exit sign) for at least 100 ft (30 m) or more beyond the gore nose. Any obstacles within approximately 350 ft (100 m) of the gore nose should be made breakaway or shielded by a barrier. See Chapter 38 for additional guidance for the treatment of roadside obstacles.

2. Curbing. Do not use curbing within the gore area of an exit terminal.

3. Side Slopes. Side slopes and ditches adjacent to the gore area should meet the same criteria as the mainline. The graded area beyond the gore nose should be as flat as practical, but still drain properly. The exit terminal should be located so there are no major elevation differences in this area. For some reconstruction projects, the vertical divergence of the ramp and mainline profiles may warrant protection for both roadways beyond the gore nose (e.g., guardrail and/or impact attenuators).

4. Cross Slopes. The paved triangular gore area between the through lanes and exit ramp should be flat and traversable. The cross slopes in the gore area from the physical nose to the gore nose are 3/16″/ft (1.5%). This design provides a drainage swale in the neutral area of the terminal and is shown in Figure 37-6.H.

5. Traffic Control Devices. Signing in advance of the exit and at the divergence should be according to the *ILMUTCD* and Bureau of Operations' *Policies and Procedures Manual*.



Note: Add drainage inlet in neutral area where required.

EXIT RAMP GORE AREA

FIGURE 37-6.H

37-6.01(f) Structures

Exit ramp terminals on or near structures can create a split-bridge design which, because of safety, economic, and maintenance considerations, should be avoided. A split-bridge deck design may be required where the distance from the right edge of the mainline traveled way to the left edge of the ramp exceeds 36 ft (11 m). This results in a fixed object on the structure that must be shielded by an impact attenuator. The following, in order of preference, presents options for addressing this problem:

1. Physical Nose Beyond Structure. Figure 37-6.I(a) illustrates the desirable position of the exit ramp terminal on a structure. This position allows an appropriate perception and reaction distance between the structure and ramp gore nose. It also permits the placement of the 30 ft (9 m) bridge approach pavement to be coordinated with the preferred terminal construction.

2. Gore Nose on Structure. Figure 37-6.I(b) illustrates a single structure design with the exit ramp terminal positioned so that the distance between the mainline and ramp does not exceed 36 ft (11 m). Preferably, the structure should be placed upstream of the 36 ft (11 m) maximum offset.

3. Gore Nose on Split Structure. Figure 37-6.I(c) illustrates a split-bridge design which cannot be avoided due to the length and location of a structure. The designer must provide an impact attenuator for this special situation. For information on the required minimum impact attenuator area, see Section 38-8.

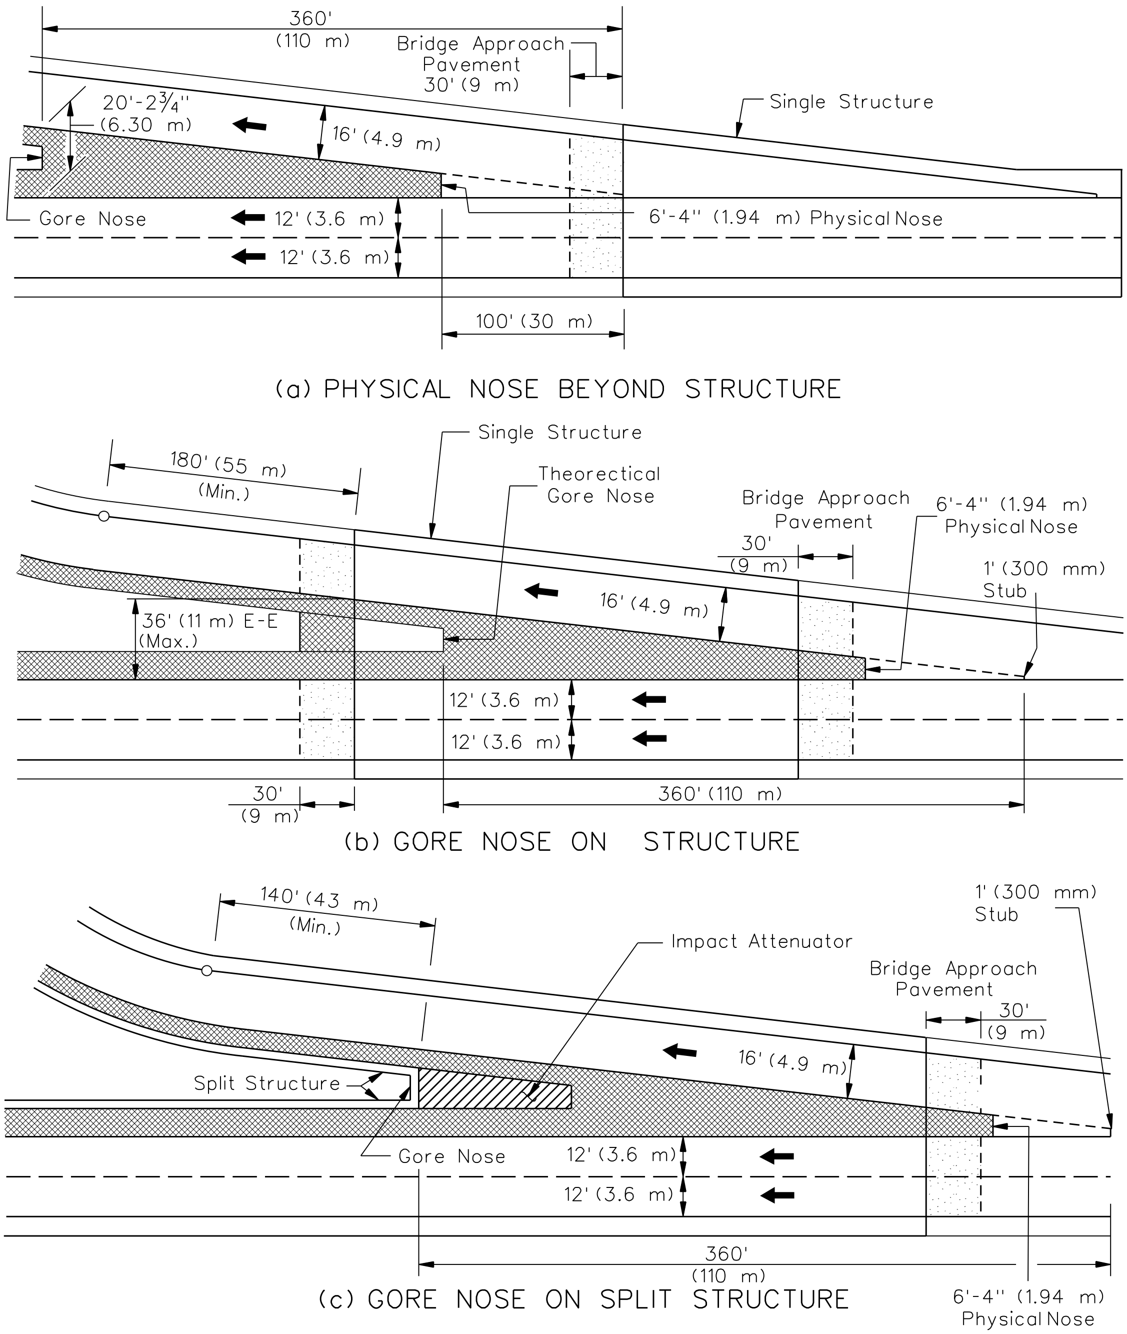
Figure 37-6.J illustrates the minimum position for an exit ramp terminal near an overhead structure. To achieve the optimized design and travel distance, locate the physical nose three seconds of travel time from the edge of the structure.

37-6.02 Entrance Ramps

37-6.02(a) Types

The entrance ramp terminal is a speed-change lane that permits ramp traffic to accelerate and merge with the high-speed traffic on the mainline. When designing the interchange, consider the following entrance ramp types:

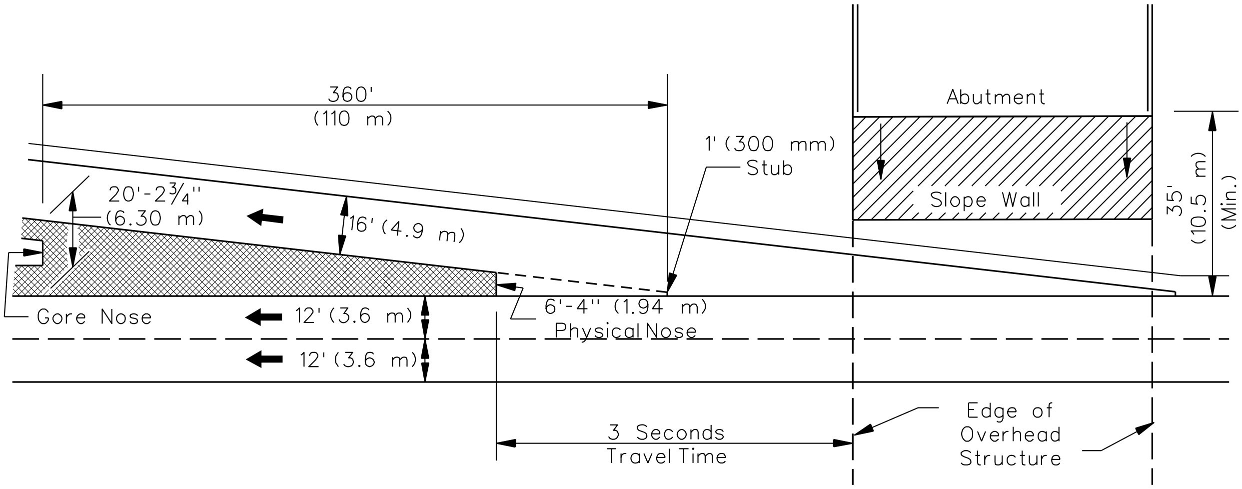
1. Standard Entrance Terminal. There are two basic types of entrance freeway ramp terminals — the parallel design and the taper design. For all new and reconstructed ramps, use the taper design, except as noted in Section 37-6.02(b). Figure 37-6.K and the *Illinois Highway Standards* illustrate the standard entrance ramp terminal design used by the Department. Use this ramp design for all single-lane entrances where the level of service of the ramp terminal is equal to or greater than that of the mainline. Entrance ramp terminals may carry a marked route provided the marked route is not a freeway or expressway. Where a freeway or expressway merges at an interchange, use the major convergence design as discussed in Section 37-6.04.



Note: Where an exit terminal is placed on a structure, the minimum cross slope is 1/4″/ft (2%). The 1/4″/ft (2%) is measured perpendicular to the edge of the mainline pavement, which will require a modification of the standard exit terminal profile.

EXIT TERMINALS ON STRUCTURES

Figure 37-6.I



EXIT TERMINAL NEAR OVERHEAD STRUCTURE

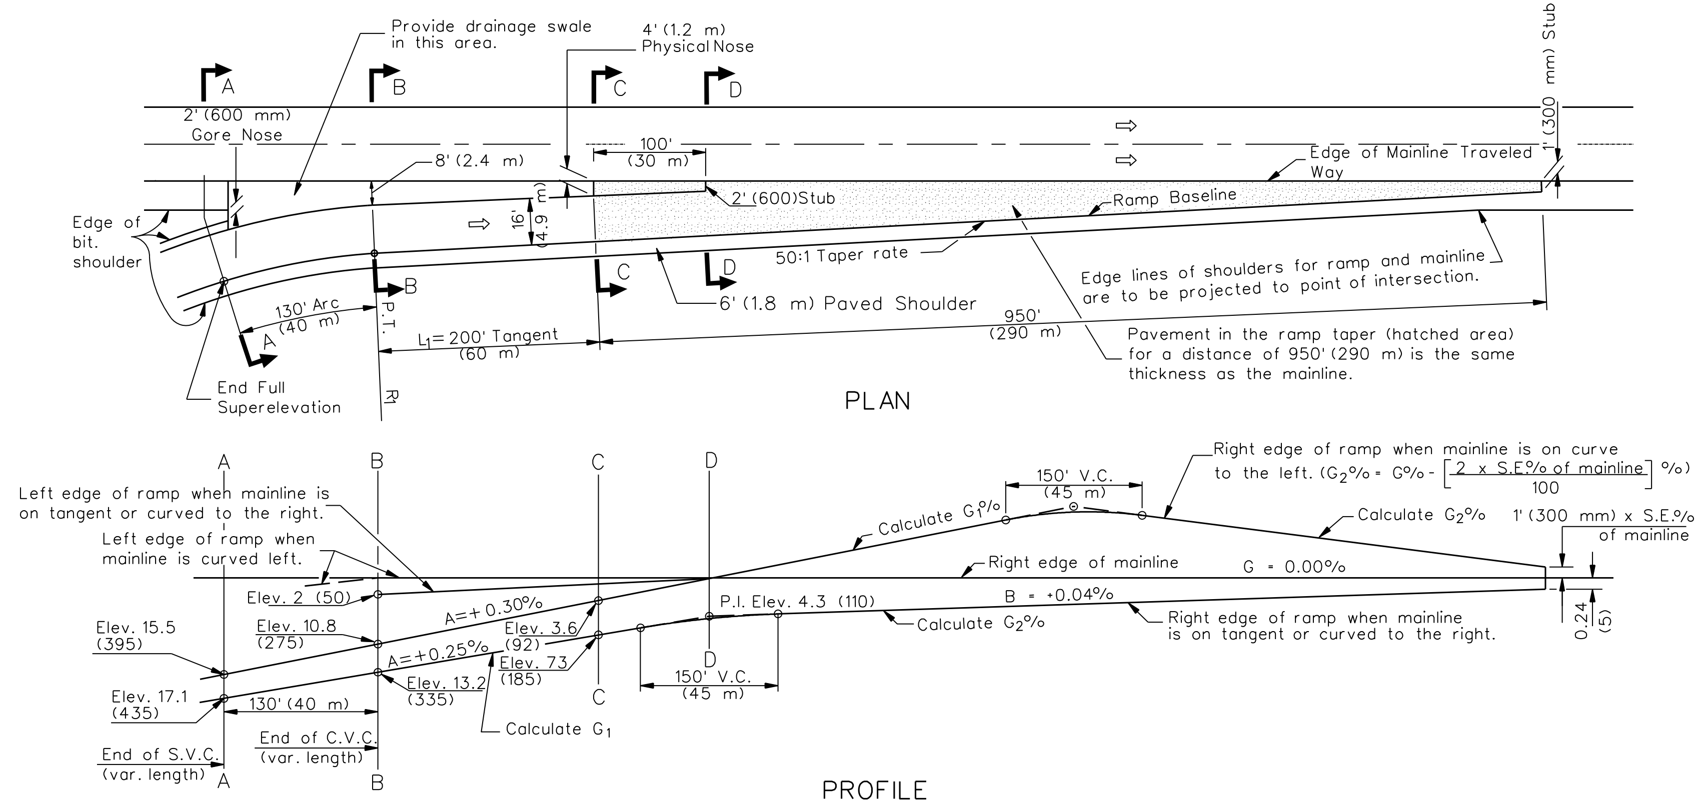
Figure 37-6.J

2. Entrance Terminal with an Auxiliary Lane. An auxiliary lane may be required after the entrance terminal:

   - to meet the requirements in Section 37-2.05, and/or
   - where the entering traffic exceeds the appropriate service volume of a standard entrance terminal design but where a two-lane entrance ramp is not required.

   Figure 37-6.L illustrates the design criteria for an entrance terminal with an auxiliary lane. The final ramp radius typically is 760 ft (230 m), which requires a 200 ft (60 m) tangent section preceding the physical nose. Typically, the auxiliary lane should be at least 1000 ft (300 m). Where the final ramp radius is less than 760 ft (230 m), the length of the auxiliary lane will be based on the necessary acceleration distance as discussed in Section 37-6.02(b).

3. Two-Lane Entrances.. Where the entrance design traffic exceeds the service volume of a single-lane entrance ramp terminal with an auxiliary lane, it may be necessary to provide a two-lane entrance terminal as illustrated in Figure 37-6.M. Where a two-lane entrance ramp is required, an additional lane on the freeway is necessary to accommodate the additional traffic. This lane may be dropped 2500 ft (750 m) downstream or at the next interchange.

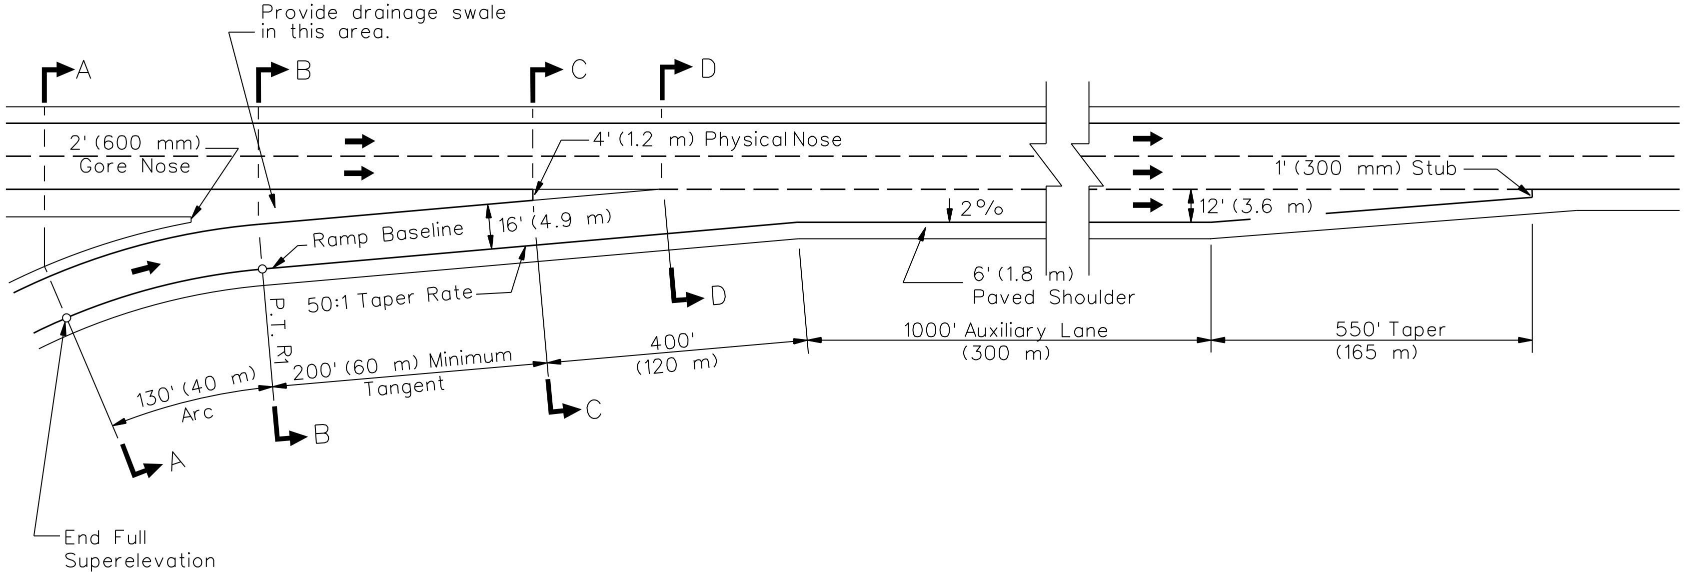


Notes:

1. *For values in %, divide by 100 to obtain vertical offsets. Vertical differences are in inches(mm).*
2. *Mainline grade is assumed to be 0%.*
3. *See* Highway Standards *for Sections B-B, C-C, and D-D.*

STANDARD ENTRANCE RAMP TERMINAL

Figure 37-6.K

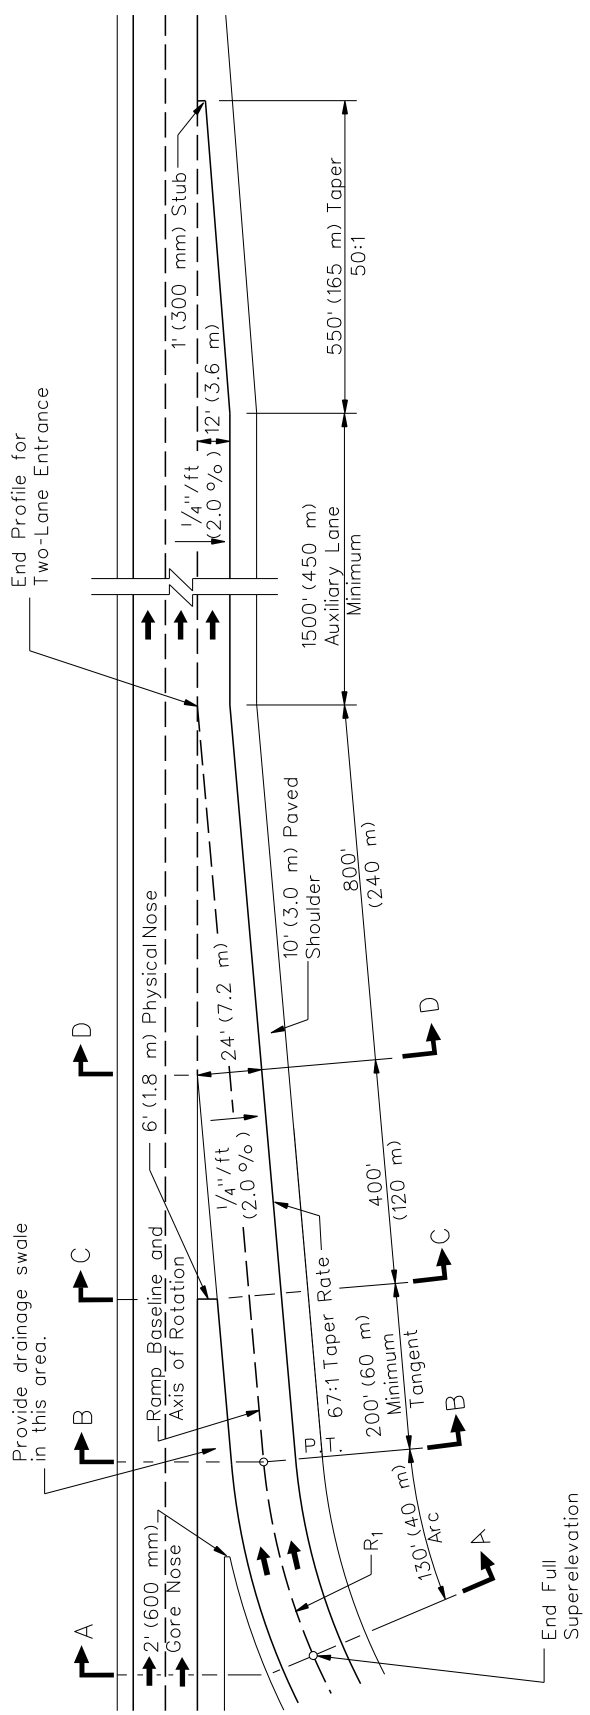


Notes:

1. *Include cross sections A-A, B-B, C-C, and D-D with the IDS.*
2. *See Figure 37-6.K for Standard Entrance Ramp Terminal.*

ENTRANCE RAMP TERMINAL WITH AUXILIARY LANE

Figure 37-6.L



Note: Include cross sections A-A, B-B, C-C, and D-D with the IDS.

TWO-LANE ENTRANCE RAMP TERMINAL

Figure 37-6.M

If the two-lane entrance is preceded by a two-lane exit ramp terminal, an increase in the basic number of lanes will generally not be required. In this case, the added lane that results from the two-lane entrance is considered an auxiliary lane. Note that this design violates lane balance guidelines discussed in Section 37-2.03. Where the demand volume of the entering traffic exceeds this design or where the entering roadway is a freeway or expressway, use the major convergence design as discussed in Section 37-6.04.

37-6.02(b) Length

Consider the following when determining the appropriate length of an entrance terminal:

1. Capacity. Where the mainline and ramp will carry traffic volumes approaching the design capacity of the merge area, consider using an auxiliary lane entrance ramp design as discussed in Section 37-6.02(a).

   Trucks. Where there are a significant number of trucks to impact the level of service on the freeway and ramp, acceleration lanes may need to be treated as truck-climbing lanes. The designer should reference the AASHTO publication *A Policy on Geometric Design of Highways and Streets* for truck acceleration rates. Typical areas where trucks might govern the ramp design include weigh stations, rest areas, truck stops, and transfer staging terminals. Also consider using truck acceleration criteria where there is substantial entering truck traffic and where the interchange crossroad has a high-skew angle or there is a significant crash history involving trucks attributable to an inadequate acceleration length.

2. Gradients. Where the gradient of the mainline and/or ramp exceeds +3%, the acceleration length may need to be adjusted. These adjustments are discussed in Section 36-2.03(e). For downgrades, use the standard entrance terminal design, and do not reduce the acceleration distance.

3. Horizontal Curves. The application of the acceleration criteria regarding horizontal curves preceding the entrance terminal are as follows:

   a. Design Speed. The design speed of the horizontal curve adjacent to an entrance terminal should be determined by open-roadway conditions. See Figure 37-4.F and Chapter 32.

   b. Curve Radii/Tangent Lengths. Figure 37-6.N provides the minimum controlling ramp curve radii (R_1) that should be used prior to the standard entrance terminal based on the mainline design speed.

4. Additional Lengths. If it has been determined that additional acceleration distance is required beyond that provided with the standard entrance terminal, the following options may be considered:

US Customary					
Mainline Design Speed (mph)					
	75	70	60	50	40(2)(3)
	Design Speed for R_1				
e_{max}	55 mph	50 mph	45 mph	40 mph	30 mph
6%	1060 ft	833 ft	643 ft	485 ft	231 ft
8%	960ft	758 ft	587 ft	444 ft	214 ft
Metric					
Mainline Design Speed (km/hr)					
	120	**110**	**100**	**80**	**60(2)(3)**
	Design Speed for R_1				
e_{max}	**90 km/hr**	**80 km/hr**	**70 km/hr**	**60 km/hr**	**50 km/hr**
6%	336 m	252 m	184 m	123 m	79 m
8%	304 m	229 m	168 m	113 m	73 m

Notes:

1. *R_1 is the radius of curve connecting to L_1 of the standard entrance terminal. See Figure 37-6.K.*
2. *Use with C-D Roads only.*
3. *100 ft (30 m) allowed for L_1 at this mainline design speed. See figure 37-6.K.*

MINIMUM CURVE RADII (R_1) FOR ENTRANCE TERMINALS

Figure 37-6.N

a. Typical Design. If substantial additional distance is required for acceleration, use the auxiliary lane terminal design as shown in Figure 37-6.L.

b. Optional Design. If only a small additional distance is required to meet the necessary acceleration length, the additional distance may be gained by extending the L_1 distance. The designer must ensure that this will not create other undesirable aspects in the design of the ramp proper.

c. Low-Volume Conditions. Where existing volumes on the mainline are low and where the slower entering vehicles will not reduce the level of service on the mainline, the use of the standard entrance terminal may be considered. The speed profile of merging trucks onto the mainline must be investigated and documented. However, provide sufficient right-of-way so that an auxiliary lane can be added in the future.

d. Secondary Impacts. Before providing any additional acceleration lane length, the designer must consider its impacts (e.g., additional construction costs, wider structures, right-of-way impacts).

37-6.02(c) Sight Distance

Decision sight distance desirably should be provided for drivers on the mainline approaching an entrance terminal. They need sufficient distance to see the merging traffic and adjust their speed or change lanes to allow the merging traffic to enter the freeway. Likewise, drivers on the entrance ramp need to see a sufficient distance to locate gaps in the traffic stream for merging. Section 31-3 discusses decision sight distance in more detail.

37-6.02(d) Superelevation and Cross Slopes

Standard entrance terminal designs have been developed to include appropriate superelevation transitions and desirable crossover crown conditions where the terminal connects onto the mainline; see Figure 37-6.K and the *Highway Standards*. When an IDS is prepared, develop and show on the IDS the detailed cross section at A-A as indicated in Figure 37-6.K.

37-6.02(e) Gore Area

The following presents the nose criteria for entrance gores:

1. Physical Nose. This is a point located at Section C-C, as illustrated in Figure 37-6.K and has a dimensional width of 4 ft (1.2 m).

2. Gore Nose. This is a point where the sodded area ends and the paved shoulders connect. The gore nose, excluding the mainline right shoulder and ramp left shoulder, is 2 ft (600 mm) wide as shown in Figure 37-6.K.

37-6.03 Ramp/Roadway Divergence Applications

37-6.03(a) Major Divergences

Where two freeways separate, provide a major divergence as shown in Figures 37-6.O, 37-6.P, and 37-3.Q. The most important concept in the use of a major divergence is that if the route turns at an interchange, the physical divergence of the roadways should also occur in the same direction. To maintain lane balance, an additional interior lane will be required preceding the divergence. The widening of the interior lane from 12 ft to 24 ft (3.6 m to 7.2 m) should occur in a distance of 1000 ft (300 m). This provides a driver in the center lane the option of selecting either direction of travel without having to change lanes.

Add additional lanes to the side of the lesser-preferred route. Check for lane balance. Pavement joints should normally favor the freeway with the higher volume of traffic. An exception to this rule is that in most cases, regardless of the traffic volume split, the Interstate is considered the preferred route. Provide a minimum tangent length of 200 ft (60 m) beyond the 6 ft (1.8 m) physical nose to facilitate a change of cross slope preceding the initial curve of any diverging roadway.

Where a major divergence is required but the preferred design of an equal split of the roadways cannot be achieved due to the existing freeway alignment, a modified divergence design can be used as shown in Figure 37-6.P. In addition, where a divergence design is required and sufficient right-of-way is not available to build the one-sided divergence and where the diverging traffic volume is not significant, a two-lane exit terminal design may be considered. However, before using the two-lane exit design, coordination and approval must be received from BDE.

37-6.03(b) Minor Divergences

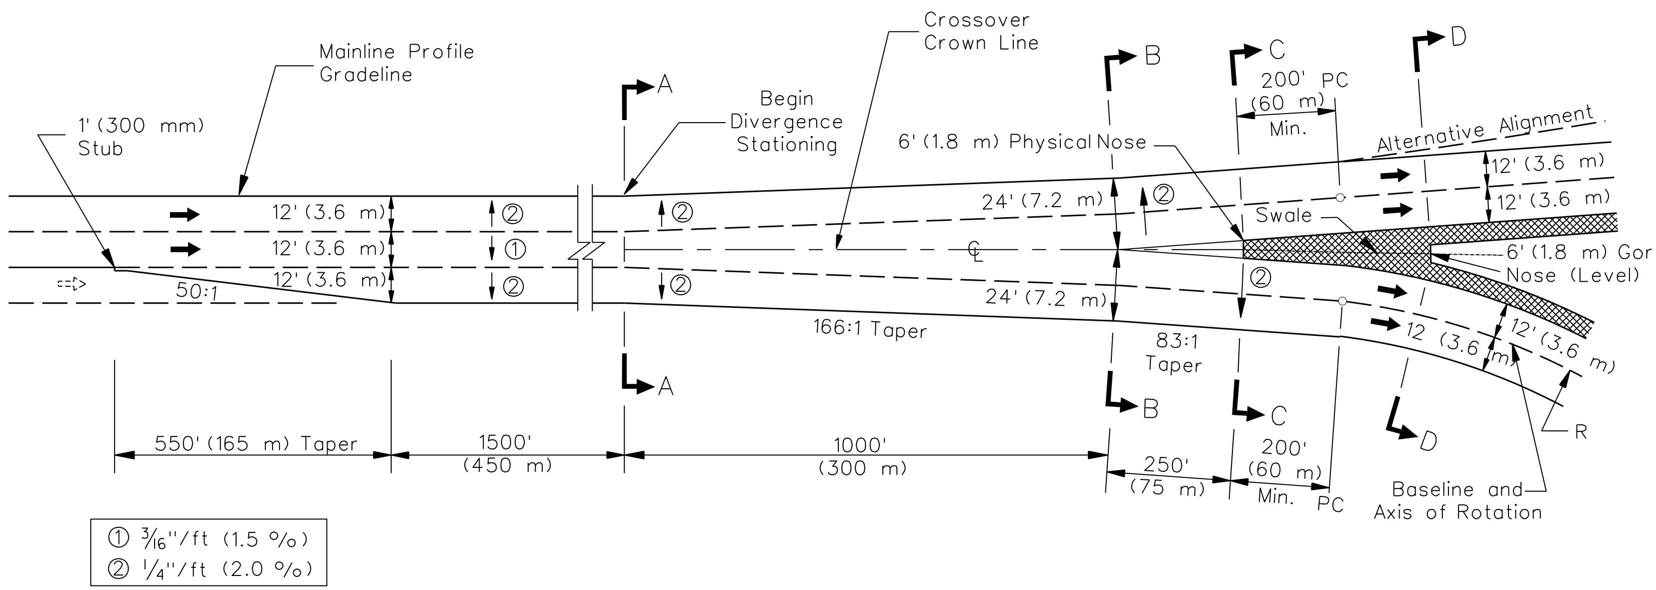
Consider a minor divergence for the following situations; see Figure 37-6.R:

- where a highway terminates into separate single lane ramps (e.g., at a trumpet interchange);
- where a ramp or roadway separates within a complex interchange (e.g., directional interchanges); or
- as part of a collector-distributor roadway design.

37-6.04 Ramp/Roadway Convergence Applications

37-6.04(a) Major Convergences

Where two freeways merge, provide a major convergence design as illustrated in Figure 37-6.S. The number of lanes downstream from the convergence generally will be one less than the combined total of the two approaching roadways. Under some circumstances, traffic demand may require that the number of lanes departing the merge area be the same number as the two approaching roadways.

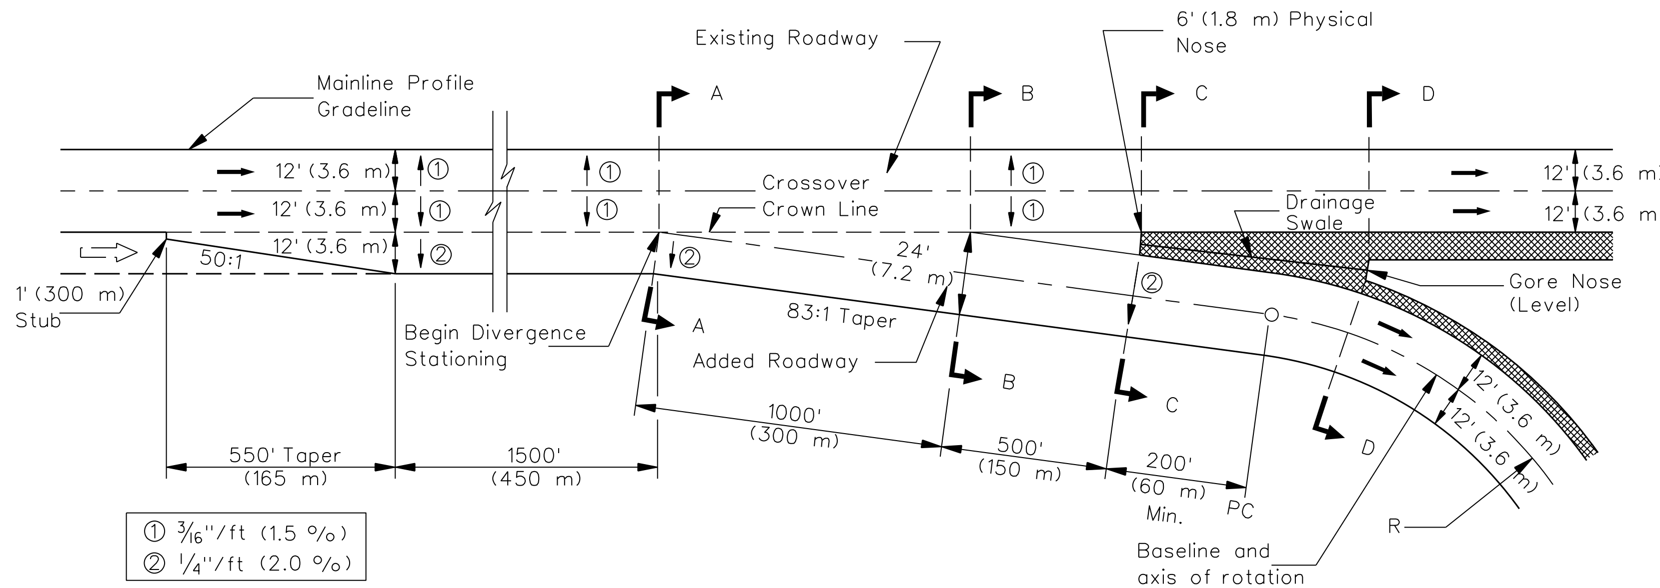


Notes:

1. *Develop cross sections A-A, B-B, C-C, and D-D during the preparation of the IDS.*
2. *The divergence can be designed to divert traffic from either side of an existing roadway.*
3. *Full superelevation is attained at Section D-D.*

EQUAL-SPLIT MAJOR DIVERGENCE
(Two- or Three-Lane Approaching Roadway with Two-Lane Roadways Diverging)

Figure 37-6.O

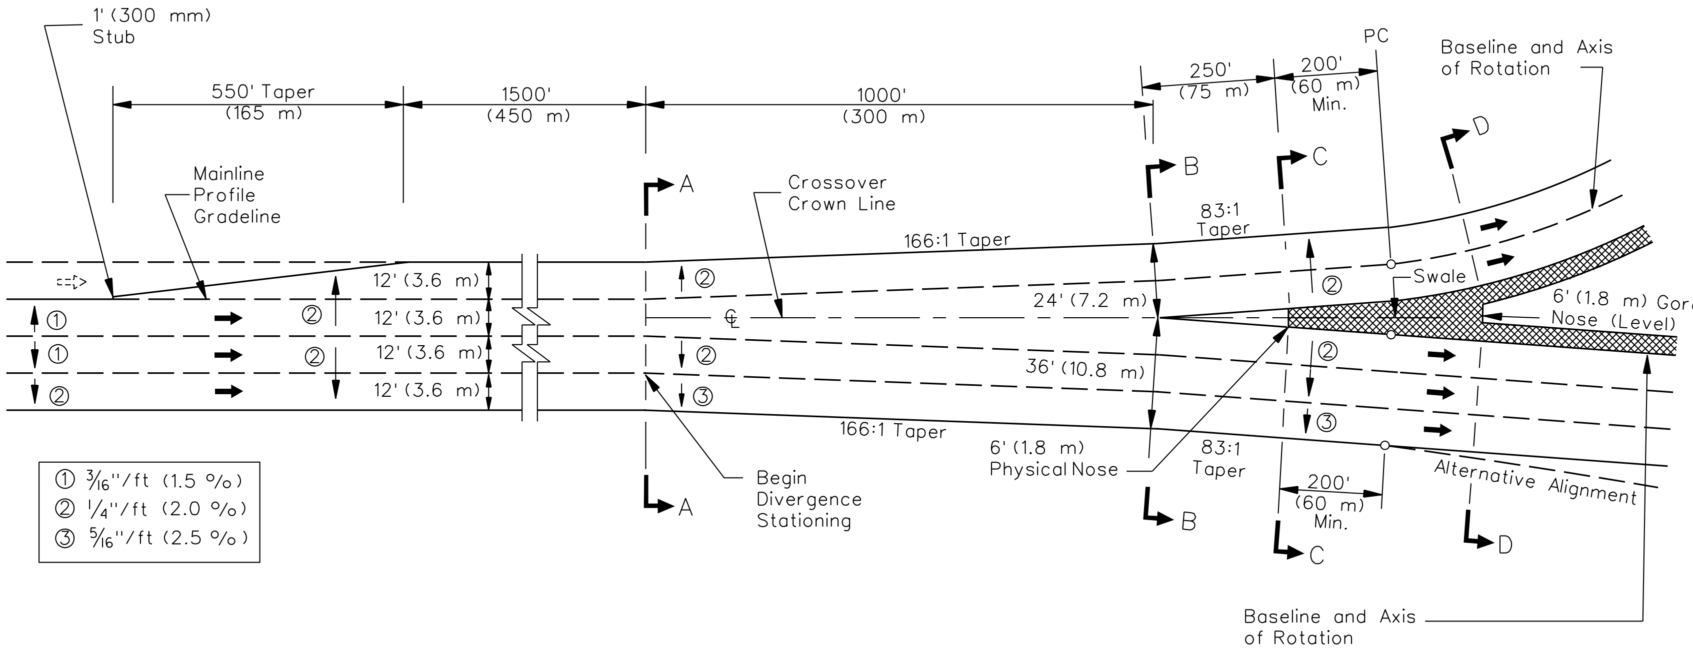


Notes:

1. *Develop cross sections A-A, B-B, C-C, and D-D during the preparation of the IDS.*
2. *The divergence can be designed to divert traffic from either side of an existing roadway.*
3. *Full superelevation is attained at Section D-D.*

ONE-SIDED MAJOR DIVERGENCE
(Two- or Three-Lane Approaching Roadway with Two-Lane Roadway Diverging)

Figure 37-6.P

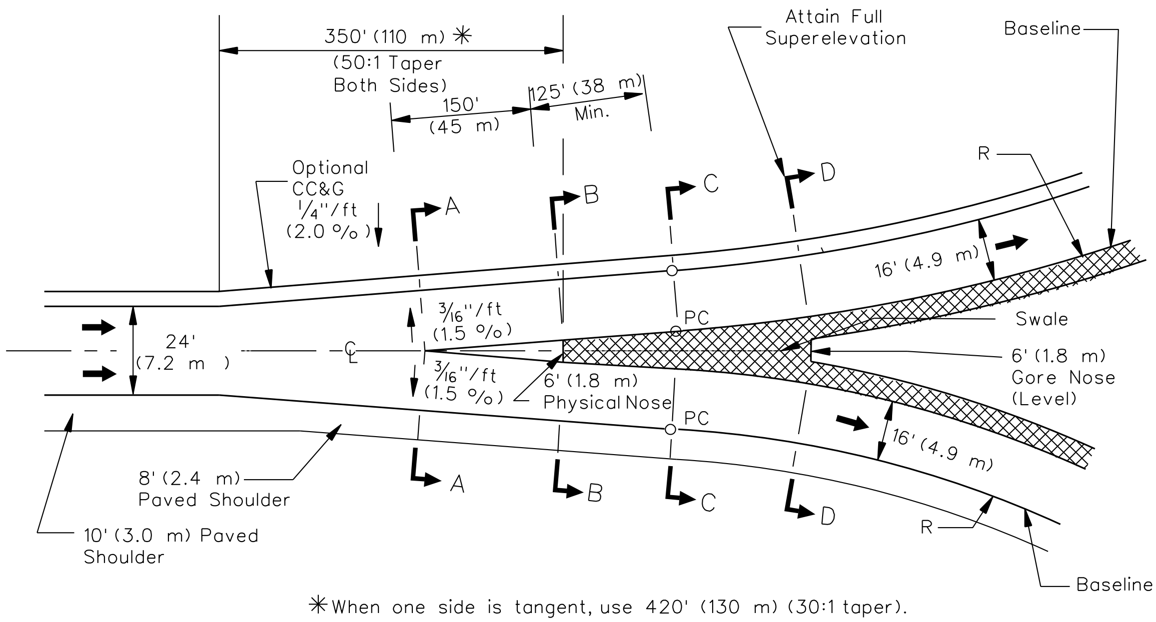


Notes:

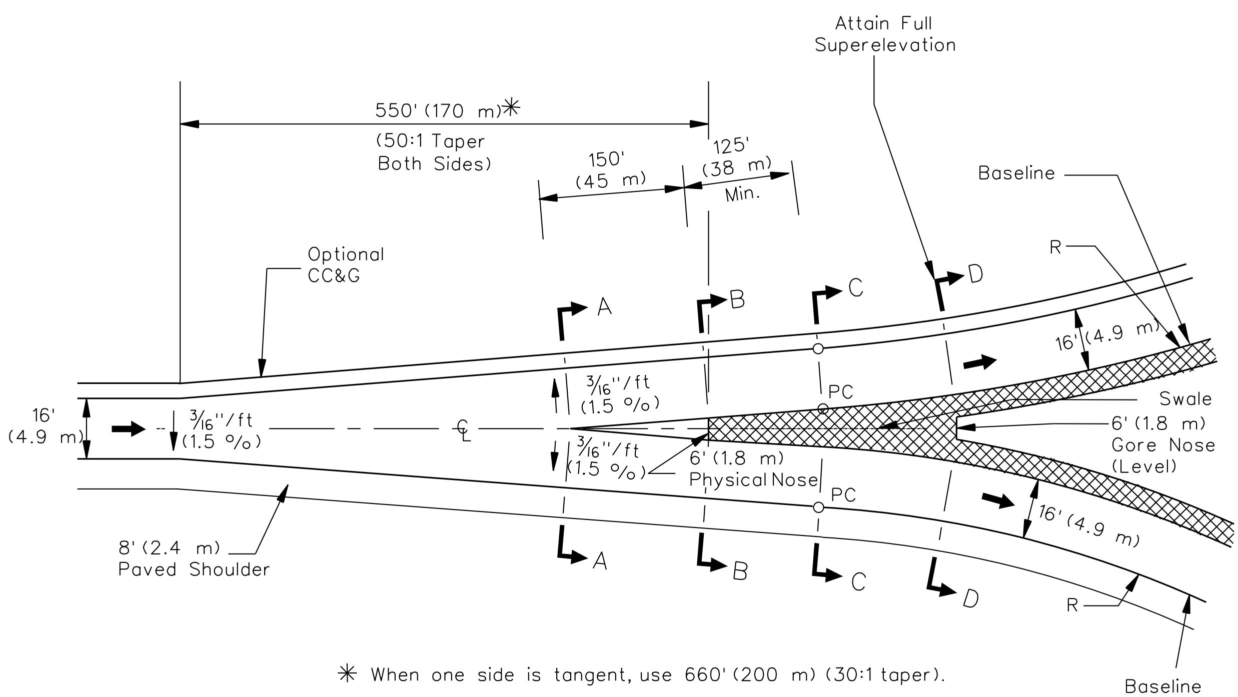
1. *Develop cross sections A-A, B-B, C-C, and D-D during the preparation of the IDS.*
2. *The divergence can be designed to divert traffic from either side of an existing roadway.*
3. *Where a horizontal curve is provided downstream from the divergence, full superelevation is attained at Section D-D.*

MAJOR DIVERGENCE
(Three- or Four-Lane Approaching Roadway with Two- and Three-Lane Roadways Diverging)

Figure 37-6.Q



TYPE A - 24 ft (7.2 m)

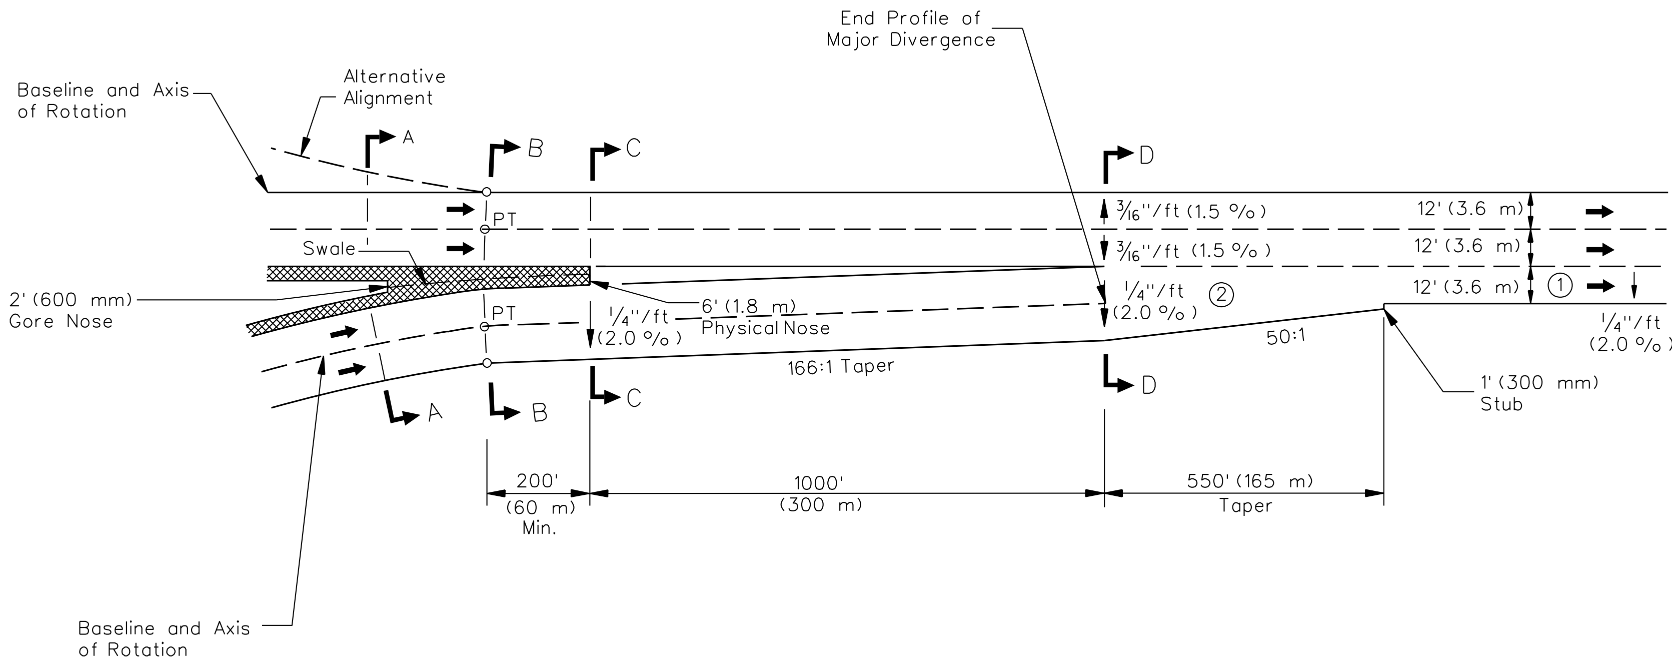


TYPE B - 16 ft (4.9 m)

Note: Develop cross sections A-A, B-B, C-C, and D-D during the preparation of IDS.

MINOR DIVERGENCES

Figure 37-6.R



Notes:

1. *If the right-hand lane is proposed to be dropped for capacity reasons, provide a minimum 1500 ft (450 m) auxiliary lane and a 550 ft (165 m) taper.*
2. *The convergence can be designed to merge from either side.*
3. *Develop cross sections A-A, B-B, C-C, and D-D during the preparation of IDS.*

MAJOR CONVERGENCE

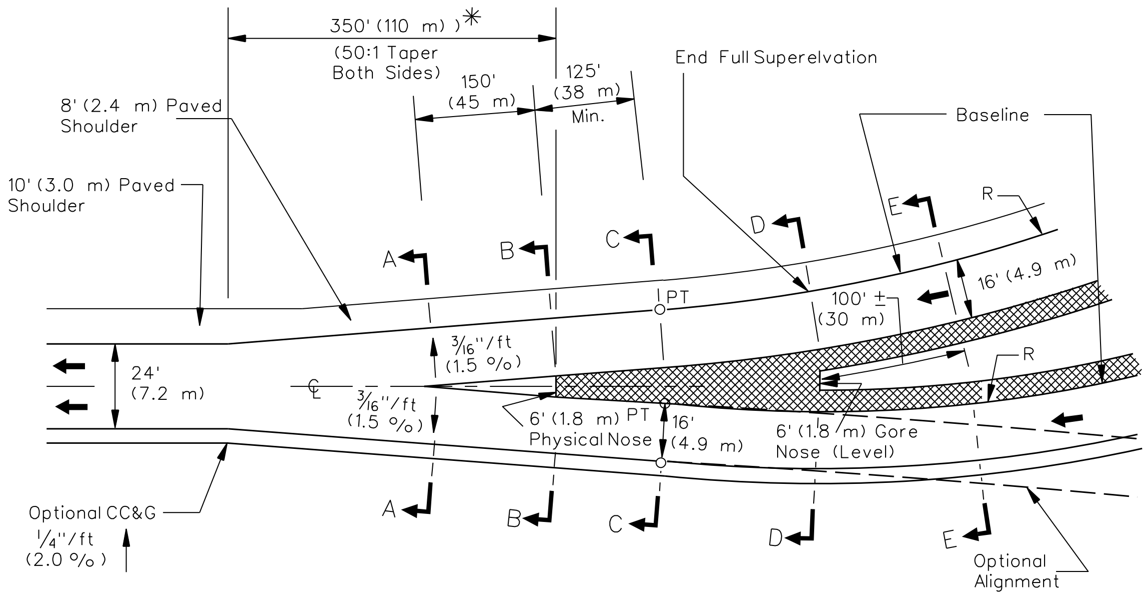
Figure 37-6.S

Typically, a lane drop will be required downstream from the convergence. The most desirable and typical design will be to drop the right slow-speed lane versus the left high-speed lane. However, it also may be desirable to drop the left lane of the merging roadway if it is serving the lowest volume per lane. This design should be reviewed during the development of the IDS.

37-6.04(b) Minor Convergences

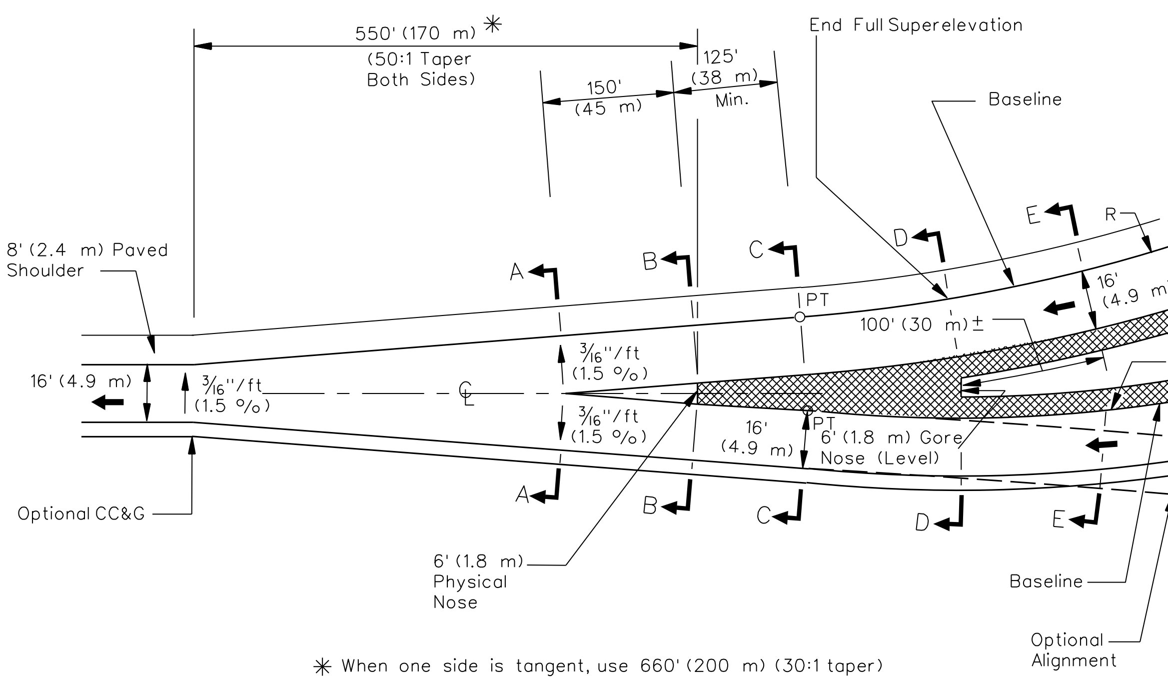
Consider a minor convergence for the following situations; see Figure 37-6.T:

- where interchange ramps converge to form either a single or double lane roadway (e.g., trumpet interchanges) within complex interchanges; or
- as part of a collector-distributor roadway design.



✳ When one side is tangent, use 420' (130 m) (30:1 taper)

TYPE A - 24 ft (7.2 m)



✳ When one side is tangent, use 660' (200 m) (30:1 taper)

TYPE B - 16 ft (4.9 m)

Notes:

1. *Develop cross sections A-A, B-B, C-C, D-D, and E-E during the preparation of IDS.*
2. *Ramp cross slope should be determined by downstream horizontal alignment.*

MINOR CONVERGENCES

Figure 37-6.T

Chapter Thirty-eight
ROADSIDE SAFETY

The ideal roadway would be entirely free of any roadside obstructions or other hazardous conditions. This is rarely practical because of natural, economic, and environmental factors. Chapter 38 presents clear zone distances which should adequately provide a clear recovery area for about 80% of the errant vehicles that run off the road and the chapter provides criteria for the use of roadside barriers, median barriers, and impact attenuators where providing the clear zone is not practical. The chapter also discusses the use of cost-effective methodologies to determine roadside safety treatments.

Information applicable to roadside safety is also included in the following Chapters:

- Chapter 7 - roadside safety near railroads.
- Chapter 17 - roadside safety along bikeways.
- Chapter 34 – roadside safety addressed through shoulder rumble strips and stripes
- Chapter 49 - roadside safety on 3R projects on rural and urban highways.
- Chapter 50 - roadside safety on 3R projects on freeways.
- Chapter 55 - roadside safety in work zones.

38-1 APPLICATION

This Section presents the IDOT application of roadside safety decisions based on project type and appurtenance type.

38-1.01 Project Type

The following summarizes the use of the *BDE Manual* for roadside safety applications based on the project type or project scope of work:

1. New Construction/Reconstruction Projects. Chapter 38 presents the roadside safety criteria for all new construction/reconstruction projects.
2. 3R Non-Freeway Projects. Chapter 49 presents the roadside safety criteria for non-freeway 3R rural and urban highway freeway projects. Roadside safety criteria not covered in Chapter 49 shall be as described in Chapter 38. For example, Chapter 49 modifies clear zone values, however it does not modify their application on non-recoverable slopes. Clear recovery area at the toe-of-slope of non-recoverable slopes is controlled by Chapter 38.
3. 3R Freeway Projects. Chapter 50 presents the roadside safety criteria for 3R freeway projects. Roadside safety criteria not covered in Chapter 50 shall be as described in Chapter 38.

4. Highway Safety Improvement Projects. The IDOT Bureau of Safety Programs and Engineering (BSPE) is responsible for approving the project scope of work for highway safety improvement projects (HSIP) that use the Federal-aid funds set aside for highway safety improvements. The scope of work for these projects may include roadside safety improvements. In this case, the designer will use the criteria in Chapter 38 with the specific application determined on a case-by-case basis considering:
   - the crash patterns at the site,
   - the project scope as outlined by the BSPE,
   - the project budget, and
   - the estimated construction costs of an application as compared to the anticipated safety benefits and the costs of other design solutions.
5. Work Zones. Chapter 55 presents the roadside safety criteria for work zones.

38-1.02 Appurtenance Type

The following summarizes the Department's roadside safety responsibilities based on type of appurtenance:

1. Bridge Rails. The IDOT Bureau of Bridges and Structures is responsible for establishing Department criteria for the selection and design of all bridge rails. The Bureau of Design and Environment (BDE) is responsible for establishing selection and design criteria for the roadside barrier and terminal section approaching the bridge rail.
2. Traffic Control Devices. The Bureau of Operations and the Bureau of Bridges and Structures are jointly responsible for establishing Department criteria for the design of structural supports for traffic control devices (e.g., breakaway bases for large signs). For the location of traffic control devices, the Bureau of Operations determines the initial placement and the road designer ensures that the proposed location is compatible with the roadway design.
3. All Other Appurtenances. BDE and BSPE are jointly responsible for establishing Department criteria for all other roadside safety appurtenances (e.g., roadside barriers, median barriers, impact attenuators, lighting).

38-2 DEFINITIONS

1. Back Slope. The side slope created by connecting the ditch bottom, shelf, or shoulder at the hinge point, upward and outward, to the natural ground line.

2. Barrier (Vertical) Curb. A longitudinal element placed at the edge of the traveled way to provide delineation, to control drainage, to manage access, and to minimize right-of-way acquisition. Barrier curbs range between 6 in. and 9 in. (150 mm to 230 mm) in height with a face steeper than 3 vertical to 1 horizontal. Barrier curbs do not have significant re-directional capability for errant vehicles.

3. Barrier Terminals. End treatments for both roadside barriers and transitions to other types of barriers (e.g., to bridge rails).

4. Clear Zone. The area provided beyond the edge of through traveled way for the recovery of errant vehicles, which ideally should be kept clear of any non-traversable hazards or fixed objects. The clear zone includes shoulders, bike lanes, and auxiliary lanes, except those auxiliary lanes that function like through lanes.

5. Concrete Barrier. A rigid barrier typically constructed in a narrow median where no deflection distance is available and which can accommodate most vehicular impacts without penetration. In most applications these barriers are double-faced as shown on the Highway Standard.

6. Critical Parallel Slope. Fill sections with front slopes steeper than 1V:3H that cannot be safely traversed by a run-off-the-road vehicle. Depending on the encroachment conditions, a vehicle on a critical slope may overturn.

7. End Treatments. The terminal devices for roadside barriers, including both the approaching and departing ends.

8. Enhanced Lateral Offset. An offset in an urban environment beyond that used to provide clearance to keep the overhang of a truck from striking an object [1.5 ft (0.5 m) from the face of the curb], but less than the normal clear-zone width. The recommended offset to obstructions typically range from 4 ft to 6 ft (1.2 m to 1.8 m) from the face of curb and 8 ft (2.4 m) without a vertical curb. A 12 ft (3.6 m) offset is recommended for urban areas which are without a vertical curb and on the outside of a horizontal curve.

9. Experimental System. A roadside barrier, end terminal, or impact attenuator which has performed satisfactorily in full-scale crash tests but has not been installed in sufficient locations or exposed to traffic for a sufficient time to adequately evaluate its in-service performance.

10. Front Slope (or Foreslope). The side slope created by connecting the shoulder or shelf at the hinge point, downward and outward, to the ditch bottom or natural ground line.

11. Gating. A term used to describe barrier end treatments which are designed to allow controlled penetration by an impacting vehicle.

12. Hinge Point. The first major discontinuity in the roadway encountered by the vehicle after it leaves the traveled way and shoulder. The top of the front slope. The planar intersection between the shoulder and the front slope when the slope of the shoulder is 1H:10V or flatter.

13. Impact Angle. For a longitudinal barrier, the angle between a tangent to the face of the barrier and a tangent to the vehicular path at impact. For an impact attenuator, it is the angle between the axis of symmetry of the impact attenuator and a tangent to the vehicular path at impact.

14. Impact Attenuator (Crash Cushion). A protective device used to safely shield roadside hazards, typically point obstacles, from approximately head-on impacts by errant vehicles.

15. Length of Need. Total length of a longitudinal barrier, measured with respect to the centerline of roadway, needed to shield an area of concern. The length of need (LON) is measured to the last point of redirective rail. The beginning point of the length of need is referred to as the BLON (beginning length of need) point.

16. MASH. Manual for Assessing Safety Hardware, AASHTO 2016. The processes and testing described in MASH typically represent the latest requirements for the range of roadside safety hardware required for use on the state highway system. The assessment of roadside hardware for crashworthiness continues to transition from NCHRP 350 standards to MASH standards, and the term *crashworthy* is used in this chapter as the general term to describe devices that satisfy current Department requirements.

17. Median Barrier. A longitudinal barrier used to prevent an errant vehicle from crossing the median of a divided highway thereby preventing head-on collisions between opposing traffic.

18. Mountable (Sloping) Curb. A longitudinal element placed at the edge of traveled way to provide delineation, to control drainage, to manage access, and to outline corner islands. Mountable curbs have a height of 6 in. (150 mm) or less with a sloping face of approximately 45 degrees. Mountable curbs do not have significant re-directional capability for errant vehicles.

19. Non-Recoverable Parallel Slope. Slopes which can be safely traversed but upon which an errant vehicle is unlikely to recover. The run-off-the-road vehicle will likely continue down to the toe of the slope. For most embankment heights, if a front slope is between 1V:3H (inclusive) and 1V:4H (exclusive), it is considered a non-recoverable parallel slope.

20. Non-Redirective. A descriptive term which indicates that the roadside safety device will not redirect an impacting vehicle but will, rather, "capture" the vehicle (e.g., sand barrels) or allow the vehicle to pass through (e.g., breakaway sign supports).

21. Operational System. A roadside barrier, end terminal, or crash cushion that has performed satisfactorily in full-scale crash tests and has demonstrated satisfactory in-service performance.

22. Parallel Slopes. Front and back slopes for which the toe runs approximately parallel to the roadway.

23. Pocketing. The potential for a vehicle impacting a redirective device to undergo relatively large lateral displacements within a relatively short longitudinal distance.

24. Recoverable Parallel Slope. Slopes that can be safely traversed and upon which an errant motorist has a reasonable opportunity to regain control of the vehicle. Front slopes 1V:4H and flatter are considered recoverable.

25. Redirective. A term which indicates that the roadside safety device is designed to redirect an impacting vehicle approximately parallel to the longitudinal axis of the device.

26. Roadside Barrier. A longitudinal barrier (e.g., guardrail, concrete barrier) used to shield roadside hazards while addressing the safety of vehicle occupants. A longitudinal barrier may occasionally be used to shield pedestrians from vehicular traffic.

27. Roadside Hazards. A general term to describe roadside features that cannot be safely impacted by a run-off-the-road vehicle. Roadside hazards include both fixed objects and non-traversable roadside features (e.g., rivers).

28. Roadway. The combination of the traveled way, both shoulders or curb and gutters, and any auxiliary lanes on the mainline highway. Traveled ways separated by a depressed median have two (or more).

29. Shy Distance. The distance from the edge of traveled way beyond which a roadside object will not be perceived as an immediate hazard by the typical driver, to the extent that the driver will change vehicular placement or speed.

30. Side Slope. A ratio used to express the steepness of a slope adjacent to the roadway. The ratio is expressed as vertical to horizontal (V:H).

31. Test Level. The test levels represent sets of conditions defined in terms of vehicular type and mass, vehicular speed, and vehicular impact angle that quantify the impact severity of a matrix of crash tests. Six performance levels, or test levels, are available. Test Levels 1 through 3 use a small passenger car and a pickup truck as design vehicles. Test Level 1 (TL-1) is applicable at roadside design speeds up to 30 mph (50 km/hr), TL-2 up to and including 45 mph (70 km/hr), and TL-3 up to 60 mph (100 km/hr). Higher test levels retain the TL-3 performance requirements for the small passenger car and pickup truck, but also introduce larger trucks. TL-4 includes a 22,000 pound (10,000 kg) single unit truck, TL-5 an 80,000 pound (36,000 kg) tractor-van trailer, and TL-6 an 80,000 pound (36,000 kg) tractor-tanker trailer.

32. Toe of Slope. The intersection of the front slope or back slope with the natural ground line or ditch bottom, before any rounding is applied.

33. Top of Slope. The intersection of the back slope with the natural ground line, before any rounding is applied.

34. Transverse Slopes. Front and back slopes for which the toe runs approximately perpendicular to the flow of traffic on the major roadway. Transverse slopes are typically formed by intersections between the mainline and entrances, median crossovers, or side roads.

35. Traveled Way. The portion of the roadway for the movement of vehicles, exclusive of medians, shoulders, curb and gutter, and auxiliary lanes.

36. Warrant. The criteria by which the justification for a safety treatment or improvement can be determined. The warrant may be based on IDOT/AASHTO guidelines, on a "cost-effective" assessment, or on engineering judgment.

38-3 ROADSIDE CLEAR ZONES

38-3.01 Background

The clear zone widths are based on limited empirical data that has then been extrapolated to a wide range of conditions. Therefore, the distances imply a degree of accuracy that does not exist. They do, however, provide a good frame of reference for making decisions on providing a safe roadside area. Each application of the clear zone distance must be evaluated individually, and the designer must exercise good judgment.

When using the recommended clear zone distances, the designer should consider the following:

1. Project Scope of Work. The clear zone distances in Section 38-3 apply to all freeway projects and to new construction/reconstruction projects on non-freeways. Chapter 49 presents the criteria for 3R projects on non-freeways.
2. Context. If a formidable obstacle lies just beyond the clear zone, it may be appropriate to remove or shield the obstacle if costs are reasonable. Conversely, the clear zone should not be achieved at all costs. Limited right-of-way (see item 4 below) or unacceptable construction costs may lead to installation of a barrier or perhaps no protection at all. As a general statement, the use of an appropriate clear zone distance is a compromise between maximum safety and minimum construction costs.
3. Boundaries. The designer should not use the clear zone distances as boundaries for introducing roadside hazards (e.g., bridge piers, non-breakaway sign supports, utility poles, landscaping features). These should be placed as far from the traveled way as practical.
4. Right-of-Way. Even for new construction/reconstruction projects, the availability of right-of-way may be a serious project issue. The acquisition of additional right-of-way solely to provide the clear zone distance may not be cost effective. If, on the other hand, the right-of-way width exceeds the design clear zone, this may offer an opportunity to increase safety by removing all hazards within the right-of-way.

38-3.02 Clear Zone Values

Figure 38-3.A presents clear zone distances for design. The following discusses the use of Figure 38-3.A to determine the applicable clear zone.

38-3.02(a) Speed

The designer will use the design speed for the facility from Figure 38-3.A to determine the applicable clear zone.

Design Speed (mph)	Design Year ADT	Front Slopes			Back Slopes		
		1V:6H or Flatter	1V:5H to 1V:4H	1V:3H	1V:3H	1V:5H to 1V:4H	1V:6H or Flatter
≤ 40	Under 750	7 – 10	7 – 10	**	7 – 10	7 – 10	7 – 10
	750 – 1500	10 – 12	12 – 14	**	10 – 12	10 – 12	10 – 12
	1500 – 6000	12 – 14	14 – 16	**	12 – 14	12 – 14	12 – 14
	Over 6000	14 – 16	16 – 18	**	14 – 16	14 – 16	14 – 16
45 – 50	Under 750	10 – 12	12 – 14	**	8 – 10	8 – 10	10 – 12
	750 – 1500	12 – 14	16 – 20	**	10 – 12	12 – 14	14 – 16

	Over 6000	18 – 20	24 – 28	**	14 – 16	18 – 20	20 – 22
55	Under 750	12 – 14	14 – 18	**	8 – 10	10 – 12	10 – 12
	750 – 1500	16 – 18	20 – 24	**	10 – 12	14 – 16	16 – 18
	1500 – 6000	20 – 22	24 – 30	**	14 – 16	16 – 18	20 – 22
	Over 6000	22 – 24	26 – 32*	**	16 – 18	20 – 22	22 – 24
60	Under 750	16 – 18	20 – 24	**	10 – 12	12 – 14	14 – 16
	750 – 1500	20 – 24	26 – 32*	**	12 – 14	16 – 18	20 – 22
	1500 – 6000	26 – 30	32 – 40*	**	14 – 18	18 – 22	24 – 26
	Over 6000	30 – 32*	36 – 44*	**	20 – 22	24 – 26	26 – 28
65 – 70[6]	Under 750	18 – 20	20 – 26	**	10 – 12	14 – 16	14 – 16
	750 – 1500	24 – 26	28 – 36*	**	12 – 16	18 – 20	20 – 22
	1500 – 6000	28 – 32*	34 – 42*	**	16 – 20	22 – 24	26 – 28
	Over 6000	30 – 34*	38 – 46*	**	22 – 24	26 – 30	28 – 30

* *Clear zones may be limited to 30 ft for practicality and to provide a consistent roadway template. When a site-specific investigation indicates a high probability of continuing crashes or when such occurrences are indicated by crash history, the designer should consider clear zone distances greater than the clear zone shown above.*

** *See procedure in Section 38-3.03(b).*

Notes:

1. *All distances are measured from the edge of the traveled way. For opposing traffic on an undivided two-way roadway, the traveled way begins at the centerline separating opposing traffic.*
2. *For clear zones, the "Design Year ADT" will be the total ADT for both directions of travel for the design year. This applies to both divided and undivided facilities. Traffic volumes will be based on a minimum 20-year projection from the anticipated date of construction.*
3. *The values for "back slopes" only apply to a section where the toe of the back slope is adjacent to the shoulder; see Figure 38-3.B(d). For sections with roadside ditches, see Section 38-3.04.*
4. *The values in the figure apply to tangent sections of highway. See the discussion in Section 38-3.02(e) for possible adjustments on horizontal curves.*
5. *The values in the figure apply to all uncurbed sections and curbed sections in rural areas. See Section 38-3.02(f) for curbed sections in urban areas.*
6. *70 mph is highest design speed provided in the Roadside Design Guide. When design speeds are greater than the values provided, the designer may provide clear-zone distances greater than those shown in the table.*

* *Clear zones may be limited to 9.0 m for practicality and to provide a consistent roadway template. When a site-specific investigation indicates a high probability of continuing crashes or when such occurrences are indicated by crash history, the designer may provide clear zone distances greater than the clear zone shown above.*

** *See procedure in Section 38-3.03(b).*

Notes:

1. *All distances are measured from the edge of the traveled way. For opposing traffic on an undivided two-way roadway, the traveled way begins at the centerline separating opposing traffic.*
2. *For clear zones, the "Design Year ADT" will be the total ADT for both directions of travel for the design year. This applies to both divided and undivided facilities. Traffic volumes will be based on a minimum 20-year projection from the anticipated date of construction.*
3. *The values for "back slopes" only apply to a section where the toe of the back slope is adjacent to the shoulder; see Figure 38-3.B(d). For sections with roadside ditches, see Section 38-3.04.*
4. *The values in the figure apply to tangent sections of highway. See the discussion in Section 38-3.02(e) for possible adjustments on horizontal curves.*
5. *The values in the figure apply to all uncurbed sections and curbed sections in rural areas. See Section 38-3.02(f) for curbed sections in urban areas.*
6. *110 km/hr is highest design speed provided in the Roadside Design Guide. When design speeds are greater than the values provided, the designer may provide clear-zone distances greater than those shown in the table.*

RECOMMENDED CLEAR ZONE DISTANCES (m)
(New Construction/Reconstruction)
(Metric)

Figure 38-3.A

38-3.02(b) Design Year

For all freeway projects and non-freeway new construction/reconstruction projects, the design year for safety features will be a minimum of 20 years from the anticipated date of construction.

38-3.02(c) Traffic Volumes

As indicated in Figure 38-3.A, the ADT is a parameter when determining the clear zone value. The figure is divided into ranges of traffic volumes and ranges of recommended clear zones. In general, the higher clear zones apply to the higher traffic volumes.

38-3.02(d) Side Slopes

The roadway side slope will influence the recommended clear zone distance from Figure 38-3.A. Figure 38-3.B presents a schematic of the general side slope configurations, which may include:

- a straight front slope,
- a variable or barn roof section,
- a section with a roadside ditch, or
- a section where the toe of the back slope is adjacent to the edge of shoulder.

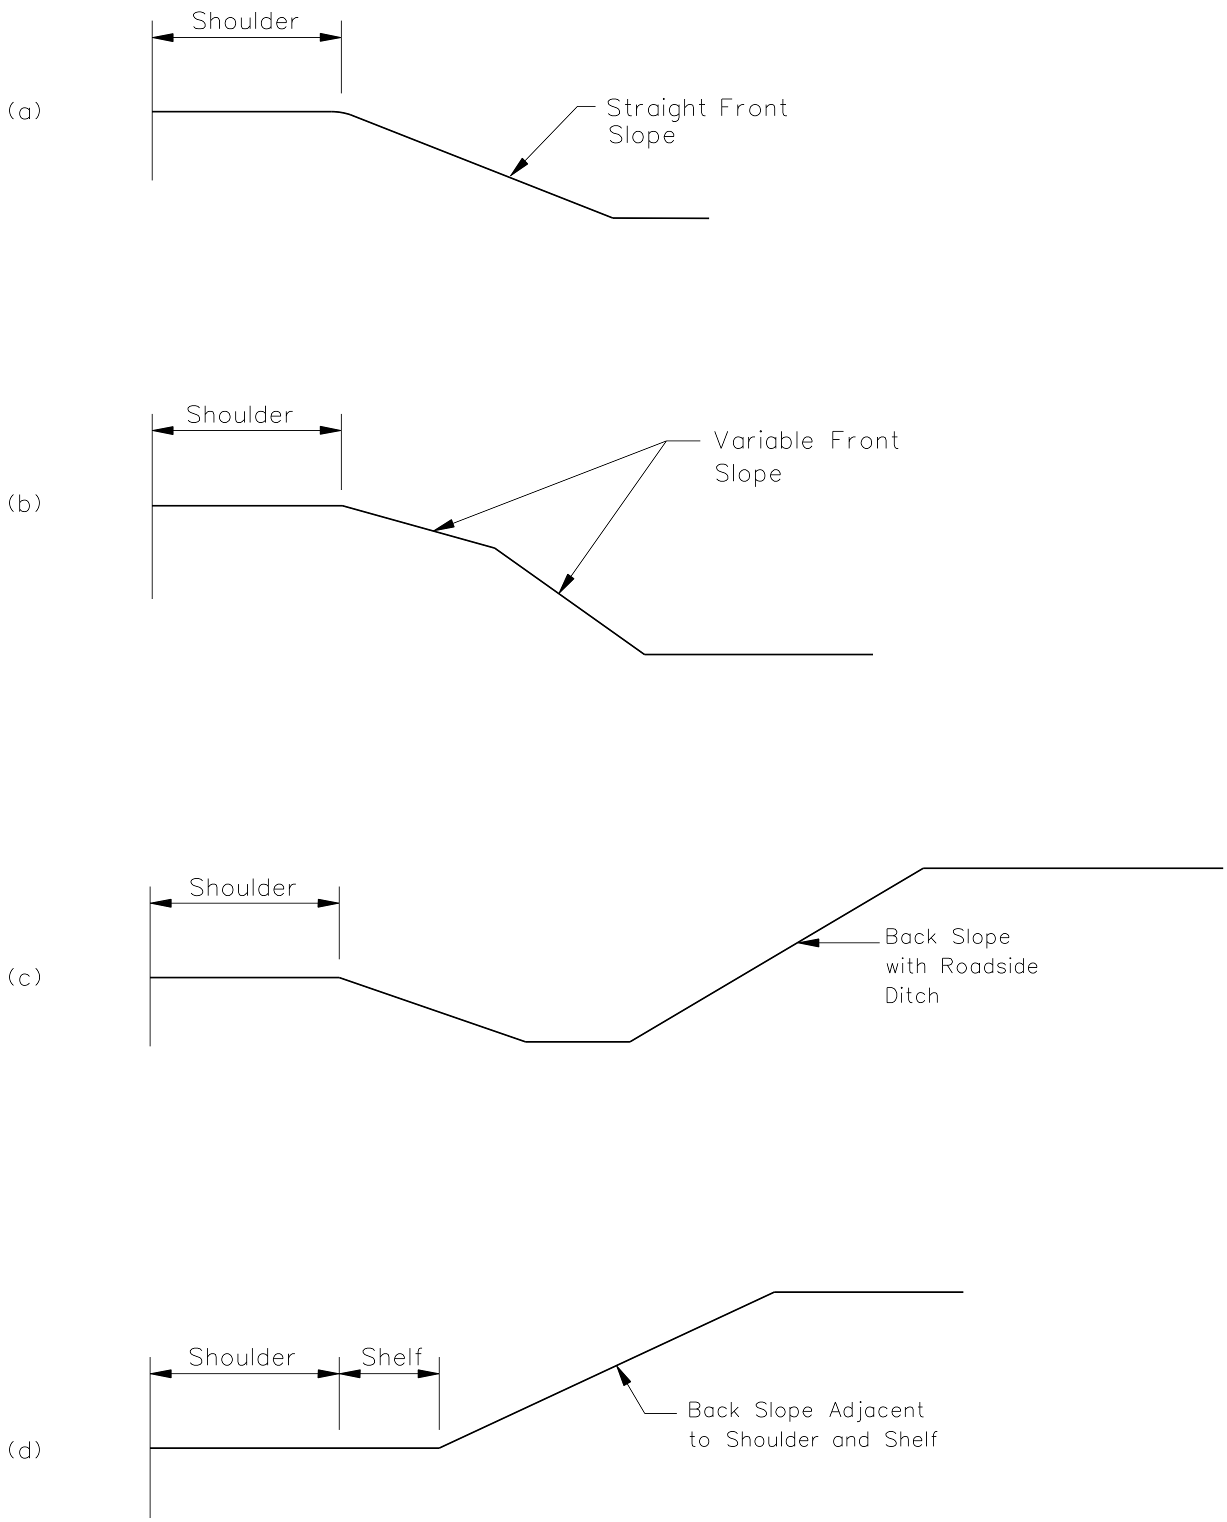
Note: The values in Figure 38-3.A for back slopes only apply to a section as illustrated in Figure 38-3.B(d); they do not apply where a roadside ditch is present.

Many variables influence the selection of a clear zone distance for the various side slope configurations. Sections 38-3.03, 38-3.04, and 38-3.05 discuss side slopes in detail.

38-3.02(e) Alignment (Horizontal Curve Adjustment)

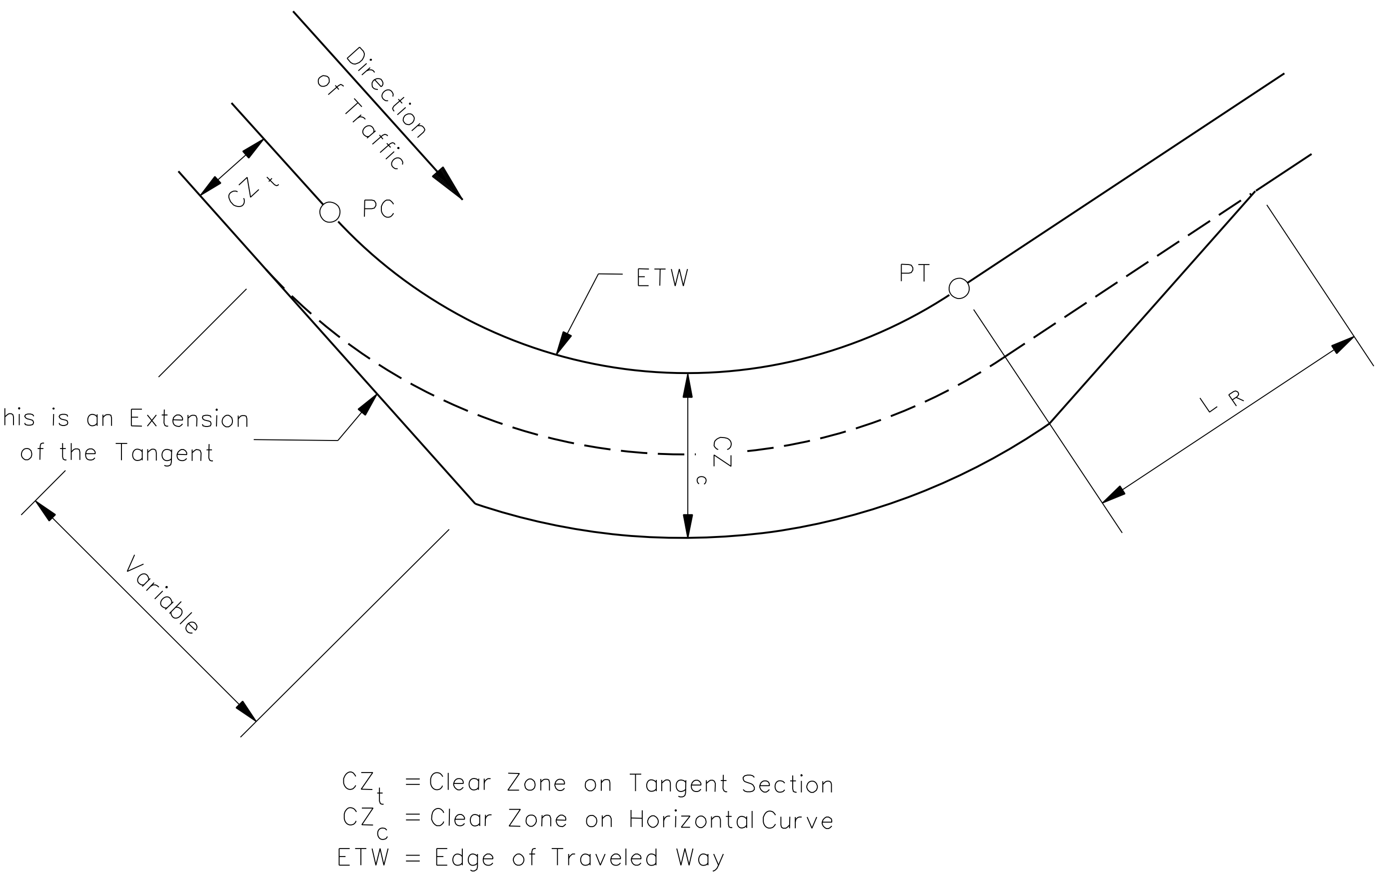
The clear zone values in Figure 38-3.A assume a tangent alignment. Horizontal curves may increase the angle of departure from the roadway, and thus increase the distance the vehicle will need to recover. Adjustments to the clear zone for curved alignment are considered only when the crash histories indicate such a need, as when a specific site investigation shows a definitive crash potential that could be significantly lessened by increasing the clear zone width, and when such increases are cost-effective.

It is unnecessary, to purchase additional right-of-way solely to provide the clear zone adjusted for horizontal curvature, unless inclusion of all right-of-way costs and impacts still shows a cost-effective safety improvement. See Section 38-4.01 for the recommended cost effectiveness software. Where adjustments are determined to be cost effective, Figure 38-3.C illustrates the application of the clear zone adjustment on a curve. Figure 38-3.D provides recommended adjustments for clear zones on horizontal curves.



SIDE SLOPE CONFIGURATIONS

Figure 38-3.B



Note: See Figure 38-6.E for L_R distances.

CLEAR ZONE WIDENING ON THE OUTSIDE OF HORIZONTAL CURVES

Figure 38-3.C

Radius (ft)	Design Speed (mph)						
	40	**45**	**50**	**55**	**60**	**65**	**70 and greater**
2860	1.1	1.1	1.1	1.2	1.2	1.2	1.3
2290	1.1	1.1	1.2	1.2	1.2	1.3	1.3
1910	1.1	1.2	1.2	1.2	1.3	1.3	1.4
1640	1.1	1.2	1.2	1.3	1.3	1.4	1.5
1430	1.2	1.2	1.3	1.3	1.4	1.4	
1270	1.2	1.2	1.3	1.3	1.4	1.5	
1150	1.2	1.2	1.3	1.4	1.5		
950	1.2	1.3	1.4	1.5	1.5		
820	1.3	1.3	1.4	1.5			
720	1.3	1.4	1.5				
640	1.3	1.4	1.5				
570	1.4	1.5					
380	1.5						

Notes:

1. *Adjustments apply to the outside of a horizontal curve only.*

2. *No adjustments are warranted for curve radii greater than 2860 ft.*

3. *The applicable clear zone distance on a horizontal curve is calculated by:*

   $CZ_c = (K_{cz})(CZ_t)$

   where:
   CZ_c = *clear zone on a curve, ft*
   K_{cz} = *curve adjustment factor*
   CZ_t = *clear zone on a tangent section from Figure 38-3.A, ft*

   Round calculated CZ_c up to the next highest 1 ft increment.

4. *For curve radii intermediate in the figure, use a straight-line interpolation.*

5. *See Figure 38-3.C for the application of CZ_c to the roadside around a curve.*

CLEAR ZONE ADJUSTMENT FACTORS FOR HORIZONTAL CURVES (K_{CZ})
(US Customary)

Figure 38-3.D

Radius (m)	Design Speed (km/hr)					
	60	70	80	90	100	110 and greater
900	1.1	1.1	1.1	1.2	1.2	1.2
850	1.1	1.1	1.1	1.2	1.2	1.3

450	1.2	1.2	1.3	1.3	1.4	
400	1.2	1.2	1.3	1.3	1.4	
350	1.2	1.2	1.3	1.4		
300	1.2	1.3	1.4	1.5		
250	1.3	1.3	1.4			
200	1.3	1.4				
150	1.4	1.5				
100	1.5					

Notes:

1. *Adjustments apply to the outside of a horizontal curve only.*

2. *No adjustments are warranted for curve radii greater than 900 m.*

3. *The applicable clear zone distance on a horizontal curve is calculated by:*

   $CZ_c = (K_{cz})(CZ_t)$

   where: CZ_c = *clear zone on a curve, m*
   K_{cz} = *curve adjustment factor*
   CZ_t = *clear zone on a tangent section from Figure 38-3.A, m*

   Round calculated CZ_c *up to the next highest 0.5 m increment.*

4. *For curve radii intermediate in the figure, use a straight-line interpolation.*

5. *See Figure 38-3.C for the application of* CZ_c *to the roadside around a curve.*

CLEAR ZONE ADJUSTMENT FACTORS FOR HORIZONTAL CURVES (K_{CZ})
(Metric)

Figure 38-3.D

Example 38-3.02(1)

Given: Design Speed = 55 mph
Design ADT = 3000
Horizontal curve with a radius of 2000 ft
Flat side slope

Problem: Find the clear zone adjusted for the horizontal curve.

Solution: From Figure 38-3.A, the clear zone on the tangent (CZ_t) = 20 ft.

From Figure 38-3.D, the curve correction factor (K_{cz}) = 1.2.
The clear zone for the curve (CZ_c) = (20)(1.2) = 24 ft.

The transition length (equal to the runout length (L_R)) from Figure 38-6.E = 185 ft.

* * * * * * * * * *

38-3.02(f) Curbed Sections

The values in Figure 38-3.A apply to curbed sections in rural areas and all uncurbed sections of highway. Where curbs are present, the following additional considerations will apply:

1. Urban/Suburban Facilities. A minimum horizontal, obstruction-free clearance of 1.5 ft (500 mm) should be provided as measured from the face of the curb. This offset provides sufficient clearance to keep the overhang of a truck from striking an object. See Section 38-9 for guidance regarding an enhanced lateral offset. This applies to both barrier and mountable curbs, except that M2 (M5) curb will be treated as an uncurbed section.

   Because curbs do not have re-directional capabilities, except at speeds below 25 mph (40 km/hr), the presence of curbs does not affect determination or application of the calculated clear zone value. See Section 38-9 for more discussion of roadside safety for urban cross sections.

5. Rural Facilities. For specific field conditions, it may be acceptable to use mountable curbs on rural facilities or barrier curbs in conjunction with standard guardrail. See Chapter 34. However, the clear zone will be determined assuming that the facility is uncurbed; i.e., the clear zone criteria presented in Chapter 38 will apply to all rural facilities whether curbed or uncurbed. Limit the location of curbs along high-speed rural facilities to the outer edge of the shoulder. See point 3 under Section 34-2.04(a) for more information.

38-3.02(g) Lane Width

The clear zone distances in Figure 38-3.A are, theoretically, predicated upon a 12 ft (3.6 m) lane width. However, they will be used for any lane width.

38-3.02(h) Auxiliary Lanes

Auxiliary lanes are defined as any lanes beyond the basic through travel lanes that are intended for use by vehicular traffic for specific functions. These include turn lanes at intersections, truck-climbing lanes, weaving lanes, acceleration/deceleration lanes at interchanges, etc. The clear zone for auxiliary lanes will be determined as follows:

1. Turn Lanes at Intersections. Where the intersection is uncurbed, clear zones will be determined based on the design speed and traffic volumes associated with the through travel lanes; i.e., the presence of the turn lane is ignored when determining clear zones, provided that a minimum 10 ft (3.0 m) clear zone is maintained beyond the outside edge of the shoulder. Where the intersection is curbed, the criteria in Section 38-3.02(f) will apply; i.e., the minimum obstruction-free zone is 1.5 ft (500 mm) from the gutter line with an enhanced lateral offset of 4 ft to 6 ft (1.2 m to 1.8 m) preferred.

2. Auxiliary Lanes Adjacent to Mainline. Use the following clear zone applications for climbing lanes, acceleration/deceleration lanes, ramp terminals, weaving lanes, etc. Two independent clear zone determinations are necessary. First, the designer calculates the clear zone from the edge of the through traveled way based on the total traffic volume, including the auxiliary lane volume. Second, the designer calculates the clear zone from the edge of the auxiliary lane based on the traffic volume in the auxiliary lane. The clear zone distance that extends further will apply.

38-3.03 Front Slopes

Figure 38-3.B illustrates the two basic configurations for front slopes (i.e., straight slope or variable slope). Section 38-2 presents definitions of parallel front slopes that apply to clear zone determinations. Figure 38-3.E presents schematics for these definitions, and the following discusses the clear zone application in conjunction with Figure 38-3.A.

38-3.03(a) Recoverable Front Slopes

For parallel front slopes 1V:4H and flatter [Figure 38-3.E(a)], the recommended clear zone distance can be determined directly from Figure 38-3.A.

38-3.03(b) Non-Recoverable Front Slopes

For parallel front slopes steeper than 1V:4H, but 1V:3H or flatter [Figure 38-3.E(b)], a clear runout area beyond the toe of the non-recoverable front slope is recommended. The width of the non-recoverable front slope is not to be counted as part of the clear runout width. Use the following procedure to determine the clear zone:

1. Determine the clear zone for a 1V:6H or flatter slope from Figure 38-3.A for the applicable design speed and traffic volume.

2. To determine the clear runout area beyond the toe, subtract the shoulder width [or the distance from the edge of traveled way to the hinge point, noted as “A” in Figure 38-3.E(b)] from the distance in Step 1.

3. The clear runout area beyond the toe shall be the greater distance of the value determined in Step 2 or 10 ft (3.0 m).

Example problem 38-3.03(2) illustrates this procedure.

38-3.03(c) Barn-Roof Front Slope (Recoverable/Non-Recoverable)

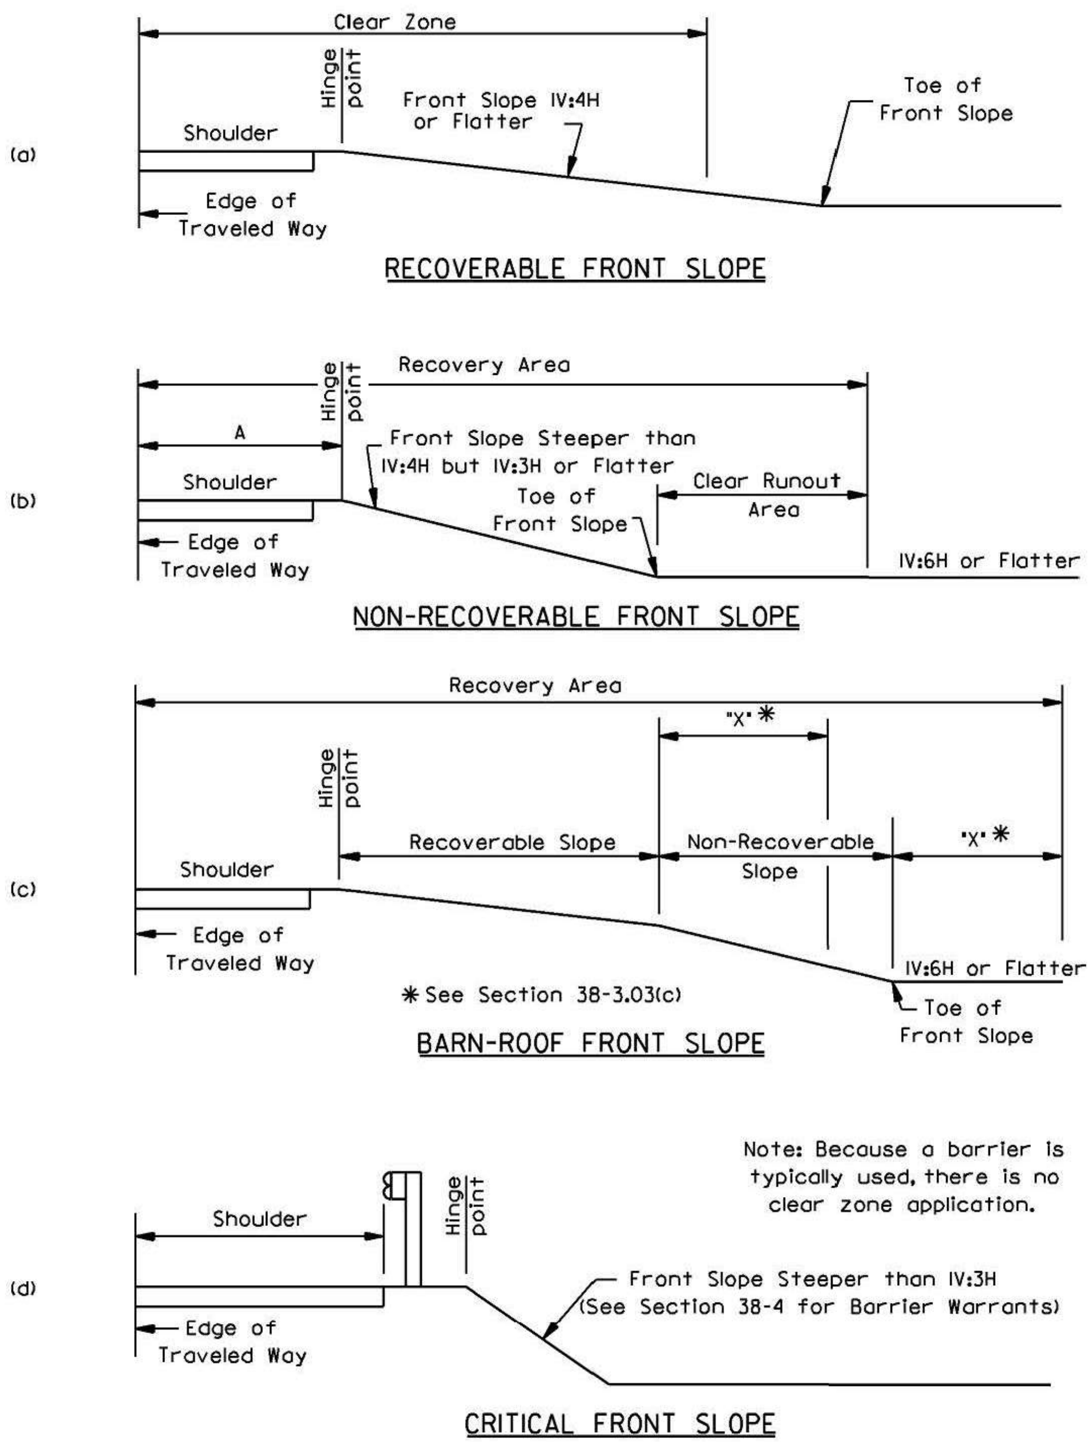
Barn-roof front slopes may be designed with a recoverable slope leading to a non-recoverable slope; see Figure 38-3.E(c). This design requires less right-of-way and embankment material than a continuous, flatter slope. The distance from the break between the two slopes to the clear zone [noted as “X” on Figure 38-3.E(c)] should be applied as an addition outside the toe of the non-recoverable slope. This addition should be a minimum of 10 ft (3.0 m) wide; i.e., a clear area of 10 ft (3.0 m) beyond the toe of slope will be needed where the clear zone extends beyond the break between the recoverable and non-recoverable slopes. If the distance from the edge of traveled way to the break between the two slopes is a minimum of 30 ft (9.0 m), no additional clear area will be required at the toe of slope.

38-3.03(d) Barn-Roof Front Slope (Recoverable/Recoverable)

Barn-roof front slopes may also be designed with consecutive recoverable slopes — the second slope steeper, but also recoverable, than the slope adjacent to the shoulder. Although a weighted average of the slopes may be used, a simple average of the clear zone distances for each slope is sufficiently accurate, if the variable slopes are approximately the same width. If one slope is significantly wider, the clear zone computation based on that slope alone may be used.

38-3.03(e) Critical Front Slope

Front slopes steeper than 1V:3H are critical; see Figure 38-3.E(d). These typically require a barrier and, therefore, there is no clear zone application; see Section 38-4.



CLEAR ZONE APPLICATION FOR FRONT SLOPES
(Uncurbed)

Figure 38-3.E

Example 38-3.03(1) (Recoverable Front Slope)

Given: Front Slope — 1V:4H
Design Speed — 60 mph
Design ADT — 7000

Problem: Determine the recommended clear zone distance.

Solution: From Figure 38-3.A, the clear zone distance should be 36 ft to 44 ft. However, as indicated in a footnote to the figure, the clear zone distance may be limited to 30 ft based on specific site conditions to provide a more practical design.

* * * * * * * * * *

Example 38-3.03(2) (Non-Recoverable Front Slope)

Given: Front Slope — 1V:3H
Shoulder Width — 10 ft
Design Speed — 60 mph
Design ADT — 7000

Problem: Determine the recommended clear zone distance.

Solution: The procedure in Section 38-3.03(b) for non-recoverable front slopes is used as follows:

1. From Figure 38-3.A, the clear zone for a front slope 1V:6H or flatter is 30 ft to 32 ft.

2. The recommended clear distance beyond the toe of the non-recoverable slope (1V:3H) is 30 ft to 32 ft (9.1 m to 9.8 m) minus 10 ft (3.0 m) shoulder width yields 20 ft to 22 ft (6.1 m to 6.7 m).

3. The clear distance beyond the toe of slope shall be the greater of the value determined in Step 2 [20 ft to 22 ft (6.1 m to 6.7 m)] , or 10 ft (3.0 m), therefore the clear zone extends to 20 ft to 22 ft (6.1 m to 6.7 m) beyond the toe of the front slope.

* * * * * * * * * *

38-3.04 Back Slopes

Back slopes in cut sections or slope walls at overhead bridges may be traversable depending upon their surface conditions and presence of fixed objects. Where the front slope is 1V:3H or flatter and the back slope is stable, firm, and free of fixed objects or snag points it may not be a significant hazard. However, back slopes that are rough-faced rock cuts, tree-lined, or where significant wheel rutting would be expected are examples of back slopes that would pose significant hazards.

Where a pier for an overhead structure is located near a back slope (i.e. a slopewall), design the roadside guardrail for the pier using a minimum clear zone value of 25 ft (7.6 m).

38-3.05 Roadside Ditches

Ditch sections, as illustrated in Figure 38-3.F, are typically constructed in roadside cut sections without curbs. Figure 38-3.H provides preferred ditch sections based on slopes and bottom widths.

When a preferred ditch cross section, according to Figure 38-3.H, is not used, the applicable clear zone across a ditch section will depend upon the front slope, the ditch width, the back slope, the horizontal location of the toe of the back slope, and various highway factors. The designer shall use the following procedure to determine the recommended clear zone distance when a preferred ditch cross section is not used:

1. Determine the Nominal Clear Zone. Use Figure 38-3.A to determine the clear zone based on the ditch front slope.

2. Check the Location of the Toe of the Back Slope. Based on the distance determined in Step 1, refer to Section 38-3.03 to establish if the toe of the back slope is within the clear zone. The toe of back slope is defined as the point at which the ditch rounding ends and the (uniform) back slope begins. If the toe is at or beyond the clear zone, then the designer usually need only consider roadside hazards within the clear zone on the front slope or within the ditch. If the toe is within the clear zone, the designer should evaluate the practicality of relocating the toe of back slope. If the toe of back slope will remain within the clear zone, Step 3 below will apply to ditch sections in earth cuts.

3. Determine Clear Zone on Back Slope (Earth Cuts). If the toe of the back slope is within the clear zone distance, a clear zone should be provided on the back slope. This clear zone will be a distance beyond the toe of back slope as follows:

    a. Where the back slope is 1V:6H or flatter, treat the back slope as level and use the clear zone based on the front slope rate to determine the clear zone limit on the back slope.

    b. Where the back slope is steeper than 1V:6H but 1V:3H or flatter [Figure 38-3.F(b)], assume the vehicle cannot make it up to the top of the back slope, if the slope is at least 10 ft (3.0 m) wide. The initial 10 ft (3.0 m) beyond the toe of the back slope or the distance in Step 3a, whichever is less, should be clear of roadside hazards. Any obstacles beyond this point would be considered outside of the clear zone.

c. Where the back slope is steeper than 1V:3H [see Figure 38-3.F(c)], the initial 5 ft (1.5 m) beyond the toe of the back slope should be clear of roadside hazards.

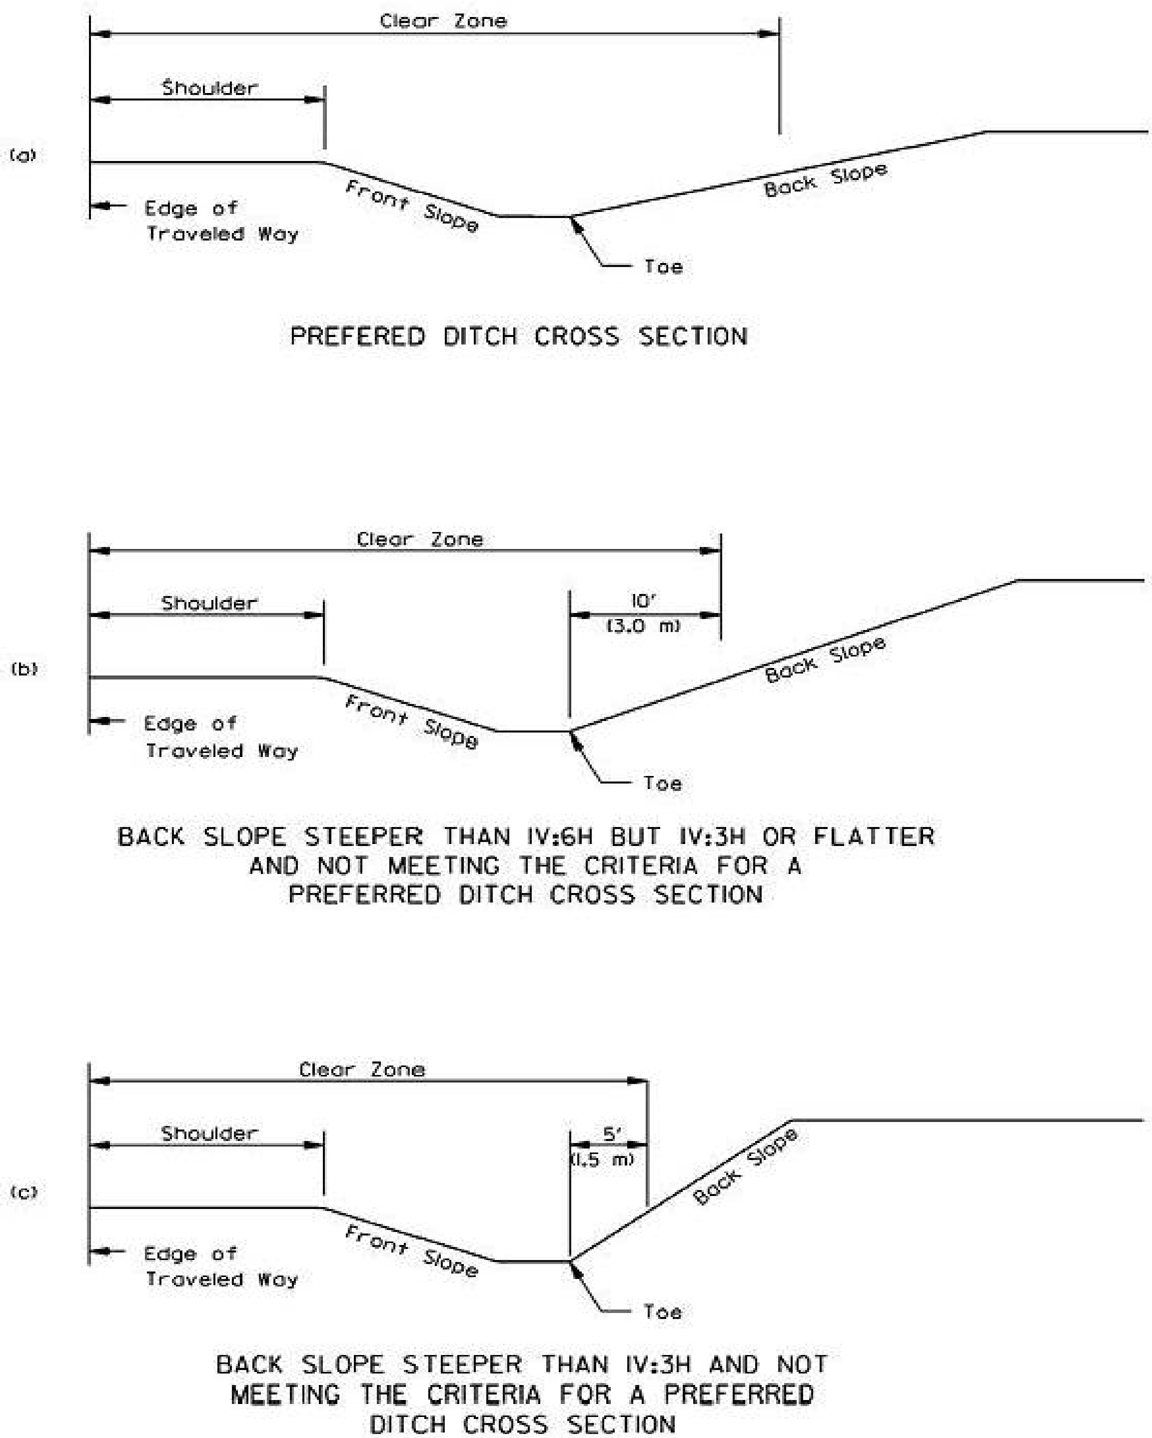
4. Clear Zones (Rock Cuts). No clear zone is required beyond the toe of back slope for rock cuts with steep back slopes. However, the rock cut should be relatively smooth to minimize the hazards of vehicular snagging. If the face of the rock is rough or rock debris is present, a barrier may be warranted.

   The Department's configuration for rock cuts, typically, is the following:

   - a 1V:6H front slope,
   - a 1.5 ft (500 mm) ditch bottom plus additional width for falling rock, and
   - a 1V:0.25H back slope or as required by rock type.

5. Deep Cuts. For earth cuts where the height of the cut from the bottom of the ditch is greater than 10 ft (3.0 m), the designer may consider using a 1V:2H back slope above the 10 ft (3.0 m) elevation to reduce costs.

Example problem 38-3.04(1), below, illustrates the method to determine the clear zone when a preferred ditch cross section is not used.



CLEAR ZONE APPLICATION FOR ROADSIDE DITCHES

Figure 38-3.F

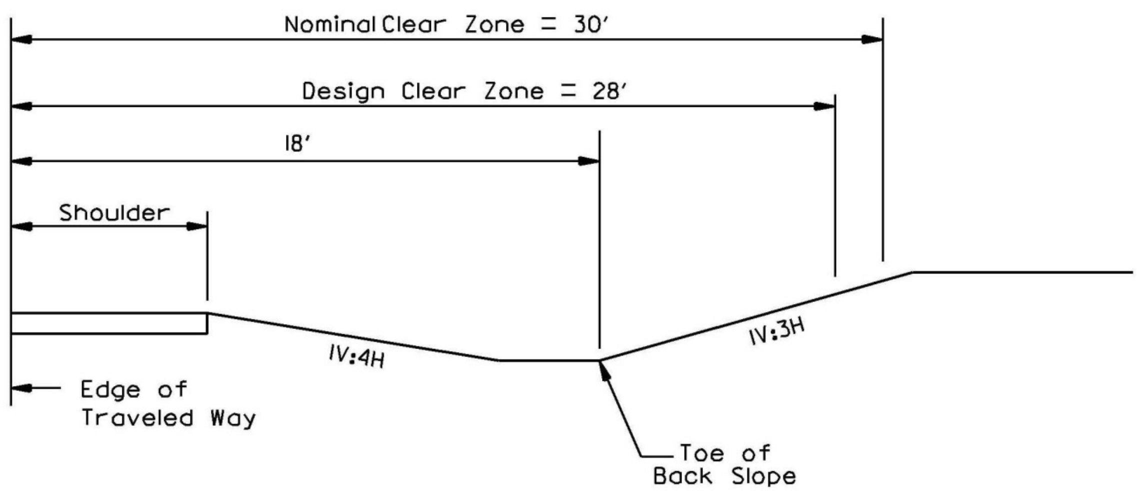
Example 38-3.04(1) (Not a Preferred Ditch Section)

Given: Design ADT = 7000
V = 60 mph
Front Slope = 1V:4H
Ditch Width = 2 ft
Back Slope = 1V:3H
Toe of back slope is 18 ft from edge of traveled way
See Figure 38-3.H

Problem: Determine the clear zone application across the ditch section.

Solution: From Figure 38-3.G, the 1V:4H front slope with 2 ft bottom and 1V:3H back slope does not meet the criteria for a preferred ditch. Using the procedure in Section 38-3.04:

1. Determine the Clear Zone. Figure 38-3.A yields a clear zone of 36 ft to 44 ft for a 1V:4H front slope. However, as indicated in the footnote, a 30-ft clear zone may be used.
2. Check the Location of the Toe of the Back slope. The toe of back slope is within the clear zone. Therefore, proceed to Step 3.
3. Determine the Clear Zone on the Back slope (Earth Cuts). With a 1V:3H back slope, the criteria in Step 3.b. will apply. Based on these criteria, the lesser of 10 ft beyond the toe of back slope or the clear zone from Step 1 above will control. 10 ft beyond the toe of back slope yields a total distance of 28 ft from the edge of traveled way versus 30 ft from Step 1. Therefore, the procedure yields a 28 ft clear zone for the roadside.



CLEAR ZONE AT DITCH SECTION
Example 38-3.04(1)

Figure 38-3.G

38-3.06 Transitional Slopes

As practical, slopes that transition between differing slope rates, types of slopes (e.g. transverse slope to front slope), or from a fill section to a cut section should be designed to provide a recoverable and forgiving roadside by meeting or exceeding the various design criteria for slopes from Section 38-3 and 38-4. Transitions of parallel front slopes, parallel back slopes, or ditch side slopes should be, over a distance, sufficient to avoid the perception of a transverse slope (suggested 25H:1V or flatter). Transitions from fill slopes to cut slopes should be designed on a case-by-case basis, with special attention given to the drainage channel created where these cross sections transition.

PREFERRED DITCH CROSS SECTIONS		
	Preferred Maximum Ditch Back Slope	
Front Slope	Trapezoidal Ditch with Vee or <4 ft (1.2 m) Flat Bottom	Trapezoidal Ditch with Minimum 4 ft (1.2 m) Flat Bottom
1:8	1:3.5	1:2.5
1:6	1:4	1:3
1:5	1:5	1:3.5
1:4	1:6	1:4

Note: For front or back slope values falling between those given above, round down to the next steeper slope, i.e., do not interpolate between slope values.

PREFERRED DITCH CROSS SECTIONS

Figure 38-3.H

38-4 ROADSIDE HAZARD REMEDIATION

During Phase I of a project the designer evaluates and establishes the roadside barrier warrants. Refer also to Section 11-2.04(g). Safety design decisions may affect right-of-way needs, earthwork quantities, and other design elements that must be recognized early in project development. Safety issues must be addressed early so as to not severely restrict the designer's options. Design exceptions related to roadside hazards should be very uncommon and will require approval and documentation in the Phase I engineering report. Refer to Section 31-7 for the design exception process and Chapter 12 regarding Phase I engineering report content.

38-4.01 Examples of Roadside Hazards

Examples of roadside hazards include:

- non-breakaway sign supports, non-breakaway luminaire supports, traffic signal poles, and railroad signal poles;
- concrete footings, traffic signal foundations, etc., extending more than 4 in. (100 mm) above the ground;
- bridge piers and abutments at underpasses;
- culvert headwalls;
- trees with diameters greater than 4 in. (100 mm) (at maturity);
- rough rock cuts;
- large boulders;
- critical parallel slopes (i.e., embankments);
- streams or permanent bodies of water (where the depth of water ≥ 2 ft (600 mm));
- non-traversable ditches;
- utility poles or towers;
- drainage appurtenances; and
- transverse slopes.

The severity of a specific roadside hazard will depend upon many factors. The Roadside Safety Analysis Program (RSAP) may be used to quantify the relative severity of roadside hazards. The RSAP software, user's manual, engineer's manual, and programmer's manual are found at: http://rsap.roadsafellc.com/. For questions about the RSAP, contact the Bureau of Safety Programs and Engineering.

38-4.02 Range of Treatments

If a roadside hazard is within the clear zone, the designer should select the treatment that is judged to be the most practical and cost-effective for the site conditions. The range of treatments, in order of preference, includes:

- Eliminate the hazard (flatten embankment, remove rock outcroppings, etc.);
- redesign the hazard so it can be safely traversed (e.g., culvert grating);
- relocate the hazard to a point where it is less likely to be struck;
- where applicable, make the hazard breakaway (sign posts, luminaire supports);
- shield the hazard with a roadside barrier;
- delineate the hazard; or
- do nothing.

38-4.03 <u>Warrant Methodologies</u>

Warrants for roadside barriers imply that other options higher in the preference order for range of treatments (see Section 38-4.02) have first been considered. Whether objectively or subjectively, the decision will be based upon the traffic volumes, roadway geometry, proximity of the hazard to the traveled way, nature of the hazard, expected crash severity, installation costs and, where applicable, crash experience. The following briefly discusses the Department's decision-making methods for barrier warrants.

38-4.03(a) Department Policy

For specific applications, the Department has adopted policies on warrants for roadside barriers. These are documented throughout Section 38-4.

38-4.03(b) Cost-Effectiveness Method

Where practical, the designer should use an approved cost-effectiveness methodology to determine roadside barrier warrants. This will provide an objective means to analyze many of the factors that impact roadside safety, and it will support effective use of funds to realize safety benefits. It will also promote uniformity of decision-making for roadside safety throughout the Department. The currently approved cost-effectiveness method is the Roadside Safety Analysis Program (RSAP) software presented in Section 38-4.01.

38-4.03(c) Engineering Judgment Method

Until the development of cost-effectiveness models, barrier warrants were typically determined based on engineering judgment. With this approach, the designer first analyzes the site by a "relative severity" assessment—which is the greater hazard, the roadside barrier or the roadside hazard? Next, the designer subjectively evaluates the site-specific parameters (e.g., traffic volumes, design speed, location of hazard, barrier installation costs) to determine if a barrier installation is a reasonable and practical solution. If yes, a barrier is warranted; if no, the do-nothing alternative is selected. For example, it would probably not be practical to install a barrier to shield an isolated point obstacle (e.g., tree) located near the edge of the clear zone. The designer must realize that a barrier is also a hazard and, if a clear decision cannot be reached, the general rule of “when in doubt, leave it out” should apply.

It is acceptable to use engineering judgment to determine the warrants for roadside barriers for two conditions:

1. If the decision is obvious for a specific site, the designer may forego the use of a cost-effectiveness method and use engineering judgment to install or not install a roadside barrier.

2. If extenuating circumstances exist, the designer may override Department policies for barrier warrants or the results of a cost-effectiveness method, either to install or not install a roadside barrier. In this case, the designer must document the reasons for the decision. This documentation should include crash histories for the section of roadway, traffic volumes, posted speed, and roadway geometry.

38-4.04 Embankments

Figure 38-4.A presents barrier warrants for embankments.

38-4.05 Transverse Slopes

Where the mainline highway intersects an entrance, side road, or median crossing, a slope transverse to the mainline will be present; see Figure 38-4.B. Even at moderate speeds, vehicles encountering transverse slopes can become airborne. Abrupt transverse slopes may also snag errant vehicles. In general, transverse slopes should be as flat as practical. Figure 38-4.C presents IDOT criteria for transverse slopes within the clear zone based on the type of facility and design speed.

The bridge cones of overhead roadway structures also introduce transverse slopes. Both the transverse slope intersecting the ditch and the transverse slope beyond the ditch, but within the clear zone, should be addressed with the slopes given in Figure 38-4.C. The recommended transverse slopes intersecting the ditch should reach to approximately 4 ft (1.2 m) vertical above the shoulder. The recommended transverse slopes beyond the ditch should reach approximately 4 ft (1.2 m) above the natural or graded ground out to the clear zone. Treat any parallel culvert as instructed in Section 38-4.06.

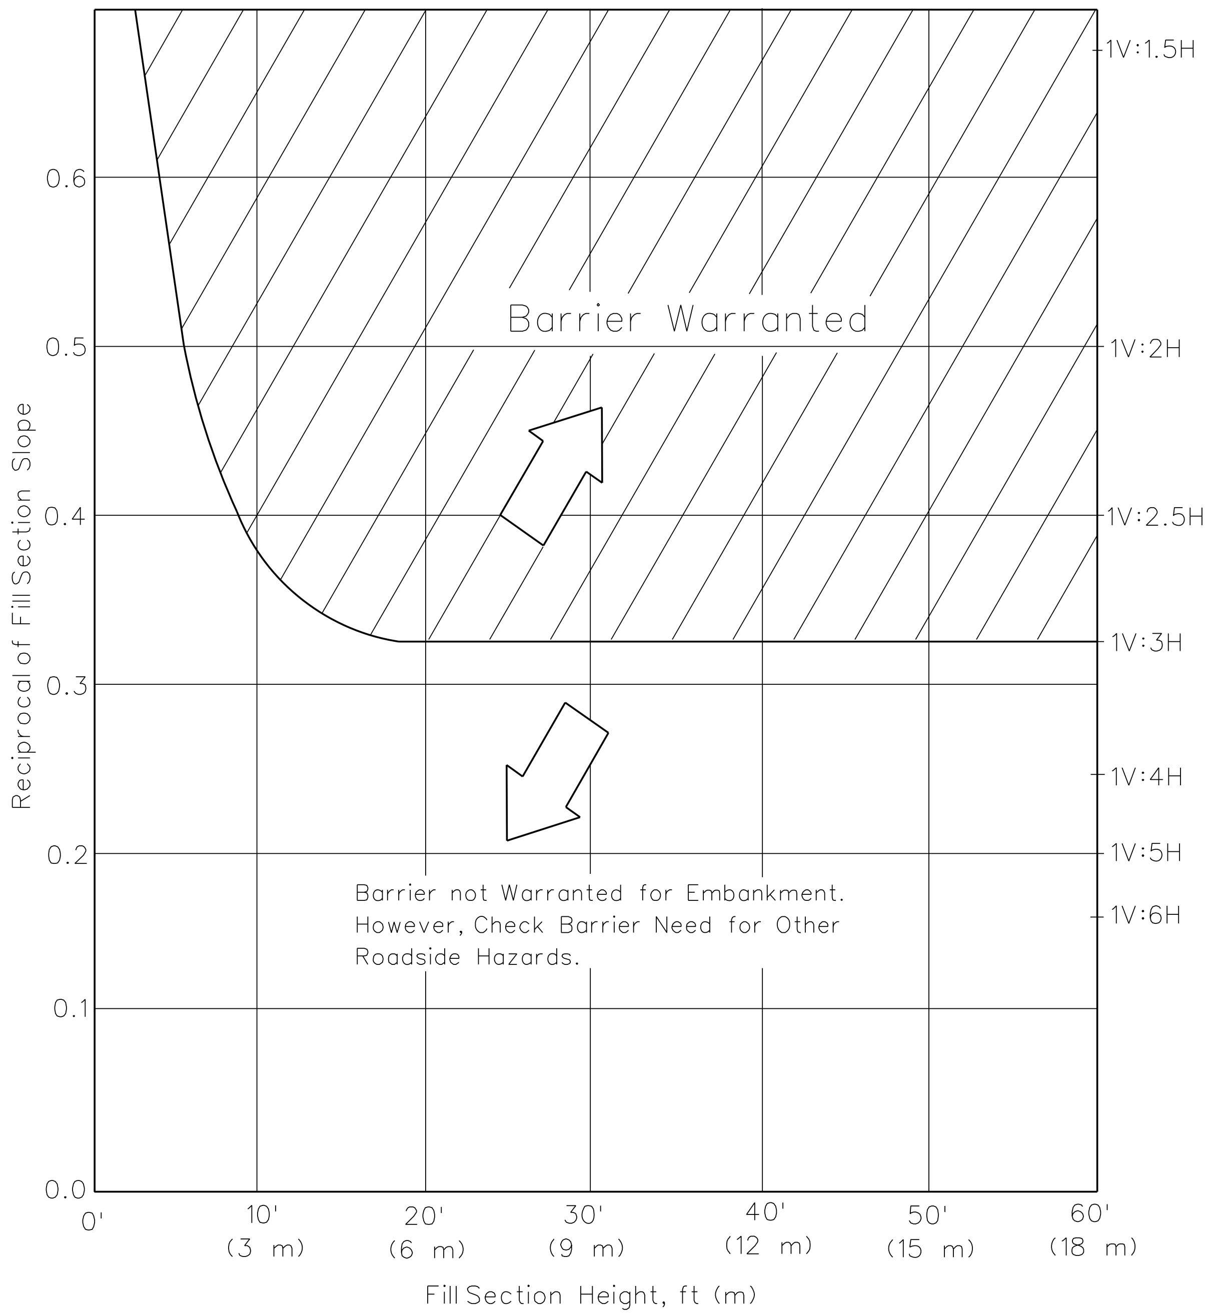
Figure 38-4.C presents both desirable (i.e., flatter) and acceptable (i.e., steeper) transverse slopes. The application at a specific site will depend upon an evaluation of many factors, including:

- height of transverse embankment,
- traffic volumes,
- design speed,
- presence of culverts and practicality of treating the culvert end (see Section 38-4.06),

- construction costs, and
- right-of-way and environmental impacts.

Although the 1V:10H transverse slope may be desirable, its practicality may be limited because of drainage structures, width restrictions, and maintenance problems associated with the long tapered ends of pipes or culverts. On arterial highways including freeways, however, the 1V:10H transverse slope should be used unless regrading of existing 1V:6H transverse slopes would require the installation of new drainage features.

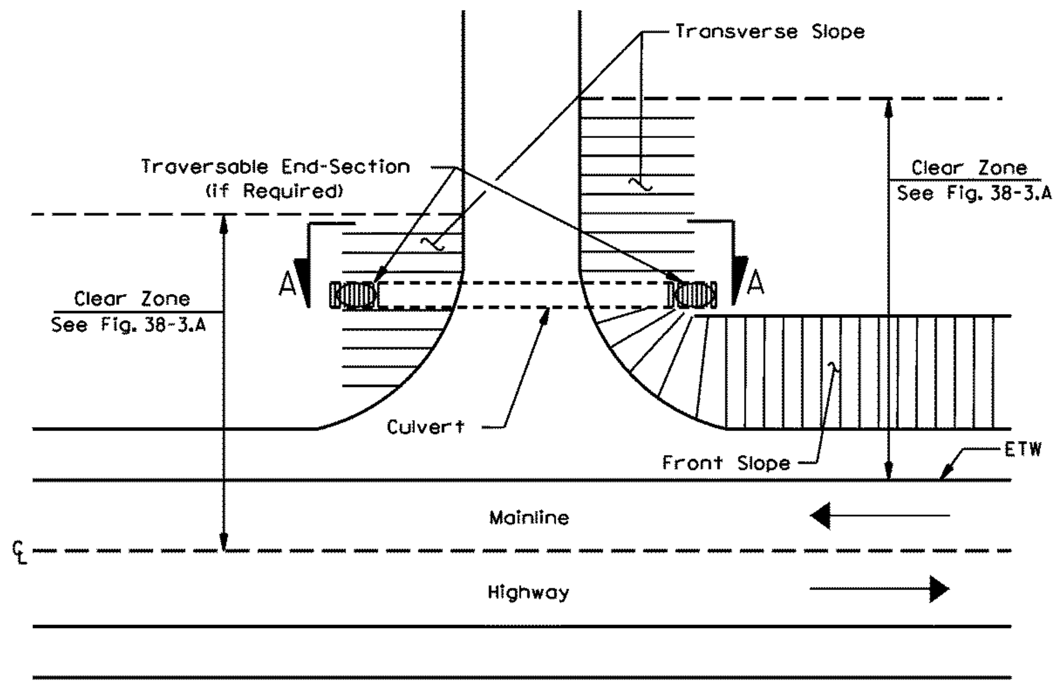
If the criteria in Figure 38-4.C cannot be met, the designer should consider the installation of a roadside barrier.



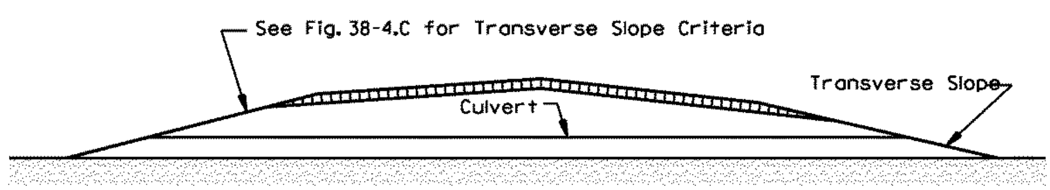
Note: Points that fall on the solid line do not warrant a barrier.

BARRIER WARRANTS FOR EMBANKMENTS

Figure 38-4.A



Note: On a one-way facility, the traversable end-section on the departure end is not required.



SECTION A-A

TRANSVERSE SLOPES ON A TWO-LANE, TWO-WAY ROADWAY

Figure 38-4.B

Type of Facility	Desirable (V:H)	Acceptable (V:H)
Freeway	1:10	1:6
Rural Non-Freeways (V ≥ 50 mph (80 km/hr))	1:10	1:6
Urban Non-Freeways (V ≥ 50 mph (80 km/hr))	1:6	1:4
Urban and Rural Low-Speed Facilities (V ≤ 45 mph (70 km/hr))	1:6	1:4

RECOMMENDED TRANSVERSE SLOPES

Figure 38-4.C

38-4.06 Roadside Drainage Features

Effective drainage is a critical element in the design of a highway or street. In addition to hydraulic considerations, ditches, curbs, culverts, and drop inlets should be designed and constructed considering their consequences to roadside safety.

The *Illinois Drainage Manual* and Chapter 40 of the *BDE Manual* discuss the Department's practices for hydrology and hydraulics and for the physical design of roadside drainage structures. Sections 38-4.06(b) discusses the safety design of these structures.

38-4.06(a) Curbs

Curbs are typically used to control drainage or to protect erodible soils. Chapter 34 and the *IDOT Highway Standards* provide detailed information on the warrants and types of curbs used by the Department. Curbs may pose a roadside hazard because of their potential to adversely affect a run-off-the-road vehicle. When evaluating curbs relative to roadside safety, the designer should consider the following:

1. Design Speed. On high speed roadways, curbs may cause errant vehicles to overturn or become airborne. Facilities with a design speed greater than 45 mph (70 km/hr) should be designed without curbs.

   However, if necessary along high-speed roadways, a 4 in. (100 mm) Type M (sloped) curb or Type B gutter may be used and placed only at the outside of the paved shoulder. If a shoulder is initially designed with aggregate, and a curb is proposed at the back of the aggregate width, change the aggregate width to a paved surface. See Section 34-2.04 for curb types for facilities with a design speed of 45 mph (70 km/hr) or less.

   Where a guardrail is proposed, a 6 in. (150 mm) barrier curb may be used if it is placed such that the face of the guardrail is within 6 in. (150 mm) behind the face of the curb.

Guardrail terminals should be placed beyond the limits of the curb in this situation. See Section
38-6.05, item 1, for more guidance regarding guardrail placement along curb.

2. <u>Roadside Barriers</u>. The use of curbs with a roadside barrier is discouraged and, specifically, curbs higher than 6 in. (150 mm) should not be used with a barrier. See Sections 38-6.03 and 38-6.05. If a guardrail adjacent to a curb is unavoidable, the lateral placement of the guardrail relative to the curb face is critical. Refer to the *Highway Standards* for proper guardrail placement and coordination with the design speed.

3. <u>Redirection</u>. Curbs offer no safety benefits on high-speed roadways and will not redirect errant vehicles.

4. <u>M2 (M5) Curb</u>. It is acceptable to use the 2 in. (50 mm) high M2 (M5) curb in conjunction with a roadside barrier.

38-4.06(b) Culverts

1. <u>Cross Drainage Structures</u>. Cross drainage structures are designed to convey water through the roadway embankment. If not properly designed, they and their associated end sections, roadside slopes and ditches may present a hazard to run-off-the-road vehicles. In priority order, the available roadside safety treatments to minimize the potential hazard of the end sections for cross drainage culverts are:

   a. eliminate the culvert;

   b. provide a traversable end section;

   c. extend the culvert opening beyond the clear zone with smooth, traversable graded earth transitions;

   d. shield the culvert with a roadside barrier; or

   e. delineate the culvert if the above alternatives are not feasible.

   The following summarizes the Department's practices for providing a traversable end section for cross drainage structures within the clear zone (note that metal end sections on front slopes are only available for slopes of 1V:4H and 1V:6H):

   - for culverts less than 27 in. (700 mm) in diameter, install an end section from the *Illinois Highway Standards* which matches the front slope; or

   - for culverts 27 in. (700 mm) and greater in diameter, install an end section with a traversable grate from the *Illinois Highway Standards* which matches the front slope. Elliptical pipe culverts are listed by equivalent round size in the Standards.

   The above requirement for a traversable grate is based upon Section 3.4.2.1 of AASHTO's *Roadside Design Guide*, which states that structures with end sections having more than a 3 ft (900 mm) wide opening can be made traversable by using a pipe grate. When evaluating the need for a traversable grate for multi-cell pipe culverts, elliptical pipes, pipe arches, or box culverts, the same end section criteria should be applied.

If the culvert end section cannot be made traversable, install an appropriate end section and then determine if guardrail is warranted based on analyses throughout this chapter.

2. Parallel Drainage Structures. Parallel drainage structures, those that are oriented parallel to the main flow of traffic, must be considered when within the mainline clear zone. They are typically used under driveways, field entrances, access ramps, intersecting side roads, and median crossovers. Such culverts represent a hazard because an errant vehicle may impact the open end of the culvert. Therefore, the designer must coordinate design of the drainage structures with that of the surrounding transverse slope (Section 38-4.05) to minimize the hazard.

   Safety treatment options are very similar to those for cross-drainage structures. In priority order, the options are:

   a. eliminate the culvert;
   b. provide a traversable end section;
   c. move the culvert laterally to a less vulnerable location;
   d. shield the culvert with a roadside barrier; or
   e. delineate the culvert if the above alternatives are not feasible.

   Figure 38-4.D presents a generic design for grate protection of a parallel drainage structure. *Highway Standards* 542411 and 542416 depict design specifications for metal end sections. Safety treatment is also subject to the following considerations for travel along both the highway and entrance:

   - For metal culverts less than 24 in. (600 mm) in diameter, install a metal end section from the *Illinois Highway Standards* which matches the transverse slope.
   - For metal culverts 24 in. (600 mm) or greater in diameter, install a metal end section and a traversable grate for metal end sections from the *Illinois Highway Standards* which matches the transverse slope.
   - If the proposed end section is an unacceptable hazard from only the entrance, driveway, etc., look to decrease the hazard along the entrance by following the guidance for cross drainage structures in the preceding section. If a guardrail installation is indicated, consider its relation to both roadways.
   - If the proposed end section remains an unacceptable hazard to both roadways and a roadside barrier is proposed along both roadways, a grate is not required. Use of guardrail will create a short radius guardrail installation, refer to 38-6.09.

   Note that per Section 38-4.05, the transverse slope should be as flat as practicable, with 1V:6H or flatter considered desirable for most urban facilities and required for freeways and rural high-speed roadways.

Parallel drainage structures may be closely spaced because of frequent driveways and intersecting roads. In such locations, it may be desirable to convert the open ditch into a closed drainage system and backfill the areas between adjacent driveways. This treatment will eliminate the ditch section and the transverse embankments with pipe inlets and outlets. However, care must be used to avoid creation of open frontage that would allow uncontrolled access.

38-4.06(c) Roadside Ditches (Earth Cuts)

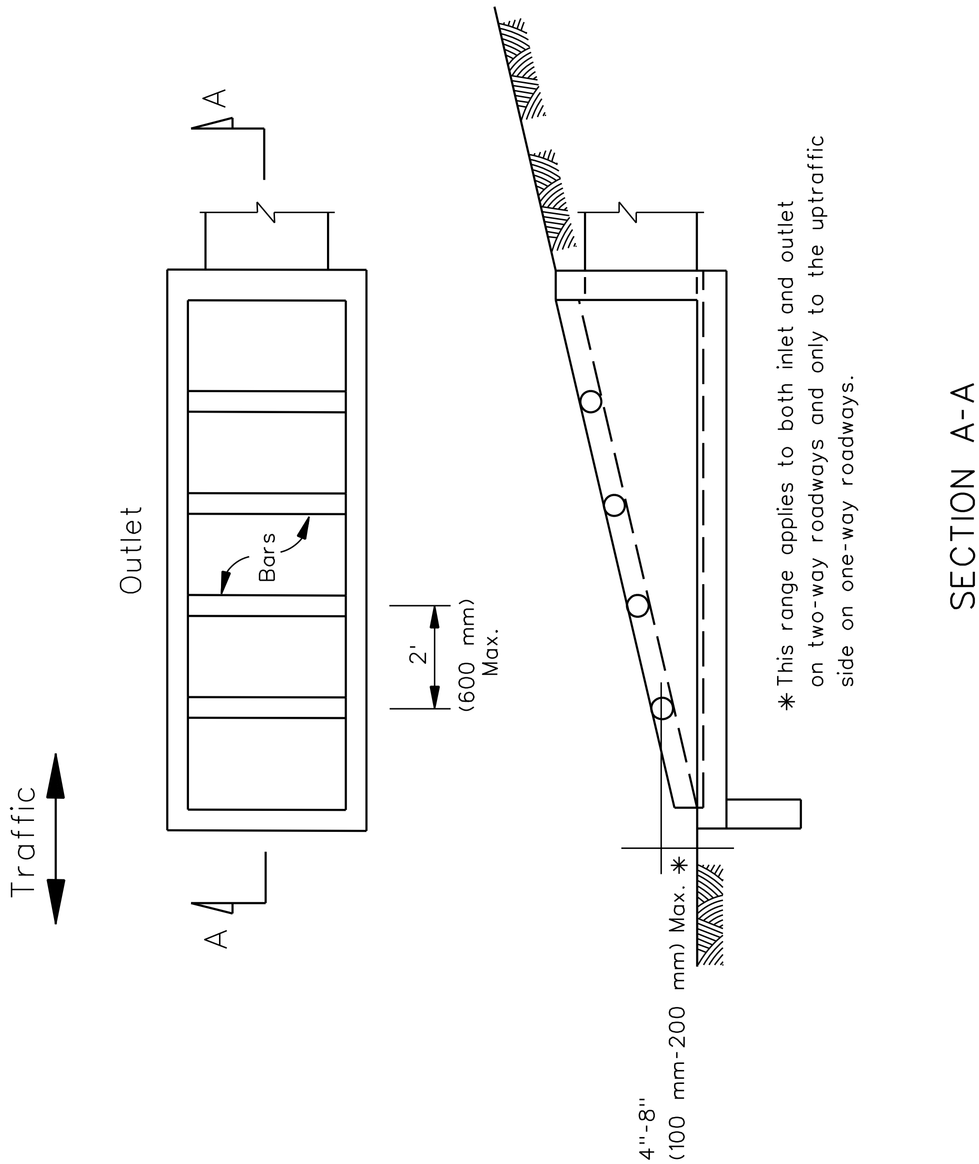
In the absence of other information (e.g., crash data), a roadside barrier is not warranted for the preferred ditch configuration shown in Figure 38-3.F. For other ditch configurations that would introduce a more abrupt change in direction for errant vehicles than a preferred ditch, the designer should conduct a cost-effective analysis to determine:

1. if a revised ditch configuration is appropriate,
2. if a roadside barrier is warranted, or
3. if the do-nothing alternative is appropriate.

38-4.07 <u>Rock Cuts</u>

If the toe of the rock cut is outside of the clear zone, or if the toe of the rock is within the clear zone and the rock face is smooth, a roadside barrier is not warranted unless other information (e.g., crash data) indicates otherwise. If the toe is within the clear zone and the rock face will cause excessive vehicle snagging, the designer should conduct a cost-effectiveness analysis to determine:

1. if the rock cut should be relocated outside of the clear zone or the face made smooth,
2. if a roadside barrier is warranted, or
3. if the do-nothing alternative is appropriate.



DESIGN FOR PARALLEL DRAINAGE STRUCTURES
(Diameter ≥ 24 in. (600 mm))

Figure 38-4.D

38-4.08 Bridge Parapet Ends

For bridge parapet ends on two-way roadways without median, a roadside barrier and transition should be installed at each corner unless the posted speed limit is less than 25 mph on an urban curbed section. No roadside barrier is needed on the departure end of a one-way roadway, unless a barrier is warranted for other reasons (e.g., front slopes steeper than 1V:3H).

If other hazards [e.g., permanent body of water more than 2 ft (600 mm) deep] exist, then additional guardrail may be considered. To determine the required length of need for the opposing traffic, use the L_C for the approach end measured from the centerline. L_B and the departing point for L_R will be measured from the centerline; also see Figures 38-6.A and 38-6.B for definitions of L_C, L_B, and L_R.

38-4.09 Retaining Walls

Barrier protection is not necessary for the face of retaining walls that are considered smooth (i.e., the general absence of any unevenness in the wall that may adversely affect an impacting vehicle). Retaining walls built of sheet piling, H-piling with timber, or precast concrete inserts are usually considered smooth. In addition, the following will apply to the roadside safety aspects of retaining walls:

1. Flare Rates. Use the same rates as those for concrete barrier. See Figure 38-6.X.
2. End Treatment. Preferably, the retaining wall will be buried in a back slope thereby shielding its end. If this is not practical, use a crashworthy end treatment or impact attenuator. Where the design speed is 35 mph (60 km/hr) or less, it is acceptable to transition the top of the wall from its normal height down to the ground line.

38-4.10 Traffic Control Devices

Traffic control devices include highway signs and traffic signals. If not properly designed and located, these devices may become a hazard to errant vehicles. The Bureau of Operations is responsible for the initial placement of traffic control devices, based on proper conveyance of information to the motorist, and the road designer reviews the location to ensure that it is compatible with the roadway design.

38-4.10(a) Highway Signs

For roadside safety applications, the following will apply to highway signs:

1. Design. The *Illinois Highway Standards* and *Sign Structures Manual* contain the Department's details for structural supports for traffic control devices.

2. Supports for Small Roadside Signs. All supports for small [< 50 ft^2 (5.0 m^2)] roadside signs should be made breakaway or yielding, including those outside of the clear zone. Where practical, the designer should locate signs behind a roadside barrier that is warranted for other reasons. There should be adequate clearance to the back of the guardrail post to provide for the barrier dynamic deflection; see Section 38-6.02. In addition, sign supports should not be placed in drainage ditches where erosion and freezing might affect the proper operation of breakaway supports. It is also possible that a vehicle entering the ditch will be inadvertently guided into the support.

   It is critical that breakaway supports not be located where a vehicle is likely to be partially airborne at the time of impact. Supports placed on a front slope of 1V:6H or flatter are acceptable. Supports placed on front slopes that are 1V:4H to 1V:6H are only acceptable when the face of the support is within 2 ft (600 mm) of the intersection of the shoulder slope and front slope.

3. Supports for Large Roadside Signs. Large signs [over 50 ft^2 (5.0 m^2) in area] should have slip base breakaway supports, whether within or outside the clear zone, and/or be located behind a roadside barrier. Where practical, the designer should locate large signs behind a roadside barrier that is warranted for other reasons, or at other locations where they are very unlikely to be hit.

   It is critical that breakaway devices, including slip bases, not be located where a vehicle is likely to be partially airborne at the time of impact. Supports placed on a front slope of 1V:6H or flatter are acceptable. Supports placed on front slopes that are 1V:4H to 1V:6H are only acceptable when the face of the support is within 2 ft (600 mm) of the intersection of the shoulder slope and front slope.

   Breakaway sign supports should not be located in or near the flow line of ditches. If these supports are placed on a back slope, they should be offset at least 5 ft (1.5 m) from the toe of the back slope of the ditch.

4. Overhead Sign Supports. All overhead signs will use non-breakaway supports. Within the clear zone, the designer should conduct a cost-effectiveness analysis to determine if these structures should be protected with a roadside barrier or, where applicable, with an impact attenuator.

38-4.10(b) Traffic Signal Equipment

In general, the designer has limited options available in determining acceptable locations for the placement of signal pedestals, signal poles, pedestrian detectors, and controllers. Considering roadside safety, these elements should be placed as far from the roadway as practical. However, due to visibility requirements, limited mast-arm lengths, limited right-of-way, restrictive geometrics, or pedestrian requirements, traffic signal equipment often must be placed relatively close to the traveled way. The designer should consider the following when determining the placement of traffic signal equipment:

1. Clear Zones. If practical, the placement of traffic signals on new construction and reconstruction projects should meet the clear zone criteria presented in Section 38-3. A cost-effectiveness analysis may be used to support this decision. In lower speed urban and suburban areas where it is not practical to place traffic signal supports outside the clear zone, the obstruction-free clearance criteria and enhanced lateral offset described in Section 38-9 apply. Where it is not practical to place isolated traffic signal supports outside the clear zone on rural high-speed facilities, evaluate shielding them with impact attenuators.

2. Controller. In determining the location of the controller cabinet, the designer should consider the following:

    a. The controller cabinet should be placed in a position so that it is unlikely to be struck by errant vehicles. It should be outside the clear zone or obstruction-free zone, if practical.

    b. The controller cabinet should be located where it can be easily accessed by maintenance personnel.

    c. The controller cabinet should be located so that a technician working in the cabinet can see the signal indications in at least one direction.

    d. The controller cabinet should be located where the potential for water damage is minimized.

    e. The controller cabinet should not obstruct intersection sight distance.

    f. The power service connection should be reasonably close to the controller cabinet.

3. Pedestrians. If the signal pole must be located very near or within the sidewalk, it shall be placed in a location that minimizes pedestrian conflicts. In addition, the signal pole shall not restrict access to curb ramps or reduce the sidewalk width below minimum; see Chapter 58.

4. Channelizing Islands. It is preferable not to place traffic signal equipment on islands within the roadway or intersection. However, the designer may need to use the islands for traffic signal placement to balance signal visibility, safety, cost and practicality.

38-4.11 Lighting

Because of the potential hazard posed to vehicles by roadside fixed objects, the general approach to lighting standards will be to use breakaway supports wherever possible. All new lighting standards located within the clear zone of a roadway where no pedestrian facilities exist will be placed on breakaway supports, unless they are located behind or on a barrier or protected by impact attenuators, which are necessary for other roadside safety reasons. Poles outside the clear zone on these roadways should be breakaway where there is a possibility of being struck by errant vehicles.

Breakaway devices should be given first consideration, except where extensive pedestrian exposure exists. Breakaway devices should be considered in urban areas where the combination of pedestrian activities concentrate during daylight hours and run-off-the road crashes are more prevalent outside of this period.

Although breakaway devices generally should receive first consideration, in some cases extensive pedestrian exposure may override the fixed object concern. Examples of locations where the hazard potential to pedestrian traffic indicate the use of non-breakaway devices include:

- transportation terminals,
- sports stadiums and associated parking areas,
- tourist attractions,
- school zones, or
- central business districts and local residential neighborhoods where the posted speed limit is 30 mph or less.

Other locations that require the use of non-breakaway bases, regardless of the pedestrian traffic volume, are rest areas and weigh station parking lots and combined light and traffic signal poles.

It is critical that breakaway devices be located where a vehicle is likely not to be partially airborne at the time of impact. Supports placed on a front slope of 1V:6H or flatter are acceptable. Supports placed on front slopes that are 1V:4H to 1V:6H are only acceptable when the face of the support is within 2 ft (600 mm) of the intersection of the shoulder slope and front slope.

Breakaway devices should not be located in or near the flow line of ditches. If these supports are placed on a back slope, they should be offset at least 5 ft (1.5 m) from the toe of the back slope of the ditch.

38-5 ROADSIDE BARRIERS

38-5.01 Types

The FHWA requires roadside safety hardware used on the National Highway System (NHS) to be crashworthy. IDOT then extends this requirement to all State jurisdiction routes for consistency. To be considered crashworthy, a piece of hardware is typically subjected to laboratory crash testing and engineering analysis which is then supported by in-service performance data. The hardware which has been accepted for use in Illinois can be found on one of several Qualified Products Lists (QPLs), as well as the *Illinois Highway Standards* maintained on the Department's website.

38-5.01(a) Steel Plate Beam Guardrail (Semi-Rigid Types)

Steel plate beam guardrail (SPBGR), commonly known as the W-beam system, is a semi-rigid system when installed with strong posts. The Department uses the Midwest Guardrail System (MGS), developed by the Midwest Roadside Safety Facility (MwRSF) under a pooled fund in which Illinois participates. Versions of the MGS using blockouts display better safety performance and are preferred over non-blocked versions of the MGS. The use of the non-blocked MGS should be limited to locations where the MGS with blockouts is not practical due to roadway width and/or steep front slope constraints. Various adaptations of the MGS are included in the *Illinois Highway Standards* and are briefly described below:

1. Type A. Type A guardrail is an MGS version with blockouts and with posts spaced at 6 ft 3 in. (1905 mm). The Type A guardrail meets Test Level 3 and is the most commonly used roadside barrier on Illinois highways. Refer to Figure 38-6.V for guardrail deflection criteria. Refer to Section 38-6.03 and Highway Standard 630001 for grading requirements behind guardrail.

2. Type B. Type B guardrail is an MGS version with blockouts and with posts at a reduced spacing of 3 ft 1½ in. (953 mm). The Type B guardrail meets Test Level 3. Type B is used where a semi-rigid roadside barrier is needed but the deflection space behind the posts is somewhat limited. Refer to Figure 38-6.V for guardrail deflection criteria. Refer to Section 38-6.03 and Highway Standard 630001 for grading requirements behind guardrail.

3. Type D. Type D guardrail is an MGS adaptation with blockouts for use as a semi-flexible median barrier. See Section 38-7.02(b) for the use of this guardrail type.

4. W-beam Guardrail with Quarter-post Spacing. This system with blockouts uses a further-reduced spacing of 1 ft 6¾ in. (476 mm). It is used where the deflection distance for the Type B system is not available. Though feasible for use in rare conditions, this post spacing is not shown in the *Illinois Highway Standards,* and job-specific details and pay items are needed in order to utilize it. Refer to Figure 38-6.V for guardrail deflection criteria.

5. Attached to Culverts. There are two options to attach MGS to culverts as described below.

    a. Strong Post Attached to Culvert. This attachment uses the conventional strong post version of the MGS with blockouts at a post spacing of 3 ft 1 ½ in. (953 mm) that can be attached to the top slab of a culvert, inboard of the culvert headwall. When transitioning from the standard MGS post spacing of 6 ft 3 in. (Type A) to the culvert-mounted MGS, at least five posts embedded 40 1/8 in. (1.02 m) in soil at half post spacing are recommended to be installed on both the upstream and downstream from the culvert-mounted posts. When transitioning from half post spacing MGS (Type B) to culvert-mounted MGS no special transition is necessary. Refer to Highway Standard 630101 for more detail.

    b. Weak Post Attached to Culvert. This attachment to culvert headwalls uses smaller "weak posts" (S3 X 5.7 [S76 X 8.5]) at a spacing of 3 ft 1½ in. (953 mm) without blockouts across the culvert. The posts are placed in steel sockets that are mounted to the face or top of the headwall. There are six different options for mounting the sockets (Case I through VI). Refer to Highway Standard 630111 for more details.

    Both options above are crashworthy. The designer may choose either option based on their unique situation.

6. Long Span Guardrail. This MGS adaptation with blockouts allows for omitting a few posts in order to span up to 25 ft (7.62 m) over low-fill culverts or where there are other obstructions to post placement. This version includes three "controlled release terminal" (CRT) posts on either side of the long span and requires a minimum installation length to assure performance consistent with the crash tested hardware. Refer to Highway Standard 630106 for more details.

7. Non-Blocked Steel Plate Beam Guardrail. The MGS without blockouts uses strong steel posts spaced at 6 ft 3 in. (1905 mm). The non-blocked guardrail meets Test Level 3; however, this system cannot be used everywhere that Type A, Type B, or guardrail with quarter-post spacing can be used. Specifically, Non-Blocked Steel Plate Beam Guardrail:

    - May not be used at the three control release terminal (CRT) post locations on either side of a long span guardrail's gap in posts. Only the CRT posts and blockouts may be used at these six posts.
    - When used where a slope steeper than 1V:3H is present within 24 in. (610 mm) from the back of post, the longer post as shown on the Standard shall be used, and a minimum top of rail height is 31 in. (787 mm).
    - Shall not be placed adjacent to or behind a curb.
    - Shall not be placed within 25 ft (7.62 m) of the pay limits of any bridge rail transition (e.g., Type 5, Type 6, Type 6A, Type 6B, Type 13, Type 14).

- Shall not be placed within 12.5 ft (3.81 m) of the pay limits of any Type 1 terminal.
- Shall not be placed within 50 ft (15.24 m) of the pay limits of a Type 2 terminal.
- Shall not be used where the post spacing is other than 6 ft 3 in. (1905 mm).
- Shall not be used with wood posts.
- Shall not be flared. It must run parallel to the traveled way.

See Section 38-6 for other roadside barrier layout requirements.

38-5.01(b) Concrete Barrier (Rigid Type)

Concrete barrier is a rigid barrier system that does not deflect upon impact. See Section 38-5.02 for information on where concrete barrier should be used.

The Department will meet MASH Test Level 5 criteria for concrete barrier at new or replacement locations. For Test Level 5 under MASH a minimum of 42 in. (1065 mm) height may be used with either a single slope barrier or vertical face barrier. However, the Department has adopted a taller concrete barrier height of 44 in. (1120 mm) to accommodate a future 2 in. (50 mm) profile increase. The barrier is single slope with a 10.3 degree slope and a top width of 19 in. (480 mm). See *Highway Standard 637006*.

For use of concrete barrier as a roadside barrier (i.e. a single faced barrier), the standard single slope shape should be used along the traffic side with a vertical face on the back. Backfill behind the barrier for lateral support (retaining wall design) or use a special footing design (e.g., barrier tied to a concrete footing with reinforcing steel). Contact BSPE for design parameters.

38-5.01(c) High-Tension Cable Barrier (Flexible Type)

Cable barrier is a flexible barrier system with weak posts. The posts are designed to bend over or break off upon impact. Cable barrier and other weak-post systems provide a forgiving impact with low deceleration forces exerted on vehicle occupants. See Section 38-5.02 for information on where cable barrier may be used.

IDOT requires the use of high-tension cable barriers that have passed Test Level 4 crash test criteria on flat slopes or Test Level 3 crash test criteria with slopes steeper than 1V:6H to as steep as 1V:4H. Deflection distances for these proprietary systems are greater than W-beam guardrail and vary depending on the product and the post spacing. See Section 38-6 for additional guidance on high-tension cable barriers.

38-5.01(d) Cable Road Guard Single Strand

Cable Road Guard Single Strand (Highway Standard 636001) is not a roadside safety system. Its only use is to inhibit unwanted vehicular encroachments. Place Cable Road Guard as far as practical from the traveled way, and well outside the clear zone.

38-5.01(e) Other Systems

Many other roadside barrier systems are available which may have application at specific sites (e.g., thrie-beam guardrail). The designer should reference the latest edition of the AASHTO *Roadside Design Guide* for information on these systems. Both BDE and BSPE must approve the use of any system not included on one of the several QPLs or in the *Illinois Highway Standards*.

38-5.01(f) Aesthetic Treatments

Aesthetic treatments are not included in the *Illinois Highway Standards* due to concerns of safety performance, durability, and cost. Weathering steel guardrail has produced excessive rusting at lap joints and has performed poorly, thus it should not be installed. Experience from other States with winter road salting have shown that embossed (form liner) patterns for concrete parapets and barriers can trap salt and accelerate deterioration. These treatments should not be used on the traffic face of any concrete barrier. Contact BSPE for information regarding suitability of any aesthetic treatments.

38-5.02 Barrier Selection

This section presents considerations when selecting barriers for specific applications along roadways in Illinois.

1. Test Levels. The designer should consider the expected speeds and vehicle composition when selecting a test level for a barrier. Barriers that have passed Test Level 3 criteria are required on high-speed roadways (design speeds higher than 45 mph [70 km/hr]). There is no Test Level defined for speeds higher than 60 mph (100 km/hr) and studies of crashes have shown that Test Level 3 is adequate for the typical mix of vehicles where the design speed is higher than 60 mph (100 km/hr). However, if the objective is a higher probability of containing large trucks or commercial passenger vehicles such as buses, a barrier that has passed Test Level 4 or 5 may be appropriate. Barriers tested at Test Level 2 may be appropriate for roadways where the design speed is 45 mph (70 km/hr) or less and this is judged to represent the typical roadway operating speed.

2. Dynamic Deflection. Allowable dynamic deflection affects barrier selection. A barrier should be selected that is consistent with the available deflection space between the barrier and fixed objects behind the barrier; see Figure 38-6.U. Figure 38-6.V provides

the deflection distances for guardrail and Section 38-7.03(b)3 discusses deflection distances for high-tension cable barrier (flexible).

3. Maintenance Considerations. Review the following maintenance issues when selecting a barrier:

   - W-beam guardrail will require structural repair after hits that contain or redirect vehicles, and nuisance hits may inflict tears or kinks requiring repairs. In high-speed, high-traffic locations it may be unacceptable to have damaged sections of guardrail at locations where repair operations can create hazardous conditions for repair crews and can degrade traffic operations and safety.
   - Concrete barrier may be the best choice in locations where traffic and speed dictate that a damaged barrier and subsequent traffic disruption for repairs are not acceptable.
   - High-tension cable barriers will require repairs for virtually all nuisance and other hits. Depending upon the design specified, many repairs may be performed without specialized or heavy equipment.
   - Taller and more substantial barriers may aggravate snow drifting.

4. Preferred Barriers. W-beam guardrail is the preferred roadside barrier for non-freeways and for rural freeways where there is adequate deflection space. However, other barriers may be considered based on site-specific traffic volumes, speeds, vehicle mix, available deflection space and cost of installation. *NCHRP Report 638*, "Guidelines for Guardrail Implementation" provides general guidance that may apply for recommending higher test levels for roadside barriers in Illinois. Detailed analysis of project alternatives may be made using the Roadside Safety Analysis Package (RSAP) software.

5. Concrete Barrier Uses. Consider using concrete barrier for urban freeways (double-faced) and the following additional cases (single- or double-faced):

   - to shield objects close to the roadway where deflection space is limited;
   - where there is a high volume of heavy trucks;
   - where there is a high volume of commercial passenger vehicles, such as buses;
   - to minimize repair and maintenance. Concrete barrier will often remain undamaged after an impact, while guardrail will require more frequent maintenance and repair;
   - to reduce headlight glare into nearby buildings or other sensitive areas;
   - to reduce headlight glare between frontage roads and the mainline, especially where the alignment directs headlights at opposing traffic; and
   - areas where it is especially critical to contain errant vehicles.

Figure 38-5.A summarizes the advantages and disadvantages of the roadside barriers used by IDOT and provides their typical usage. Figure 38-5.B summarizes the general selection criteria that apply.

System	Advantages	Disadvantages	Typical Usage
High Tension Cable Barrier	1. Lower initial cost. 2. More forgiving impact. 3. Weak-post systems maintain vehicle stability. 4. Relatively easy installation. 5. Remains functional after moderate collisions. 6. Some systems have features that make repair more efficient. 7. Minimizes snow drifting.	1. Larger deflection spaces needed. 2. Less likely to contain large vehicles than concrete barrier, although the systems used by IDOT have passed Test Level 4 (single-unit truck crash test) on slopes of 1:6 or flatter. 3. Some potential for vehicles to under ride the barrier. 4. Cannot be used in conjunction with curbing. 5. Any impact requires repair.	1. Non-freeways. 2. Rural freeways. 3. Side hazards where deflection space is adequate and a Test Level 4 barrier is preferred.
W-Beam Guardrail	1. Lower initial cost. 2. High level of familiarity by maintenance personnel. 3. Can safely accommodate a wide range of impact conditions for passenger vehicles. 4. Relatively easy installation. 5. Remains functional after nuisance collisions. 6. Can be used in conjunction with curbing.	1. Less likely to contain large vehicles than concrete barrier or cable barrier. 2. At high-impact locations, will require frequent maintenance. 3. Will cause more snow drifting than cable barrier. 4. Hits that redirect or contain vehicles will require repair.	1. Non-freeways with narrow medians. 2. Rural freeways. 3. Side hazards where deflection space is adequate.
Concrete Barrier	1. Can accommodate most vehicular impacts without penetration. 2. No deflection distance required behind barrier. 3. Little or no damage sustained for most vehicular impacts; therefore, least need for maintenance. 4. Minimal vehicular under ride/ override potential for snagging potential.	1. Highest initial cost. 2. For given impact conditions, highest occupant decelerations; therefore, least forgiving of barrier systems 3. Reduced performance where offset between traveled way and barrier exceeds 12 ft (3.6 m). 4. Usually requires subsurface drainage. 5. Increased snow drifting.	1. Urban freeways. 2. Where very high traffic volumes are present. 3. Where high volumes of large vehicles are present. 4. Narrow medians.

ROADSIDE BARRIER SELECTION

Figure 38-5.A

Criteria	Comments
1. Performance Capability	Barrier must be structurally able to contain and redirect design vehicle.
2. Deflection	Adequate deflection space should be available so that the barrier can deflect on impact without contacting fixed objects behind the barrier.
3. Site Conditions	Slope approaching the barrier, slope behind the barrier, and distance from traveled way may preclude use of some barrier types.
4. Compatibility	Barrier must be compatible with planned terminal treatment and capable of transition to other barrier systems (e.g., bridge railing).
5. Cost	Standard barrier systems are relatively consistent in cost, but special-use systems can cost significantly more.
6. Maintenance	
a. Routine	Few systems require a significant amount of routine maintenance.
b. Collision Damage	W-beam guardrail will require the most extensive repair after a collision. Many high-tension cable barriers will require less extensive repair. Concrete barrier will have the least repair requirements after a collision.
c. Nuisance Hits	High-tension cable barrier will require the most frequent attention for nuisance hits (e.g., mowers, snowplows, minor vehicular encroachments). W-beam guardrail will require repairs where nuisance hits causes kinks or tears or disturbance of terminal impact heads. Concrete barrier will seldom require repairs for nuisance hits.
d. Materials Storage	The fewer the number of different systems used, the fewer inventory items/storage space required. High-tension cable barrier specifications allow a number of competing proprietary systems.
e. Simplicity	Simpler designs, in addition to costing less, are more likely to be repaired properly by field personnel.
7. Aesthetics	Use caution in applying aesthetic treatments to roadside hardware. See Section 38-5.01.
8. Field Experience	The performance and maintenance requirements of existing systems should be monitored to identify problems that could be lessened or eliminated by using a different barrier type.

SELECTION CRITERIA FOR ROADSIDE BARRIERS

Figure 38-5.B

38-6 ROADSIDE BARRIER LAYOUT

38-6.01 Length of Need

A roadside barrier must intercept and contain or redirect errant vehicles before they reach the roadside hazard or area to be shielded. The barrier should extend a sufficient distance upstream and/or downstream of the hazard such that a vehicle does not travel behind the barrier and reach the hazard.

Figures 38-6.A and 38-6.B show the principal dimensions and relationships necessary to design a roadside barrier system that will adequately shield traffic from reaching a hazard area. Figure 38-6.A is applicable to a one-way roadway and to a two-way roadway where the roadside hazard and guardrail is not within the clear zone for opposing traffic. Figure 38-6.B applies to a two-way roadway where the hazard is within the clear zone for opposing traffic. The essence of the procedure is to find the intersection of the vehicle’s runout path for use in setting the location of the beginning of redirective barrier (the beginning of length of need point, or BLON point) of the proposed guardrail or other barrier.

The clear zone on the right begins at the edge of the traveled way. For traffic on a two-way roadway without a median, the clear zone on the left begins at the centerline of the roadway. The departure end of a roadside barrier on a two-way roadway may or may not be within the clear zone of the opposing traffic. However, this departure end of the roadside barrier is a formidable hazard introduced to the roadside and should typically be shielded, regardless of lateral offset. When beyond the clear zone for opposing traffic, at a minimum, provide an approved crashworthy end section to the end of the roadside barrier facing opposing traffic.

Terminal ends for guardrail are discussed in Section 38-6.06. The selection of the terminal end in the design phase will affect LON. Therefore Section 38-6.06 should be reviewed along with Figures 38-6.A and 38-6.B, the example problems located in this section, and specific manufacturer information available on the IDOT Qualified Products List (QPL) when determining LON and quantities for design purposes. The procedures presented in this chapter will result in sufficient quantities of guardrail being included in the plans. The contractor’s selection of terminals will affect the final contract quantity of guardrail. Conservative assumptions are necessary in the design process to prevent conflicts with adjacent driveways or field entrances during construction, assure that appropriate length of need will be installed in the field, and ensure sufficient guardrail quantity is provided in the construction plans.

Example problems 38-6.01(1) through 38-6.01(6) show how to determine the required LON for various design situations. The assumptions made for TBT T1 devices in these examples do not reflect actual MASH devices and are meant only to illustrate the procedures. Note that calculations are typically not rounded in these examples; the designer should apply significant figures consistent with actual design precision. Guardrail quantity rounding is covered in Chapter 64.

Note that Figures 38-6.A and 38-6.B are depicted for a tangent alignment, as are the following development of length of need examples. When curves are present, a graphical, plan-based solution is necessary, as described below. Designers may also reference the equations in the Roadside Design Guide.

Divided highway medians warrant unique considerations. The practice of limiting clear zone widths based on practicality often may not be appropriate. Median piers should be shielded with barrier runs or crash cushions in accordance with Section 38-8.2. The openings created when freeways overpass roadways, railroads and rivers may be considered by designers to represent severe hazards that can be addressed by shielding a wider-than-typical clear zone. Refer to Example 38-6.01(4) for further discussion.

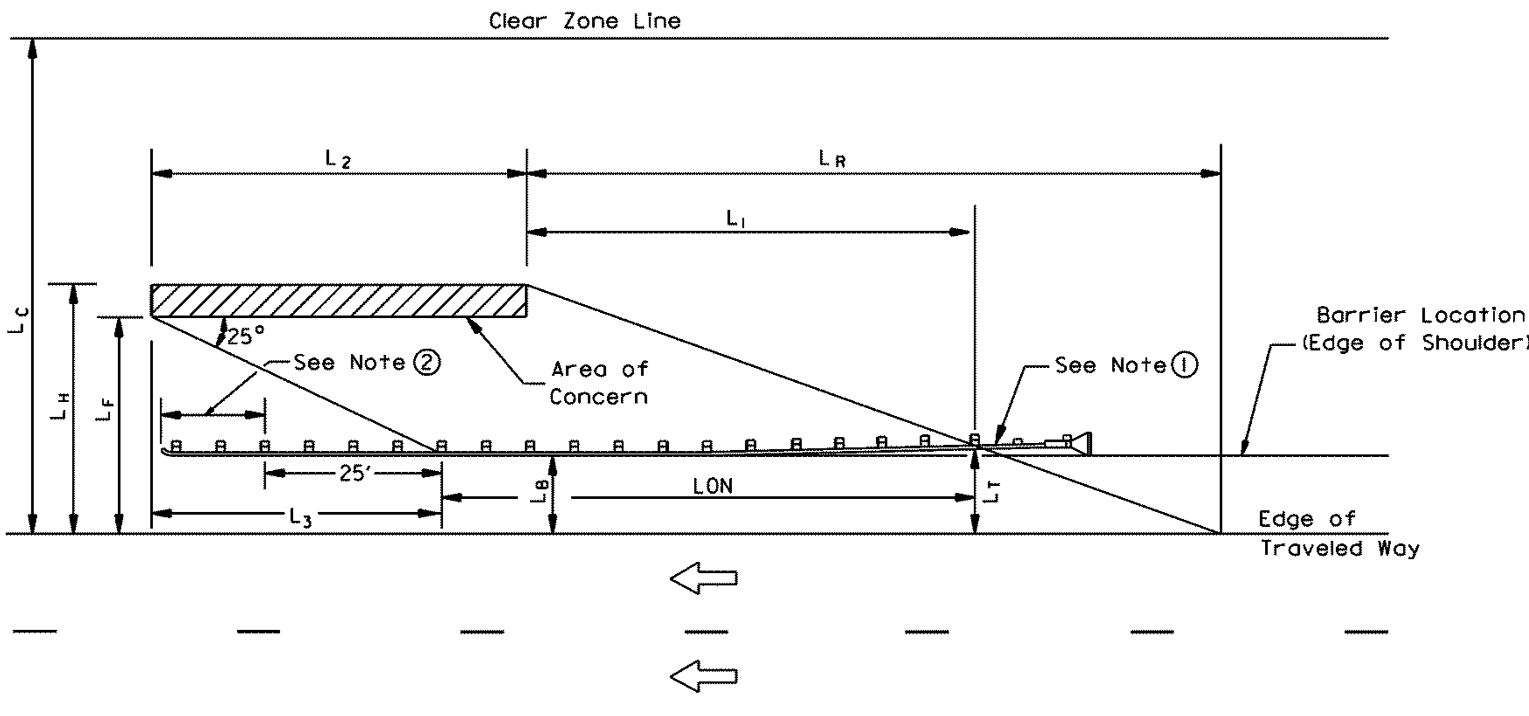
38-6.01(a) Graphical Solution

Whether on tangent or curved alignment, the preferred way to lay out guardrail and determine the length of need is by drawing and measuring the installation in plan view using CADD software. Designing graphically offers several advantages:

- Laying out installations along horizontal curves often requires some judgment, and it is helpful to review the design visually and to-scale; see Figure 38-6.C.
- A graphical layout allows the designer to look at various flare rates (note that non-blocked guardrail shall not be flared) while considering guardrail length and the extent to which the guardrail projects toward the ditch; see Figure 38-6.D. Greater flare rates will shorten guardrail lengths, but may increase the amount of earthwork required in order to provide the 1V:10H slopes needed in front of the guardrail. Designers will typically balance these issues based on site-specific characteristics (e.g., steepness of the front slope, width of the ditch).
- When designing graphically in plan view, the designer can look at contours and cross sections to determine if guardrail should be extended for steep slopes.
- As a quality-control measure, a graphical layout allows the designer to simply look at the design, drawn to scale, and confirm that the design is appropriate.
- Graphic layout can accurately depict all post locations, and related utility, drainage, or other conflicts.

For guardrail layout on curves, Figure 38-6.C shows an example of using the tangential runout path from the edge of traveled way to the back of the hazard or area of concern. Compare the tangential runout path and the runout length (L_R) and use the shorter of these values for design. The tangential runout path will tend to control on smaller radius curves, and the runout length on flatter curves. This procedure will help to minimize the required guardrail installation. The general relationship between flaring of guardrail and the grading required is depicted on Figure 38-6.D.

Using CADD is particularly efficient if cells are developed for the various guardrail components that make up a guardrail installation. Cells can be created for transitions to bridge ends, terminals, standard 12.5 ft (3.81 m) sections, and other components, etc., which can be efficiently placed in CADD to develop layouts and compare designs.



$LON = L_1 + L_2 - L_3$

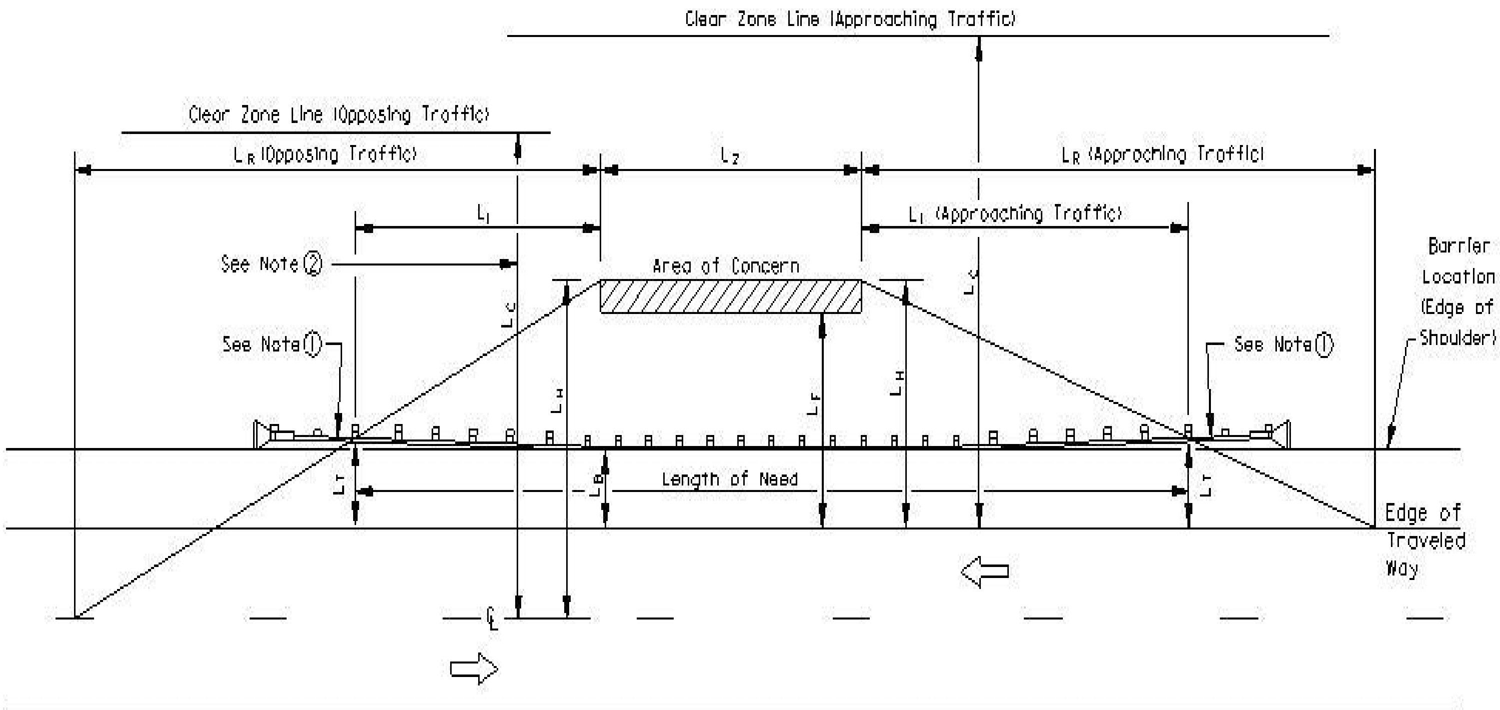
L_T = Distance to the barrier at the third post of the terminal
L_B = Distance to the barrier
L_C = Distance to the clear zone
L_H = Distance to the back of the hazard
L_F = Distance to the front of the hazard
L_R = Runout length (see Figure 38-6.E)
L_1 = Length of need for the approach end
L_2 = Length of the hazard
L_3 = Distance from the downstream end of the hazard
LON = Length of Need

Notes:

① Use appropriate crashworthy terminal. See Section 38-6.06.
② Use a Type 2 terminal for one-way traffic. For two way traffic where L_c for opposing traffic > (L_F + 12), use an appropriate crashworthy terminal, with LON point passing through the third post of the crashworthy terminal.

BARRIER LENGTH OF NEED LAYOUT
(One-Way Roadways or Two-Way Roadways Where the Hazard and Guardrail are Beyond the Clear Zone of Opposing Traffic)

Figure 38-6.A



LON = L_1 (approaching) + L_2 + L_1 (opposing)

Notes:

① Use appropriate crashworthy terminal. See Section 38-6.06.
② If L_c for opposing traffic < (L_F + 12) then refer to Figure 38-6.A.

L_T = Distance to the barrier at the third post of the terminal
L_B = Distance to the barrier
L_C = Distance to the clear zone
L_H = Distance to the back of the hazard
L_F = Distance to the front of the hazard
L_R = Runout length (see Figure 38-6.E)
L_1 = Length of need for the approach end
L_2 = Length of the hazard
LON = Length of Need

BARRIER LENGTH OF NEED LAYOUT
(Two-Way Roadways Where the Hazard and Guardrail are within the Clear Zone of Opposing Traffic)

Figure 38-6.B

38-6.01(b) Nomograph Solution

If the installation is on a tangent section of roadway, the nomograph in Figure 38-6.F can be used to determine the length of need. The procedure for using the nomograph is as follows, assuming a hazard is present requiring protection:

1. Draw a horizontal line at L_B on the y-axis (the lateral distance of the barrier from the edge of traveled way). This assumes that the barrier is not flared; i.e., it is parallel to the roadway.

   If a crashworthy terminal is provided, draw the horizontal line at L_T instead of L_B to account for the offset at the third post of the Traffic Barrier Type 1, Special (TBT T1). Normally this is an additional 2.7 ft (0.8 m) for a TBT T1 (Flared) and 0.75 ft (0.2 m) for a TBT T1 (Tangent).

   If the guardrail itself is flared, draw a line from L_B on the y-axis equal to the flare rate of the guardrail. If a flared section of guardrail connects to a tangent portion, such as a Type 6 terminal, show both the tangent and flared portions on the nomograph. For a TBT T1 attached to a flared section of guardrail, the TBT T1 will often have the same flare rate as the guardrail to which it is attached, but the flare rate must not exceed the maximum rate established through crash testing for the terminal selected. Example problem 38-6.01(5) illustrates all of these scenarios.

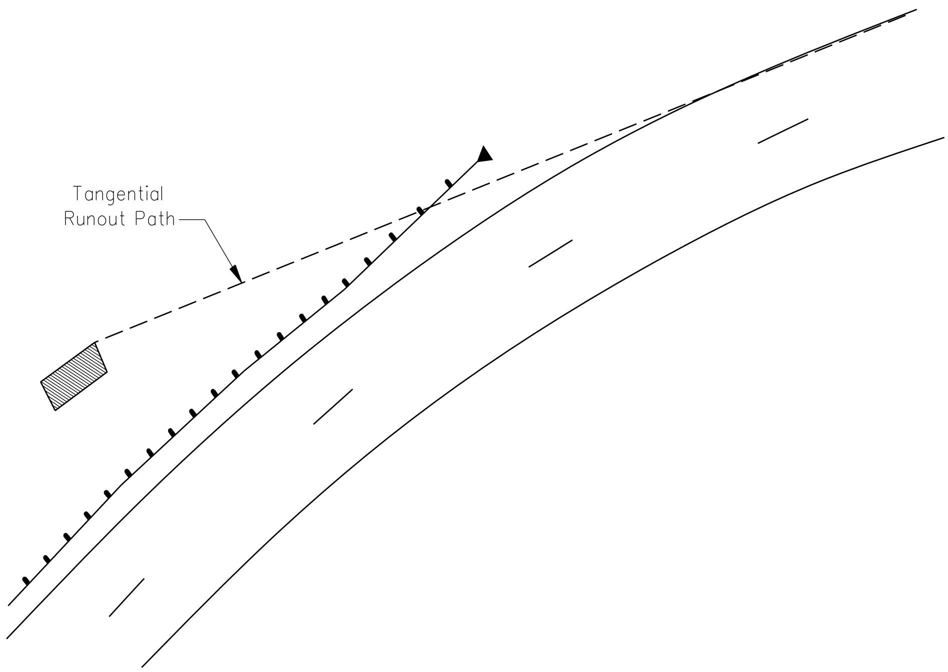
2. Locate L_H or L_C, whichever is less, on the y-axis. Check the hazard location for the opposing direction if the roadway is two-way. Also check for the need of a crashworthy terminal end section for the opposing direction of traffic. Example problem 36-6.01(3) illustrates this situation.

3. Determine L_R from Figure 38-6.E and locate L_R on the x-axis. If barrier protection is needed for only the approaching traffic, use only the “Edge of Traveled Way Scale.” If needed for both directions of travel, locate L_R on both the “Edge of Traveled Way Scale” and the “Centerline Scale.” See Step 7 to address the downstream end of the barrier where the hazard does not require shielding for the opposing traffic.

4. Connect the points in Steps 2 and 3 with a straight line(s).

5. Locate the intersection(s) of the lines in Steps 1 and 4. From this point(s), draw a line vertically to the “Edge of Traveled Way Scale” and, if required, to the “Centerline Scale” to determine L_1.

6. Read L_1 from the “Edge of Traveled Way Scale” and, if required, from the “Centerline Scale.” As illustrated on Figures 38-6.A and 38-6.B, L_1 is measured from the lateral edge of the hazard to the third post of the terminal. The LON does not include the gating portion of the terminal.



GRAPHICAL LAYOUT OF GUARDRAIL ALONG A HORIZONTAL CURVE

**Based on a 10 year projection from the anticipated date of construction*.

RUNOUT LENGTHS (L_R) FOR BARRIER DESIGN

Figure 38-6.E

7. If barrier protection is only warranted for one direction of travel (Figure 38-6.A), use the following procedure to determine the downstream end of the length of need, otherwise proceed to Step 8:

   a. If not done in Step 1, draw a horizontal line from L_B at the y-axis to represent the lateral distance of the barrier from the edge of travel way (i.e., no adjustment for the flare of the terminal).

   b. Locate L_F on the y-axis as the distance from the hazard to the edge of traveled way, at the downstream end of the hazard.

   c. From point L_F, draw a line parallel to the 25 degree line in Figure 38-6.F until it intersects the L_B line.

   d. From the intersection between the L_B line and the L_F line, draw a line vertically to the “Edge of Traveled Way Scale” and read L_3.

8. Calculate the length of need (LON):

If barrier protection is warranted for only one direction of travel:

$$LON = L_1 + L_2 - L_3 \qquad \text{Equation 38-6.1}$$

If barrier protection is warranted for both directions of travel:

$$LON = L_1 \text{ approaching} + L_2 + L_1 \text{ opposing} \qquad \text{Equation 38-6.2}$$

The next three steps consider the contribution of various guardrail terminals to completing the length of need.

9. Because the various proprietary TBT T1 terminals vary in the location of their beginning of length of need (BLON) point and in total length, it is not possible to provide absolute positions of the end of guardrail or the limits of the terminal. Where a TBT T1 is to be installed, specify the BLON station and offset in the plans. For design purposes, use a consistent TBT T1 available from the Qualified Products List (QPL) throughout the project, with the BLON point at post 3. Use this information to determine how much redirective barrier the TBT T1 provides toward completing the LON. While utilizing the shortest available TBT T1 will provide the most conservative value for guardrail plan quantity, consider the effects of a longer TBT T1 being used in the field and its impact on the location of proposed entrances and grading. Standard assumptions introduce an assumed gating section 12.5 ft long from post 1 to post 3 of the TBT T1.

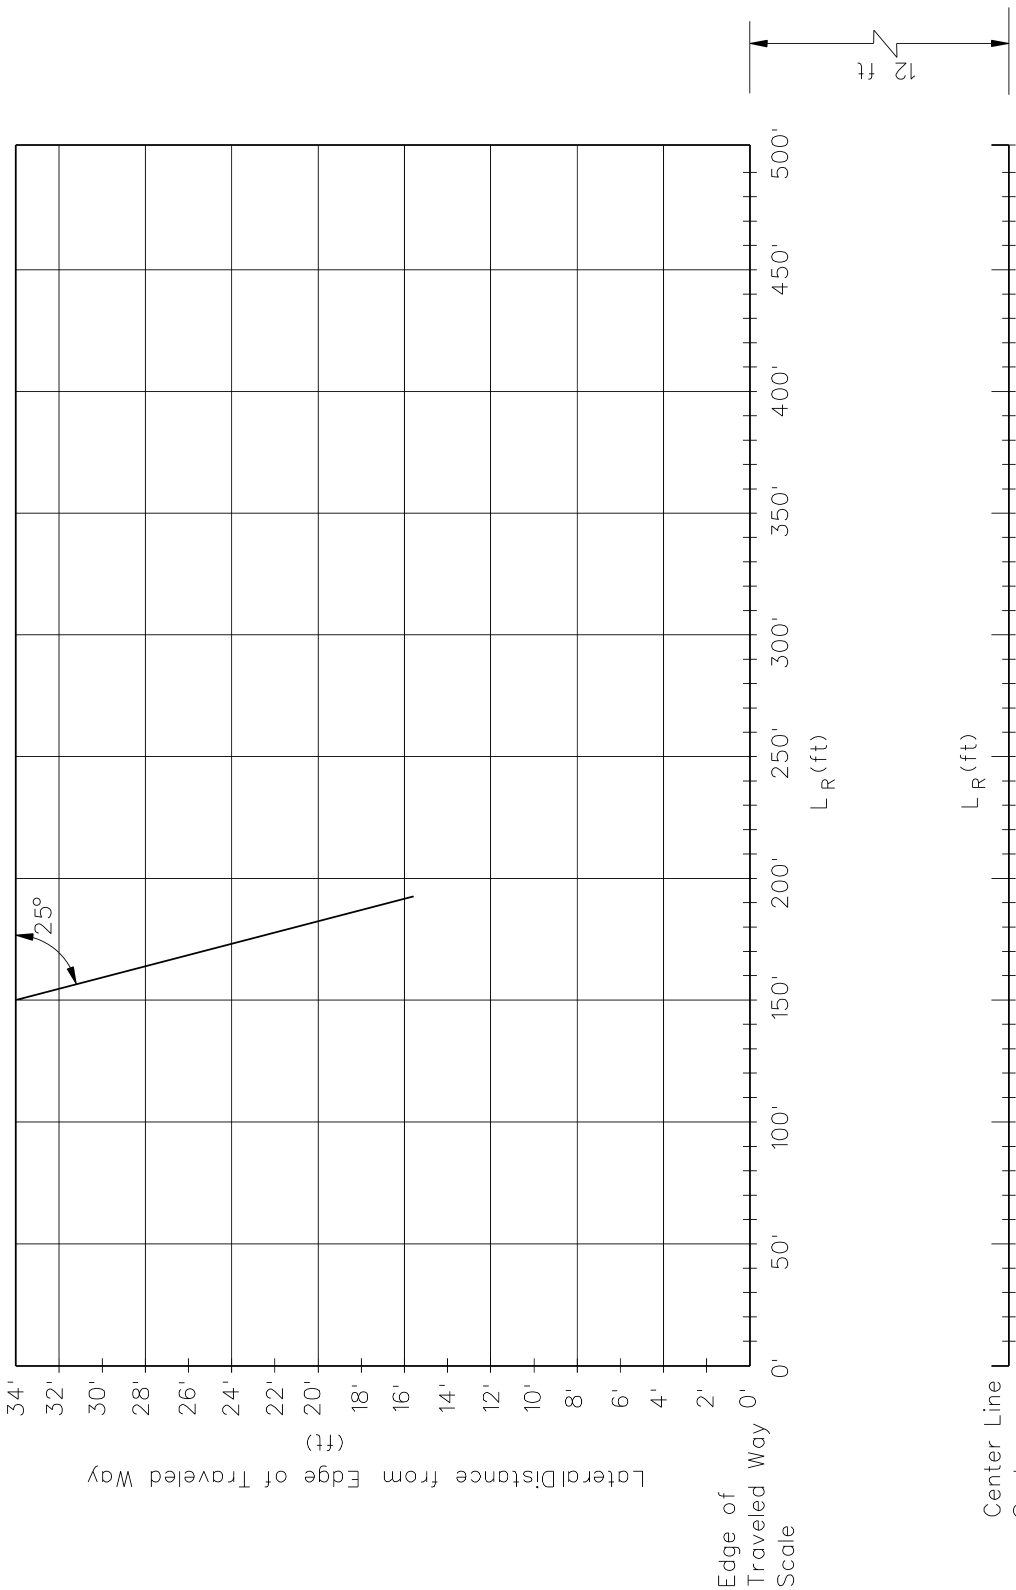
   For a TBT T2 the length of need begins at 37.5 ft (11.43 m) from the end post of the TBT T2. This means that the TBT T2 and the adjacent 25 ft (3.81 m) of guardrail do not contribute to the LON. Using a TBT T2 requires adding at least 25 ft (3.81 m) of guardrail beyond the LON when calculating the pay item quantities.

10. For connection of guardrail to other terminals from the *Illinois Highway Standards,* determine the contribution of the terminals toward completing the LON. These terminals are connections between guardrail and other barrier types. Typically, their entire length contributes to the LON. For example:

    - The entire length of a TBT Type 6, 6A, or 6B counts toward the LON so that length needs to be subtracted from the LON adjusted in Step 9 (see applicable *IDOT Highway Standard* for terminal length).

11. Check that the LON and layout is adequate and does not create conflicts.

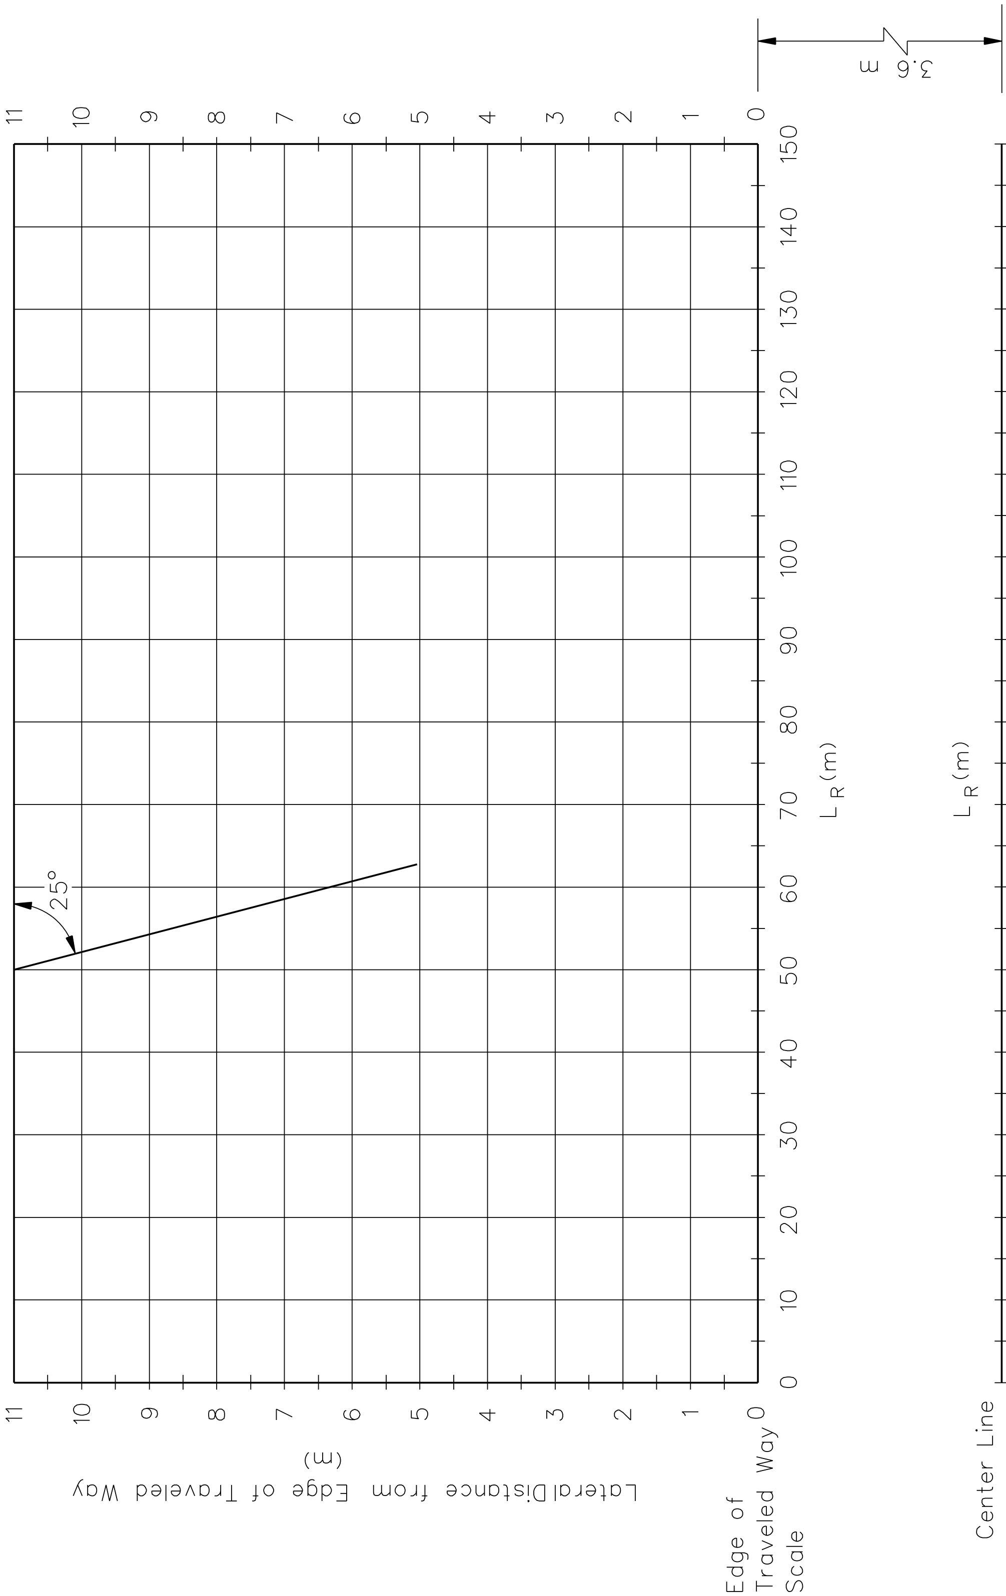
    Determine the pay item plan locations and quantities. When a TBT T1 is used in a run of guardrail, it is not necessary or possible to determine the guardrail or terminal limits with certainty. Use the nominal pay item limits based on the BLON location and assume TBT T1 parameters. As-built adjustments in construction will be necessary to determine splice locations, specific devices to be used, and final pay quantities. These adjustments are considered nominal in providing the LON.



Note: Centerline scale assumes a 12-ft lane width. For other lane widths, appropriate adjustments must be made.

BARRIER LENGTH OF NEED CALCULATION (TANGENT ROADWAYS ONLY)
(US Customary)

Figure 38-6.F



Note: Centerline scale assumes a 3.6-m lane width. For other lane widths, appropriate adjustments must be made.

BARRIER LENGTH OF NEED CALCULATIONS
(Metric)

Figure 38-6.F

Example 38-6.01(1) (One-Way Traffic)

Given: New Construction (See Figure 38-6.G)
One-way roadway
Design ADT = 7000 vpd
Design speed = 70 mph
Slope = 1V:6H front slope
Tangent roadway
Shoulder width = 10 ft
L_H = 25 ft
L_2 = 40 ft
L_F = 15 ft
Unflared barrier (steel plate beam guardrail, Type A) located at the edge of the shoulder (L_B = 10 ft).
Traffic Barrier Terminal Type 1 (TBT T1), Special (Flared)

Problem: Determine the barrier length of need (LON) and plan length of guardrail, Type A.

Solution: Use the nomograph procedure starting on page 38-6.5 (refer to the nomograph in Figure 38-6.H).

1. Since a TBT T1, Special (Flared) terminal is proposed, draw a horizontal line at L_T on the y-axis of the nomograph,

   Where: L_T = 10 + 2.7 = 12.7 ft

   The 2.7 ft is added to the shoulder width to take into account the flare of the guardrail terminal at the third post.

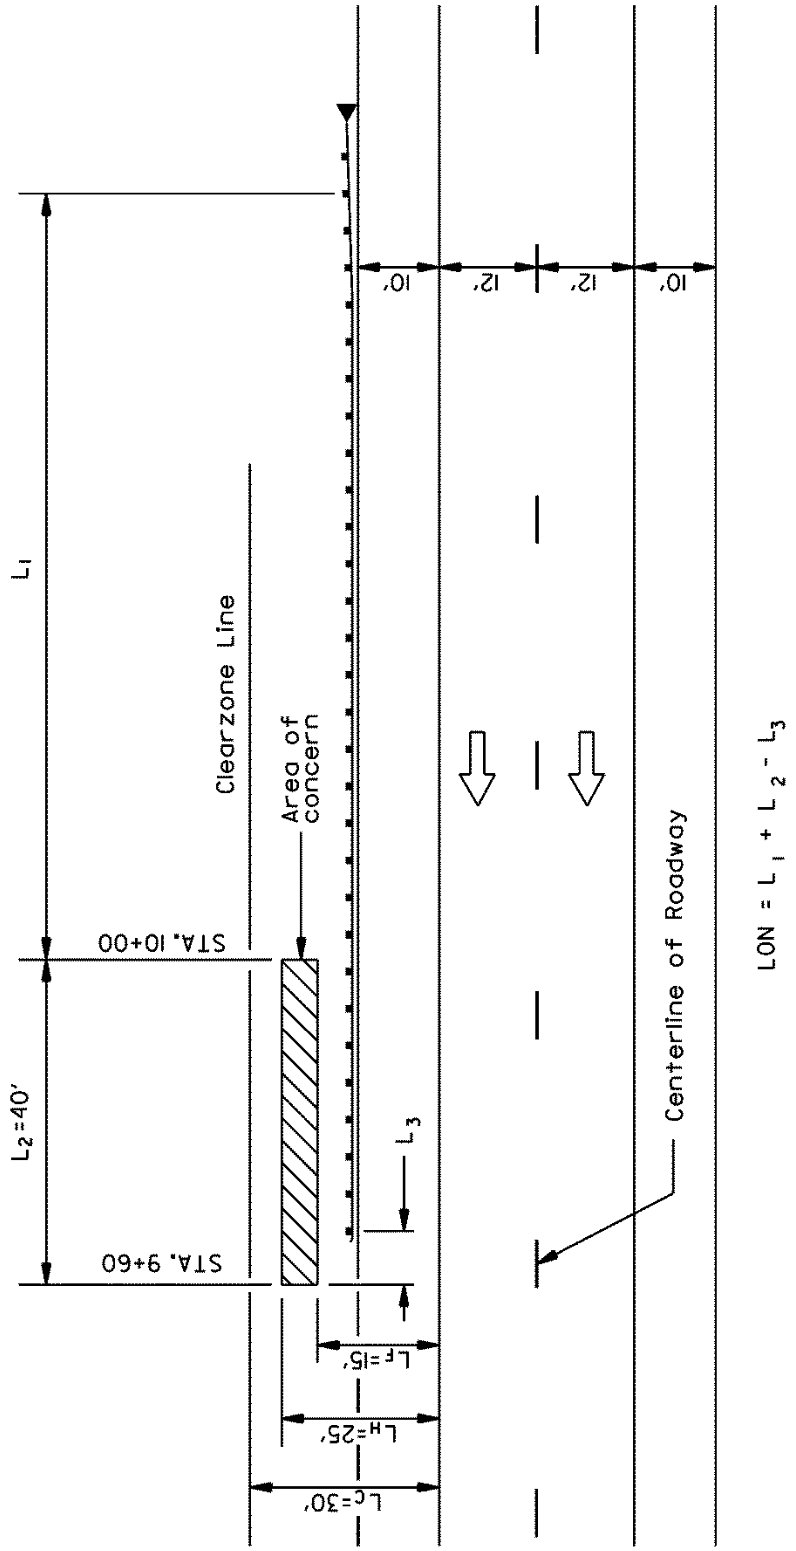
2. From Figure 38-3.A, the clear zone (L_C) is 30 ft and the hazard warrants protection since $L_F < L_C$. Locate the lesser of L_H or L_C, on the y axis. In this case locate L_H = 25 ft on the y-axis.

3. From Figure 38-6.E, L_R = 330 ft. Locate this point on the “Edge of Traveled Way Scale.” Since the roadway is one-way, protection is only warranted from one direction, and therefore L_R is not located on the “Centerline Scale.”

4. Connect the points in Steps 2 and 3.

5. From the intersection between the lines from Step 1 and Step 4, draw a vertical line down to the “Edge of Traveled Way Scale” to get L_1.

6. Read L_1 = 162 ft from the “Edge of Traveled Way Scale.”



PLAN VIEW
EXAMPLE 38-6.01(1)

Figure 38-6.G

7. Since barrier protection is only warranted for one direction, perform the following steps to establish L_3, and thus determine the location of the downstream end of the barrier:

   a. Draw a horizontal line from L_B = 10 on the y-axis.
   b. Locate L_F = 15 ft on the y-axis.
   c. Draw a line from L_F parallel to the 25 degree line until it intersects the L_B line.
   d. From the intersection between the lines formed from Step 7a and Step 7c, draw a vertical line down to the "Edge of Traveled Way Scale" to find L_3. Read L_3 = 11 ft.

8. Calculate the length of need (LON) of guardrail. In this example barrier protection is needed only in one direction of travel. Therefore:

   LON = 162 + 40 – 11 = 191 ft Equation 38-6.1

9. Based on the stationing shown in Figure 38-6.G, the BLON for the approach end (TBT T1) falls at, Station 11+62.00, 24.7 ft left. This is set as the face of rail location at post 3 of the TBT T1 (see QPL for specific end terminal dimensions). For this example, a 37.5 ft long TBT T1 is selected from the QPL. So the TBT T1 will provide at least (37.5 ft– 12.5 ft =) 25 ft of the length of need. As described, this TBT T1 will also include a gating section from post 1 to post 3 (12.5 ft).

10. A TBT T2 is used for the departure end of the guardrail since there is one-way traffic. The TBT T2 requires an additional 25 ft of guardrail which is added to the estimated length beyond the BLON for the TBT T2.

11. Standard terminals other than the TBT T2 are not used, so this step does not apply

12. Determine the pay item plan locations and quantities.

    The BLON for the approach end (TBT T1) is at Station 11+62.00, 24.7 ft left.

    The steel plate beam guardrail has one end at:

    (Station 11+62) – 25 ft = Station 11+37.00

    The other end of the steel plate beam guardrail is at:

    (Station 11+37) – (191 ft (LON) + 25 ft (provided by TBT T1) – 25 ft (additional needed with TBT T2) = Station 9+46.00

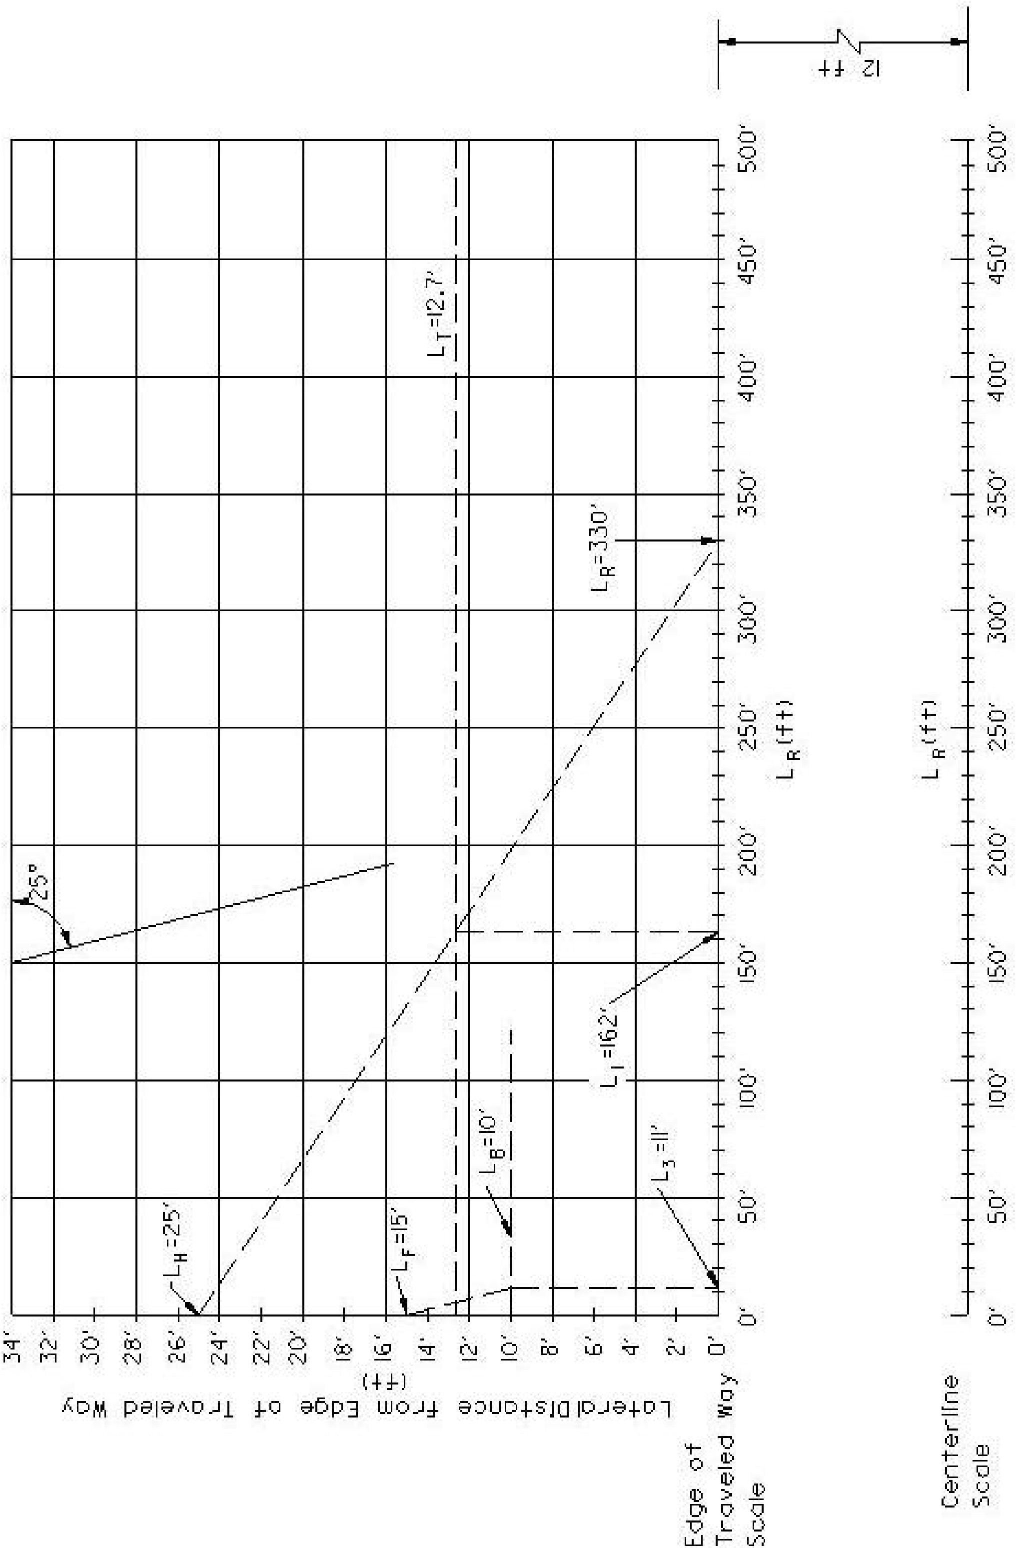
    The pay item quantity of guardrail is (Station 11+37) – Station (9+46) = 191 ft.

    The TBT T2 is from Station 9+46, 22.0 ft left to:

    (Station 9+46) – 12.5 ft = Station 9+33.50, 22.0 ft left.

13. Check that the LON and layout is adequate after all adjustments. By inspection, the design LON matches the LON from the nomograph and plan layout. For the TBT T1, the BLON is at 24.7 ft left of roadway centerline at Station 11+62.00.

    No constraints are shown that would interfere with a gating end of a TBT T1, or adjustment of +/- 12.5 ft of the Station of the TBT T1 location.



BARRIER LENGTH OF NEED CALCULATION
Example 38-6.01(1)

Figure 38-6.H

Example 38-6.01(2) (Two-Way Traffic)

Given: Reconstruction (See Figure 38-6.I)
Two-lane/two-way roadway
Design ADT = 5000 vpd
Design speed = 60 mph
Slope = 1V:4H front slope
Tangent roadway
Lane width = 12 ft
Shoulder width = 8 ft
L_H = 15 ft
L_2 = 10 ft
L_F = 10 ft
Traffic Barrier Terminal Type 1 (TBT T1), Special (Tangent)

Problem: Determine the barrier length of need and plan length of guardrail needed.

Solution: Use the nomograph procedure starting on page 38-6.5 (refer to the nomograph in Figure 38-6.J).

1. Since a TBT T1 (Tangent) terminal is proposed, draw a horizontal line at L_T on the y-axis of the nomograph,

   Where: L_T = 8 + 0.75 = 8.75 ft

   The 0.75 ft is added to the shoulder width to take into account the flare of the guardrail terminal at the third post. The offset from the centerline is thus: 12 +8 + 0.75 = 20.75 ft.

2. From Figure 38-3.A, the clear zone (L_C) is 30 ft and the hazard warrants protection for approaching traffic since $L_F < L_C$. Locate the lesser of L_C or L_H on the y-axis. In this case locate L_H = 15 ft on the y-axis for the travel lane closest to the hazard.

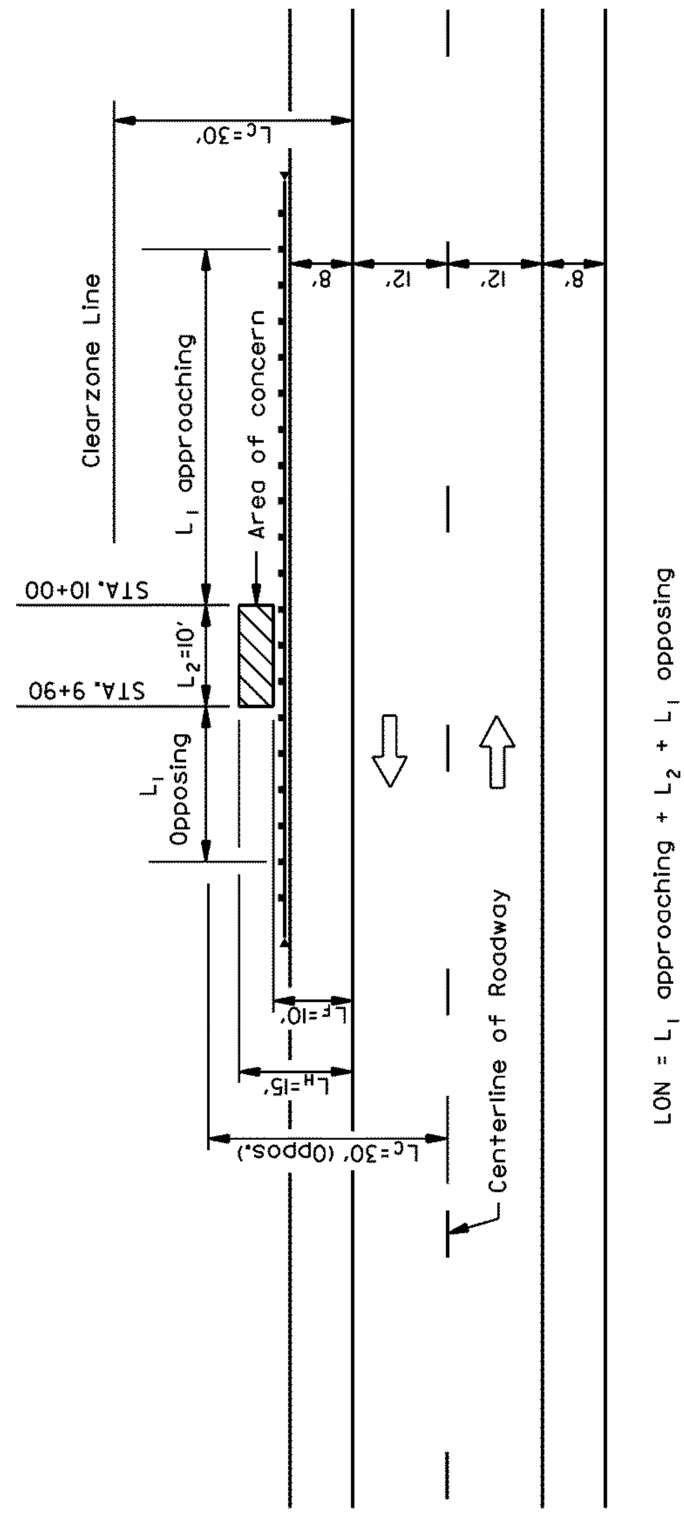
   Add 12 ft, the lane width, to L_F to determine if the hazard is within the clear zone for opposing traffic.

   Since L_F + 12 = 22 ft, and is less than the L_C, guardrail protection is also needed for the opposing direction of traffic at the face of the hazard.

   Similarly, L_H + 12 = 27 ft which is also less than L_C, therefore protection is needed for the full lateral width of the hazard.

3. From Figure 38-6.E, L_R = 250 ft Locate this point on the “Edge of Traveled Way Scale” and the “Center Line Scale”, since protection is required for both directions of travel.

4. Connect the points in Steps 2 and 3. Draw a line for the approaching traffic from the y-axis to the “Edge of Traveled Way Scale” and a line for the opposing traffic from the y-axis to the “Center Line Scale.”



PLAN VIEW
EXAMPLE 38-6.01(2)
Figure 38-6.I

5. From the intersection between the lines from Step 1 and Step 4, draw vertical lines down to the "Edge of Traveled Way Scale" and the "Centerline Scale" to get L_1 for both directions of travel.

6. Read L_1 = 103 ft from the "Edge of Traveled Way Scale" and L_1 = 57 ft from the "Centerline Scale."

7. Skip this step, since protection is warranted from both directions of travel.

8. Calculate the length of need, LON, of guardrail. In this example, barrier protection is needed from both directions. Therefore:

   LON = 103 ft + 10 ft + 57 ft = 170 ft Equation 38-6.2

9. Based on the stationing shown in Figure 38-6.I, the station and offset of the approach end BLON is

   (Station 10+00) + 103 ft = Station 11+03.00, 20.75 ft left.

   The station for the end of opposing traffic is:

   (Station 10+00) – 10 ft – 57 ft = Station 9+33.00, 20.75 ft left.

10. Step 10 does not require any action as no terminals from the *Illinois Highway Standards* are used.

11. Step 11 does not apply as no TBT T2 terminals are being placed.

12. Determine the pay item lengths and plan locations.

    By inspection, placement of the TBT T1 BLON points at the plan locations will satisfy the design length of need. Although some field adjustment using standard panels and specific TBT T1 products will be needed, these adjustments are considered nominal.

    The plan Stations of the TBTs T1 are:

    The selected TBT T1 for this example is 37.5 ft long, and its BLON is at post 3, 12.5 ft from its end.

    BLON is at Station 11+03.00, 20.75 ft left.

    Begin TBT T1 at (Station 11+03) – 25 ft = Station 10+78.00, 20.0 ft left.

    End TBT T1 at (Station 11+03) + 12.5 ft = Station 11+15.50 ft, 20.75 ft left.

    BLON is at Station 9+33.00, 20.75 ft left.

    Begin TBT T1 at (Station 9+33) - 12.5 ft = Station 9+20.50, 20.75 ft left.

    End TBT T1 at (Station 9+33) + 25 ft = Station 9+58.00, 20.0 ft left.

The plan stations for the guardrail pay item are thus:

Station 9+58.00, 20.0 ft left.

To

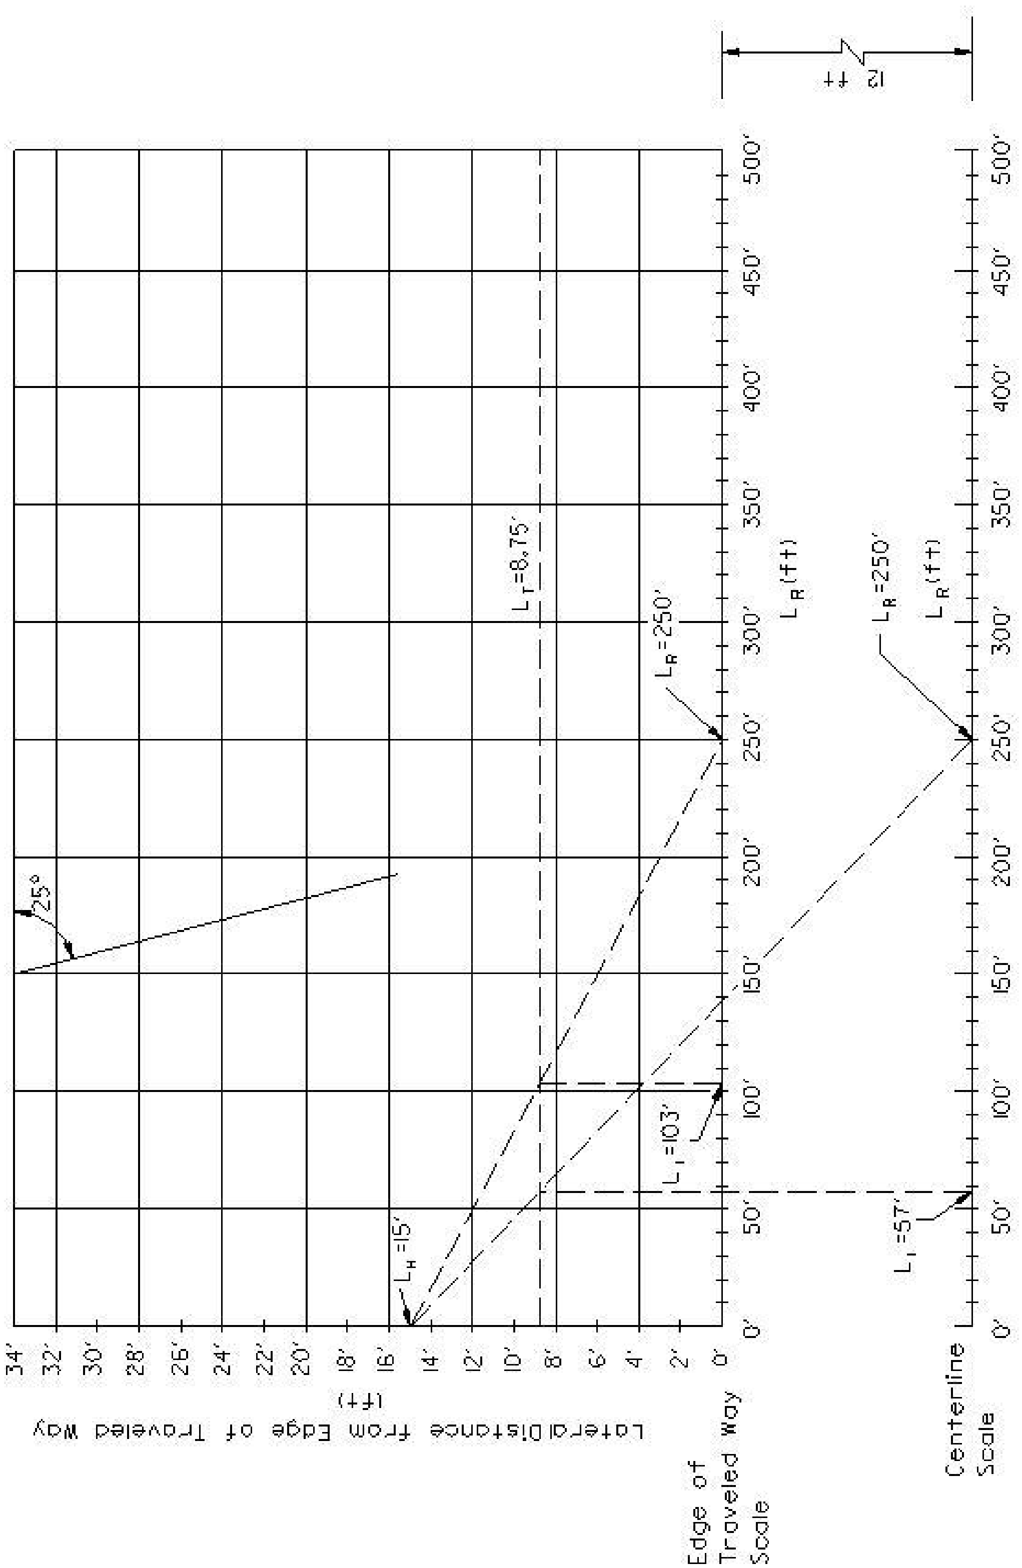
Station 10+78.00, 20.0 ft left.

Quantity of guardrail pay item = (Station 10+78) – (Station 9+58) = 120 ft.

It is not necessary to round to an even number of 12.5 ft guardrail panels because the precise location and dimensions of the TBTs T1 are not known until the contractor selects an item from the QPL.

Special design note. A special design will be needed at the hazard because the space from the face of guardrail (L_B = 8 ft) and the face of the hazard (L_F = 10 ft) is only 2 ft. Because the width of the guardrail system is 21 in., there are only 3 in. between the back of the posts and the face of the hazard for deflection of the guardrail. Per Figure 38-6.V, Type A guardrail requires 38 in. clear width for deflection between the back of the post and the face of the hazard.

Because there is not an acceptable deflection distance between the back of the guardrail posts and the area of concern (hazard), the guardrail needs to transition to a rigid barrier across the width of the hazard. If the nature of the hazard is such that guardrail may be bolted to it, using details similar to the Traffic Barrier Terminal Type 6B, transition the post spacing on both sides of the structure to minimize the consequence of “pocketing”, and carry a continuous barrier across the structure. If the area of concern does not provide a suitable backup for guardrail attachment, then provide a concrete barrier and provide transitions and connections as just described. Job-specific details and special provisions will be needed.



BARRIER LENGTH OF NEED CALCULATION
Example 38-6.01(2)

Figure 38-6.J

Example 38-6.01(3) (Two-Way Traffic — Hazard Beyond Opposing Traffic's Clear Zone)

Given: Reconstruction (See Figure 38-6.K)
Two-lane/two-way roadway
Design ADT = 5000 vpd
Design speed = 60 mph
Slope = 1V:4H front slope
Tangent roadway
Shoulder width = 8 ft
L_H = 23 ft
L_2 = 2 ft (i.e., a point hazard)
L_F = 21 ft
L_B = 8 ft
Traffic Barrier Terminal Type 1, Special (Tangent) (TBT T1)

Problem: Determine the barrier length of need and plan length of guardrail, Type A.

Solution: Use the nomograph procedure starting on page 38-6.5 (refer to the nomograph in Figure 38-6.L).

1. Since a TBT T1 (Tangent) terminal is proposed, draw a horizontal line at L_T on the y-axis of the nomograph,

   Where L_T = 8 + 0.75 = 8.75 ft.

   The 0.75 ft is added to the shoulder width to take into account the flare of the guardrail terminal at the third post. The offset from the centerline is thus: 12 +8 + 0.75 = 20.75 ft.

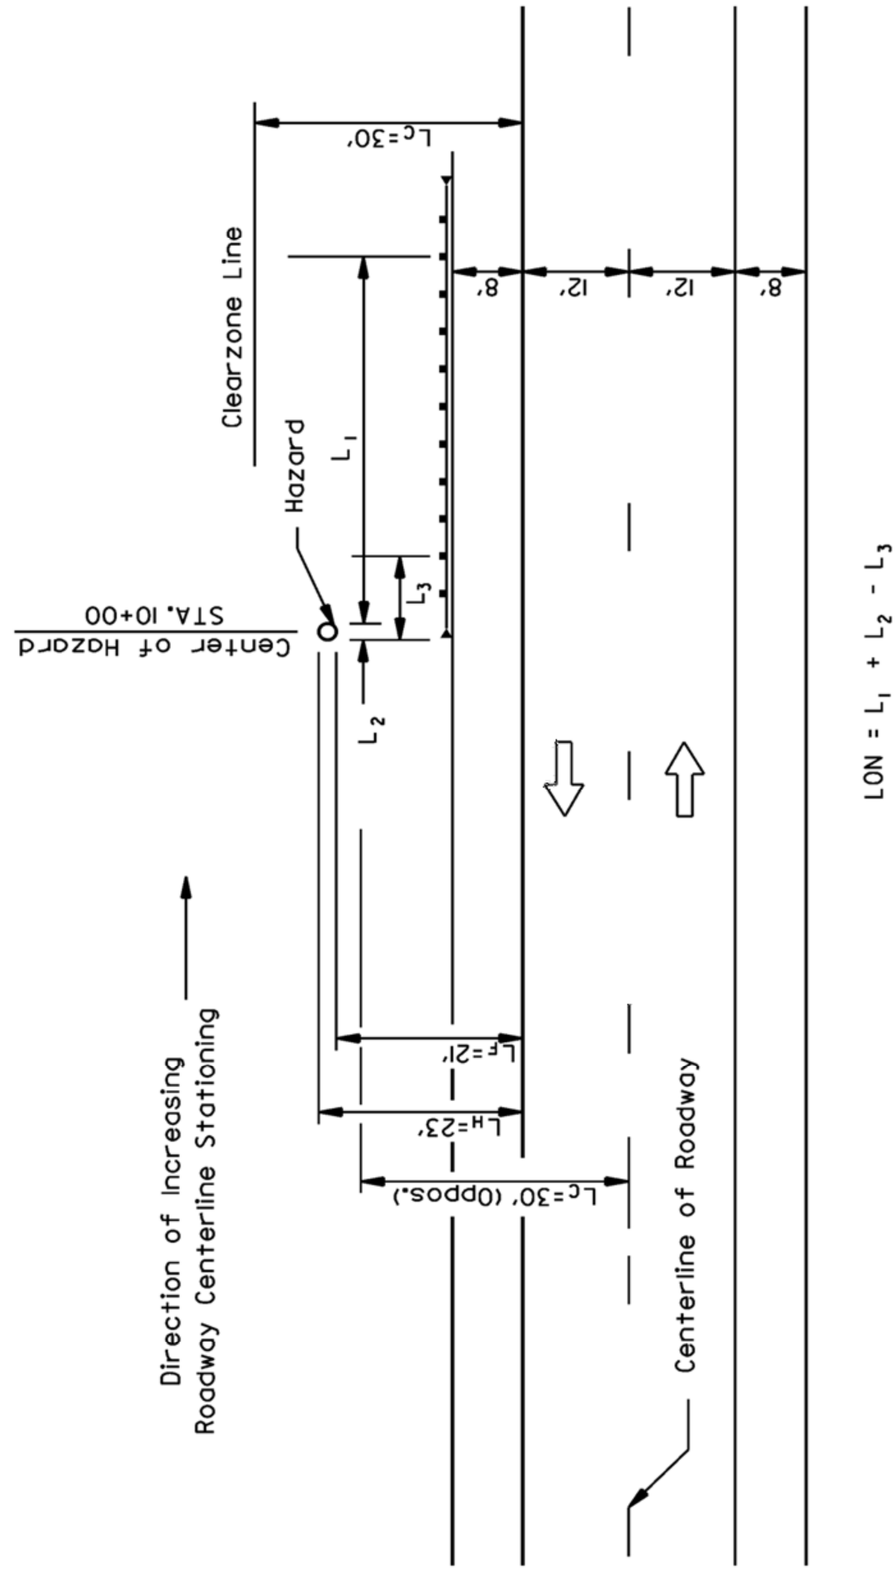
2. From Figure 38-3.A, the clear zone (L_C) is 30 ft and the hazard warrants protection for approaching traffic since $L_F < L_C$. Locate the lesser of L_C or L_H on the y-axis. In this case locate L_H = 23 ft on the y-axis.

   Add 12 ft, the lane width, to L_F to determine if the hazard is within the clear zone for opposing traffic.

   Since L_F + 12 = 33 ft, and is greater than L_C, guardrail protection may not be required for the opposing direction of traffic. Use engineering judgment or follow the guidance in Section 38-3 to determine the need for roadway protection for the opposing direction of traffic.

   Although, for this example, it is assumed guardrail protection from the point hazard for the opposing direction traffic is not required, a crashworthy terminal is needed downstream because of two-way traffic.

3. From Figure 38-6.E, L_R = 250 ft. Locate this point on "Edge of Traveled Way Scale." Since protection is warranted for approaching traffic only, there is no need to locate L_R on the "Centerline Scale."



PLAN VIEW
EXAMPLE 38-6.01(3)
Figure 38-6.K

4. Connect the points in Steps 2 and 3.

5. From the intersection between the lines from Step 1 and Step 4, draw a vertical line down to the "Edge of Traveled Way Scale" To get L_1.

6. Read L_1 = 153 ft from the "Edge of Traveled Way Scale" for approaching traffic.

7. Since barrier protection is only warranted for one direction, perform the following steps to establish L_3, and thus determine the location of the downstream end of the barrier.

   a. Draw a horizontal line L_B. L_B = 8 ft.

   b. Locate L_F = 21 ft on the y-axis.

   c. Draw a line parallel to the 25 degree line from L_F until it intersects the L_B line.

   d. From the intersection between the lines formed from Step 7a and 7c, draw a vertical line down to the "Edge of Traveled Way Scale." Read L_3 = 29 ft.

8. Calculate the length need, LON, of guardrail. In this example barrier protection is needed in one direction of traffic. Therefore:

   LON = 153 + 2 - 29 = 126 ft Equation 38-6.1

9. Based on the stationing shown in Figure 38-6.K, the station and offset of the approach end BLON is:

   (Station 10+00)+ 1 ft + 153 ft = Station 11+54.00, 20.75 ft left.

   The stationing for the opposing traffic's end is:

   (Station 10+00) – 1 ft + 29 ft = Station 10+28.00, 20.75 ft left.

10. Step 10 does not require any action as no terminals from the *Illinois Highway Standards* are used.

11. Step 11 does not apply as no TBT T2 terminals are being placed.

12. Determine the pay item lengths and plan locations.

    By inspection, placement of the TBT T1 BLON points at the plan locations will satisfy the design length of need. Although some field adjustment using standard panels and specific TBT T1 products will be needed, these adjustments are considered nominal.

    The plan Stations of the TBTs T1 are calculated as follows:

    The selected TBT T1 for this example is 37.5 ft long, and its BLON is at post 3, 12.5 ft from its end.

    The BLON is at Station 11+54.00, 20.75 ft left. Therefore:

    Begin TBT T1 at (Station 11+54) - 25 ft = Station 11+29.00, 20.0 ft left.

End TBT T1 at (Station 11+54) + 12.5 ft = Station 11+66.50, 20.75 ft left.

BLON at Station 10+28.00, and 20.75 ft left.

Begin TBT T1 at (10+28) - 12.5 ft = Station 10+15.50, 20.75 ft left.

End TBT T1 at (10+28) + 25 ft = Station 10+53.00, 20.0 ft left.

The plan stations for the guardrail pay item are thus:

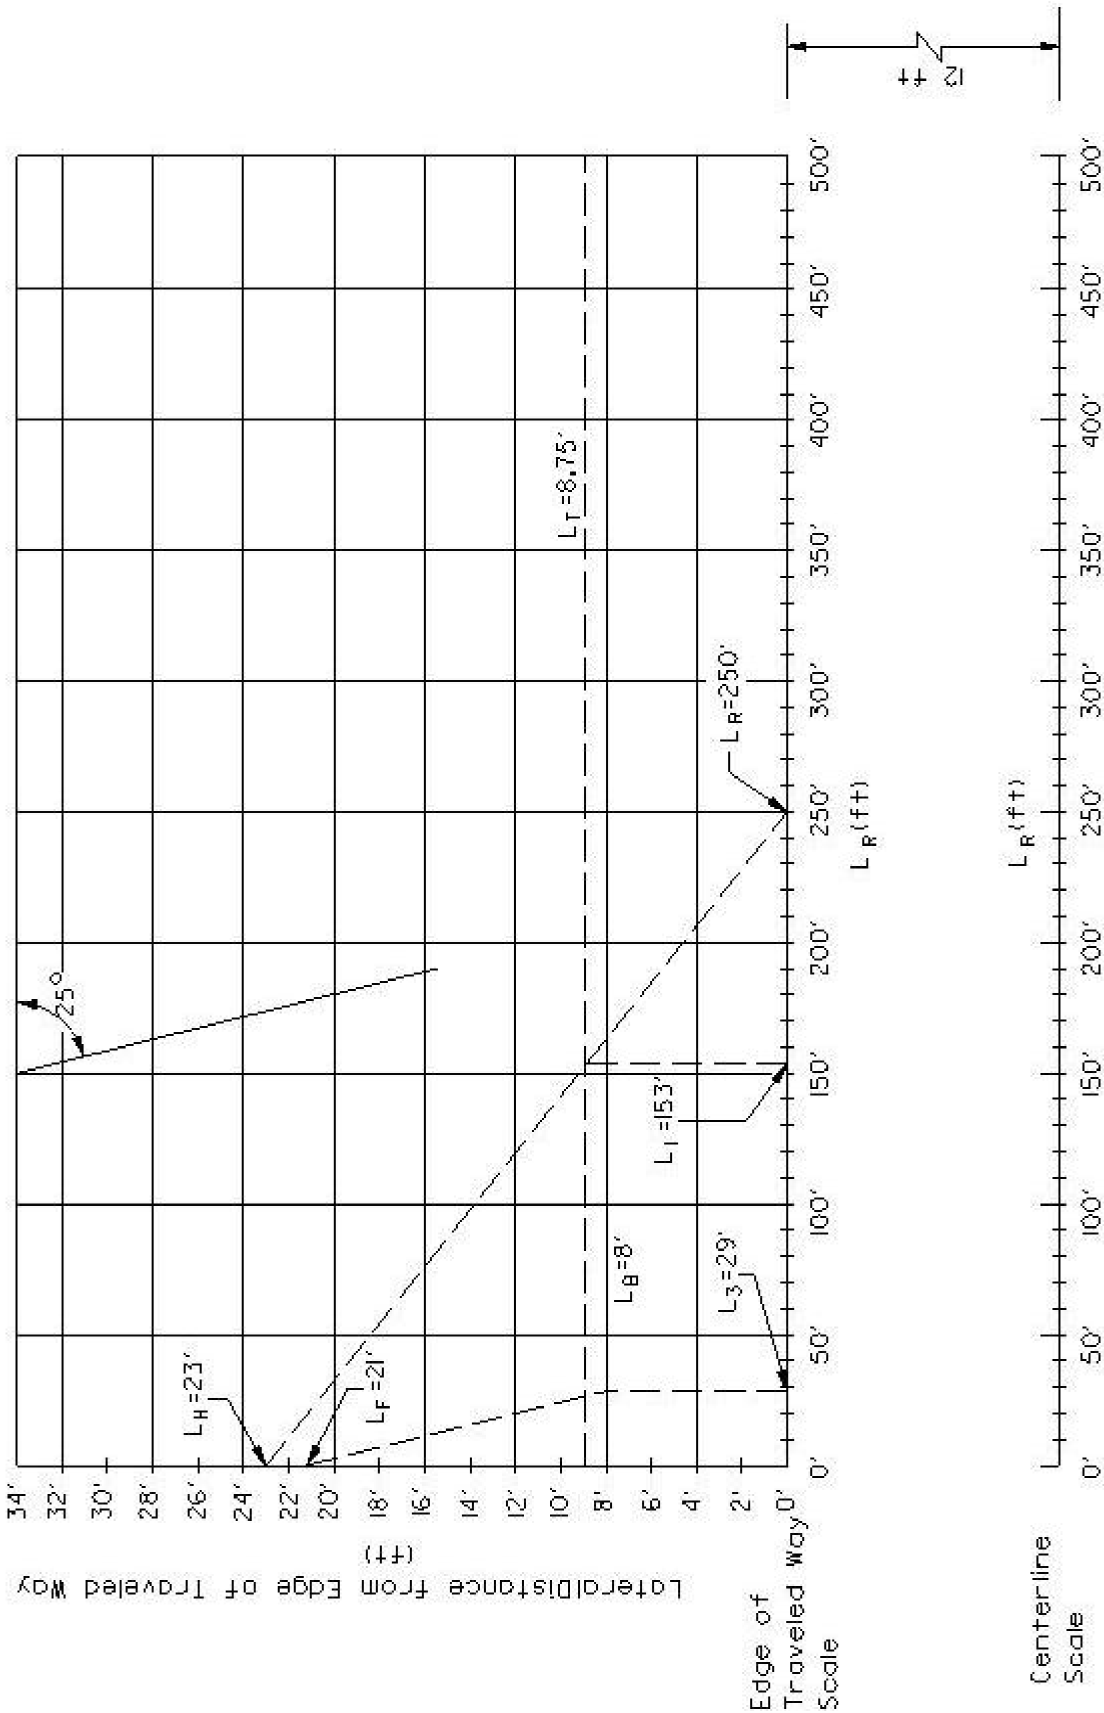
Station 10+53.00, 20.0 ft left.

To

Station 11+29.00, 20.0 ft left.

Quantity of guardrail pay item = (Station 11+29) – (Station 10+53) = 76 ft.

It is not necessary to round to an even number of 12.5 ft guardrail panels because the precise location and dimensions of the TBTs T1 are not known until the contractor selects an item from the QPL.



BARRIER LENGTH OF NEED CALCULATION
Example 38-6.01(3)

Figure 38-6.L

Example 38-6.01(4) (Bridge on Two-Way Two-Lane Highway with Recoverable Front Slope)

Given: New Construction (See Figure 38-6.M)
Two-way, two-lane highway
Design ADT = 5500 vpd
Design speed = 60 mph
Guardrail for shielding of bridge parapet ends and steep slope adjacent to the slope wall
Bridge slope wall = 1V:2H
Typical front slopes = 1V:4H (Assume a front slope of at least 1V:3H prevails to within 100 ft of the bridge, then transitions over 100 ft to match the bridge cone/slopewall).
Tangent roadway
Lane width = 12 ft
Shoulder width = 8 ft
Unflared barrier (steel plate beam guardrail, Type A) located at the edge of the shoulder (L_B = 8 ft)
Traffic Barrier Terminal Type 1 (TBT T1), Special (Flared)

Problem: Determine the location and limits of the hazard, the barrier length of need, and the pay item length of guardrail. This problem assumes a symmetrical layout with the same hazards for traffic approaching at both ends of the bridge.

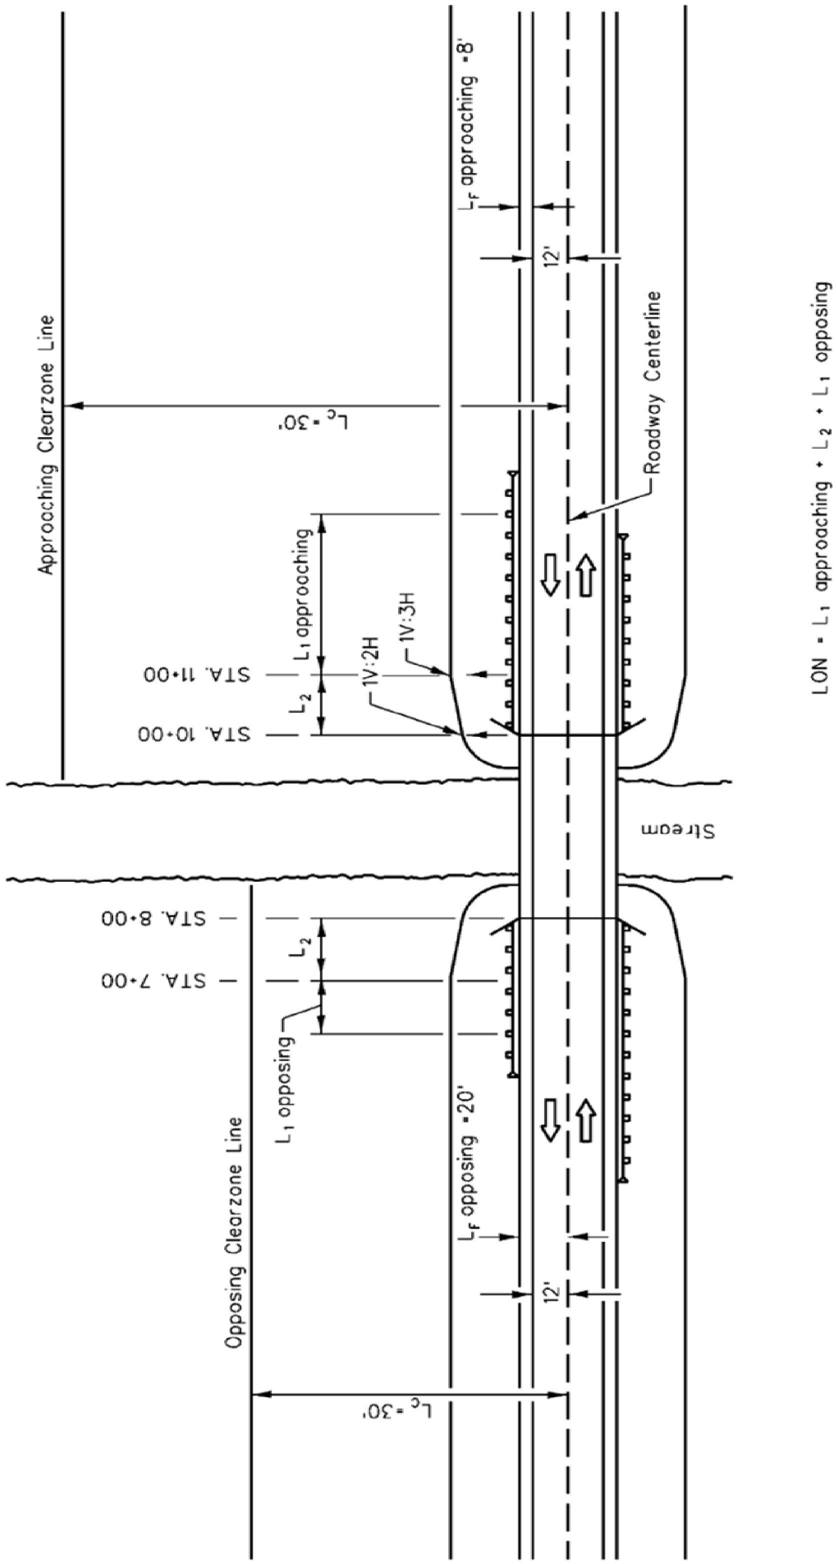
Solution: Approach Side:

The hazards are the 1V:2H slope off the end of the bridge cone, the drop-off to the stream below the bridge, and the transition slope steeper than 1V:3H. For simplicity, it has been previously determined that the location where the slope becomes steeper than 1V:3H is located 100 ft from either side of the bridge. Since the layout is symmetrical, for simplicity, the analysis will be done for one side of the bridge/one direction of travel. Use the nomograph procedure starting on page 38-6.5 (refer to the nomograph in Figure 38-6.N).

1. Since a TBT T1 (Flared) terminal is proposed, draw a horizontal line at L_T on the y-axis of the nomograph for the approach side of the roadway, where:

L_T = 8 ft + 2.7 ft = 10.7 ft

The 2.7 ft is added to the shoulder width to take into account the flare of the guardrail terminal at the third post. The offset from the centerline is thus: 12 + 8 + 2.7 = 22.7 ft.



PLAN VIEW
EXAMPLE 38-6.01(4)
Figure 38-6.M

2. The face of the closest hazards, L_F, the end of the parapet wall and the drop-off below the bridge, is 8 ft from the edge of the traveled way. From Figure 38-3.A, the clear zone (L_C) is 30 ft, thus the hazard warrants protection for the approach side since $L_F < L_C$. Locate the lesser of L_H or L_C on the y-axis. The L_H, defined by the drop-off below the bridge and the end of the bridge embankment cone, extends to the flood plain beyond the clear zone, so plot L_C = 30 ft on the y-axis. This represents the largest offset that is of concern for shielding.

3. From Figure 38-6.E, L_R = 250 ft. Locate this point on the “Edge of Traveled Way Scale.”

4. Connect the points in Steps 2 and 3. Draw a line for the right side of traffic from the y-axis to the “Edge of Traveled Way Scale.”

5. From the intersection between the lines from Step 1 and Step 4, draw vertical lines down to the “Edge of Traveled Way Scale.”

6. Read L_1 = 161 ft from the “Edge of Traveled Way Scale.” Note that assuming the layout is symmetrical, this need be calculated only once, and then mirrored for the other direction of travel.

7. This is a two-way, two-lane roadway and the guardrail is within the clear zone for both directions, so Step 7 does not apply.

8. Calculate the length of need, LON, of guardrail for the approach side.

   Guardrail upstream from the bridge, L_1 protects vehicles from the transition side slope to the bridge cone. Because this is the widest area protected and because the parapet wall and bridge cone are located further downstream for traffic, they are also protected at least to the clear zone. The parapet wall protects vehicles from the bridge drop-off. Thus, for analyzing the approach sides, L_2 starts 100 ft from the end of the parapet wall. The parapet wall is not part of the guardrail LON, thus:

   L_2 = 100 ft

   So, L_1 for the approaching direction on the right side is 161 ft.

   LON = 100 ft + 161 ft = 261 ft Equation 38-6.2

9. Based on the stationing shown in Figure 38-6.M, the stations and offsets of the BLON points are:

   (Station 10+00) + 261 ft = Station 12+61.00, 22.7 ft left.

   Selecting a 37.5 ft TBT T1 from the QPL for this example, and applying the BLON at post 3 (12.5 ft from the end), the plan Stations of the TBT T1 are:

   (Station 12+61) - 25 ft = Station 12+36.00, 20.0 ft left

   To

   (Station 12+61) + 12.5 ft = Station 12+73.50, 22.7 ft left.

10. At each corner of the bridge a TBT T6 will connect to the bridge parapet. As noted from *Highway Standard* 631031, the length of the pay item for the TBT T6 is 37.5 ft and this overlaps the end of the bridge parapet by 7.25 in. (0.6 ft) The distance from the end of the parapet to the end of the TBT T6 pay item is then 36.9 ft.

    The pay item limits for the TBT T6 are:

    (Station 10+00) – 0.6 = Station 9+99.40, 20.0 ft left

    To Station 10+36.90, 20.0 ft left.

11. Step 11 does not apply as no TBTs T2 are being used.

12. Based on the information provided, and by inspection, the BLON points are set to provide adequate length of need for all hazards. The designer should also check the locations of the TBTs T1 to determine if the sites are suitable for the required grading at these terminals and that the typical cross sections stated still prevail at these locations.

13. Determine the plan lengths and stationing for guardrail. Use the stations for the TBTs T1 and TBTs T6 from above to determine the plan quantities and stationing.

    Station 10+36.90, 20.0 ft left to Station 12+36.00, 20.0 ft left = 199.1 ft.

<u>Opposing Side</u>:

The hazards are the 1V:2H slope off the end of the bridge cone, the drop-off to the stream below the bridge, and the transition slope steeper than 1V:3H. For simplicity, it has been previously determined that the location where the slope becomes steeper than 1V:3H is located 100 ft from either side of the bridge. Since the layout is symmetrical, and for simplicity, the analysis will be done for one side of the bridge/one direction of travel. Use the nomograph procedure starting on page 38-6.5 (refer to the nomograph in Figure 38-6.N).

1. Since a TBT T1 (Flared) terminal is proposed, draw a horizontal line at L_T on the y-axis of the nomograph for the opposing side of the structure, where:

    L_T = 8 ft + 2.7 ft = 10.7 ft

    The 2.7 ft is added to the shoulder width to take into account the flare of the guardrail terminal at the third post. The offset from the centerline is thus: 12 +8 + 2.7 = 22.7 ft.

2. Add 12 ft, the lane width to L_F to determine if the hazard is within the clear zone for an opposing departure. Since L_F + Lane width = 12 + 8 = 20 ft, is less than L_C, protection is also needed from hazards on the left side of the roadway. L_C is less than L_H, so plot L_C = 30 ft from the centerline scale on the y-axis for the left side of the roadway. In this case a distance 30 ft from the road centerline scale falls at 18 ft from the edge of travelled way scale.

3. From Figure 38-6.E, L_R = 250 ft. Locate this point on the “Center Line Scale.”

4. Connect the points in Steps 2 and 3. Draw a line for the left side departure of traffic from the y-axis to the “Center Line Scale.”

5. From the intersection between the lines from Step 1 and Step 4, draw a vertical line down to the “Center Line Scale.”

6. Read L_1 = 61 ft from the “Center Line Scale” Note that assuming the layout is symmetrical, this need be calculated only once, and then mirrored for the other side of the bridge.

7. This is a two-lane, two-way roadway and the guardrail is within the clear zone for both directions, so Step 7 does not apply.

8. Calculate the length of need, LON, of guardrail for the opposing side.

   Guardrail upstream from the bridge, L_1 protects vehicles from the transition side slope and bridge cone. Because this is the widest area protected and because the parapet wall and bridge cone are located further upstream, they are also protected to at least the clear zone. The parapet wall protects vehicles from the bridge drop-off. Thus, for analyzing the right side, L_1 starts 100 ft from the end of the parapet wall. The parapet wall is not part of the guardrail LON, thus:

   L_2 = 100 ft

   And, L_1 for the opposing direction is 61 ft.

   So, LON = 100 ft + 61 ft = 161 ft. Equation 38-6.2

9. Based on the stationing shown in Figure 38-6.M, the stations and offsets of the BLON points are:

   (Station 8+00) - 161 ft = Station 6+39.00, 22.7 ft left.

   Using a 37.5 ft TBT T1 from the QPL ,for this example, and applying the BLON at post 3 (12.5 ft from the end), the plan Stations of the TBT T1 are:

   (Station 6+39) – 12.5 ft = Station 6+26.50, 22.7 ft left.

   To

   (Station 6+39) + 25 ft = Station 6+64.00, 20.0 ft left.

10. At each corner of the bridge a TBT T6 will connect to the bridge parapet. The length of the pay item for the TBT T6 is 37.5 ft and this overlaps the end of the bridge parapet by 7.25 in. (0.6 ft). The distance from the end of the parapet to the end of the TBT T6 pay item is then 36.9 ft.

    The pay item limits of the TBT T6 for the opposing approach to the bridge are:

    Station 8+00.60, 20.0 ft left.

    To

Station 7+63.10, 20.0 ft left.

11. Step 11 does not apply as no TBTs T2 are being used.

12. Based on the information provided and by inspection the BLON points are set to provide adequate length of need for all hazards. The designer should also check the locations of the TBT T1s to determine if the sites are suitable for the required grading at these terminals and that the typical cross sections stated still prevail at these locations.

13. Determine the plan lengths and stationing for guardrail. Use the stations for the TBTs T1 and TBTs T6 from above to determine the plan quantities and stationing.

Station 6+64.00, 20.0 ft left to Station 7+63.10, 20.0 ft left = 99.1 ft.

Discussion: This example illustrates compliance with nominal clear zone requirements. However, engineering judgment may apply for application of clear zones. Suppose the vertical drop of the bridge cones to the flood plain is 20 ft. Also note that the discussion of clear zones in Section 38-3.01(2) states: "If a formidable obstacle lies just beyond the clear zone, it may be appropriate to remove or shield the obstacle if costs are reasonable."

The guardrail as designed protects against vehicles traversing it as far as the 30 ft clear zone. However, this leaves another 5 ft vertically (10 ft horizontally) unshielded. Note also that except for the transition slope in the last 100 ft approaching the bridge, the roadside slopes are traversable and a vehicle running out behind the guardrail might reach the transition area with some speed remaining and still some drop to the flood plain.

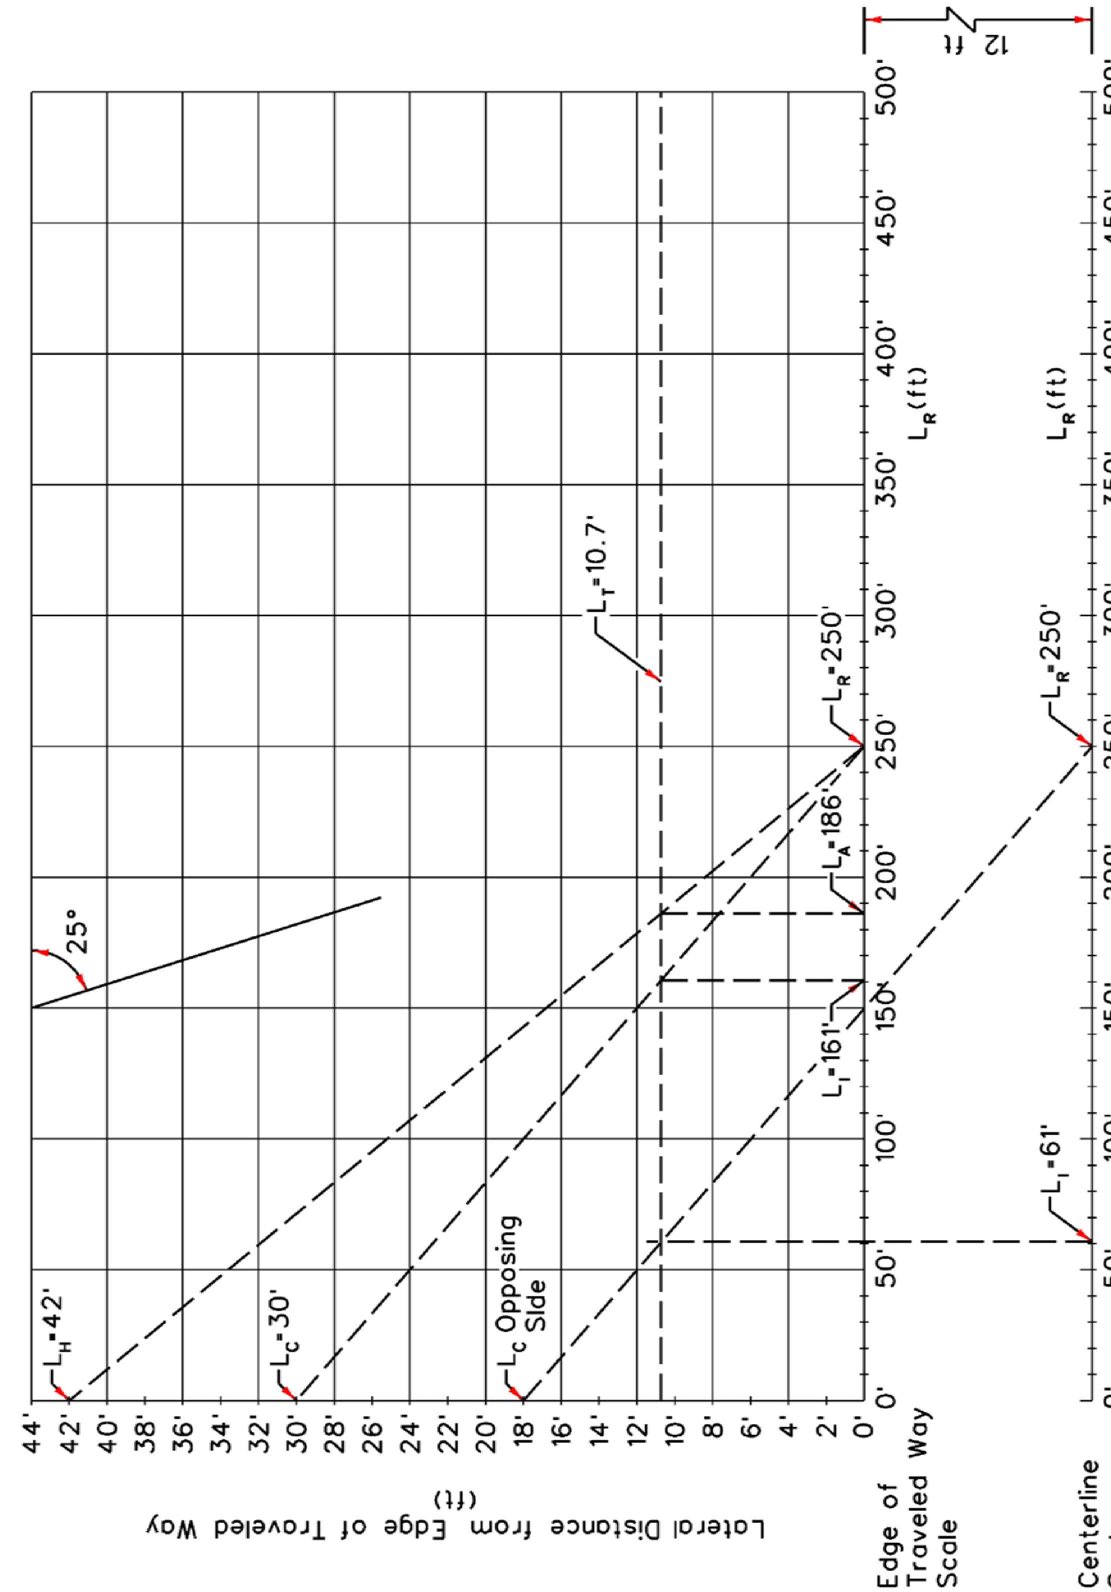
How much additional guardrail would be needed to shield against roadway departures to the toe of the bridge cones?

The bridge cone begins about 2 ft beyond the shoulder and then extends horizontally about 40 ft to the flood plain. For the approach side roadway departure, extend the vertical axis and plot a point at 42 ft, the total width of the bridge cone hazard, L_H. See Figure 38- 6.N.

Connect this point to the runout length point (250 ft) on the "Edge of Traveled Way Scale."

Connect these two points and draw a vertical line where they cross L_T = 10.7 ft and find that this intersects the "Edge of Traveled Way Scale" at 186 ft.

Therefore, in this case, the length of need in advance of the bridge (L_A), 186 ft, needed to shield the full bridge cone is less than the total length of need to shield the slope transition area (261 ft) and this concern is resolved.



BARRIER LENGTH OF NEED CALCULATION
Example 38-6.01(4)

Figure 38-6.N

Example 38-6.01(5) (Bridge on Two-Way Two-Lane Highway with Non-recoverable Front Slope)

Given: New Construction (See Figure 38-6.O)
Two-way, two-lane highway
Design ADT = 7000 vpd
Design speed = 60 mph
Guardrail for shielding of bridge parapet ends and steep slope adjacent to the slope wall
Bridge slope wall = 1V:2H
Typical front slopes = 1V:3H
Tangent roadway
Lane width = 12 ft
Shoulder width = 8 ft
Unflared barrier (steel plate beam guardrail, Type A) located at the edge of the shoulder (L_B = 8 ft)
Traffic Barrier Terminal Type 1 (TBT T1), Special (Flared)

Problem: Determine the location and limits of the hazard, the barrier length of need, and the pay item length of guardrail. This problem assumes a symmetrical layout with the same hazards for traffic approaching at both ends of the bridge.

Solution: Approach Side:

The hazards are the 1V:2H slope off the end of the bridge cone, the drop-off below the bridge, and the transition slope steeper than 1V:3H. For simplicity, it has been previously determined that the location where the slope becomes steeper than 1V:3H is located 100 ft from either side of the bridge. Since the layout is symmetrical, and for simplicity, the analysis will be done for one side of the bridge. First, complete the non-recoverable front slope procedure. See Section 38-3.03(b) to determine the recommended clear zone distance. Then use the nomograph procedure starting on page 38-6.5 (refer to the nomograph in Figure 38-6.P).

Non-Recoverable Front Slope Procedure

1. Determine the clear zone for a 1V:6H or flatter slope for the design speed and traffic volume given above. From Figure 38-3.A, the standard clear zone value for this case is 30 ft to 32 ft.

2. To determine the clear runout area beyond the toe of the front slope, subtract the shoulder width or the distance from the edge of the travelled way to the shoulder hinge point from the distance in Step 1. For this example, the shoulder width is 8 ft and the bridge cone begins about 2 ft beyond the shoulder and then extends horizontally about 40 ft to the flood plain. At minimum, the recommended clear distance beyond the toe of the non-recoverable slope (1V:3H) is:

30 ft minus 22 ft, which yields 8 ft.

3. The clear runout area beyond the toe of the front slope is the greater distance of the value determined in Step 2 (8 ft) or 10 ft. Thus for this example the clear zone, L_c, extends 10 ft beyond the toe of the front slope, which is 40 ft from the hinge point. Utilizing this more conservative value of 10 ft yields a recommended clear zone for approaching traffic of 8 ft + 2 ft + 40 ft + 10 ft = 60 ft.

Length of Need Procedure

1. Since a TBT T1 (Flared) terminal is proposed, draw a horizontal line at L_T on the y-axis of the nomograph for the approach side of the roadway, where:

   L_T = 8 ft + 2.7 ft = 10.7 ft

   The 2.7 ft is added to the shoulder width to take into account the flare of the guardrail terminal at the third post. The offset from the centerline is thus: 12 + 8 + 2.7 = 22.7 ft.

2. The face of the closest hazards, L_F, the end of the parapet wall and the drop-off below the bridge, is 8 ft from the edge of the traveled way. From the discussion above, the clear zone (L_C) is 60 ft, thus the hazard warrants protection for the approach side since $L_F < L_C$.

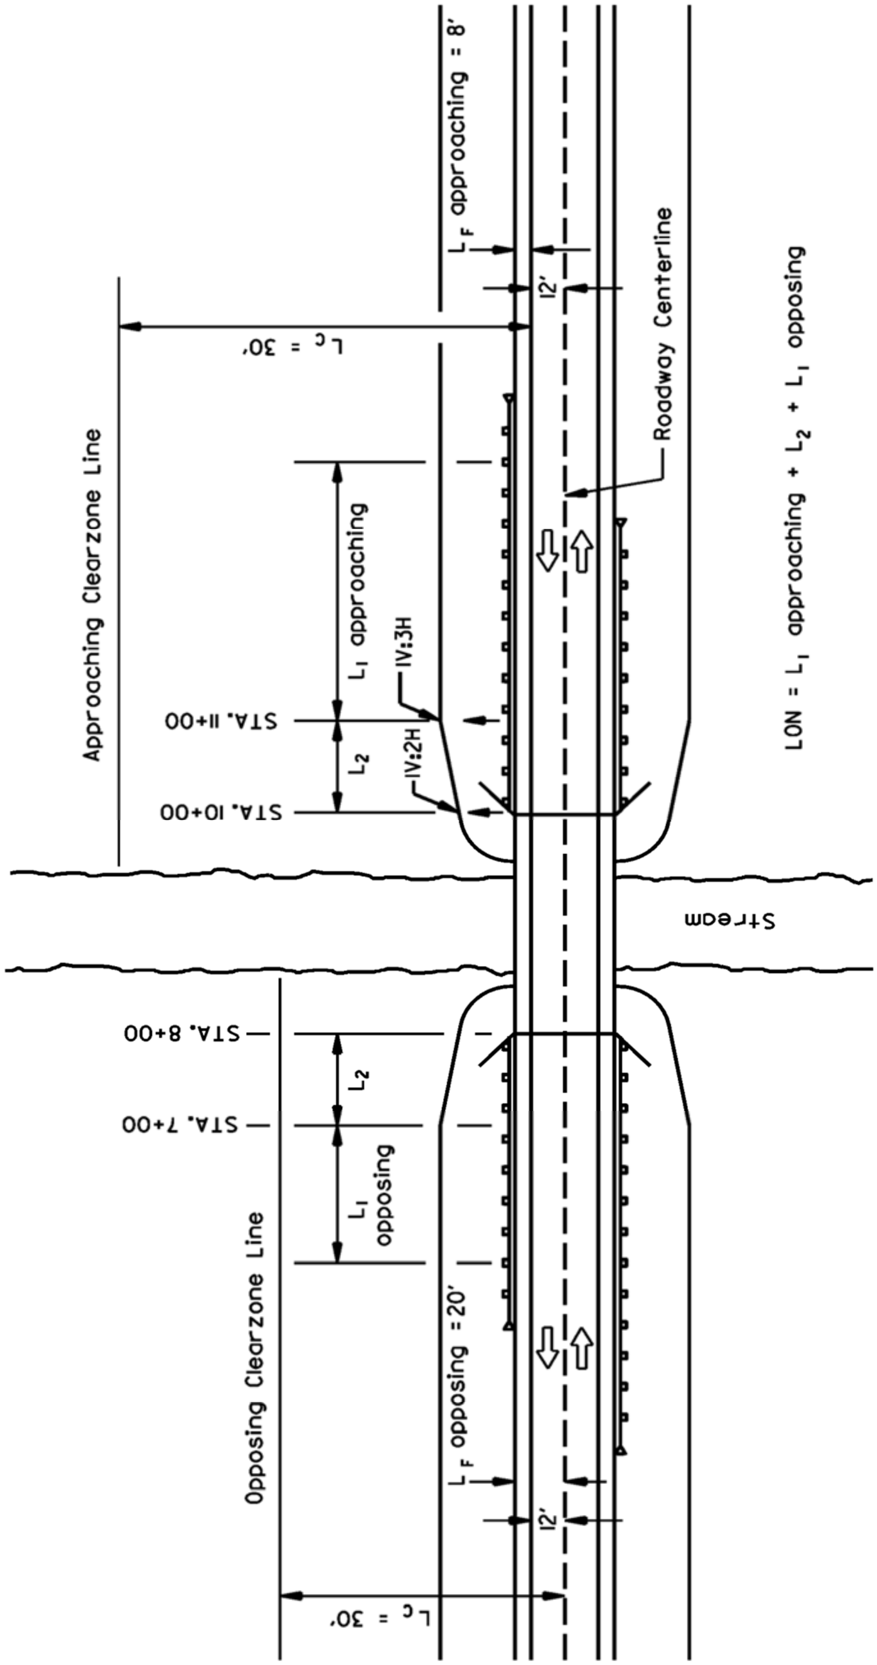
3. Locate the lesser of L_H or L_C on the y-axis. The L_H, defined by the drop-off below the bridge and the end of the bridge embankment cone, extends to the flood plain beyond the clear zone, so plot L_C = 60 ft on the y-axis. This represents the largest offset that is of concern for shielding. From Figure 38-6.E, L_R = 250 ft. Locate this point on the “Edge of Traveled Way Scale.”

4. Connect the points in Steps 2 and 3. Draw a line for the right side of traffic from the y-axis to the “Edge of Traveled Way Scale.”

5. From the intersection between the lines from Step 1 and Step 4, draw vertical lines down to the “Edge of Traveled Way Scale.”

6. Read L_1 = 205 ft from the “Edge of Traveled Way Scale.” Note that assuming the layout is symmetrical, this need be calculated only once, and then mirrored for the other direction of travel.

7. This is a two-way, two-lane roadway and the guardrail is within the clear zone for both directions, so Step 7 does not apply.



PLAN VIEW
EXAMPLE 38-6.01(5)

Figure 38-6.O

8. Calculate the length of need, LON, of guardrail for the approach side.

   Guardrail upstream from the bridge, L_1, protects vehicles from the transition side slope to the bridge cone. Because this is the widest area protected and because the parapet wall and bridge cone are located further downstream for traffic, they are also protected

   at least to the clear zone. The parapet wall protects vehicles from the bridge drop-off. Thus for analyzing the approach sides, L_2 starts 100 ft from the end of the parapet wall. The parapet wall is not part of the guardrail LON, thus:

   L_2 = 100 ft

   So, L_1 for the approaching direction on the right side is 205 ft.

   LON = 100 ft + 205 ft = 305 ft Equation 38-6.2

9. Based on the stationing shown in Figure 38-6.O, the stations and offsets of the BLON points are:

   (Station 10+00) + 305 ft = Station 13+05.00, 22.7 ft left.

   Selecting a 37.5 ft TBT T1 from the QPL for this example, and applying the BLON at post 3 (12.5 ft from the end), the plan Stations of the TBT T1 are:

   (Station 13+05) - 25 ft = Station 12+80.00, 20.0 ft left

   To

   (Station 13+05) + 12.5 ft = Station 13+17.50, 22.7 ft left.

10. At each corner of the bridge a TBT T6 will connect to the bridge parapet. As noted from *Highway Standard* 631031, the length of the pay item for the TBT T6 is 37.5 ft and this overlaps the end of the bridge parapet by 7.25 in. (0.6 ft). The distance from the end of the parapet to the end of the TBT T6 pay item is then 36.9 ft.

    The pay item limits for the TBT T6 are:

    (Station 10+00) – 0.6 = Station 9+99.40, 20.0 ft left

    To Station 10+36.90, 20.0 ft left.

11. Step 11 does not apply as no TBTs T2 are being used.

12. Based on the information provided, and by inspection, the BLON points are set to provide adequate length of need for all hazards. The designer should also check the locations of the TBTs T1 to determine if the sites are suitable for the required grading at these terminals and that the typical cross sections stated still prevail at these locations.

13. Determine the plan lengths and stationing for guardrail. Use the stations for the TBTs T1 and TBTs T6 from above to determine the plan quantities and stationing.

    Station 10+36.90, 20.0 ft left to Station 12+80.00, 20.0 ft left = 243.1 ft.

Opposing Side:

The hazards are the 1V:2H slope off the end of the bridge cone, the drop-off below the bridge, and the transition slope steeper than 1V:3H. For simplicity, it has been previously determined that the location where the slope becomes steeper than 1V:3H is located 100 ft from either side of the bridge. Since the layout is symmetrical, and for simplicity, the analysis will be done for one side of the bridge/one direction of travel. Use the nomograph procedure starting on page 38-6.5 (refer to the nomograph in Figure 38-6.P).

1. Since a TBT T1 (Flared) terminal is proposed, draw a horizontal line at L_T on the y-axis of the nomograph for the opposing side of the roadway, where:

   L_T = 8 ft + 2.7 ft = 10.7 ft

   The 2.7 ft is added to the shoulder width to take into account the flare of the guardrail terminal at the third post. The offset from the centerline is thus: 12 + 8 + 2.7 = 22.7 ft.

2. Add 12 ft, the lane width to L_F to determine if the hazard is within the clear zone for an opposing departure. Since L_F + Lane width = 12 + 8 + 2 = 22 ft, is less than L_C, protection is also needed from hazards on the left side of the roadway, opposing side. L_C is less than L_H, so plot the enhanced L_C = 60 ft on the y-axis and note that this falls 72 ft from the centerline scale.

3. From Figure 38-6.E, L_R = 250 ft. Locate this point on the “Center Line Scale”.

4. Connect the points in Steps 2 and 3. Draw a line for the left side departure of traffic from the y-axis to the “Center Line Scale.”

5. From the intersection between the lines from Step 1 and Step 4, draw a vertical line down to the “Center Line Scale.”

6. Read L_1 = 171 ft from the “Center Line Scale” Note that assuming the layout is symmetrical, this need be calculated only once, and then mirrored for the other side of the bridge.

7. This is a two-lane, two-way roadway and the guardrail is within the clear zone for both directions, so Step 7 does not apply.

8. Calculate the length of need, LON, of guardrail for the opposing side.

   Guardrail upstream from the bridge, L_1 protects vehicles from the transition side slope and bridge cone. Because this is the widest area protected and because the parapet wall and bridge cone are located further upstream, they are also protected to at least the clear zone. The parapet wall protects vehicles from the bridge drop-off. Thus for analyzing the right side, L_1 starts 100 ft from the end of the parapet wall. The parapet wall is not part of the guardrail LON, thus:

L_2 = 100 ft

And, L_1 for the opposing direction is 171 ft.

So, LON = 100 ft + 171 ft = 271 ft Equation 38-6.2

9. Based on the stationing shown in Figure 38-6.O, the stations and offsets of the BLON points are:

   (Station 8+00) - 271 ft = Station 5+29.00, 22.7 ft left.

   Using a 37.5 ft TBT T1 from the QPL, for this example, and applying the BLON at post 3 (12.5 ft from the end), the plan Stations of the TBT T1 are:

   (Station 5+29) – 12.5 ft = Station 5+16.50, 22.7 ft left.

   To

   (Station 5+29) + 25 ft = Station 5+54.00, 20.0 ft left.

10. At each corner of the bridge a TBT T6 will connect to the bridge parapet. The length of the pay item for the TBT T6 is 37.5 ft and this overlaps the end of the bridge parapet by 7.25 in. (0.6 ft). The distance from the end of the parapet to the end of the TBT T6 pay item is then 36.9 ft.

    The pay item limits of the TBT T6 for the opposing departure approaching the bridge are:

    Station 8+00.60, 20.0 ft left.

    To

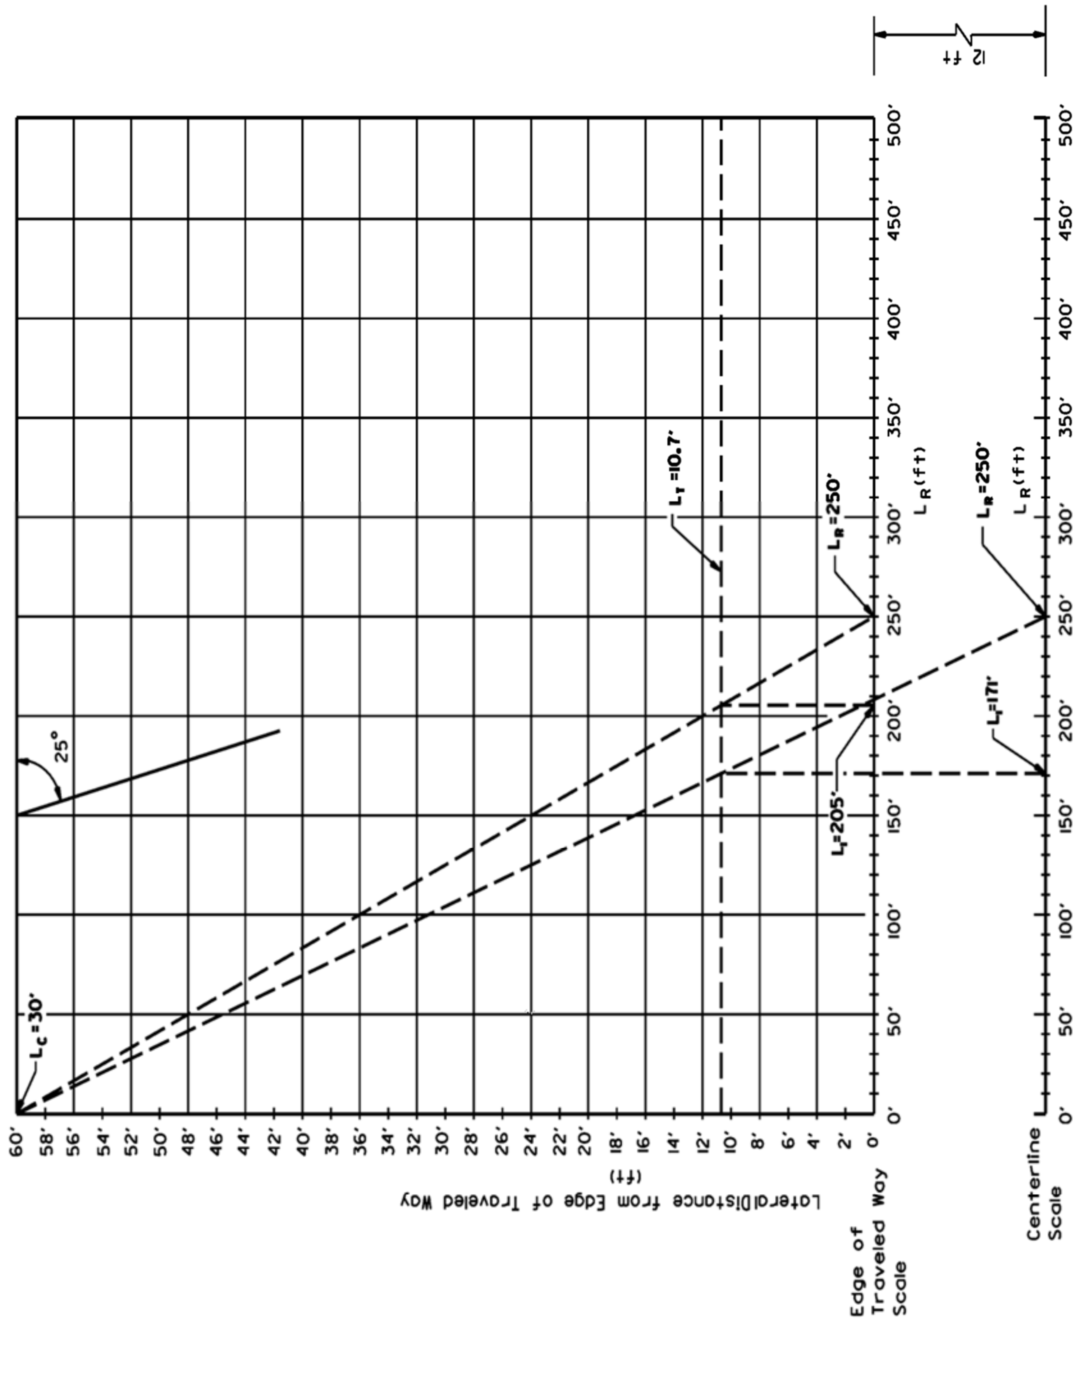
    Station 7+63.10, 20.0 ft left.

11. Step 11 does not apply as no TBTs T2 are being used.

12. Based on the information provided and by inspection the BLON points are set to provide adequate length of need for all hazards. The designer should also check the locations of the TBT T1s to determine if the sites are suitable for the required grading at these terminals and that the typical cross sections stated still prevail at these locations.

13. Determine the plan lengths and stationing for guardrail. Use the stations for the TBTs T1 and TBTs T6 from above to determine the plan quantities and stationing.

    Station 5+54.00, 20.0 ft left to Station 7+63.10, 20.0 ft left = 209.1 ft.



BARRIER LENTGH OF NEED CALCULATION EXAMPLE 38-6.01(5)

Figure 38-6.P

Example 38-6.01(6) (Divided Four-lane Freeway with 64 ft Median between Dual Structures)

Given: Reconstruction (See Figure 38-6.Q)
Divided four-lane freeway with 64 ft median between dual structures
Design ADT = 20,000 vpd
Design speed = 75 mph
Tangent roadway
Lane width = 12 ft
Shoulder width (right) = 10 ft
Shoulder width (left) = 6 ft
Unflared barrier (steel plate beam guardrail, Type A) located along the right edge of the shoulder (L_B = 10 ft).
Traffic Barrier Terminal Type 1, Special (Flared) (TBT T1) on right side of the shoulder
Traffic Barrier Type 6 at each bridge parapet end
Flared (1:20) barrier (steel plate beam guardrail, Type A) with a Traffic Barrier Terminal Type 1, Special on the median side of the roadway

Side slopes on the right edge of roadway:

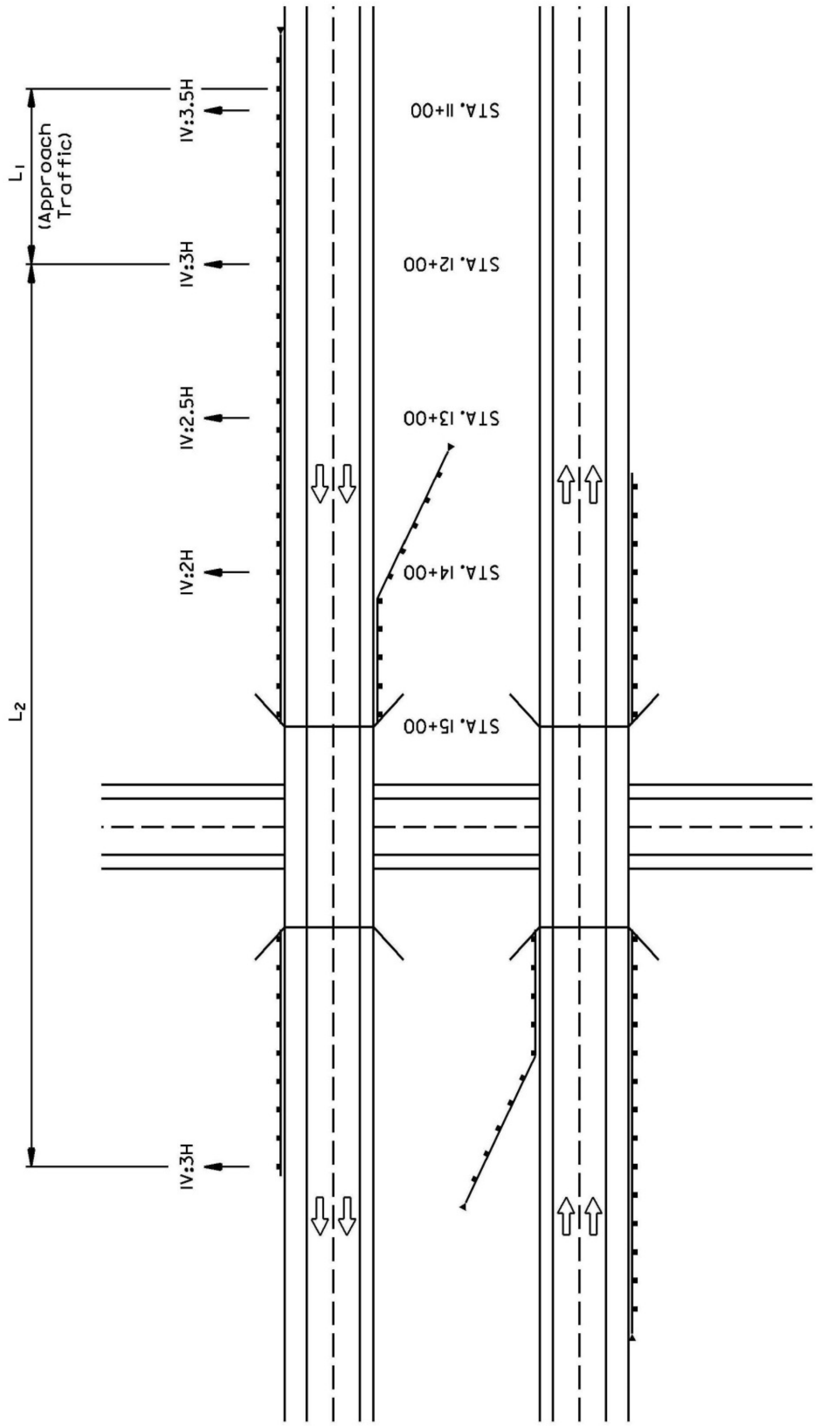
Station	Front Slope*	Height
Project limit to 11+00	1V:4H	10 ft
11+00 to 12+00	1V:3.5H	12 ft
12+00 to 13+00	1V:3H	15 ft
13+00 to 14+00	1V:2.5H	18 ft
14+00 to 15+00	1V:2H	20 ft

Beginning of bridge parapet at Station 15+00.

*Front slope begins at 14 ft from the edge of pavement to allow for 2 ft of embankment behind the guardrail posts. (10 ft shoulder, 2 ft guardrail width, and 2 ft additional embankment width for guardrail post support.)

Problem: Determine the barrier length of need and length of guardrail pay item for the roadside guardrail on the right side and on the median side.

Solution: Guardrail is needed on the approach of the right side of the roadway for shielding from the front slope steeper than 1V:3H,and the bridge cone, on the approach for the median side of the roadway for the gap between the dual structures in the median, and on the approach for both sides of the roadway due to the highway beneath. Each side of the roadway must be analyzed independently. This problem will only analyze the roadway approaching the bridge and not any of the roadway past the bridge. Use the nomograph procedure starting on page 38-6.5 (refer to the nomographs in Figure 38-6.R and Figure 38-6.S).



PLAN VIEWW
EXAMPLE 38-6.01(6)
Figure 38-6.Q

Length of Need – Right Side

1. Since a TBT T1 (Flared) terminal is proposed on the right side, draw a horizontal line at L_T on the nomograph for the right side of the roadway, where:

   L_T = 10 ft + 2.7 ft = 12.7 ft

   The 2.7 ft is added to the shoulder width to take into account the flare of the guardrail terminal at the third post. The offset from the centerline is thus: ½(64) + 24 + 10 + 2.7 = 68.7 ft.

2. From Figure 38-3.A, the clear zone (L_C) is 30 ft and the hazard warrants protection for traffic on the right side approach since L_F (10 ft) < L_C. Locate the lesser of L_C or L_H on the y-axis. L_H, defined by front slope and bridge embankment cones, begins longitudinally at the station of the critical slope (Sta. 12+00) and extends laterally to the flood plain beyond the clear zone, so plot L_C = 30 ft on the y-axis.

3. From Figure 38-6.E, L_R = 360 ft. Locate this point on the “Edge of Traveled Way Scale.” The two directions of travel are separated by a 64 ft median, so the separate roadways can be analyzed independently for roadside hazards as two one-way roadways. There is no need to locate L_R on the “Centerline Scale.” Protection is needed on the left side of the roadway for traffic approaching the bridge, however. This is addressed below.

4. Connect the points in Steps 2 and 3. Draw a line for the traffic on the right from the y-axis to the “Edge of Traveled Way Scale.”

5. From the intersection between the lines from Step 1 and Step 4, draw vertical lines down to the “Edge of Traveled Way Scale” to get L_1.

6. Read L_1 = 207 ft from the “Edge of Traveled Way Scale.”

7. This step determines L_3, for situations where barrier protection is only warranted for one direction of traffic. L_3 determines the amount of barrier protection that may be deducted due to the lateral location of the hazard. Although this design would result in an L_3 analysis, L_3 is on the downstream end of the bridge, thus an analysis is beyond the scope of this problem and therefore not needed.

8. Calculate the length of need, LON, of guardrail. The length of need due to the critical side slope, or L_1, is 207 ft upstream of Station 12+00. The L_2 distance is made up of a combination of lengths. L_2 is the length of guardrail from Sta. 12+00 to the parapet wall end at Sta. 15+00, includes the parapet wall across the bridge, and includes the guardrail downstream of the bridge end, therefore:

   LON = 207 + 300 + 0 + 0 = 507 ft Equation 38-6.2

   Since the scope of this problem is only to calculate the amount of Steel Plate Beam Guardrail upstream from the bridge end, and not the guardrail downstream from the bridge or length of the concrete parapet wall representing part of L_2, the length of the parapet wall and guardrail downstream from the bridge end are both set equal to 0.

9. Based on the stationing shown in Figure 38-6.Q, the station and offset of the approach end BLON is:

   (Station 15+00) -507 ft = Station 9+93, 68.7 ft right.

   Limits of the TBT T1, using a length of 37.5 ft and the BLON point at post 3,

   12.5 ft from the end of the TBT T1.

   (Station 9+93) + 25 ft = Station 10+18.00, 66.0 ft right.

   To

   (Station 9+93) – 12.5 ft = Station 9+80.50, 68.7 ft right.

10. At each corner of the bridges a TBT T6 will connect to the bridge parapet. The length of the pay item for the TBT T6 is 37.5 ft and this overlaps the end of the bridge parapet by 7.25 in. (0.6 ft). The distance from the end of the parapet to the end of the TBT T6 pay item is then 36.9 ft.

    The pay item limits for the TBT T6 are:

    (Station 15+00) + 0.6 ft = Station 15+00.60, 66.0 ft right.

    To

    (Station 15+00.6) - 37.5 ft = Station 14+63.10, 66.0 ft right.

11. Step 11 does not apply, as no TBT T2s are being used.

12. Determine the pay item quantity and stations for the remaining item(s).

    The guardrail run will connect the TBT T6 and the TBT T1.

    From

    End of TBT T6 = Station 14+63.10, 66.0 ft right.

    To

    End of TBT T1 = Station 10+18.00, 66.0 ft right.

    Length of guardrail plan quantity = 445.1 ft.

13. Check that LON is adequate and check for conflicts.

    Sum the redirective portion of the TBT T1, the TBT T6, and the guardrail.

    25 ft + 36.9 ft + 445.1 ft = 507 ft.

    This is as expected because the nominal BLON point has been used without adjustment. Because the actual dimensions of the TBT T1 are not known until construction, use this information for plan locations and quantities. Field adjustments to accommodate a specific proprietary device and common guardrail panel lengths are considered nominal.

    The designer should also check the location of the TBTs T1 to assure that they can be installed with proper grading and that design assumptions for the front slopes or other roadside obstacles are valid.

Length of Need – Median (left) side (Use a new nomograph for the median side of the roadway from that used for the right side of the roadway)

1. With the left side having a flared barrier and a TBT Type 6, which offers protection from the bridge parapet end, multiple considerations are required for the guardrail run. The TBT Type 6 is not designed to be flared, therefore it is located at the back of shoulder. Draw a horizontal line at L_B, equal to 36.9 ft long, for the length of the TBT Type 6 on the nomograph for the left side of the roadway, where:

   L_B = 6 ft on the y-axis

   From 36.9 ft the steel plate beam guardrail, Type A flares at a ratio of 1 lateral: 20 longitudinal. Draw a line on the nomograph with a 1:20 flare starting at 36.9 feet. The TBT T1, Special is to be placed in line with the guardrail flare, therefore do not show any additional offset or flaring for the TBT T1, Special.

2. From Figure 38-3.A, the clear zone (L_C) is 30 ft. The hazards are the bridge parapet end at 6 feet and the gap between the dual structures that can lead onto the highway below. The left side of the roadway warrants protection for approaching traffic since $L_F < L_C$. Locate the lesser of L_C or L_H on the y-axis, so plot L_C = 30 ft on the y-axis.

3. From Figure 38-6.E, L_R = 360 ft. Locate this point on "Edge of Traveled Way Scale." Since the approaching and opposing roadways are on separate alignment, this problem resembles a one-way alignment, and there is no need to locate L_R on the "Centerline Scale."

4. Draw a line connecting the points plotted in steps 2 and 3.

5. From the intersection between the lines from Step 1 and Step 4, draw vertical line down to the "Edge of Traveled Way Scale" to get L_1.

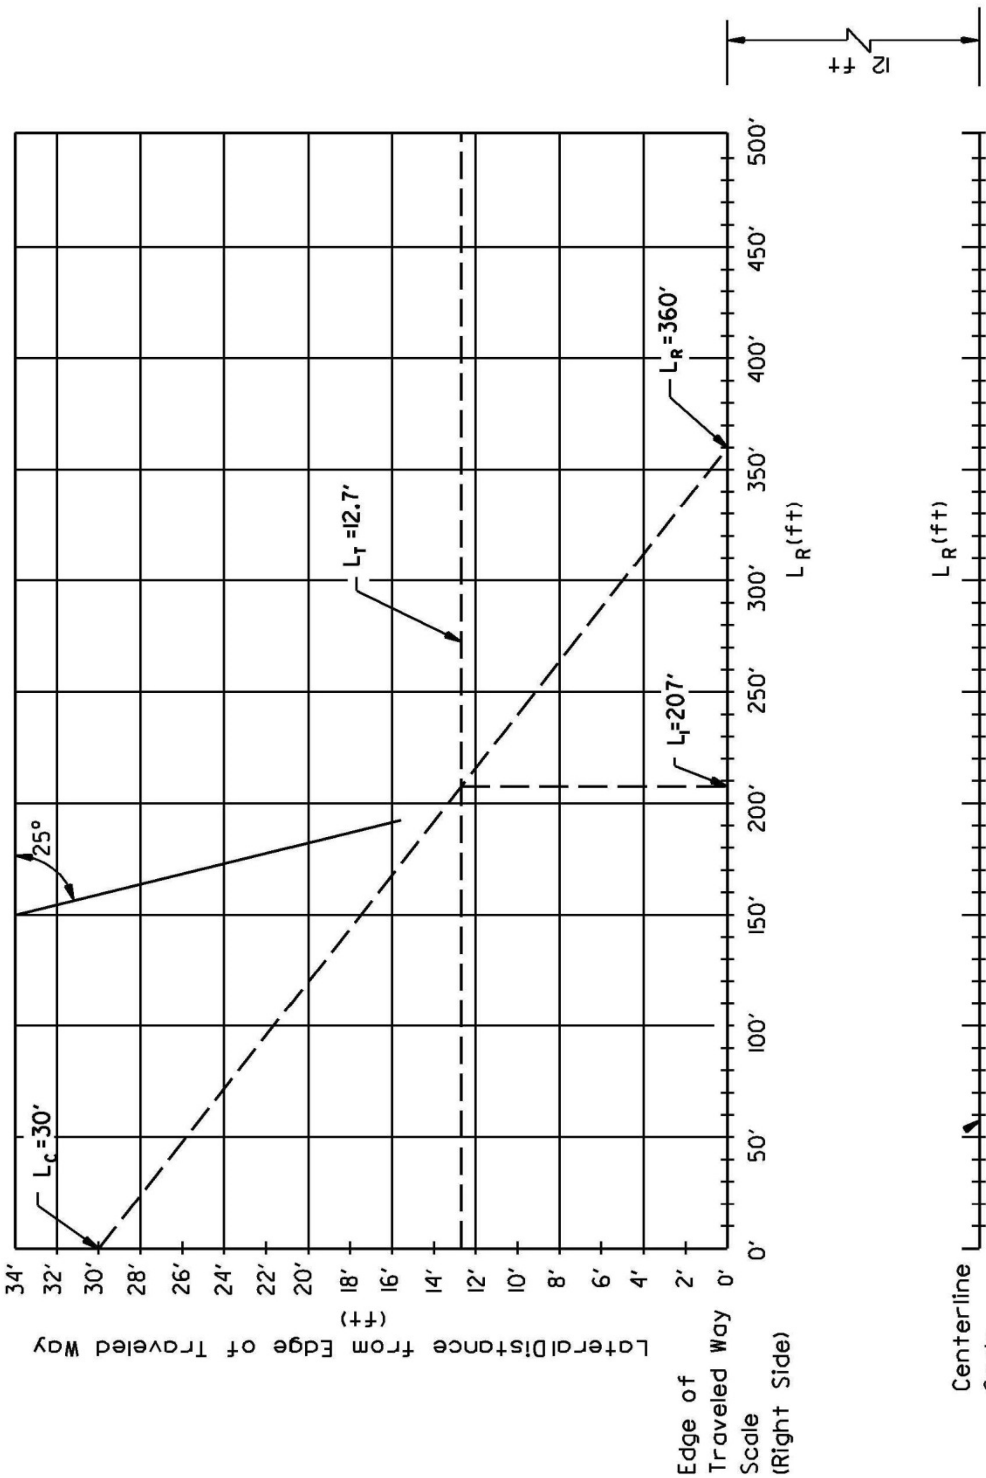
6. Read L_1 = 194 ft from the "Edge of Traveled Way Scale"

7. This step determines L_3, for situations where barrier protection is only warranted for one direction of traffic. L_3 determines the amount of barrier protection that may be deducted due to the lateral location of the hazard. Although this design would result in an L_3 analysis, L_3 is on the downstream end of the bridge, thus an analysis is beyond the scope of this problem and not needed.

8. Calculate the length need, LON, of guardrail.

   LON = 194 + (length of the concrete parapet wall) - 0 = 194 ft Equation 38-6.1

   Since the scope of this problem is only to calculate the amount of Steel Plate Beam Guardrail upstream from the bridge end, and not the guardrail downstream from the



BARRIER LENGTH OF NEED CALCULATION
Example 38-6.01(6)

Figure 38-6.R

bridge or length of the concrete parapet wall representing part of L_2, the length of the parapet wall and guardrail downstream from the bridge end is set equal to 0.

9. Based on the stationing shown in Figure 38-6.Q, the station and offset of the BLON for the median side barrier is:

    (Station 15+00) – 194 ft = Station 13+06.00.

    The guardrail is flared at 1:20 beyond (Station 15+00)-36.9 ft = Station 14+63.10

    The additional offset is [(Station 14+63.1) - Station 13+06)]/20 = 7.9 ft.

    The total offset from the edge of pavement is 7.9 ft taper + 6 ft shoulder = 13.9 ft.

    The edge of pavement is located at 32.0 ft right.

    The BLON is located at Station 13+06.00, 18.1 ft right.

    No length corrections are made for the 1:20 flare because field adjustments of pay item lengths will be needed, and the adjustment factor would be only 1.00125.

    The pay item limits for the TBT T1, assuming a 37.5 ft long device from the QPL and assuming that the BLON of the device is at post 3, 12.5 ft from its end:

        (Station 13+06) + 25 ft = Station 13+31.00, 19.35 ft right.

    To

        (Station 13+06 – 12.5 ft = Station 12+93.50, 17.48 ft right.

        With 18.1 ft + (25/20) = 19.35 ft, and

        19.35 ft - (37.5/20) = 17.48 ft.

10. At each corner of the bridges a TBT T6 will connect to the bridge parapet. The length of the pay item for the TBT T6 is 37.5 ft and this overlaps the end of the bridge parapet by 7.25 in. (0.6 ft). The distance from the end of the parapet to the end of the TBT T6 pay item is then 36.9 ft.

    The pay item limits for the TBT T6 are:

        (Station 15+00) + 0.6 ft = Station 15+00.60, 32.0 ft right.

    To

        (Station 15+00.6) - 37.5 ft = Station 14+63.10, 32.0 ft right.

11. Step 11 does not apply, as no TBTs T2 are being used.

12. Determine the pay item limits and quantities for the remaining items.

Guardrail will connect from the TBT T6 to the TBT T1.

Station 14+63.10, 32.0 ft right

To

Station 13+31.00, 19.35 ft right

Length of guardrail = 132.1 ft

13. Check that the LON is adequate.

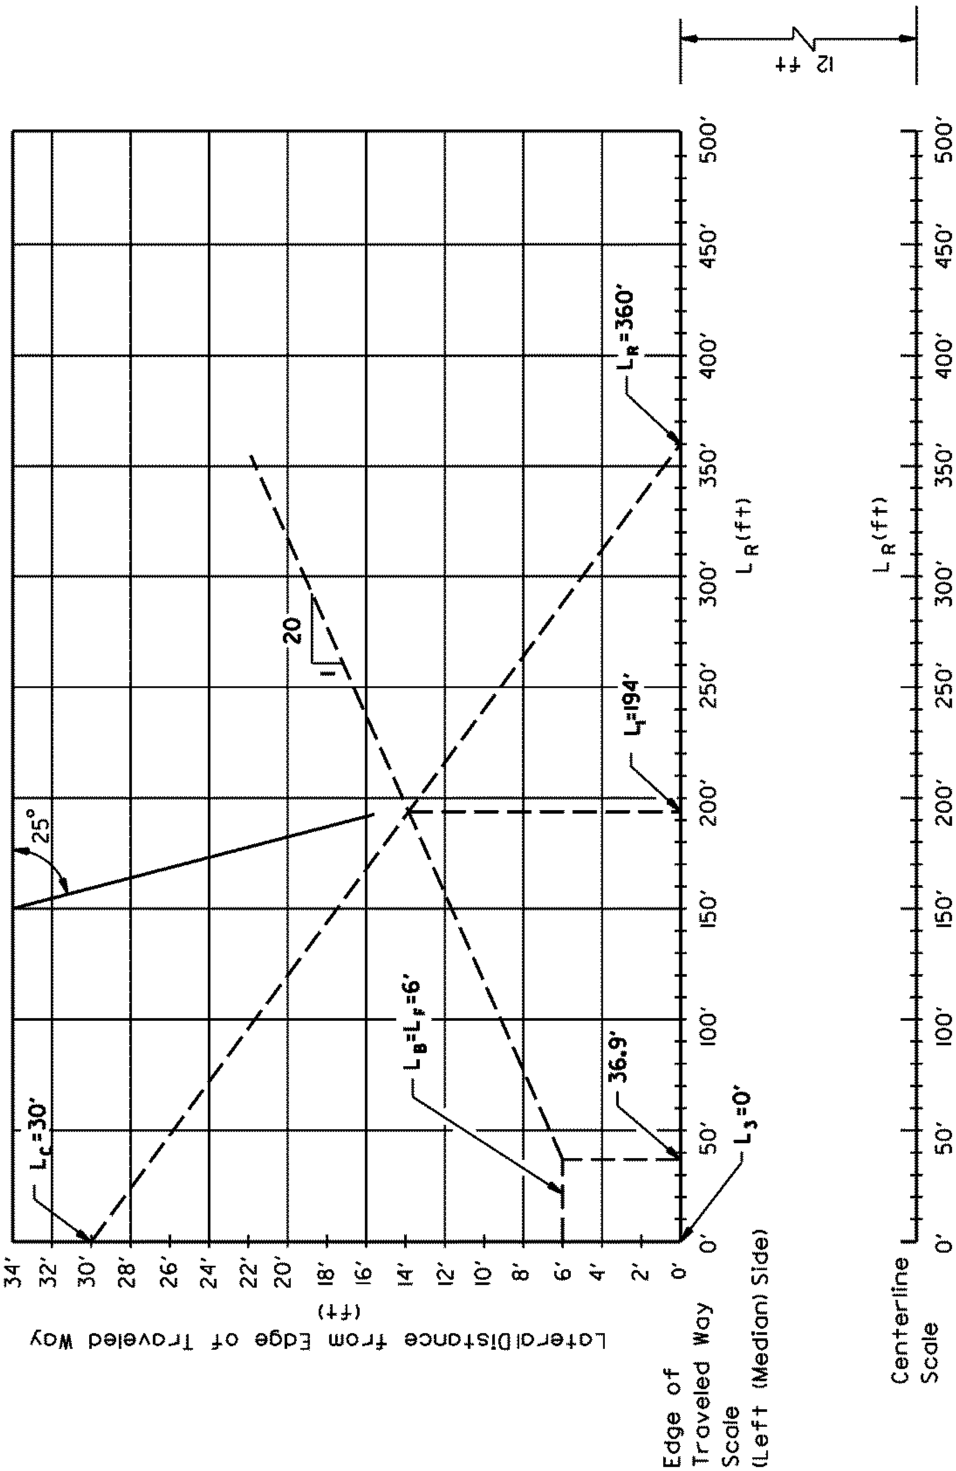
TBT T6 = 36.9 ft

Guardrail = 132.1 ft

TBT T1 = 25 ft

Total = 194 ft

As expected, placing the BLON at the design length of need point results in a design that exactly matches the calculated length of need. Minor field adjustments will account for the specific proprietary device selected for the TBT T1 and for use of common guardrail panel lengths and splice locations.



BARRIER LENGTH OF NEED CALCULATION
Example 38-6.01(6)

Figure 38-6.S

38-6.02 Guardrail Post Foundations

Design and testing of strong post guardrail are generally done using strong soils. The systems allow the posts to rotate in the soil such that vehicle impact loads are distributed through the post into the soil material, avoiding bending or breaking of the posts. With the Midwest Guardrail System, this movement of the post along with the 12 in. (300 mm) blockout also keeps the rail near its design height until the rail releases from the blockout. If posts bend or break due to excessive foundation strength, they can provide excessive resistance to movement of the rail, resulting in failure of the rail. Also, the bent posts can become launching ramps to an errant vehicle.

The following are general guidance on use of guardrail with a full range of foundation types:

1. Guardrail Posts in Soil. *Highway Standard* 630001 shows the application of guardrail posts in soil. Where the front slope falls within 2 ft (600 mm) behind the guardrail posts and is steeper than 1V:3H use 9 ft (2.74 m) posts. Otherwise use the 6 ft (1.83 m) posts.

2. Guardrail Posts in Mow Strips [≤ 8 in. (200 mm) thick]. *Highway Standard* 630001 shows the provisions needed to allow guardrail posts to function when placed in a stabilized surface no thicker than 8 in. (200 mm). The “leave out” or backfilled cored hole for the post is designed to allow the post to deflect and absorb a portion of the impact energy before the rail releases from the deflected post. Also, allowing the post to rotate in the soil is critical to avoid both over-stressing of the rail element and excessive vehicle uplift along a bending post. The capping material for the post deflection space is intended as a weed suppression layer, and is intentionally weak to allow the post to break through when hit. Although the minimum dimensions for the deflection space are shown, wider “leave outs” may be used if this reduces crash damage to the shoulder or mow strip.

3. Guardrail Posts in Rock or in Paved Areas >8 in. (200 mm) Thick. Where rock is encountered, or where the depth of a paved area exceeds 8 in. (200 mm), the detail “Footing for Post When Impervious Material is Encountered” (from *Highway Standard* 630001) should be applied. For paved locations, the “V” value shown is the thickness of the paved material at the post location. Where no rock or other impervious material is encountered below the paved area, the post should not be shortened.

38-6.03 Barrier Offset and Grading

Generally, roadside hardware should be placed as far as practical from the edge of traveled way consistent with proper operation and performance of the barrier system. Such placement gives an errant motorist a greater chance to regain control and avoid a crash. It also provides for increased sight distance. Consider the following when determining barrier lateral placement:

1. Driver Expectations. It is generally desirable to have consistent clearance between traffic and roadside features such as bridge railings, parapets, retaining walls, and roadside barriers, particularly in urban areas where there is a preponderance of these elements. Uniform development enhances highway safety by providing the driver with a level of

expectation, thus reducing driver concern, and perceived need for altering their driving path within the lane.

2. Shoulder. Typically, the roadside barrier is located with the face of barrier at the edge of the shoulder unless flared away from the shoulder. In areas with SPBG this will result in the hinge point for the front slope being located approximately 4 ft (1.2 m) from the outside edge of shoulder to provide proper backfilling to the posts. Refer to Standard 630001.

3. Shy Line. The distance from the edge of the traveled way beyond which a roadside object will not be perceived as an obstacle and result in a motorist's reducing speed or changing vehicle position on the roadway is called the shy-line offset. (See Figure 38-6.T). Where possible, barriers should be placed beyond the shy line. This is more important for short, isolated instances. For long, continuous runs of barrier this is less important, especially if the barrier is introduced outside the shy line and gradually tapered in toward the traveled way.

4. Embankment. Where possible, provide 2 ft (600 mm) of embankment at a 1:10 or flatter slope between the back of guardrail barrier posts to the hinge point with the front slope. See *Highway Standard* 630001 for options.

5. Deflection Distance. Most roadside barriers will deflect when impacted. Adequate deflection space should be provided so that guardrail can deflect without contacting fixed objects behind the barrier as displayed in Figure 38-6.U. Figure 38-6.V provides the deflection distances for the types of guardrail typically used by IDOT. Refer to Section 38-7.03(b)3 for a discussion on the deflection distance of high-tension cable.

6. Zone of Intrusion. The Zone of Intrusion (ZOI) is the region measured above and behind the face of a barrier system where an impacting vehicle or any major part of the system may extend during an impact. The amount of intrusion behind the barrier is related to the barrier height and profile as well as the vehicle size, speed, and angle of impact. For TL-2, TL-3 and TL-4 where practical, the designer should try to accommodate this additional distance behind the barrier as part of new construction or reconstruction projects. Figure 38-6.W shows the ZOI for TL-2, TL-3 and TL-4 for a typical concrete barrier wall section. No ZOI is currently available for TL-5. Narrowing of the roadway is not preferred on high-speed facilities to accommodate additional clearance for ZOI. For example, at an existing overpass structure where the pavement underneath is being reconstructed, it is usually not recommended to reduce shoulder width in order to gain additional clearance behind the barrier to provide ZOI clearance.

Customary		Metric	
Design Speed (mph)	Shy Line Offset, S (ft)	Design Speed (km/hr)	Shy Line Offset, S (m)

SELECTED ZONE of INTRUSION VALUES

Figure 38-6.W

38-6.04 Barrier Flare

A roadside barrier is considered flared when it is not parallel to the edge of the traveled way. Barrier flare has advantages and disadvantages. Flaring moves the barrier further from the traveled way where it is less likely to be hit, it helps to reduce the length of need and amount of barrier needed, it can improve sight distance, and it can serve to introduce a barrier from outside the shy zone into the shy zone. However, flared barrier increases the quantities of earthwork, and results in increased angles of impact.

At the point where tangent guardrail meets flared guardrail, a 12.5 ft (3.81 m) section of guardrail is normally installed on a slight curve by adjusting the posts back a small distance at the transition. This creates a smoother transition and makes the guardrail easier to construct at this point.

Cable barrier for shielding roadside hazards is normally installed parallel to the roadway, with no flare. In special situations where flare is needed with cable barrier, use a 1:50 flare rate.

Figure 38-6.X presents the maximum recommended flare rates as a function of roadside safety, design speed, and barrier type. Flatter flare rates may be used, and can still be very effective in reducing length. Where a barrier approaches or crosses the shy line with approaching traffic, flatter flare rates based on “inside shy line” values should be considered.

Design Speed		Flare Rate for Barrier Inside Shy Line*	Flare Rate for Barrier Beyond Shy Line*		
(mph)	(km/hr)		Rigid (Concrete)	Semi-Rigid (W-Beam)	Flexible (Cable)
70	110	1:30	1:20	1:15	1:50
60	100	1:26	1:18	1:14	1:50
55	90	1:24	1:16	1:12	1:50
50	80	1:21	1:14	1:11	1:50
45	70	1:18	1:12	1:10	1:50
40	60	1:16	1:10	1:8	1:50
30	50	1:13	1:8	1:7	1:50

**See Figure 38-6.T for shy line distances.*

Note: Non-blocked guardrail is not to be flared.

MAXIMUM FLARE RATES FOR BARRIER DESIGN

Figure 38-6.X

38-6.05 Terrain

Crash testing and acceptance of roadside safety hardware is based on test conditions with the impacting vehicle rolling on all four wheels, and at normal ride height when it impacts the device or feature. Vehicles traversing curbs, slopes, or changes in slopes may arrive at a roadside device sliding, spinning, or above or below normal ride height. This can result in unfavorable crash results. Roadside terrain needs to be considered in roadside safety design to achieve a more forgiving roadside.

1. Curbs. When practical, avoid combining a curb and guardrail when using the Midwest Guardrail System (MGS) and blockouts. Where a curb up to 6 in. (150 mm) and guardrail combination is needed, two applications, as noted below, have been crash tested and accepted using the Midwest Guardrail System.

   a. Test Level 3 (TL 3). MGS Type A guardrail may be placed with the face of guardrail located zero to 6 in. (150 mm) behind the face of curb. Figure 38-6.Y shows this configuration. Note that the height of this installation is referenced from the edge of pavement in front of the guardrail face.

   b. Test Level 2 (TL 2). At locations where the roadside safety design speed is 45 mph (70 km/hr) or less, MGS Type A guardrail may be placed at offsets from 4 ft (1.2 m) to 12 ft (3.6 m) from the face of curb. This is useful for placement behind sidewalks in urban areas, including approaches to bridges. Note that the height of this installation is referenced from the ground surface at the guardrail. The terminal section may be tangent or flared, provided it is within the 4 ft to 12 ft (1.2 m to 3.6 m) zone; see Figure 38-6.Z.

   Designers should consider options for avoiding placement of curb in advance and adjacent to a Traffic Barrier Terminal Type 1 or Type 2 guardrail terminal. Neither of these terminals has been tested with a curb. As a first choice, extend the guardrail beyond the limits of the curbing, tapering out the curb height appropriately. It may also be possible to shift the curb laterally behind the terminal and apply the same shift on the approach. If a terminal end is needed along the section with curb, provide a tangent terminal with a 50:1 flare so that the impact head of the terminal does not protrude on the roadway. Whenever curbs and guardrail terminals will be in close proximity review the design to confirm that the terminal will operate properly at the proposed height. Vertical transitions may be necessary in some cases.

2. Slopes. Slopes in front of a W-beam guardrail system should be 1V:10H or flatter. This also applies to the embankment between the back of the guardrail posts and the hinge point, the areas in front of the flared section of guardrail, the area approaching the terminal ends, and the area behind the terminal ends as shown on *Highway Standard* 630301.

   Some high tension cable barriers may be used on approach slopes of 1V:4H or flatter; see Section 38-7.03(b).

38-6.06 Terminal Treatments

Barrier terminal sections present potential roadside hazards for run-off-the-road vehicles; however, they are also critical to the proper structural performance of the barrier system. Therefore, the designer must carefully consider the selection and placement of the terminal end.

The *Illinois Highway Standards* present the design details for several end treatments used by the Department. Other proprietary terminal treatments are allowed under various Specifications and Special Provisions. The particular proprietary items routinely allowed for use on IDOT projects are included in the Department's Qualified Products List (QPL) that is published in the Material Approvals section of the "Doing Business" page of the IDOT internet site. The process of approving MASH-tested devices, replacing NCHRP Report 350 devices, is continuing for several of these systems. The QPL lists both the products and the current requirements during this transition period. The following sections briefly describe each system and, where applicable, discuss typical uses of the system.

38-6.06(a) Guardrail End Terminals

The following terminals are applicable to the steel plate beam guardrail:

1. Type 1, Special (Flared). This terminal section is for use with steel plate beam guardrail. The designer should choose a flared terminal where practical, if no additional right-of-way must be purchased for installation and the grading needed to provide a 1V:10H approach slope to the terminal is reasonable. Each device has a maximum flare rate measured versus normal traffic flow. Note that this flare rate can potentially be flatter than a flare rate proposed for a guardrail run.

   Note that both the beginning of length of need (BLON) location point and the length of the Traffic Barrier Terminal Type 1, Special (TBT T1 SPL), will vary depending on which proprietary item the contractor chooses for termination of the guardrail. Refer to the QPL for drawings showing detailed dimensions of, and maximum flare rates for, the currently-approved devices.

   For design purposes, using the shortest TBT T1 SPL will provide the most conservative guardrail plan quantity; however, the effects of the contractor's potential selection of a longer TBT T1 SPL than assumed in design must be evaluated in the design phase for its impact on the location of proposed entrances and grading.

   The ends of some TBT T1 SPL devices have redirective properties beginning at the first post, however the first 12.5 ft (3.81 m) of most TBT T1 SPL terminals is called the gating portion and is not included in the length of need. The purpose of the non-redirective, or gating portion of the TBT's, is to provide anchorage for the adjacent redirective guardrail run. A steel cable, with ends attached to the first rail and the first post, provides tension that stiffens the adjacent redirective rail pieces. Therefore, when designing a TBT T1 SPL end terminal, assume the length of need begins at the third post, 12.5 ft (3.81 m) from the free end. This conservative assumption will ensure sufficient guardrail quantities are present in the plans and will prevent conflicts with driveways, etc., during construction.

Based on crash testing, the area behind and beyond the terminal should be traversable and free of fixed objects. The minimum recommended distance is a rectangular area approximately 75 ft (23 m) beyond the terminal parallel to the rail and 20 ft (6.0 m) behind and perpendicular to the rail, where right-of-way, environmental concerns, and other resources allow.

2. Type 1, Special (Tangent). This terminal section is for use with steel plate beam guardrail. Tangent terminals should typically be chosen in areas where the cross section or drainage requirements would require additional right-of-way to accommodate the Type 1 Special (Flared) terminal. Each device has a maximum flare rate measured versus normal traffic flow. Note that this flare rate can potentially be flatter than a flare rate proposed for a guardrail run.

   Note that both the beginning of length of need (BLON) location point and the length of the Traffic Barrier Terminal Type 1, Special (TBT T1 SPL), will vary depending on which proprietary item the contractor chooses for termination of the guardrail. Refer to the QPL for drawings showing detailed dimensions of, and maximum flare rates for, the currently-approved devices.

   For design purposes, using the shortest TBT T1 SPL will provide the most conservative guardrail plan quantity; however, the effects of the contractor's potential selection of a longer TBT T1 SPL than assumed in design must be evaluated in the design phase for its impact on the location of proposed entrances and grading.

   The ends of some TBT T1 SPL devices have redirective abilities beginning at the first post, however the first 12.5 ft (3.81 m) of most TBT T1 SPL terminals is called the gating portion and is not included in the length of need. The purpose of the non-redirective, or gating portion of the TBT's, is to provide anchorage for the adjacent redirective guardrail run. A steel cable, with ends attached to the first rail and the first post, provides tension that stiffens the adjacent redirective rail pieces. Therefore, when designing a TBT T1 SPL end terminal, assume the length of need begins at the third post, 12.5 ft (3.81 m) from the free end. This conservative assumption will ensure sufficient guardrail quantities are present in the plans and will prevent conflicts with driveways, etc. during construction.

   Based on crash testing, the area behind and beyond the terminal should be traversable and free of fixed objects. The minimum recommended distance is a rectangular area approximately 75 ft (23 m) beyond the terminal parallel to the rail and 20 ft (6.0 m) behind and perpendicular to the rail where right-of-way, environmental concerns, and other resources allow.

3. Type 1B. In areas of cut sections on the roadway, or where the road is transitioning from cut to fill, it is sometimes possible to terminate a guardrail installation by burying the end in the natural or typically-graded back slope. When properly designed and located, this generic system provides full shielding of the identified hazard, eliminates the possibility of

any end-on impact with the terminal, and minimizes the likelihood of the vehicle passing behind the rail. The length of need point for this terminal begins at the transition from cut to fill, and the guardrail and terminal extend more than 75 ft (23 m) beyond this point.

Currently, the Type 1B end terminal meets NCHRP Report 350 criteria. Through research there is potential for approval of a MASH Type 1B terminal; in the meantime Highway Standard 631006 can be applied in the specific circumstances described here. Use of the Type 1B terminal shall meet all of the following criteria:

a. The steepness of the slope into which the barrier is buried should be as nearly vertical as possible, so the slope effectively becomes part of the barrier. This slope should be at least 1V:3H or steeper, with steeper slopes preferred.

b. The length of need for the roadside barrier begins where the guardrail crosses the ditch flowline.

c. The beginning of the length of need for the roadside barrier (where it crosses the ditch flowline) is positioned about 75 ft (23 m) upstream of the transition from cut to fill. This provides a buffer area for any vehicles that might get behind or over the buried terminal.

d. Front slopes must be 1V:4H or flatter.

e. The height of the rail must be held constant with respect to the edge of the roadway shoulder.

f. The maximum height of the top of the rail where it crosses the ditch bottom is 45 in. (1143 mm).

g. Depending on site conditions, the terminal may be anchored by driven posts or a poured concrete block or may be anchored to sound rock.

Careful site review, along with design of profiles and cross slopes, is necessary to satisfy the criteria listed above. If all of these criteria cannot be met, another terminal type should be considered.

4. Type 2. This is an unflared terminal with a cable anchor. The Traffic Barrier Terminal, Type 2 (TBT T2), should be used on the departing end of W-beam guardrail where end-on impacts are not a consideration; i.e., on one-way roadways. The full length of a TBT T2 plus the adjacent 25 ft (7.62 m) will not redirect an impacting vehicle and is therefore not to be considered as part of the length of need required to shield the hazard. Therefore, the BLON for a guardrail run with a TBT T2, is at 37.5 ft (11.43 m) from the end post of the TBT T2.

   When providing the additional 25 ft of steel plate beam guardrail as shown in Figure 38- 6.A, the Type 2 end terminal is considered crashworthy for departing impacts only.

38-6.06(b) Median Barriers

See Section 38-7.04(d) for guidance on Department-approved end terminals (impact attenuators) for median barriers. These also apply to the ends of the concrete barrier where it is used as a roadside barrier.

38-6.06(c) Bridge Rail Connections

Roadside barriers are often terminated with a transition into a bridge rail. Terminals used as bridge rail connections are discussed below and shown on the Highway Standards.

1. Type 5. This is a connector terminal that should be used to connect steel plate beam guardrail to the concrete bridge parapet or end post at the departing end of a new one-way bridge. Refer to Highway Standard 631026 for more detail.

2. Type 5A. This is a connector terminal that should be used only for repair of existing installations on the State system, and for Local Roads projects, if specified by the Local Agency. It is used to connect steel plate beam guardrail to a steel bridge rail at either the approaching end or departing end of the bridge. For applications on the State highway system, or other locations where compliance with *NCHRP Report 350* or *MASH* is required, see Type 6A.

3. Type 6. This is a connector terminal that includes a transition section, special posts, blockouts, and end shoe. It also requires the use of a curb. Use Type 6 to attach steel plate beam guardrail to the end(s) of bridges with concrete parapet or to a permanent concrete barrier. It may also be used to connect the steel plate beam guardrail to the face of other concrete structures where the required curb can be installed. Refer to Highway Standard 631031 for more detail.

4. Type 6A. This is a connector terminal that is similar to the Type 6, except it is used for attachment of steel plate beam guardrail to side-mounted steel bridge rail (SMX and SM). When used with a bridge rail system that includes a curb, a curb must be used with the Type 6A. If there is no curb used on the bridge, do not use a curb with the Type 6A. Refer to Highway Standard 631032 for more detail.

5. Type 6B. This is a connector terminal that should be used when connecting steel plate beam guardrail to the face of a concrete structure (e.g., a pier) and where the installation of a curb is either not possible or not desirable. It requires blocking out the thrie beam rail of the transition by 8 in. (200 mm) at the connection point. The designer must carefully weigh the relative merits of this potential loss of horizontal clearance against the complications of adding a curb when selecting between the Type 6B terminal and the Type 6 for attachment to a structure. Refer to Highway Standard 631033 for more detail.

6. Type 10. This is a connector terminal that may be used to connect steel plate beam guardrail to the departing end of concrete parapets or concrete bridge rails of one-way

bridges, except for bridges or culverts with concrete post and beam rails. Existing concrete post and beam rails should be removed and retrofitted with a steel bridge rail or a structurally designed concrete parapet and connected using an appropriate connector. Refer to Highway Standard 631046 for more detail.

7. Type 11. This is a connector terminal that should be used to connect temporary bridge railing to temporary concrete barrier. Specifications for the temporary concrete barrier require that the last segment of barrier be fixed in place by anchor pins. These pins are critical to the performance of this terminal to avoid a potential "pocketing" location for impacting vehicles. This terminal, as shown on *Highway Standard* 631051, is considered adequate for *NCHRP Report 350* Test Level 2; for design speeds up to 45 mph (70 km/hr). Where speeds are higher, the post spacing for the temporary bridge railing shall be no more than 3′ -1½″ (953 mm). With the reduced post spacing for the temporary bridge rail, this transition is considered adequate for *NCHRP Report 350* Test Level 3. Refer to Highway Standard 6310051 for more detail.

8. Type 13. This is a connector terminal that should be used to connect the steel plate beam guardrail to the steel-tube side mounted bridge railing (Type IL -OH, R-40). The thrie beam section of the terminal is designed with a top mounting height of 34 in. (864 mm) at the bridge rail connection to account for future deck overlays of up to 3 in. (76 mm). Refer to Highway Standard 631061 for more detail.

9. Type 14. This is a connector terminal that should be used to connect the steel plate beam guardrail to the curb mounted bridge rail (Type CO-10). Refer to Highway Standard 631066 for more detail.

38-6.07 Minimum Length/Gaps

The minimum length of guardrail should include 75 ft (23 m) of length of need (redirective) guardrail. Common configurations meeting this minimum requirement include a pair of Traffic Barrier Terminals Type 1, Special; a Traffic Barrier Terminal Type 1, Special, connected to a Traffic Barrier Terminal Type 6, 6A, 6B, 13 or 14; or a Traffic Barrier Terminal Type 1, Special, plus 50 ft (15.24 m) of guardrail connected to a Traffic Barrier Terminal Type 2.

Where gaps exist in the need for a roadside barrier, it is typically economically justified to provide continuous runs of guardrail, rather than to leave gaps of 200 ft (60 m) or less. This is because the pair of Traffic Barrier Terminals Type 1, Special, that would be required to form a gap cost about the same as a run of guardrail 200 ft (60 m) long. It may also be safer by reducing exposure to additional terminal ends. Shorter gaps may be necessary and prudent where the guardrail is warranted, as access needs, sight distance, or other reasons dictate the need for a gap.

38-6.08 Typical Applications

Figures 38-6.AA through 38-6.CC illustrate typical applications of roadside barrier installations. See Figure 38-6.DD for the minimum length of Type A or Type B guardrail that must be installed between non-blocked guardrail and a traffic barrier terminal (TBT).

38-6.09 Short Radius Guardrail

There are currently no short radius (radius = 150 ft (45 m) or less) guardrail systems that the Department has identified and adopted as a standard design element. A side road or entrance within the length of need of a guardrail installation poses a severe challenge to the design of a safe roadside. Although installing a short radius Type A guardrail around one or both of the roadway radius returns is possible, a vehicle impacting the radius at a high angle and speed may penetrate the barrier, or vault over the barrier after the posts lean back, creating a ramping effect. Where penetration or vaulting does not occur, the vehicle may be decelerated at an excessive rate.

Recognizing that it is often not practical to change the site conditions by relocating the roadway or entrance to allow for the proper length of need of guardrail, the 2011 edition of the AASHTO *Roadside Design Guide* (*RDG*) acknowledges that some compromise will be necessary. Where a short radius guardrail is appropriate for addressing roadside safety the RDG recommends that the installation should be made as forgiving as practical. However, prior to choosing this solution, alternatives should be assessed as summarized in this section.

38-6.09(a) Design Alternatives

1. Relocate or Close the Intersecting Roadway/Entrance. This is the preferred solution and should be considered during project scoping or Phase I preliminary engineering. Proceeding with a relocation or closure will involve consideration of expected crash risk, barrier maintenance costs, project scope, cost, and impacts to adjacent properties and the environment. This action generally provides the most positive solution for roadside safety. If it is undertaken, give additional consideration to flattening side slopes, widening embankments, etc., to reduce the need for any barrier.

2. Terminate the Guardrail in Advance of the Intersecting Roadway. When relocating or closing the roadway/entrance is not feasible and where the nominal length of need falls near the intersecting roadway the designer may choose to truncate the standard guardrail with an approved terminal section or impact attenuator in advance of the intersection. Flaring the guardrail away from the roadway can be combined with guardrail truncation to improve length of need coverage. Truncating a guardrail run and exposing a hazard such as a slope or dropoff should be compared to the hazard posed by a short radius guardrail installation.

Termination of guardrail short of the length of need is considered a design exception and shall be discussed at a coordination meeting with the reason(s) for the short length documented in the meeting minutes; see Section 31-7.

3. Short Radius Guardrail. If relocating a roadway/entrance cannot be accomplished and terminating the guardrail short of its length of need is undesirable, the designer may consider a short radius guardrail installation. Considerations in application include how close it can be installed to a bridge, what radius can be used, and how far it must run along the intersecting side road.

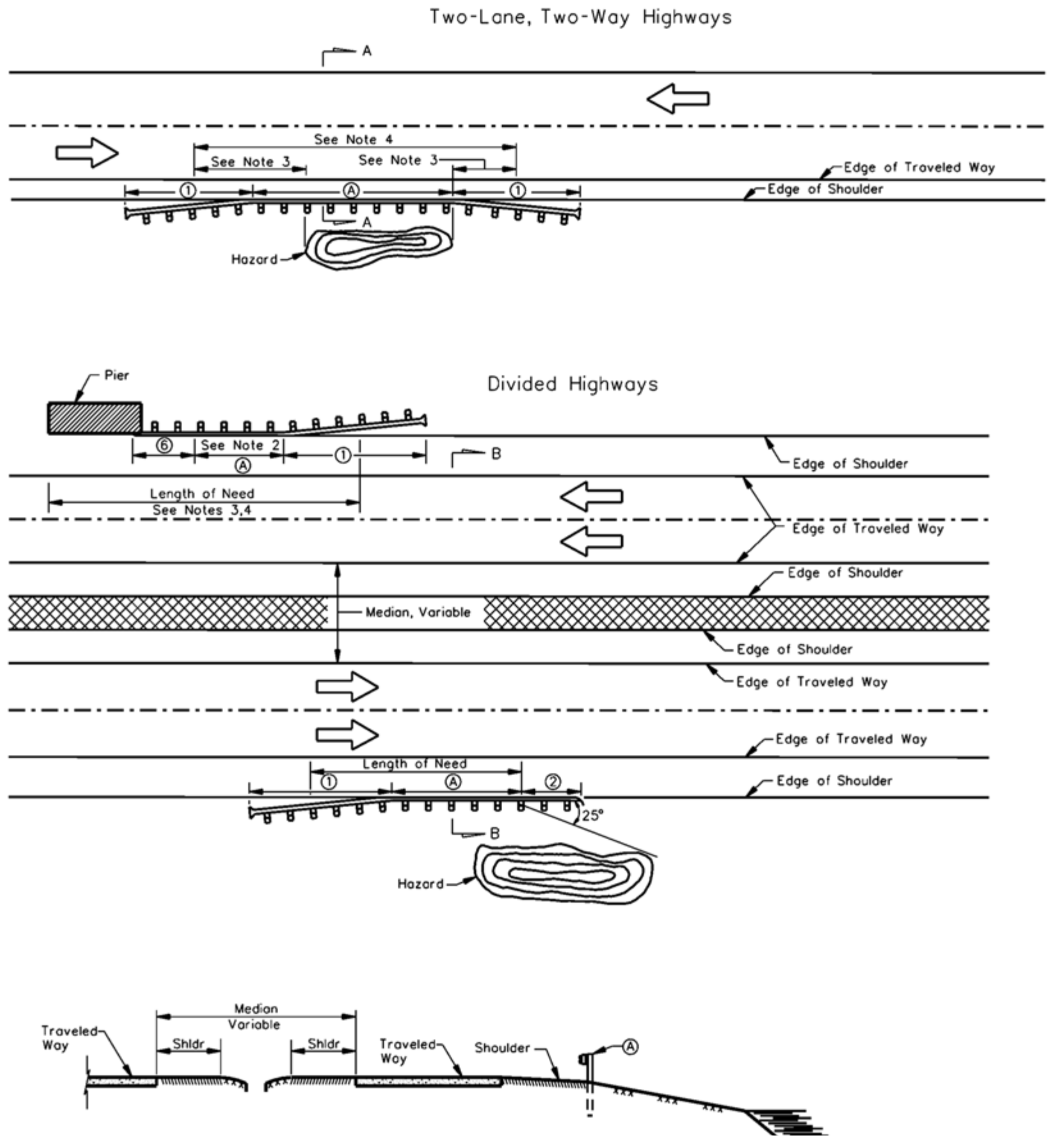
   Steel Plate Beam Guardrail, Type A is the only current system usable for a short radius installation. The design should introduce strong posts likely to rotate out of a vehicle's path and minimize vaulting, blockouts to minimize snagging, and mounting height to minimize override. This system has not met any crash testing criteria, but when a short radius guardrail installation is required, it represents an effort to provide a forgiving installation.

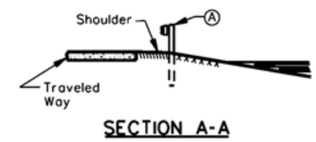
   When terminating the radius guardrail system, the guardrail on the intersecting roadway should be completed to any required length of need and terminated with an appropriate end treatment. On a very low speed roadway (e.g., private driveway), this may be a Type 2 terminal. On most public roadways, or other roadways where higher speeds are possible, provide a Traffic Barrier Terminal Type 1, Special. These terminals are important to provide adequate anchoring of the radius system, and safety for the traffic on the intersecting roadway.

   Given that the preferred method is to relocate or close the intersecting roadway or entrance, and that the short radius guardrail does not meet *MASH* or *NCHRP Report 350* criteria, the decision to use the strong post design (current standard) for a short radius installation is considered a design exception. The design shall be discussed at a coordination meeting and documented in the meeting minutes. The strong post design is the Department's current Standard Type A guardrail installed on the necessary radius. Do not use Type B guardrail in radius applications, as it increases the likelihood that posts will only deflect partially and launch a vehicle.

   Because the strong post radius guardrail system represents some compromise in roadside design, consider an attempt to shadow it from impacts. This can be done by applying a tangent run of guardrail on the approach side of the intersecting roadway. Radius guardrail is available in five foot increments of radius from 5 ft (1.52 m) to 150 ft (45.72 m). For radii longer than 150 ft (45.72 m), the straight sections can be deflected in the field to match curves.

4. Other Solutions. Other solutions may be possible on a case-by-case basis. For example, in some locations it may be feasible to locate an impact attenuator system in the radius area. Another idea is to flare the guardrail approaching the short radius and provide guardrail on the other side of the entrance to "shadow" the radius installation. If desired, coordinate with BSPE for specific situations that may present multiple design options.





Notes:

1. Traffic Barrier Terminal Types:
   ① Type 1, Special (Tangent or Flared)
   ② Type 2
   ⑥ Type 6 (Type 6B may also be considered)
2. Steel Plate Beam Guardrail Types:
   Ⓐ Type A (Type B may be used if needed)
3. Length of need in advance of the hazard should be determined using Figure 38-6F.
4. Total length of need includes length of need at each end of the hazard plus the length required immediatley adjacent to the hazard. See Section 38-6.01.
5. When Traffic Barrier Terminal Type 1, Special is used, a portion is applied to the length of need.
6. Flare of terminals must not exceed maximum rate for device type selected as measured versus normal traffic flow.

Not to scale.

38-7 MEDIAN BARRIERS

Median barriers prevent errant vehicles from crossing the median of a divided highway and colliding with vehicles in the opposing direction of travel. The decision to use a median barrier, as well as the selection of barrier type should be identified in the Phase I engineering report for the project. This decision is especially important for early and accurate coordination with bridge cross section details.

38-7.01 Median Barrier Warrants

38-7.01(a) Freeways

For freeways with a posted speed of 55 mph or greater, use Figure 38-7.B to determine if a median barrier may be warranted. The figure uses the inputs of median width and traffic volume, along with Illinois-specific cross-median crash data, to determine the benefit/cost (B/C) ratio of installing a barrier using the procedure shown in Section 38-7.01(c).

In the “Median Barrier Recommended” area of the Figure 38-7.B, the B/C ratio is expected to be at least 2.00 and the barrier is warranted. In the “Evaluate Cost Effectiveness” area of the figure, the B/C ratio is less definitive and additional analysis should be performed to determine if the barrier is warranted.

For existing freeways, the additional analysis involves determining a project specific B/C ratio using existing crash data for the section and other factors such as: route continuity of the median barrier, a progressive and logical “build out” of the barriers, area development trends, future programming for the location, and proximity to interchanges. A study of Illinois’ fatal cross-median crashes has shown that almost 70% happen within one mile (1.6 km) of an interchange.

For proposed freeways, the additional analysis is similar to that above for existing freeways, except for the need to use the Enhanced Interchange Safety Analysis Tool (ISATe) to predict crash frequency and severity in determining a more project-specific B/C ratio for installation of median barrier. Alternatively, the ISATe and cost-effectiveness study can be used to determine if the use of a wider median, which will eliminate the need for median barrier on a new facility, is a preferable alternative to the initial construction of the barrier. Contact BSPE regarding the use of ISATe.

38-7.01(b) Highways with a Flush/Depressed Median and Partial Access Control

For highways with both a flush/depressed median and partial access control, the decision to use a median barrier should consider the B/C ratio. As the median barrier must terminate at each at-grade intersection, give special consideration to sight distance and the need to provide a safety treatment at each end of the barrier, as well as right-of-way constraints, property access needs, number of intersections and driveway openings, and adjacent commercial development.

38-7.01(c) Benefit/Cost (B/C) Ratio Procedure

To determine the B/C ratio of a median barrier, use the following procedure. This procedure assumes a 15-year life for the median barrier and a 3% discount rate:

1. Determine the Benefit.

   - Determine the annual number of fatal (K), severe injury (A), and moderate injury (B) cross-median crashes. Cross median crashes shall be determined from reading the narrative portions of crash reports. For existing roadways, use an average of at least five years of crash data.
   - Determine the annual cost of K, A, and B cross-median crashes. Apply the cost per crash method (not per fatality or injury) according to Figure 38-7.A to determine the annual cost.
   - Determine the annual benefit (AB) for installing the median barrier. The AB is estimated as the current year KAB crash cost multiplied by 0.92.

     AB = Current year KAB crash cost X 0.92.

   - Determine the total benefit (B) of the median barrier.

     B = AB x 11.94

     where: 11.94 = present worth factor (for current year)

2. Determine the Cost.

   - Select the most appropriate median barrier according to Sections 38-7.02 and 38-7.03.
   - Determine the installation cost (IC) of the median barrier. Include in the cost any additional items that are required for the selected barrier (e.g., grading, drainage, paving, mow strips).
   - Estimate the number of crashes (encroachments) into the median barrier per year using the Roadside Safety Analysis Program (RSAP).
   - Determine the annual repair cost (ARC) of the median barrier. Multiply the estimated number of crashes per year (from the RSAP) by the following:

     + $0 for rigid median barrier,
     + $1200 x $(1.03)^{(\text{Construction Year - 2012})}$ for semi-rigid median barrier, and
     + $800 x $(1.03)^{(\text{Construction Year - 2012})}$ for flexible median barrier.

     Documented repair costs in the area may be used in place of these.

   - Determine the total cost (C) of the median barrier.

     C = IC + (ARC x 11.94)

     where: 11.94 = present worth factor (for current year)

3. Determine the Benefit/Cost Ratio.

B/C ratio = B/C

A minimum B/C ratio of 2.00 warrants installation of a median barrier. When the B/C ratio is between 1.00 and 2.00, other factors should be considered. Other factors include route continuity of median barrier, a progressive and logical "build out" of the barriers, area development trends, future programming for the location, and proximity to interchanges. A study of Illinois' fatal, cross-median crashes has shown that almost 70% happen within one mile (1.6 km) of an interchange.

Crash Severity*	2018 Cost Per Crash
Fatal Crash (K)	$ 6,626,000
Severe Injury Crash (A)	$ 357,000
Moderate Injury Crash (B)	$ 131,000

* Crash severity is determined by the most severe injury in a given crash.

Use the following procedures to determine the cost (losses) over a study period due to cross median crashes.

1. Cross median crashes are those in which a vehicle traveling in the correct direction on one side of a divided freeway crosses the median into opposing traffic and has a collision with a vehicle traveling in its correct direction in the opposing traffic lanes.

   #K cross median crashes x ($ 6,626,000)
   \+ #A cross median crashes x ($ 357,000)
   \+ #B cross median crashes x ($ 131,000)

   Total KAB crash cost for the study period (2018 dollars)

2. Annual KAB crash cost for the study period

   = (Total KAB crash cost for the study period) / N

   where N = Length of study period

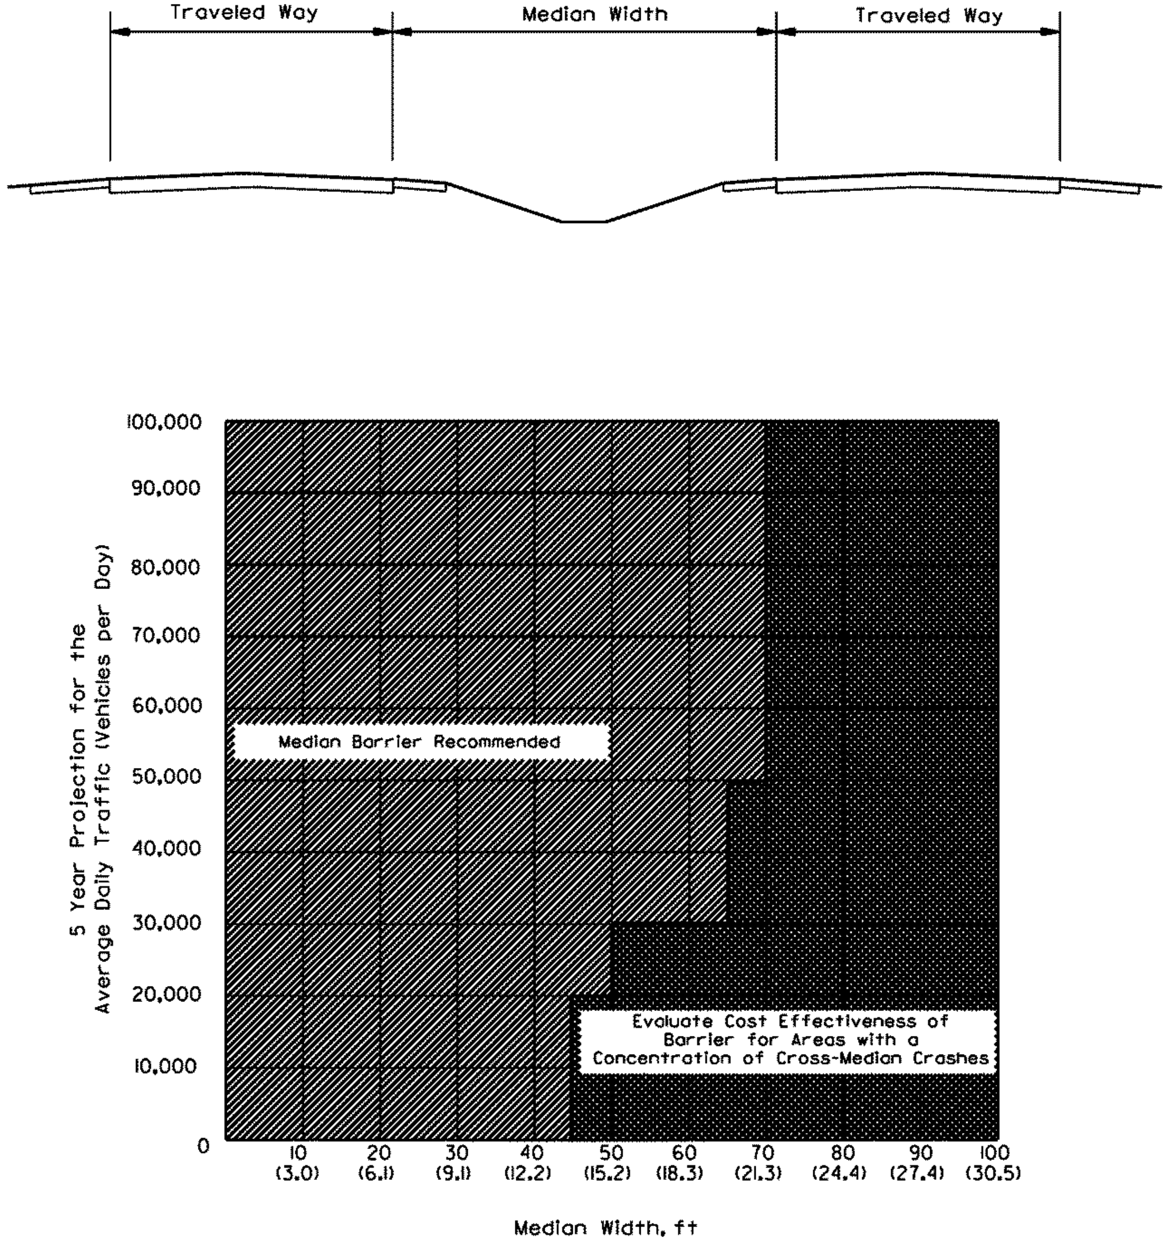
3. The designer must update this dollar figure to the current year using a 3% discount rate.

   Current year annual KAB crash cost

   = Annual KAB crash cost x $1.03^{\text{(current year - 2018)}}$

ANNUAL KAB CRASH COST FOR A STUDY PERIOD

Figure 38-7.A



WARRANTS FOR MEDIAN BARRIERS ON FREEWAYS

Figure 38-7.B

38-7.02 Median Barrier Types

As with roadside barriers, median barriers can be categorized as rigid, semi-rigid, and flexible.

38-7.02(a) Rigid Median Barriers

The rigid median barrier currently used by the Department is a single slope concrete barrier with a 44 in. (1120 mm) height. See *Highway Standard* 637006. This design has been certified as meeting MASH (Test Level 5). The minimum height required for Test Level 5 is 42 in. (1065 mm) but the additional height of the current design allows for a future 2 in. (50 mm) overlay and matches the height of the Test Level 5 parapet design used by the Bureau of Bridges and Structures.

In the median, the concrete barrier it typically double faced but a single-faced design may be used to go around a fixed object in the median (e.g., bridge piers) or where twin separated structures are encountered. Single-faced barriers must be designed on a case-by-case basis, require structural reinforcement, and are normally tied to the supporting pavement/shoulder.

Prior to the current single slope design, the Department used two different heights of F-Shape concrete barrier and they are allowed to remain in service until a project scope involves barrier replacement. The 32 in (815 mm) height F-Shape design was an NCHRP Report 350 Test Level 4 barrier. The 42 in (1065 mm) height design was an NCHRP Report 350 Test Level 5 barrier.

38-7.02(b) Semi-Rigid Median Barriers

The semi-rigid median barrier used by the Department is steel plate beam guardrail, Type D (double rail). See *Highway Standard* 630001. This median barrier meets Test Level 3 and is most applicable to medians with intermediate widths of 20 ft to 30 ft (6.0 m to 9.0 m) and/or low-to-moderate truck traffic volumes (< 5000 MU per day). Another application is for the separation of adjacent on/off ramps at interchanges.

38-7.02(c) Flexible Median Barriers

The flexible median barriers used by the Department are high-tension cable (HTC) median barriers. HTC median barriers consist of cables under high tension, suspended on lightweight posts, with an anchorage foundation at each end to hold the tension on the cables.

The tension present in the cables of an HTC system allow the cable to remain at an effective height after the removal of several supporting posts. This is valuable after a moderate crash, as some level of protection remains until repairs can be completed. However, the weak post component of these systems usually results in some damage, even from minor or nuisance hits. The repair of the weak posts is straightforward, and with socketed systems may not require any specialized equipment.

The HTC median barriers approved for use on slopes of 1V:6H or flatter meet *Test Level 4*. The barriers approved for use on slopes steeper than 1V:6H, but not steeper than 1V:4H, meet *Test Level 3*. The terminals for HTC median barriers meet *Test Level 3*. For each of these systems slope, placement, and other criteria limit where and how they may be used.

38-7.03 Median Barrier Selection

38-7.03(a) Selection Guidelines

The selection of a median barrier type starts with the median width and slopes. These two median conditions will have the greatest impact on the barrier's performance. Figure 38-7.C provides selection guidelines based upon these conditions and also provides the recommended placement for that barrier within the median.

Where more than one type of median barrier is recommended, consider the following factors:

1. Traffic Volumes. Higher traffic volumes generate more impacts on a median barrier. Also, closing lanes to work on median barriers causes more traffic complications where traffic volumes are high. In high-traffic volume locations, rigid barriers are generally preferred because they usually provide continuous, crashworthy service without generating maintenance and repair.

   As a guide, a rigid barrier is likely to be more cost-effective where the peak hour level of service is LOS C or worse and the distance to the median barrier from the traveled way is 12 ft (3.6 m) or less.

2. Heavy Vehicle Traffic. Where there is a high volume of heavy vehicles, or a history of heavy vehicle, cross-median crashes, a rigid barrier would be preferred as it is more likely to contain and redirect heavy vehicles. Maintenance and repairs are not usually required after a hit.

3. Median Appurtenances. A roadway with a median barrier may also warrant other appurtenances in the median (e.g., highway lighting, signs, glare screens). This favors the use of the concrete barrier, which can more readily accommodate these appurtenances.

4. Maintenance Operations. Two factors are important:

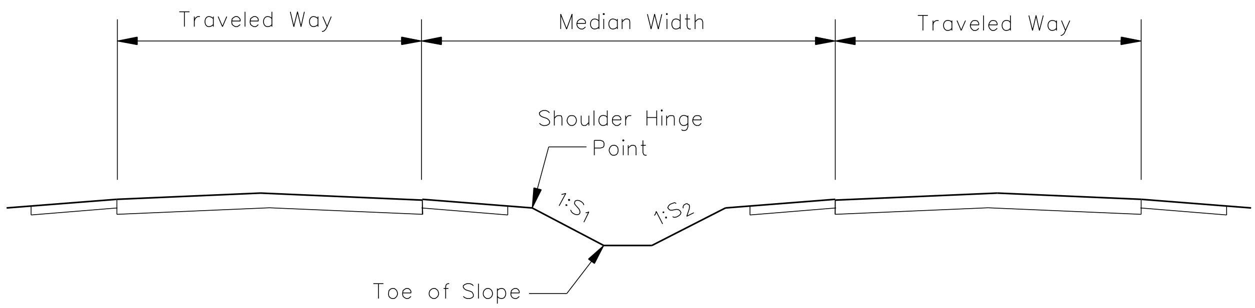
   a. First, maintenance response time will influence safety. The longer a damaged section of median barrier is present, the greater the likelihood of a second impact with a damaged barrier. A damaged semi-rigid barrier may remain at operational height after some impacts and may still provide protection in the event of a second impact. However, if substantially damaged it can itself become a greater hazard close to traffic until it is fully repaired and operational. This consideration favors the use of a rigid barrier which normally sustains little or no damage when impacted.

b. Second, the maintenance operations for repairing a median barrier can be disruptive to traffic. It is important to consider worker safety and traffic safety when developing a traffic control scheme for barrier repair. Lane closures are typically necessary where working room is limited. This consideration favors the use of a rigid barrier in narrow medians and/or high-traffic volume areas, or a flexible barrier where sufficient space is available adjacent to or behind the barrier to accommodate the smaller equipment needed to repair it.

5. Benefit/Cost Ratio. The B/C ratio is important but does not consider additional crash or user delay costs due to traffic backups for repair. Consider the safety consequences based on the other factors listed above to make sure the system is acceptable for the specific site.

Figure 38-7.D compares the advantages and disadvantages of the different types of median barriers used by the Department and their typical usage.

Median barriers may also be used in locations other than medians. This would typically occur where a barrier is needed to separate lanes of traffic moving in the same direction or beginning to diverge.



Median Conditions		Recommended Median Barrier Type	Recommended Placement
Width	**Slopes**		
W < 25 ft (7.6 m)	S_1 and $S_2 \geq 10$	Rigid or Semi-Rigid	Near center of median
	S_1 or $S_2 < 10$ and S_1 and $S_2 \geq 8$	Semi-Rigid	Near center of median
	S_1 or $S_2 < 8$	N/A – Consider a roadside barrier along each shoulder.	
W ≥ 25 ft (7.6 m)	S_1 and $S_2 \geq 10$	Rigid, Semi-Rigid, or Flexible	Near center of median
	S_1 or $S_2 < 10$ and S_1 and $S_2 \geq 8$	Semi-Rigid or Flexible	Near center of median
	S_1 or $S_2 < 8$ and S_1 and $S_2 \geq 6$	Flexible	2 ft (600 mm) or more from shoulder hinge point <u>and</u> more than 8 ft (2.4 m) from the ditch line bottom
	S_1 or $S_2 < 6$ and S_1 and $S_2 \geq 4$	Flexible	Within 4 ft (1.2 m) of shoulder hinge point <u>and</u> more than 8 ft (2.4 m) from the toe of any front slope
	S_1 or $S_2 < 4$	N/A – Consider a roadside barrier along each shoulder.	
Other median conditions (e.g., stepped, bermed)		Contact the Bureau of Safety Programs and Engineering.	

GUIDELINES FOR MEDIAN BARRIER SELECTION/PLACEMENT

Figure 38-7.C

38-7.03(b) Design Considerations

Each type of median barrier involves design elements that must be considered in the selection process. Consider the following:

1. Rigid Median Barriers. As noted earlier, the IDOT 44 in. (1120 mm) Double Face Concrete Barrier has been certified as meeting MASH criteria (Test Level 5). As a double-face concrete barrier nears the median pier of an overhead structure or twin separated structures, it may be necessary to split the barrier into two single-face barriers; this requires detailed design. There may also be a need to design details for a transition from the current single-sloped barrier into one of the older F-shape or New Jersey shaped barriers. The Bureau of Bridges and Structures and Bureau of Safety Programs and Engineering should be asked to provide guidance when such treatment is necessary.

2. Semi-Rigid Median Barriers. See Section 38-7.02(b) as it applies to Type D guardrail.

3. Flexible Median Barriers.

    a. Line Post Foundations. The line posts of High Tension Cable (HTC) median barriers may be driven directly into the ground or through a mow strip or may be set into socket-type concrete foundations. Consider the depth of frost penetration. As a rule of thumb, the foundations should be at least 30 in. (762 mm) deep south of I-72, 36 in. (915 m) deep along, and north of, I-72 to I-80, and 42 in. (1065 mm) deep along I-80 and north to the state border.

    b. End Anchorages. HTC median barriers use significant anchorages (foundations) at each end of a run of cables to hold the high tension. The HTC specifications set design requirements and require shop drawings from the contractor for the end anchorages. Where it is necessary to change from a flexible median barrier to another roadside barrier or median barrier, provide an appropriate longitudinal overlap so that each system can operate and the entire median has adequate protection. Leave at least a 10 ft (3.0 m) transverse gap between the systems to provide access and ensure operational integrity. Another option for avoiding conflicts between different barrier types is to begin runs of flexible barrier at the departure ends of bridges; see Figure 38-7.E.

    c. Mow Strips. Mow strips provide a paved area under and immediately adjacent to the barrier. They are provided as a maintenance consideration to ease mowing and minimize nuisance hits. A typical design is a 4 ft (1.2 m) wide, 4 in. (100 mm) thick mat of hot-mix asphalt. If within the shoulder limits, mow strips need to conform to the shoulder slope. Beyond the shoulder limits, mow strips need to conform to the front slope. Avoid drop-offs along the edge of a mow strip. Provide grading, if necessary, to smoothly match the mow strips to the slopes.

    d. Length of Need. The length of an HTC median barrier that can be used to satisfy the length of need (see Section 38-6.01) will vary among the manufacturers.

Because the brand of HTC will not be known during the design, define the length of need point for all types as 50 ft (15.2 m) from the end of the terminal section.

Type	Advantages	Disadvantages	Typical Usage
Rigid	1. Can accommodate most vehicular impacts without penetration 2. Little or no deflection distance required behind the barrier. 3. Little or no damage sustained for most vehicular impacts; therefore, least need for maintenance. 4. Minimum potential for vehicle underride/override or snags. 5. Light supports, sign supports, glare screens, etc., may be mounted on top.	1. Highest initial cost. 2. Can induce vehicular rollover. 3. For some conditions, it has highest occupant decelerations (i.e., it is the least forgiving barrier type). 4. Reduced performance where offset between the barrier and the traveled way exceeds 12 ft (3.6 m). 5. Snow drifting.	1. Urban freeways. 2. For high traffic volumes. 3. For high volumes of heavy vehicles. 4. Where maintenance of a median barrier would result in lane closures with significant impacts to traffic. 5. Works well for moderate to narrow medians.
Semi-Rigid	1. Lower initial cost. 2. High level of familiarity by maintenance personnel. 3. Can safely accommodate wide range of impact conditions for passenger vehicles. 4. Relatively easy installation.	1. Performance for vehicles above 5000 lb (2270 kg) (PU) is not assured. 2. At high-impact locations, will require frequent maintenance. 3. Snow drifting. 4. Hazard until repaired.	1. Moderate median widths, 25 ft to 40 ft (7.6 m to 12.2 m). 2. Low to mid-range of traffic volumes.
Flexible	1. Lowest initial cost. 2. Can be installed in medians where slopes are as steep as 1V:4H. 3. Repairs usually do not require specialized or heavy equipment. 4. Repairs can be quick. 5. Minimizes snow drifting. 6. Can safely accommodate wide range of impact conditions for passenger vehicles and, on 1V:6H or flatter slopes, single-unit trucks. 7. Remains at height and provides some protection after moderate hits.	1. Performance for heavy vehicles (above 18000 lb (8000 kg) (SU) is not assured where slopes are 1:6 or flatter. 2. Performance for vehicles above 5000 lb (2270 kg) (PU) is not assured where slopes are 1:4 to 1:6. 3. Virtually every impact will require some repair. 4. Susceptible to snowplow damage. 5. Learning curve for maintenance forces when introduced to a new area. 6. Deflection space required behind the barrier is 12 ft (3.6 m) unless special designs are developed.	1. Medians wider than 25 ft (7.6 m). 2. For low to moderate traffic volumes where repairs can be made without significant traffic impacts.

COMPARISON OF MEDIAN BARRIER TYPES

Figure 38-7.D

e. Deflection. Flexible median barriers will deflect more than the other median barrier types. When laying out a flexible barrier, allow for 12 ft (3.6 m) of deflection.

If designs for reduced deflection are needed, refer to Figure 38-7.F. This figure allows for reduced deflection based on 10 ft (3.0 m) or 15 ft (4.6 m) post spacing and limited space between end anchors from 300 ft (90 m) and 3000 ft (915 m). If reduced post spacing and/or reduced anchor spacing are required, these must be shown in the contract documents. Deflection values may be interpolated between these two curves, but may not be extrapolated. These curves are not to be used where the convex side of a curved flexible barrier installation is between traffic and a hazard. Contact BSPE for this case.

It is desirable to locate flexible median barriers so that an impacting vehicle will not be allowed to encroach into the traveled way beyond the barrier. However, in some applications, the deflection distance of a median barrier will encroach into the opposing lane. This is permissible when the barrier placement requirements dictate because not all hits will develop the full deflection, the encroachments will be momentary, and the limited encroachment is preferable to allowing a vehicle to enter the opposing traffic unchecked. In addition, many cases may occur where the cable is an interim safety measure until more extensive reconstruction can be accomplished.

f. Length of Installation. Very long installations (more than 3 miles (5.0 km)) of HTC may be possible; review manufacturer's recommendations. However, the designer should remember that an impact at the terminal will release tension throughout the entire run of cable. The designer should weigh the advantages and disadvantages of long runs of barrier versus the loss of performance during the time between a terminal hit and its repair.

Very long runs of HTC will also inhibit turnarounds by police and emergency first responders.

g. Alignment. HTC will not accommodate abrupt changes in vertical alignment. Crossing of abrupt sags will leave the cable too high and cause posts to be pulled upwards or cables to be lifted above correct mounting heights. Crossing of abrupt crests will place severe downward stress on cable supports and will result in low cable height after one impact. Mainline freeway alignments are unlikely to experience this problem, but cable profiles along median surfaces may vary due to drainage features, crossovers, pier locations, and other median details. These issues are minimized with an installation along or near a shoulder and usually must be addressed for locations closer to the median center. Breaking and overlapping the runs of HTC at crest or sag vertical curves is a strategy to minimize this effect, and may also be coordinated with changes in the preferred side of installation; see Figure 38-7.E.

If the radius of horizontal curvature is 1200 ft (366 m) or less, check the manufacturers' recommendations to confirm which systems may be used.

When placing HTC near a shoulder around a curve, it should ideally be located where the near traffic is making the left-hand curve (inside of curve relative to near traffic). This may reduce nuisance hits and allow more vehicles leaving the opposing roadway to come to a stop in the median before reaching the barrier. Also, traffic impacting the barrier on its convex side will result in increased deflection that can better be tolerated in the median.

If the barrier must be placed on the outside of a curve with superelevation of 3% or greater, it must be within 2 ft (0.600 m) of the edge of shoulder.

h. Elevation Differences. Where each roadway is on independent profile, especially if one is significantly higher than the other, it is generally preferred to place the median barrier along the higher roadway. This consideration should be balanced along with the alignment considerations; see Item g. above.

i. Delineation. Where the HTC is placed along a shoulder, apply reflective caps, reflective tape, or reflectors to the posts of the system at spacing and offsets similar to those used for guardrail reflectors.

j. Coordination. It is important to involve local emergency responders during Phase I development, at the preconstruction meeting, and during any hands-on demonstrations provided by the HTC manufacturer. Cutting of cables should be discouraged. Replacement/splicing of cut cables is much more expensive and time consuming than resetting of intact cables. Contractor and manufacturer personnel can instruct emergency responders about alternatives to cutting cables and methods to disengage vehicles. Also, coordinate with emergency responders to ensure safe median and shoulder access is provided.

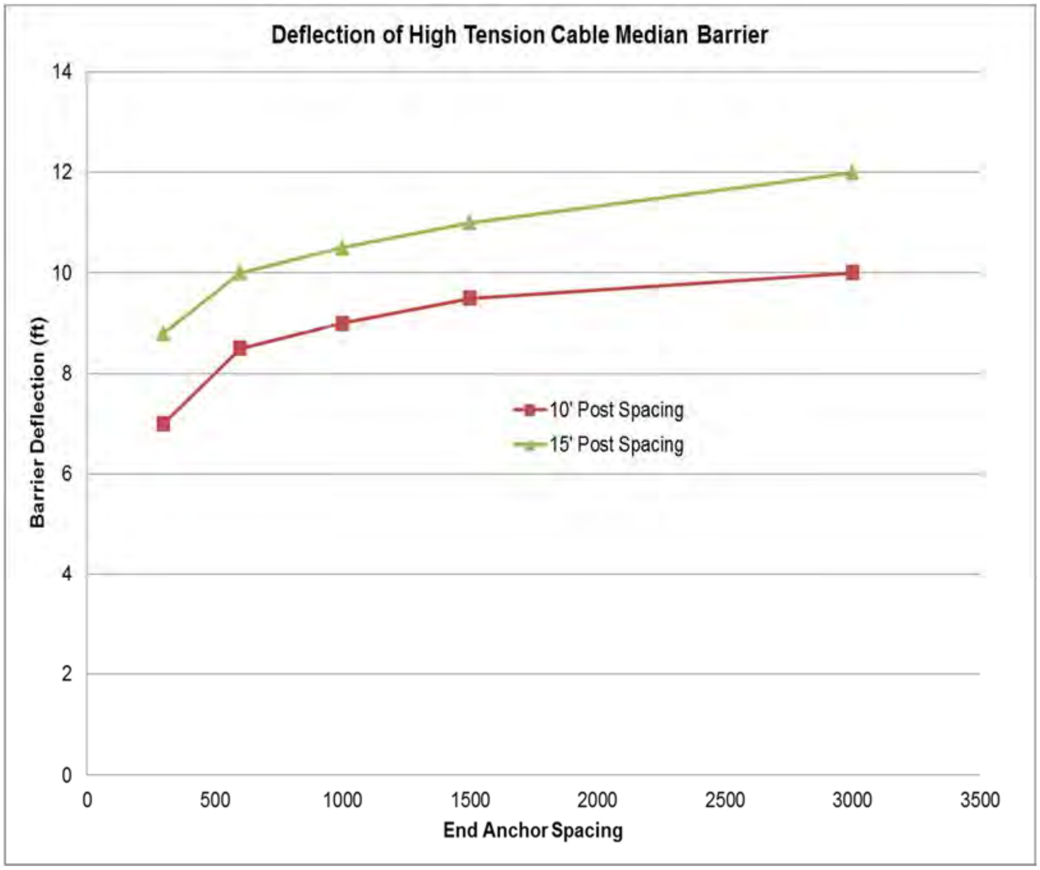
COORDINATION OF HIGH TENSION CABLE WITH STRUCTURES AND CROSSOVERS

Figure 38-7.E



Cable Median Barrier Deflection vs Post Spacing and End Anchor Spacing

Figure 38-7.F

38-7.04 Median Barrier Layout

Much of the information presented in Section 38-6 on roadside barrier layout also applies to median barriers (e.g., placement behind curbs). The following sections present criteria specifically for the design of median barriers.

38-7.04(a) Sloped Medians

Slopes in the median affect the performance of a barrier. A vehicle traversing a slope, or transitioning between two slopes, prior to impact may not impact the barrier with all four tires on the ground, may have its suspension compressed, or may have a tendency to roll. Where the impact is made under these types of conditions, the crash results may be undesirable. The recommendations for median barrier type and placement considering slopes are shown in Figure 38-7.C.

38-7.04(b) Flared/Divided Median Barriers

It may be necessary to flare a median barrier to a different offset from the traffic lane. Also, a sloped median, a fixed object in the median, or twin separate bridges may require that a median barrier be divided. The median barrier may be divided by one of the following methods:

1. Rigid Median Barriers. A fixed object may be encased within a concrete barrier or a single-faced concrete barrier may be placed on both sides of a fixed object, see Figure 38-7.G.
2. Semi-Rigid Median Barriers. Steel plate beam guardrail, Type D, may be divided into two separate runs of guardrail passing on each side of the median hazard (fixed object or slope), see Figure 38-7.H.
3. Flexible Median Barriers. HTC barriers may be placed on either or both sides of a median hazard, provided adequate deflection distance is available. If the HTC runs on only one side of the hazard, a roadside barrier or impact attenuator should be used as needed to protect traffic in the opposing direction.

Flare rates for rigid or semi-rigid systems should be according to the guidelines for roadside barriers. Flexible barrier may be flared at a rate of 1:50.

38-7.04(c) Barrier-Mounted Features

Luminaire supports are often mounted on top of concrete barriers, and the top height is typically able to accommodate them. However, the designer should recognize that a zone of intrusion [see Section 38-6.03(6)] is a relevant concern when a concrete barrier divides to pass on either side of an obstacle or when features are mounted on top of a concrete barrier. If trucks or buses impact the concrete barrier, their high center of gravity may result in a vehicular roll angle which possibly will allow the truck or bus to impact the features on top of or immediately adjacent to the concrete barrier. The 44 in. (1120 mm) Double Face Concrete Barrier provides sufficient height to substantially reduce past concerns (with lower-height barriers) regarding the zone of intrusion. However, a designer should consider whether there are opportunities to split a standard barrier into two separate single-face barriers while providing a 2 ft (600 mm) to 3 ft (900 mm) offset distance between the barrier face and obstacle (e.g., bridge piers or poles).

38-7.04(d) Terminal Treatments

As with roadside barrier terminals, median barrier terminals present a potential roadside hazard for run-off-the-road vehicles. Therefore, the designer must carefully consider the selection and placement of the terminal end. Where practical, the median barrier should be extended into a wider median area so that the terminal is further from traffic. The following *NCHRP Report 350* or MASH terminals are used by the Department for median barriers:

1. Rigid Median Barriers. The end of a concrete barrier is typically shielded with an impact attenuator. The Department maintains a Qualified Products List (QPL) on its website. *NCHRP Report 350* or *MASH* passed devices are required as noted on the QPL, which is regularly updated to list the approved devices, noting their MASH testing status and associated Test Level.

2. Semi-Rigid Median Barriers. Steel plate beam guardrail, Type D, is typically shielded with an impact attenuator. Refer to the discussion on rigid median barriers above.

3. Flexible Median Barriers. For HTC barriers each system has its own proprietary terminals. The terminals included in the QPL meet the requirements of *NCHRP Report 350* or MASH, and testing status is noted.

38-7.04(e) Superelevation

Chapter 32 discusses superelevation development for multilane divided facilities. Where a median barrier is present, the axis of rotation is typically about the two median edges. This will allow the median (and the barrier) to remain in a horizontal plane through the curve. See Chapter 32 for more information.

38-7.04(f) Median Crossovers Locations

1. Permanent Locations. Chapter 44 provides guidance and further reference for the location and design of permanent median crossovers. Proper installation of median barriers must take permanent median crossovers into account as there will be a break in the barrier. Where a break is exposed to approaching traffic, it will require treatment according to Section 38-7.04(d). Consider the following:

    a. The most common method for providing an opening in a median barrier for a permanent crossover is to establish a gap in the barrier.

b. For rigid or semi-rigid barriers, the gap should fit the geometry of the permanent crossover and provide the required throat width for the crossover, plus allowance for any radii or flares.

c. For flexible barriers, keep the end anchorage location about an additional 30 ft (9.0 m) away from the completion of the radii or flares. This will help to prevent damage to the terminals by vehicles using the median crossovers that would release tension on the entire run of barrier. Also, for HTC consider changing sides of the median at median crossovers. This will provide slightly better length of need coverage and also provide an opportunity to introduce the change of sides for reasons discussed in Section 38-7.03(b) and as shown in Figure 38-7.I.

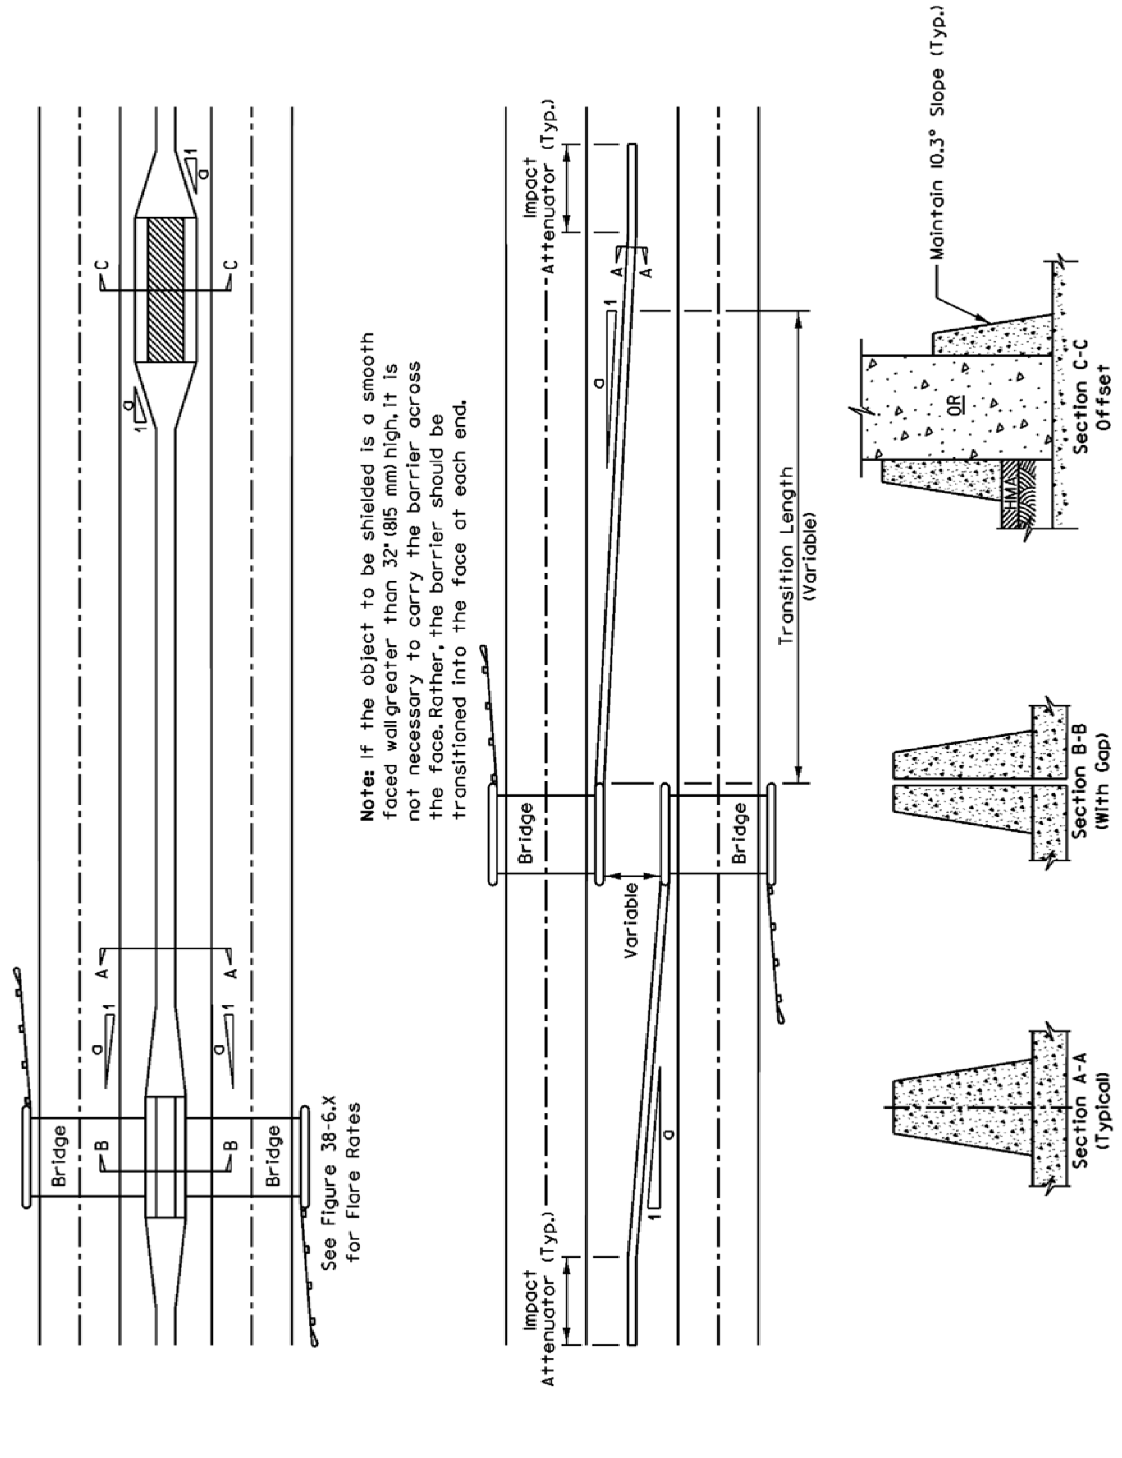
d. Another way to create an emergency location for crossing the median is to leave a gap while at the same time changing the side of the median for the barrier. In this application, the length of need points for the barriers should be connected by a line departing the traveled way at a 25 degree angle. This will provide continuous protection of the median for most departing vehicles; see Figure 38-7.E.

e. Proprietary barrier gates are available for concrete median barriers. These gates are opened by manual means or by electric motors depending on the brand and options selected. These gates should only be used on a case-by-case basis and when supported by a decision according to Section 66-1.04(b).

2. <u>Temporary Locations</u>. For HTC barriers it is possible to create or anticipate temporary locations for emergency use.

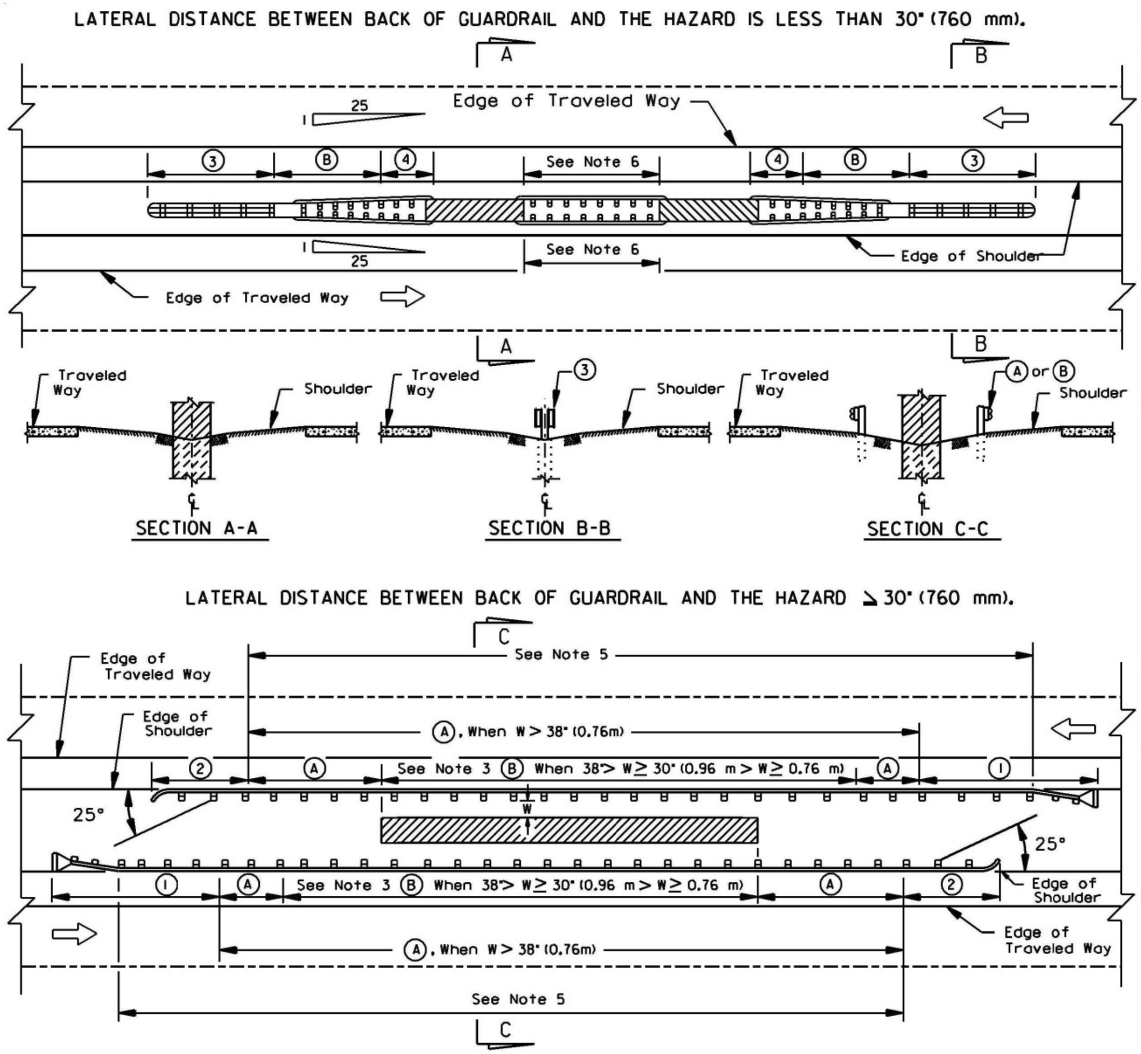
a. Where socketed posts are used, it is possible to remove the cables from a sufficient number of posts, or disconnect the cables at the turnbuckles, and create slack. Once cable slack is present, sufficient posts may be removed to create temporary crossover locations.

b. Careful selection of well-drained locations for changing sides for HTC can allow emergency vehicles to make serpentine moves across the median were soil conditions are sufficiently stable. For example, this may indicate ditch check locations or pier locations.



FLARING/DIVIDING CONCRETE BARRIER

Figure 38-7.G



Notes:

1. Traffic Barrier Terminal Types:
   - (1) Type 1(Special)
   - (2) Type 2
   - (3) Impact Attenuator
   - (4) Type 6 or 6B
2. Steel Plate Beam Guardrail Types:
   - (A) Type A
   - (B) Type B
3. Provide min. 25' (7.62 m) of Type B guardrail in advance of hazard. Provide Type A guardrail as needed to meet length of need. If Type A guardrail is not required, Type B guardrail may be connected directly to traffic barrier terminal Type 1, special.
4. Where the foreslope is 1V:10H or steeper, locate guardrail at shoulder edge.
5. Total length of barrier includes length of need on each end of the hazard plus the length required immediately adjacent to the hazard. See Section 38-6.01.
6. Close gap between piers with concrete barrier, or connect Type 6 or 6B terminals to each, and maintain 18.5" (470 mm) post spacing and nested thrie beam from pier to pier.

Drawing not to scale.

Figure 38-7.I

38-7.05 Glare Screens

38-7.05(a) General

Headlight glare may be defined as a sensation experienced when a person's vision is interrupted by a light source which has a much higher intensity than the surrounding area. It is frequently cited as a major contributing factor in nighttime crashes that occur on unlighted highways The magnitude and severity of headlight glare depends on various combinations of a wide variety of factors, including:

- headlight systems, which include the headlight configuration, mounting height, and output intensity;
- roadway features, which include the roadway alignment, geometrics, and pavement reflectivity;
- transmission media, which includes the atmosphere and physical features through which the light must pass, such as windshields and eyeglasses; and
- human variables, which include driver's age, visual ability, and fatigue.

Depending on the severity and effect glare has on a driver, it may be classified as discomfort or disability glare, defined as follows:

1. Discomfort. Discomfort glare does not necessarily impair the vision. However, it frequently causes drivers to become tense and apprehensive, which increases the level of fatigue and may lead to driver error. This type of glare is common and usually occurs where median or outer separator widths are greater than approximately 30 ft (10 m).

2. Disability. Disability glare definitively impairs a driver's vision, frequently causing temporary blindness; consequently, it should be addressed whenever practical. Disability glare occurs usually where median or outer separator widths are less than approximately 30 ft (10 m) in width, on horizontal curves, where the opposing traveled ways are at different elevations, and/or where transitions alter the highway horizontal alignments of the directional roadways.

38-7.05(b) Design Considerations

As indicated, headlight glare from opposing traffic can be bothersome and distracting. Glare screens can be used with or without median barriers to greatly reduce the problem and should be used when no other practical alternative exists to eliminate disability glare (e.g., wider median, outer separation, highway lighting, landscaping). The designer should consider if the following conditions exist when determining the need for a glare screen:

- unlighted divided highways where design speeds are 50 mph (80 km/hr) or greater and medians 30 ft (9.0 m) or less in width;
- horizontal curves on divided highways;
- points where the separation between a mainline and frontage road is minimal and alignment is such that mainline traffic is affected by the lights of vehicles using the frontage road;
- points of transition which create critical glare angles between opposing vehicles;
- locations where nighttime crash rates are unusually high; and
- any location where conflicting light sources cause a distorted or confusing view of the driver's field of vision.

The Department has not adopted specific warrants for the use of glare screens. The typical application, however, is on urban freeways with narrow medians and high traffic volumes. Another application is between on/off ramps at interchanges where the two ramps adjoin each other. Here, the sharp radii and the narrow separation may make headlight glare especially bothersome. The designer should consider the use of glare screens at these sites. A key element warranting their use is the number of public complaints received for a highway section.

38-7.05(c) Glare Screen Types

The following describes the glare screens used by the Department:

1. Concrete Glare Screen. The current single slope double face concrete barrier has a height that lessens the frequency of glare concerns compared to older lower barriers, but these concerns persist under certain conditions. Where a glare screen is warranted for a section of roadway with concrete barrier, the designer may specify a concrete glare screen. See the *Illinois Highway Standards* for details. This type of glare screen is advantageous on high-volume routes due to its low maintenance.

2. Glare Screen Blades. As an alternative to the concrete glare screen, a series of thin vertical blades may be mounted on top of the concrete barrier. The designer must specify the spacing, height, and longitudinal spacing of the blades on the plans. Please contact the Central Bureau of Materials when considering the use of glare screen blades.

3. Fence Glare Screen. A fence glare screen usually consists of fabric lined fence or a fence with slats woven into the fence material. This type of glare screen is typically used in controlling glare between the mainline and adjacent frontage roads where an access control fence is usually required. In addition to alleviating glare, the fence will restrict potential unpermitted access between two closely spaced facilities.

38-7.05(d) Glare Screen Design

The following applies to the design of a glare screen:

1. General. Glare screens must not be used as a wind or snow shield nor should they detract from the aesthetics of the highway. However, they should be durable and easy to maintain.

2. Cutoff Angle. Glare screens should be designed for a cutoff angle of 22 degrees. This is the angle between the median centerline and the line of sight between two vehicles traveling in opposite directions; see Figure 38-7.J. The glare screen should be designed to block the headlights of oncoming vehicles up to the 22 degree cutoff angle. On horizontal curves, the design cutoff angle should be increased to allow for the effect of curvature on headlight direction:

   $$\text{Cutoff Angle (in degrees)} = 22 + \frac{5729.6}{R} \qquad \text{(US Customary)}$$

   $$\text{Cutoff Angle (in degrees)} = 22 + \frac{1746.8}{R} \qquad \text{(Metric)}$$

   Where:

   R = radius of horizontal curve in feet (meters)

3. <u>Horizontal Sight Distance</u>. Glare screens may reduce the available horizontal sight distance. For curves to the left, the designer will need to check the middle ordinate to determine if adequate stopping sight distance will be available; see Section 32-4.

4. <u>Sag Vertical Curves</u>. When determining the necessary glare screen height, the designer may ignore the effect of sag vertical curvature.

5. <u>Height of Eye</u>. The average driver's eye height is 3.5 ft (1065 mm) for passenger vehicles and 7.6 ft (2.3 m) for large trucks. These heights are averages and must be adjusted when considering outlying conditions.

6. <u>Glare Screen Height</u>. The upper and lower elevations of the glare screen must be such that light does not shine over or under the barrier. The height of glare screens may be established by examining the following factors:

   a. height of driver's eye in relation to the pavement,

   b. height of the headlights of various size vehicles in relation to the pavement, and

   c. changes in elevation across the entire roadway width including the median.

7. <u>Coordination of Glare Screen with Concrete Barrier</u>. The preceding steps cover design of glare screen. However, calculation of detailed height requirements does not imply that the height of glare screen should vary repeatedly from location to location along a job. Select the height to bracket the needs of the section or logical segments. In addition, the height to the top of glare screen should be determined using standard devices and the following steps:

   For locations where the 44 in. (1120 mm) concrete barrier is used, the concrete glare screen may be added to reach a height of 63 in. (1600 mm). If heights greater than 63 in. (1600 mm) are required, then glare screen blades or special designs using concrete may be considered. The addition of taller concrete barrier or concrete glare screen raises issues regarding control of debris scatter from a collision, as well as the necessary shape and slopes for the taller sections. Contact BDE to coordinate any designs using concrete glare screens above a height of 63 in. (1600 mm).

* * * * * * * * * *

Example 38-7.05(1)

Given: Six-lane divided highway
12 ft travel lanes
2% pavement cross slope
5 ft median width

Problem: Determine the upper and lower elevations of the glare screen.

Solution: First, determine the lower elevation based on the following factors:

1. The most severe condition is two sport cars traveling in opposite directions each using the right-hand lane.
2. The eye level of the drivers is 3 ft above the pavement.
3. The lower edge of the sport car's headlights is 1.75 ft above the pavement.
4. The driver's eyes are approximately 8.75 ft from the outer edge of the traveled way.
5. Figure 38-7.K presents the determination of the lower edge of the glare screen.

Next, determine the upper elevation based on the following factors:

1. The most severe condition is two large trucks traveling in opposite directions, one using the right-hand lane and the other using the left-hand lane.
2. The eye level of the drivers is approximately 7.6 ft above the pavement.
3. The lower edge of the truck headlights is 3.75 ft above the pavement.
4. The eye of the driver using the left-hand lane is approximately 5.75 ft from the median centerline.
5. The left headlight of the truck using the right-hand lane is approximately 4.5 ft from the outer edge of the traveled way.
6. Figure 38-7.L presents the determination of the upper edge of the glare screen.

For most locations, it is not necessary to use this upper level; see Section 38-7.05(c).

38-8 IMPACT ATTENUATORS (Crash Cushions)

38-8.01 General

Impact attenuators (crash cushions) are protective systems that prevent errant vehicles from impacting hazards by decelerating them to a stop after a frontal impact, by redirecting them away from the hazard, or by decelerating them after a side impact. They operate on the basis of either energy absorption or momentum transfer. Impact attenuators are adaptable to many roadside hazard locations where longitudinal barriers cannot practically be used. Selection of the appropriate device or system must consider the corridor design speed and required test level as described earlier in this chapter.

Impact attenuators have two primary applications. They may be installed as stand-alone devices to shield point hazards (e.g., bridge piers, sign foundations) or they may be used as terminal treatments for roadside or median barrier systems. Where used to shield a point hazard, the impact attenuator is placed very near or in contact with the hazard; therefore, no length of need applies, and no additional barrier is required. This application may be appropriate only where the shoulder and/or front slope in the runout area is 1V:10H or flatter and other requirements of the impact attenuator layout (e.g., pad or base, physical room for the system) can be accommodated. Otherwise, a roadside barrier or median barrier, as appropriate should be used.

38-8.02 Warrants

Impact attenuator warrants are the same as barrier warrants. Once a hazard is identified, the designer should first attempt to remove, relocate, or make the hazard break away. If these options are impractical an impact attenuator should be considered.

For median widths of 84 ft (26 m) or less, all piers, sign foundations, and similar hazards in medians of divided highways warrant shielding. For median widths greater than 84 ft (26 m), the need should be considered on a case-by-case basis.

38-8.03 Impact Attenuator Types

38-8.03(a) Overview

Selection of the most appropriate impact attenuator type depends on a variety of factors:

1. Redirective Properties. The impact attenuator devices have various properties related to the path of a vehicle after impact.
2. Operational Principles. The systems have varied means to deal with the energy or momentum impacted by an impact.
3. Maintenance and Repair Issues. Some systems retain residual capacity to absorb additional frontal impacts during the time between an initial crash and full repair of the system. Systems vary in the cost and effort required for repair of crash and nuisance hits.

4. Approved Devices. To be considered for use on Illinois highways, a given device must be included on the Department's QPL.

5. Physical Placement Requirements. The size, layout and anchorage requirements may dictate or eliminate various systems depending on the type of location where protection is required.

6. Costs. Given the wide variation in the approaches to the above considerations, the systems vary in cost of installation and repair. Life cycle cost analysis using the Roadside Safety Analysis Program (RSAP) may be a useful tool.

7. Pedestrians/Bicyclists. In some installations, impact attenuators may be introduced into the pedestrian/bicyclist environment. This will require consideration of various factors to evaluate the relative risks to the vehicular traffic and pedestrian/bicyclist traffic.

All of these factors, taken together, guide impact attenuator selection. The selection process for both permanent and temporary devices, is covered in this section. Impact attenuators are moving toward compliance with MASH testing criteria. The QPL is regularly updated to note the testing status of each proprietary device as well as the approved test levels.

38-8.03(b) Redirective Properties

Impact attenuators are further categorized by how they redirect impacting vehicles.

1. Fully Redirective Devices. A fully redirective device will safely redirect a vehicle that impacts at any location along the face of the device.

2. Partially Redirective Devices. A partially redirective device will safely redirect a vehicle that impacts downstream of a given length of need point along the length of the device. This type of device will allow a vehicle impacting between the length of need point and the free end of the impact attenuator to pass through to the area behind the device.

3. Non-Redirective Devices. A non-redirective device will either capture an impacting vehicle or allow it to pass through when hit along the face of the device.

38-8.03(c) Operational Principles

1. Energy Absorbing Devices. This type of impact attenuator operates on the principle of absorbing the energy of the vehicle by various means, including crushing or deformation of engineered modules, friction of moving parts, or by compression of a hydraulic cylinder. Some energy is also absorbed by the impacting vehicle as the front end of the vehicle is crushed on impact. Energy absorbing attenuators require rigid back-up support or connection to another barrier system to contain the forces created by the deformation of the device. This support may be supplied as part of the impact attenuator or may be derived from its connection to the barrier or hazard (e.g., concrete structure). This distinction may preclude the use of some systems for shielding point hazards that will not

provide this support. In these cases, a special provision limiting the selection to no less than two alternatives may be required. This type of device also requires vertical and lateral anchoring. This is accomplished by attachment to a bituminous or concrete base or by placement of posts. Devices of this type capture or rebound the vehicle in a frontal impact. For side impacts, the devices work either as fully redirective or partially redirective.

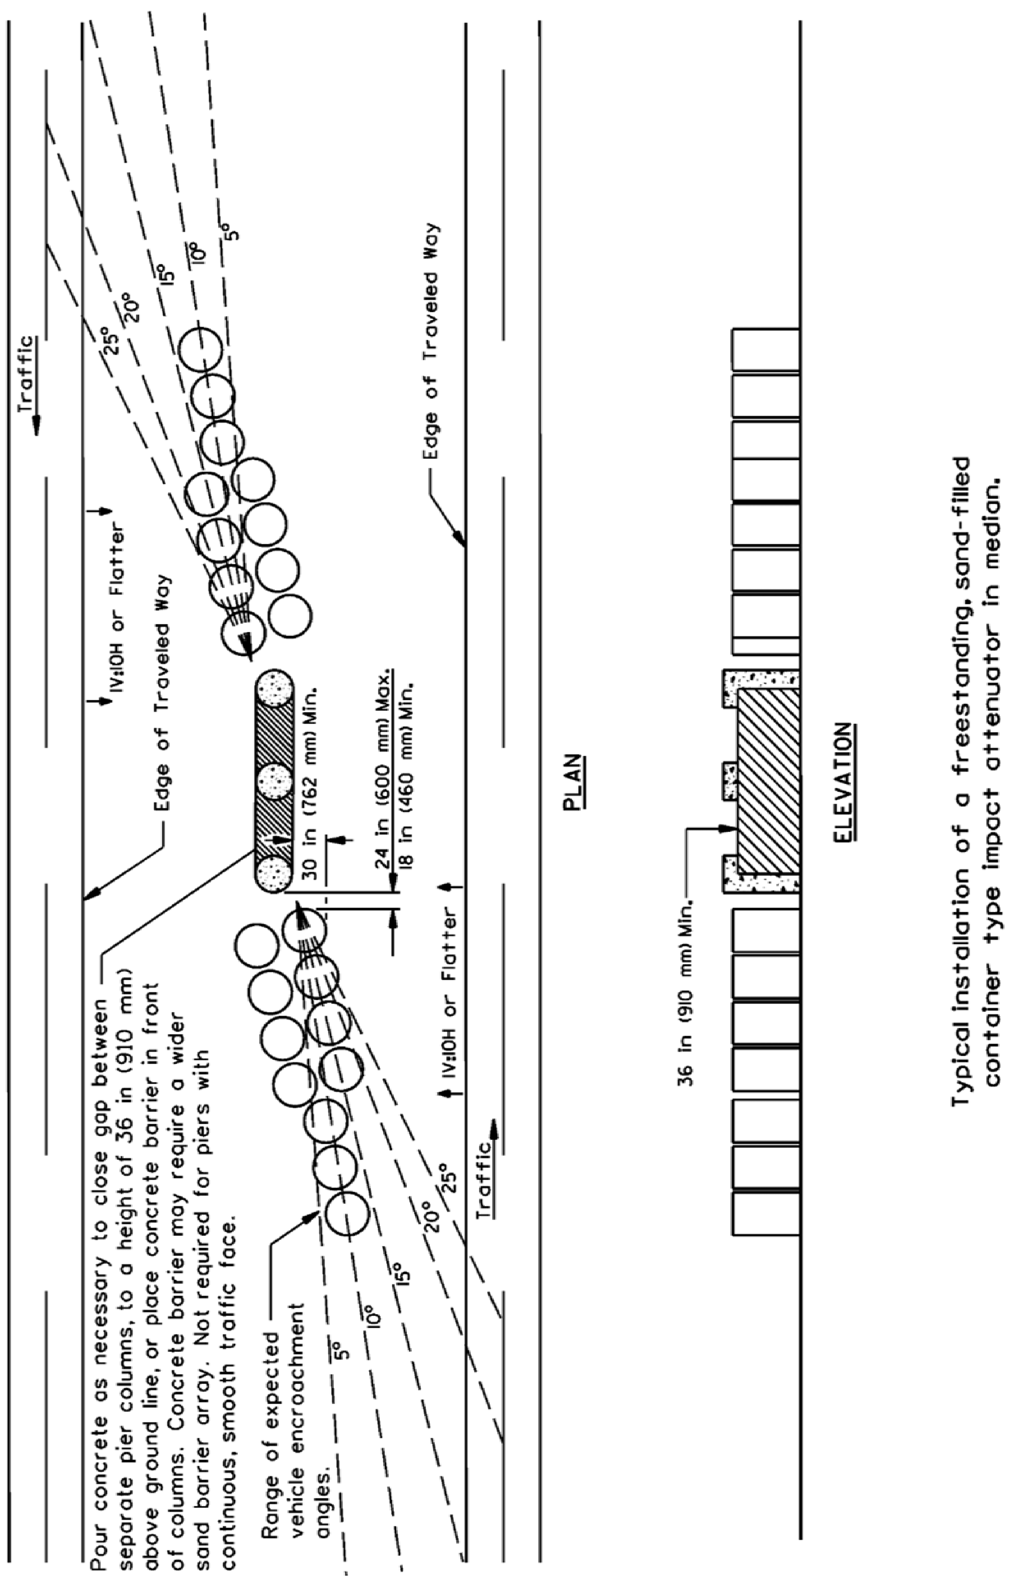
2. Momentum Transfer Devices. This type of system operates by transferring the momentum of an impacting vehicle to an expendable mass of material contained in the device.

   a. Sand Modules. A typical momentum transfer device is an array of sand-filled plastic modules. The Department has developed standard arrays for both Test Level 2 and Test Level 3 (see *Highway Standard* 643001). Once the Test Level is selected for a project (TL-2 or TL-3), the number of modules used in the standard sand module array need not be altered, except to provide lateral protection as discussed immediately below:

   The sand module impact attenuator design should allow for safe side impacts. Figures 38-8.A and 38-8.B illustrate two methods to modify the sand module design to accommodate angle impacts. Figure 38-8.A illustrates how the modules may be shifted to afford attenuation at the end points and direction along the sides of the hazard by closing or covering the gap between pier columns. Figure 38-8.B illustrates where the side of the hazard and available space are such that full protection, through attenuation only, can be provided by the use of additional modules to widen the standard array. Although the entire area of the hazard must be shielded from angle impacts either by attenuation or redirection, the permissible attenuation may be varied to optimize space and economy.

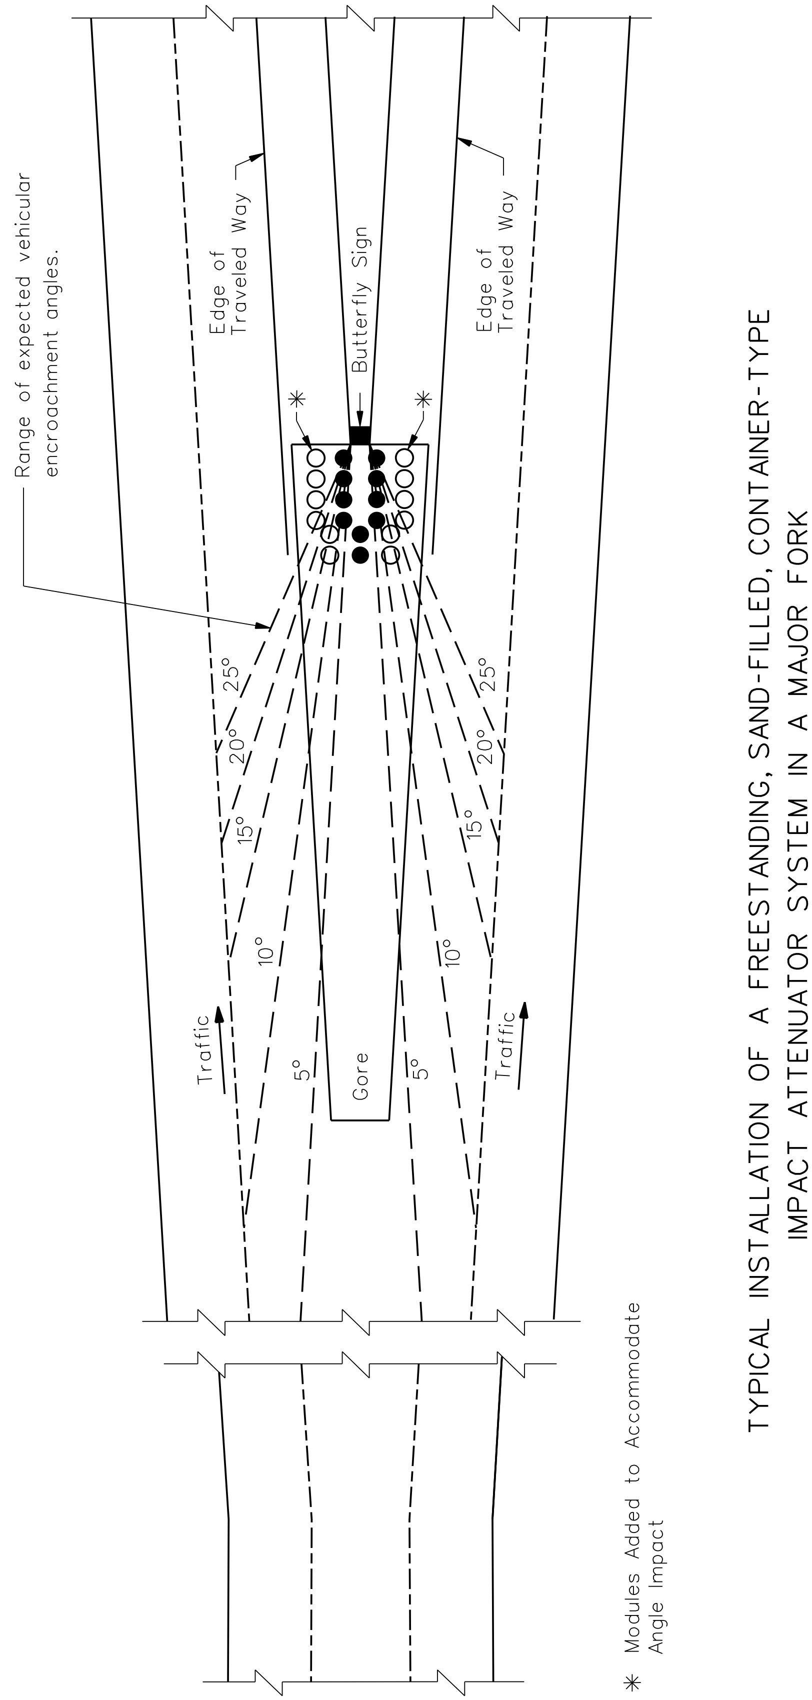
   The sand module systems require no back-up support or connection to another system. However, they do require a firm and stable base. For permanent systems, an HMA or PCC base is required. For temporary installations not to be placed over a winter, an aggregate base may be used. Sand modules have no redirective capability and generate considerable debris upon impact. On the approaching traffic corner, the exterior modules must be laterally offset at least 2.5 ft (750 mm) from the corner of the hazard; see Figure 38-8.A.

   Show the layout of sand modules, including positioning relative to the hazard, in the plans. Note the Test Level (TL-2 or TL-3) for which the array is designed.



ANGLE IMPACT AND POSITIONING DESIGN FOR SAND BARRELS

Figure 38-8.A



ANGLE IMPACT DESIGN FOR SAND BARRELS

Figure 38-8.B

b. Water Filled Impact Attenuator. The water-filled barrier dissipates energy both by energy transfer (crushing of modules) and by momentum transfer to the system's mass. Water filled impact attenuators also have no redirective capability and may spread water in the area of an impact. These impact attenuators are used with temporary barriers only when freezing is not a concern, and must be attached to the barrier system. They do not require anchorage to the pavement or base. Water filled impact attenuators require less width for placement than do sand module impact attenuators.

Figure 38-8.C gives comparisons of systems based on their operational principles.

38-8.04 Maintenance and Repair Considerations

Some systems require extensive repairs or replacement after a full speed impact, while some others may only require minor adjustments and/or replacement of drop-in modules or simply resetting with minimal repair parts. Additionally, some systems retain partial capability to shield a hazard after an initial impact and before repair.

Sand modules are particularly vulnerable to nuisance hits from mowers or wide vehicles. Such occurrences may puncture the plastic modules and cause loss of sand, thereby rendering the devices less effective. Care should be taken to provide some buffer space on the pad for sand modules to allow for mower overhang. A minimum suggested buffer is 12 in. (300 mm) along the sides and front of the array.

Impact attenuators that incorporate tracks or guides anchored to a base may be subject to accumulation of road debris (e.g., sand and silt). In extreme cases and conditions these may interfere with the operation of the attenuator. Generally, attenuator locations should be kept out of depressed locations or other sites that encourage deposition of debris. Where this is unavoidable, the designer may "write out," by special provision, any specific impact attenuators that have critical moving parts (e.g., tracks, guides, rollers, cables) near the ground line.

38-8.04(a) Resettable Devices

Resettable devices are those that do not usually require significant repair parts but may require some work to return the system to a crashworthy configuration ready for the next impact. The initial cost for these systems is intermediate between severe use (see Section 38-8.04(b)) and other fully-redirective devices. These devices are cost-effective where significant impacts may occur one or more times in a three-year period. Spreadsheets are available for more detailed analysis. Contact the Bureau of Safety Programs and Engineering for more information.

Operational Principal	Advantages	Disadvantages
Energy Absorbing Devices	• Little or no debris after a hit. • Ease of maintenance after a hit. • Some systems retain partial attenuation capacity after a hit. • Protection from pocketing at transition from impact attenuator to hazard. • Adaptable to very narrow hazards.	• Possible high initial cost. • Considerable site preparation (e.g., pad, back-up structure, mounting bolts or anchors). • IDOT pay items and specifications will cover hazards up to only 90 in. (2.25 m) wide. See Section 38-8.06. • Not suitable for spanning structural expansion joints. Special details required in plans. Contact BSPE if this application is required.
Momentum Transfer Devices (Sand Modules)	• Relatively low initial cost. • Ease of installation. • Versatile; can be used to cover a large area.	• Considerable debris after a unit is hit. • Generally, no residual attenuation capacity after a major hit. • No side redirection and little or no protection at transition for impact attenuator to hazard. • Considerable inventory of parts and space for replacements required. • Modules may "walk" when placed on structures. Contact BDE if this application is required.
Momentum Transfer Devices (Water Filled)	• Relatively low initial cost. • Ease of installation. • Little or no site preparation. • Does not require anchorage to a paved base. • Adaptable to very narrow hazards. • After impact, can be restored quickly by two laborers and a water supply/tank.	• Water on ground or pavement immediately after a hit. • Require environmentally friendly antifreeze for cold weather application. • Attaches only to concrete barrier, although the barrier may transition then to other systems. • Generally, no residual attenuation capacity after a major hit. • No side redirection. Must be placed beyond the length of need point. • Modules may "walk" when place on cross-sloped structures. Contact BDE if this application is required.

COMPARISON BY OPERATIONAL PRINCIPLE

Figure 38-8.C

There is no specification for wide impact attenuators in the resettable category. This is because the available systems vary in their treatment of this issue. Where a wide hazard is to be shielded with a resettable attenuator, the designer may prepare a special barrier transition from the hazard to the attenuator connection. See the manufacturer's specifications and drawings as well as Section 38-6.05.

38-8.04(b) Severe Use

Severe use applies to installations where the crash cushion should retain some residual capacity to absorb additional frontal impacts while awaiting repairs. The crash cushion should also require minimum cost and time for repairs after an impact. These installations are those where repeated or frequent hits are known or anticipated, and where lane closures to repair the crash cushion need to be kept to a minimum time window.

The residual frontal impact capacity available in the severe use items may be offset by some reduction in redirective capability. The residual capacity is not a substitute for proper inspection and repair after each impact. Also, the elastic components will deteriorate with time and repeated impacts and will require replacement. Some current indications are that about 13 to 15 impacts may warrant replacement.

38-8.05 Approved Devices

1. Approved Devices. For routine use by the Department, a system must be on the Department's QPL for Impact Attenuators. Unless otherwise noted, all items on the QPL are crash tested and accepted at Test Level 3. This level of safety is adequate for facilities with design speeds greater than 45 mph. For facilities with normal roadside design speeds of 45 mph or less, the designer may specify the use of devices accepted at Test Level 2. Information relative to Test Level 2 devices is included in Figure 38-8.G and the list of approved devices. Also, see Figure 38-8.G for a partial review and comparison of attributes of various approved systems.

2. Other Devices. There are some crashworthy devices that are not listed on the Department's QPL. For information about these devices, see the FHWA website, the AASHTO *Roadside Design Guide*, and the various manufacturers' brochures and Internet sites. A proposed use of these devices must be coordinated with BDE and BSPE.

Figure 38-8.H correlates the various systems relative to contract pay items.

38-8.06 Physical Placement Requirements

Several factors should be considered in the placement of an impact attenuator:

1. Level Terrain. All impact attenuators have been designed and tested for level conditions. Vehicular impacts on devices placed on an excessively sloped site could result in an impact at an improper height, which could produce undesirable vehicular behavior. Therefore, the attenuator should be placed on a base or pavement slightly sloped to

facilitate drainage, but the cross slope should not to exceed 5%, or as allowed by the proprietary specifications. Impact attenuators that require anchorage to the base should not be placed over a break in slope as this can misalign necessary guide rails and other components.

2. <u>Curbs</u>. No curbs higher than 2 in. (50 mm) should be constructed at impact attenuator installations. On existing highways, all curbs higher than 4 in. (100 mm) should be removed at proposed installations, if feasible.

3. <u>Surface</u>. Many impact attenuator systems require a paved, bituminous or concrete pad. To minimize nuisance hits, especially for sand module impact attenuators, the total base width should be 2 ft (600 mm) wider than the array.

4. <u>Elevated Structures</u>. The unanchored sand modules or water-filled impact attenuators may "walk" due to the vibration of an elevated structure with a cross-sloped surface. This could adversely affect its performance. If it is necessary to place sand modules or water-filled impact attenuators on elevated structures, contact BDE for assistance.

5. <u>Orientation</u>. The impact attenuator should be oriented to accommodate the probable impact angle of an encroaching vehicle. See Figures 38-8.A and 38-8.B for sand modules. This will maximize the likelihood of a head-on impact. However, this is not as important for impact attenuators with redirective capability. The proper orientation angle will depend upon the design speed, roadway alignment, and lateral offset distance to the attenuator. A maximum angle of approximately 15° toward oncoming traffic, as measured between the highway and impact attenuator longitudinal centerlines, is considered appropriate.

6. <u>Location</u>. The system must not infringe on the traveled way. There should be a minimum of 2 ft (600 mm) behind sand module systems and in front of the hazard to allow access to the system. The space or transition behind other impact attenuator systems should be according to the manufacturer's specifications.

7. <u>Bridge Joints</u>. Avoid the placement of fully or partially redirective impact attenuators over bridge expansion joints or deflection joints in deep superstructures because movement in these joints could create destructive strains on the system's anchor cables or other continuous parts.

8. <u>Transitions</u>. If required, transitions between systems and backwalls, bridge rails, or other objects are detailed in various proprietary systems. Review the acceptance information and Figure 38-8.G to ensure that systems are approved for bidirectional applications where necessary.

   Many impact attenuators can connect to guardrail or to concrete barrier. In these cases, and where the available length allows, width transitions may be designed using a barrier extended back from the impact attenuator to a connection to or protective position in front of the wide hazard. The barrier design and flare rates should be according to Section 38-6 and the *IDOT Highway Standards*. Any flared barrier or impact attenuator may somewhat increase the redirection angle for impacting vehicles.

38-8.07 Cost

The designer should investigate relative costs for items under consideration. In some cases, a premium for fully redirective properties, for a resettable system, or for items for severe use installations will be offset by the maintenance or repair benefits provided. However, the designer should be careful not to apply premium systems where crashes are rare (1 or less expected impact per 10 years). In these cases, consider using simpler, lower priced systems.

Conversely, use of a low-cost, sacrificial system in an area with occasional (up to 1 crash per 3 years) to frequent impacts (2 or more impacts per year) will lead to high costs for repeated replacement of the attenuator.

38-8.08 Pedestrian/Bicyclist Environment

Impact attenuators are designed to contribute to a forgiving roadside for errant vehicles. The crash testing takes place at 60 mph (100 km/hr) (nominal) and angles up to 25° for Test Level 3 and at 45 mph (70 km/hr) (nominal) and similar angles for Test Level 2 devices. The impact attenuators developed to buffer such crashes are often constructed of steel panels and frames, cables, and steel or wood posts. Also, during an impact, these parts are designed to move, crush, or break in a controlled manner. As result, the impacting vehicle may rotate, rebound, or glance off the impact attenuator.

Placing an impact attenuator in a pedestrian environment imposes compromises and tradeoffs between vehicle occupant safety and pedestrian/bicyclist safety. Consider the following:

- As much as practical, impact attenuators should be placed away from pedestrian/bicyclist facilities. For example, where an impact attenuator must be located at the end of a parapet or wall crossing a bridge, if space permits, extend the wall or parapet beyond the bridge and separate the pedestrian/bicyclist pathway from the wall and roadway before introducing the impact attenuator.
- Evaluation of the tradeoffs between vehicular and pedestrian/safety should include factors contributing to the relative risk for each user class. These include exposure of individuals, quality of the design/design constraints, and expected severity of each crash category.
- Exposure measures include ADT for vehicular traffic, pedestrian volumes, and bicycles.
- Measuring the quality of the design includes mainly the offset between the impact attenuator and the roadway and/or pedestrian/bicyclist way along with any constraints on developing the offset.
- To evaluate the expected severity of any crashes, consider the operating speed of the roadway facility, the treatment under consideration (e.g., impact attenuator, blunt end, sloped end), and the nature of any particular impact attenuators.
- Figure 38-8.D offers guidance regarding pedestrian/bicyclist considerations for particular impact attenuators.

Impact Attenuator System or Family	Pedestrian/Bicyclist Considerations
QuadGuard	• Side panels face pedestrians/bicyclists from opposing direction. • Gaps should be installed as tight as possible on pedestrian side. • Top edge exposed similar to guardrail.
SCI-100GM	• Side panels face pedestrians/bicyclists from opposing direction. • Exposed edges are beveled and should minimize snagging. • Side panels remain nested upon head on impact. • Gaps should be installed as tight as possible on pedestrian side. • Top edge exposed similar to guardrail.
TRACC	• Side panels face pedestrians/bicyclists from opposing direction. • Gaps should be installed as tight as possible on pedestrian side. • Top edge exposed similar to guardrail.
TAU-II	• Same as TRACC.
QUEST	• Same as TRACC.
REACT 350	• Heavy plastic drums connected/restrained by steel cables. • Steel cables are main hazard to pedestrians/bicyclists on the face. • Tops are 4.5 ft (1.4 m) off the ground and should not be hazardous to pedestrians/bicyclists.
CAT-350	• Similar to guardrail terminal.
Brakemaster 350	• Similar to guardrail terminal.
FLEAT-MT	• Similar to guardrail terminal.
Sand Modules	• Plastic drums weighted with sand. Any spilled sand may affect walking/cycling surface.
ABSORB 350	• Plastic barrier shape filled with water. • Temporary use only. • Any spilled water may freeze or otherwise wet the walking/cycling surface.
Compressor	• Steel side panels with exposed ends edges and connectors. • Varying height, including heavy plastic energy absorbing panels.
HEART	• Heavy plastic side panels surround and overhang steel diaphragms, posts, and base. • Bolted external steel retainers hold plastic panels to diaphragms.
SLED	• Water filled plastic modules. • External steel framing on first module.

PEDESTRIAN/BICYCLIST CONSIDERATIONS FOR IMPACT ATTENUATORS

Figure 38-8.D

38-8.09 Impact Attenuator Selection

The selected impact attenuator must be compatible with the specific site characteristics. For each category of device, more than one approved system must be allowed for competitive bidding, unless specific approval is made according to Section 66-1.04(b). Selection of the correct category (pay item) will require comparison and analysis of possible solutions. Factors to consider include:

- type and width of hazard (see Section 38-8.06 on transitions);
- space, or reserve area, available for installation of the system. The reserve area allows for placement of the barrier and any necessary clearances; see Figure 38-8.E;
- whether the hazard to be shielded is located in a high- or low-risk impact area;
- initial, maintenance, and restoration costs;
- ease or difficulty of restoration of the system after impact. The importance of this factor will be related to the traffic and hazard levels at a site. More traffic and higher hazards will make speedy repair or replacement a higher priority; and
- presence and direction of travel of traffic on each side of the impact attenuator.

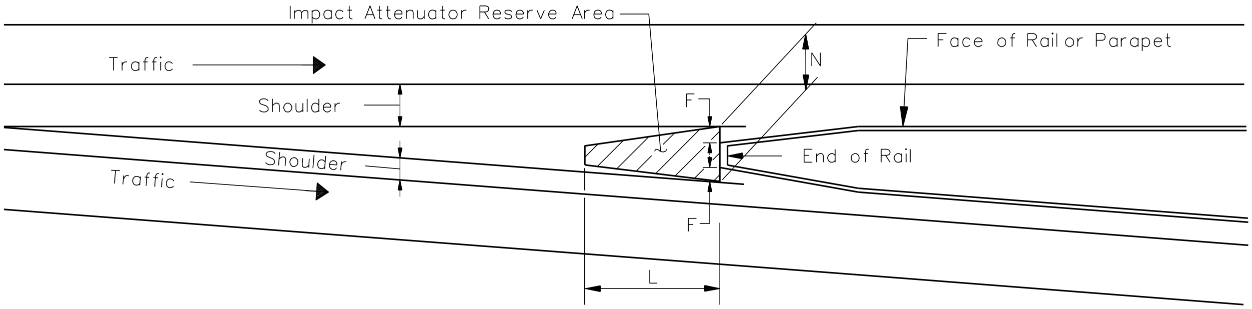
Figure 38-8.F summarizes the advantages and disadvantages of the impact attenuator principles and categories provided in Department specifications. There are many other factors that will influence the selection of an impact attenuator for a given site. Therefore, the designer should only use this figure as a starting point in the comparison and analysis process for selection of the best category.

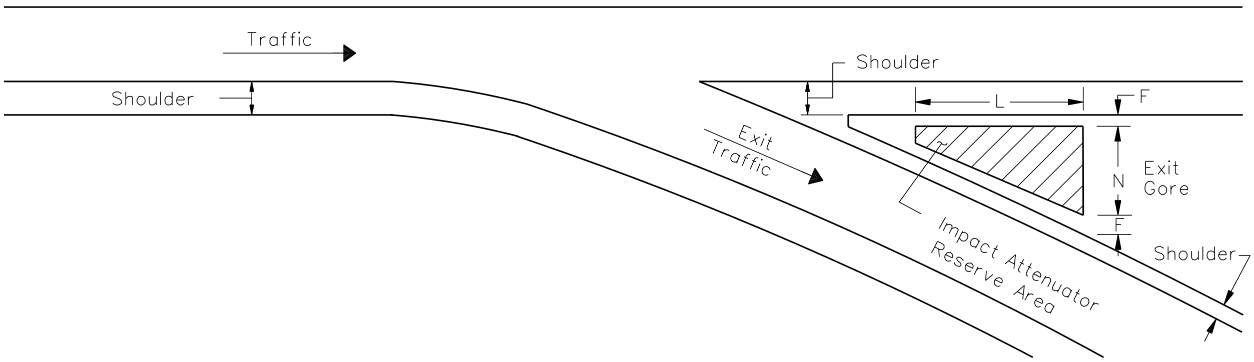
38-8.10 Temporary Installations

Access to the work site becomes an additional consideration for temporary installations, especially where temporary concrete barriers are used to close a lane or to channel traffic.

Also, in some cases (e.g., stage construction of two-lane bridges) it may be desirable for the impact attenuator to block the closed lane, reducing the likelihood that an errant vehicle could reach the construction area. These competing needs, access and physical closure of the lane, may be mutually exclusive at some sites where shoulders and right of way are restrictive.

Where construction access can be provided on the shoulders or by other available means (e.g., temporary widening, easement), the preferred layout would include concrete barriers and an impact attenuator placed to effectively block the closed lane. The designer should provide necessary plan details to show the positioning of the concrete barrier and impact attenuator devices. If sand module impact attenuators are allowed, appropriate configuration from *Highway Standard* 643001 should be noted in the plans. Width restrictions may not allow for angling the array toward traffic. In this case, the array should be installed parallel to the roadway.





Design Speed (DS) On Mainline (mph)	Dimensions for Impact Attenuator Reserve Area (feet)								
	Minimum						Preferred		
	Restricted Conditions			Unrestricted Conditions					
	N	L	F	N	L	F	N	L	F

RESERVE AREA FOR IMPACT ATTENUATORS

Figure 38-8.E

Operational Principle (Pay Item)	Advantages	Disadvantages	Typical Uses*
Energy Absorbing	See Figure 38-8.C.	See Figure 38-8.C.	
Impact Attenuators (fully redirective, narrow) and Impact Attenuators, Temporary (fully redirective, narrow)	• Prevents encroaching vehicle from traveling behind the impact attenuator. • Space efficient. • Can fit narrow hazards. • Where space permits, connection to a barrier system may allow shielding of wider hazards.	• Residual capacity after an impact varies among items. • Requires anchoring to a slab or pavement. • Not suited to wide hazards.	• Ends of concrete barrier beyond full shoulder width where impacts are expected to be rare. • Intermediate width medians, piers. • Type D guardrail.
Impact Attenuators (fully redirective, wide), and Impact Attenuators, Temporary (fully redirective, wide)	• Prevents encroaching vehicle from traveling behind the impact attenuator. • IDOT pay items and specifications will cover hazards up to only 90 in (2.25 m) wide. See Section 38-8.06 • Space efficient.	• Residual capacity after an impact varies among items in this category. • Requires anchoring to a slab or pavement.	• As above, but for wide hazards (e.g., wide piers) or gore hazards.
Impact Attenuators (severe use, narrow) and Impact Attenuators, Temporary (severe use, narrow)	• Prevents encroaching vehicle from traveling behind the impact attenuator. • May retain significant useful impact capacity after some hits. • Space efficient. • Can fit narrow hazard.	• Higher cost than items not requiring severe use characteristics. • Requires anchoring to a slab or pavement. • Not suited to wide hazards. • May rebound a vehicle as the system restores after a frontal hit. This may create secondary collisions with traffic. • Requires post impact monitoring to ensure that reusable modules are replaced at the end of their service life.	• Ends of concrete barrier separating opposing traffic where repeated or frequent hits are expected and/or where it is necessary to keep repair visits and times to a minimum. • Narrow medians. • Type D guardrail. • Roadside concrete barrier or bridge parapet in a temporary application. • Other narrow point hazards. This may require limiting the list of devices to those that are free-standing with respect to the hazard.

** See Figures 38-8H and 38-8.I for additional information.*

COMPARISON BY PAY ITEM
Figure 38-8.F

Operational Principle (Pay Item)	Advantages	Disadvantages	Typical Uses*
Energy Absorbing	See Figure 38-8.C.	See Figure 38-8.C.	
Impact Attenuators (fully redirective, resettable)	• Requires minimal parts and labor for repairs. Low life-cycle cost where there are occasional to frequent impacts. • Prevents encroaching vehicle from getting behind the impact attenuator. • Space efficient. • Can fit narrow hazard.	• Initial cost higher than non-premium system. • Not required to self-restore after impact. • May require a special barrier detail to transition to a wide hazard.	• As above, but where impacts are expected on an occasional basis. (At least 1 per 3 years, up to 2 per year, depending on accessibility for repairs and impacts to traffic.)
Impact Attenuators (severe use, wide) and Impact Attenuators, Temporary (severe use, wide)	• May retain significant useful frontal impact capacity after some hits. • Space efficient. • Can cover a hazard width up to about 90 in (2.25 m).	• Higher cost than items not requiring severe use characteristics. • Requires anchoring to a slab or pavement. • May rebound a vehicle as the system restores after a frontal hit. This may create secondary collisions with traffic.	• Piers or gore areas separating opposing traffic where repeated or frequent hits are expected and/or where it is necessary to keep repair visits and times to a minimum. • Narrow medians.
Impact Attenuators (partially redirective)	• Lower cost than fully redirective systems. • Suited for direct attachment to Type D guardrail.	• For narrow hazards. • Requires posts to be driven. • Lack of reserve impact capacity after a hit.	• Ends of Type D guardrail separating traffic lanes moving in the same direction, and where impacts are expected to be infrequent. • Wide medians, gore areas. • Concrete barrier on right side shoulders, or at gores.
Impact Attenuators (non-redirective)	See Figure 38-8.C for Sand Modules.	See Figure 38-8.C for Sand Modules.	Point hazards (e.g., piers or sign foundations) not near a travel lane.

**See Figures 38-8.H and 38-8.I for additional information.*

COMPARISON BY PAY ITEM

Figure 38-8.F
(Continued**)**

Operational Principle (Pay Item)	Advantages	Disadvantages	Typical Uses*
Momentum Transfer	See Figure 38-8.C.	See Figure 38-8.C.	
Impact Attenuators Temporary (non-redirective)	See Figure 38-8.C.	• Area for application must have enough room to accommodate either the sand modules or the water filled impact attenuator (ABSORB 350). • Applies principally where it will shield end of a temporary concrete barrier.	• Ends of concrete barriers or other hazards well off the traffic lane, and where it is acceptable to allow a vehicle to encroach behind the device. • See *Highway Standards* 701321 and 701402.

**See Figures 38-8.H and 38-8.I for additional information.*

COMPARISON BY PAY ITEM

Figure 38-8.F
(Continued)

Where shoulders of sufficient width or other means of access are not available, the designer can arrange the concrete barriers according to the minimums shown on the *Illinois Highway Standards* and choose among the various pay items for temporary impact attenuators, as appropriate for the site and traffic. This will allow the contractor a range of options to weigh for access, cost and maintenance factors.

38-8.11 Additional Guidance

Figure 38-8.G provides a partial review and comparisons of the attributes for the various Department approved systems. Figures 38-8.H and 38-8.I correlate the operational principles to the specific systems and typical applications; refer to the QPL regarding any questions regarding these systems and their MASH testing status.

Specific dimensions, installation requirements, and other details are best documented by the various manufacturers. Refer to the Department's lists of approved devices for manufacturer names, contact information and web page links.

Notes:

The TRACC may be widened. At its nominal length and at Test Level 3, the maximum width is 58 in. (1.47 m). Additional width may be gained in approximately 6½ in. (165.1 mm) increments by the addition of 28 in. (711 mm) extension wings.

* *The minimum widths shown are nominal out-to-out of the impact attenuator. The various backup systems, transition pieces, etc., are considered part of the impact attenuator, and are to be considered part of the pay item.*

ATTRIBUTES OF IMPACT ATTENUATORS

38-9 ROADSIDE SAFETY IN URBAN OR RESTRICTED ENVIRONMENTS

This section applies to roadways characterized by built-up locations with curbed sections, frequent stops, off-peak operating speeds of 45 mph (70 km/hr) and lower, frequent traffic conflicts with driveways and side streets, multiple fixed objects in the roadside, restricted right of way, and closed drainage.

Within such areas, the application of open road clear zones may not be practical. This guidance will balance the need for a clear zone with practicality and demonstrated safety benefits in urban and restricted environments.

38-9.01 Safety Performance – Evaluation of Urban and Restricted Locations

Although a clear roadside concept is still preferred, it is more practical and most cost-beneficial to identify critical locations and features with a history of over-representation for roadside crash mitigation in urban/restricted locations.

The general hierarchy of treatments, as shown in Section 38-4.02, applies also in urban/restricted environments.

38-9.02 Operational Offset, Clear Zone, and Enhanced Lateral Offset

The lateral offset procedures in this section should be applied to any urban facility where feasible. However, lower speed facilities (posted speed limit below 30 mph), central business districts, locations with 24 hour on-street parking, and locations with limited right of way and competing uses for roadside space may minimize the application of this section.

Lateral offset concepts should be applied to built-up locations with curbed sections, frequent stops, off-peak operating speeds 45 mph (70 km/hr) and lower, frequent traffic conflicts with driveways and side streets, multiple fixed objects in the roadside, restricted right of way, and closed drainage. Lateral offset concepts and other focused roadside safety treatments should be emphasized at locations of safety performance problems related to roadside safety, and systematically to types of locations representing roadside safety issues.

1. Operational Offset. At a minimum, provide an operational offset from the face of curb to fixed objects of 1.5 ft (0.5 m) on tangents and 3 ft (0.9 m) along the radii of the curb return at intersections. These values are intended only to ease traffic operations, preserve sight distance, keep truck mirrors from striking objects, and do not represent a criterion for roadside safety design.

2. Clear Zone. Section 38-3 or applicable portions of Chapter 49 or 50 provide the appropriate clear zone values for roads, including urban and restricted locations. However, achieving full clear zones in urban or restricted environments is often not practical due to limited right of way and the many competing transportation uses and other uses in the corridor.

3. Enhanced Lateral Offset. An enhanced lateral offset of 4 ft (1.2 m) from the face of curb to any fixed object should be provided on tangent sections, and an enhanced lateral offset of 6 ft (1.8 m) should be provided on the outside of curves. For built up urban locations with no curb, the greater of these offsets doubled, or the clear zone, should be applied and measured from the edge of the traveled way.

   Additional lateral offset (wider than the enhanced lateral offset) should be provided at some specific locations.

   a. Inside of Curves. In addition to creating a wider lateral offset on the outside of curves, attention should be paid to (stopping) sight distance at the inside of sharp horizontal curves to assure that the roadway is not obstructed by roadside objects or embankments; see Figure 38-9.A.

   b. Lane Merge Locations. At the taper point where the lane drop is complete, a lateral offset of 12 ft (3.6 m) should be considered. This offset should be extended at least 10 ft (3.0 m) in both directions from the taper point, and desirably along the taper to where it will intersect the extension of the lateral offset of the roadway prior to the beginning of the lane drop. Breakaway objects should have lateral offsets of at least 4 ft to 6 ft (1.2 m to 1.8 m) at these locations. A wider lateral offset at taper points on urban roadways will reduce roadside crashes at these locations and allow the driver to focus solely on merging into the traffic stream; see Figure 38-9.B.

   c. Driveway locations. A lateral offset of 10 ft to 15 ft (3.0 m to 4.6 m) should be considered for a distance of 10 ft to 15 ft (3.0 m to 4.6 m) beyond the far edge of driveways to account for driver error and times of poor visibility. Sight triangles should also be maintained; see Figure 38-9.C.

   d. Intersections. Roadside crashes at intersections are a significant concern. Particular configurations related to roadside crashes include channelization islands, objects in the curb/radius return, and objects aligned opposite pedestrian curb ramps.

      - Channelizing islands and median noses should be designed according to Chapter 36. Rigid objects at either the corner island or the median nose should be avoided where practical.

      - Object placement on the inside edge of intersection turning movements should be as far as practical from the curb face or lane edge. A target lateral offset value of the intersection return should be 6 ft (1.8 m) for curbed facilities with a minimum value of 3 ft (0.9 m). Similarly, for locations without curbs, these values should be as far as possible from the edge of the traveled way because drivers will not have a curb to help them realize their vehicles have strayed from the designated turning path.

- Rigid objects should not be positioned such that errant vehicles are directed toward them along the path of a curb ramp. It is preferable that the pedestrian pushbutton be placed on a breakaway pedestal pole adjacent to the curb ramp rather than on a rigid traffic signal pole when possible. This may also enable the traffic signal pole placement to occur further away from the curb return region.

38-9.03 Roadside Features in Urban and Restricted Areas

1. Curbs. Curbs do not typically redirect errant vehicles. Vehicles impacting barrier curbs are likely to lose contact with the ground and become uncontrollable for some distance.

   When a vehicle strikes a curb, the trajectory depends on several variables including the size and suspension characteristics of the vehicle, its impact speed and angle, and the height and shape of the curb. Details of guardrail placement behind curbs are shown in *Highway Standard* 630001. Guardrail placed from 4 ft to 12 ft (1.2 m to 3.6 m) behind a curb, as shown on the standard has been crash tested to comply with *MASH* at Test Level 2.

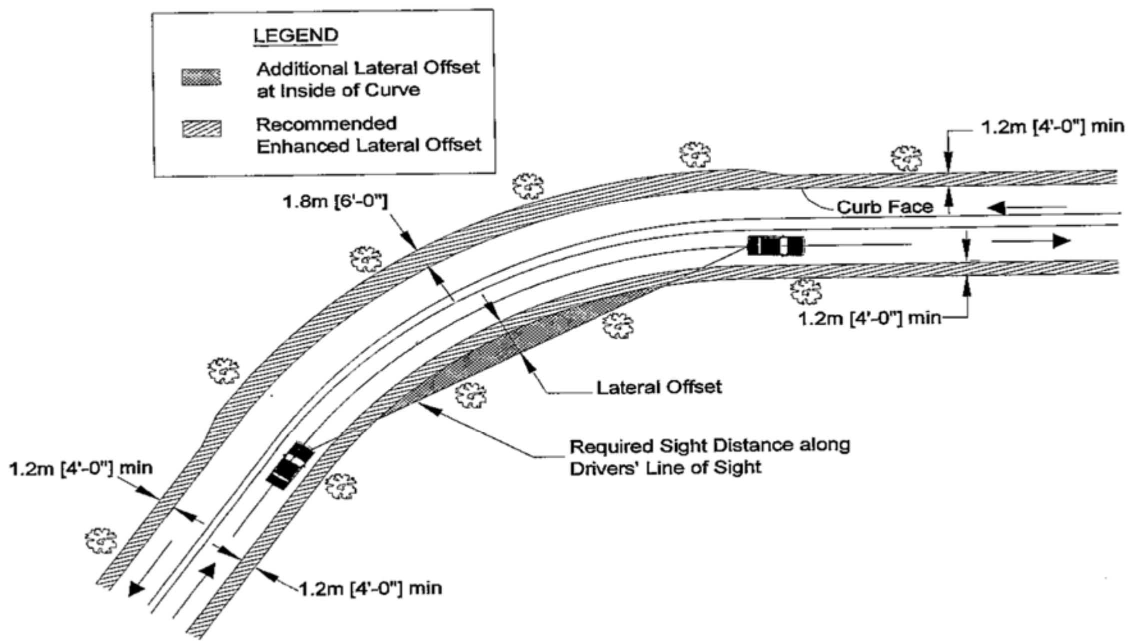
2. Roadside Development. If objects must be placed within the enhanced lateral offset, these should be frangible or breakaway objects that do not trigger further remediation.

3. Utility Poles. Utility poles are the second most common object hit in fatal fixed object crashes and are predominately represented in urban locations.

   Some practical suggestions for mitigating utility pole crashes include:

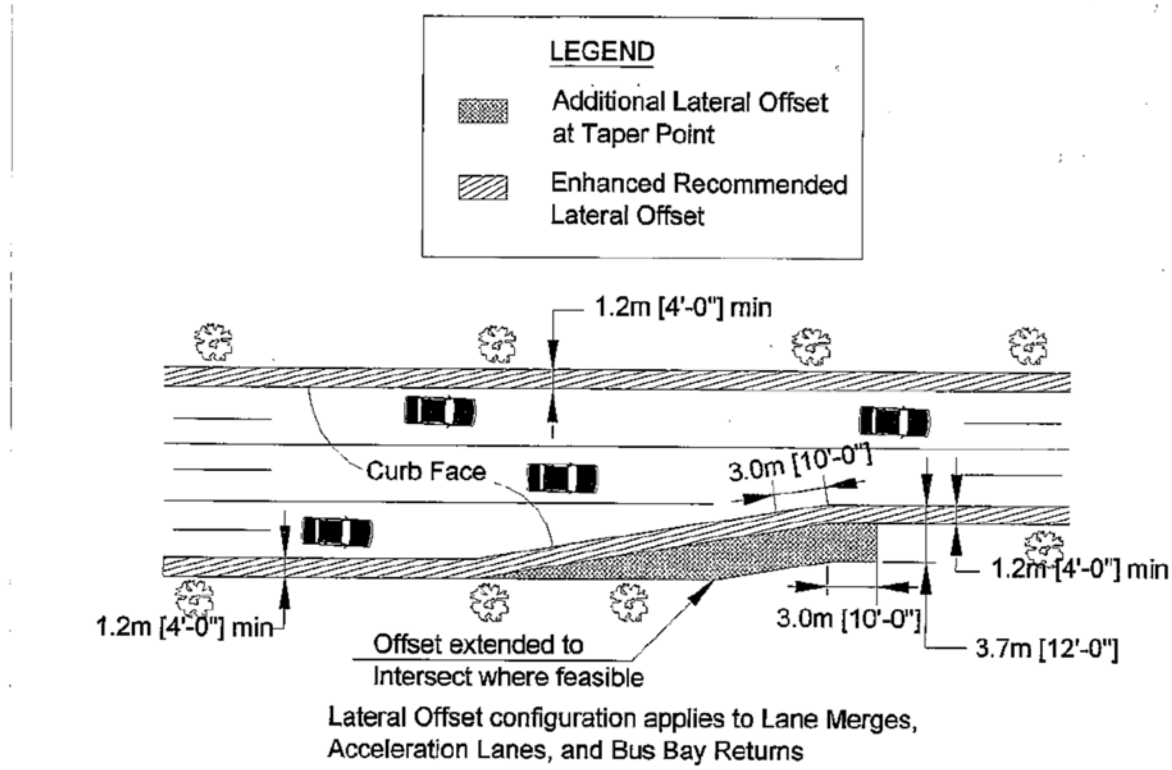
   - Place utility poles as far as possible from the active travel lanes.
   - Place utility poles away from access points where poles may restrict sight distance and be more likely to be struck.
   - Place utility poles on the inside of sharp horizontal curves.
   - Place utility poles only on one side of the road.

4. Lighting. Refer to 38-4.11 for recommendations regarding rigid versus breakaway light supports.



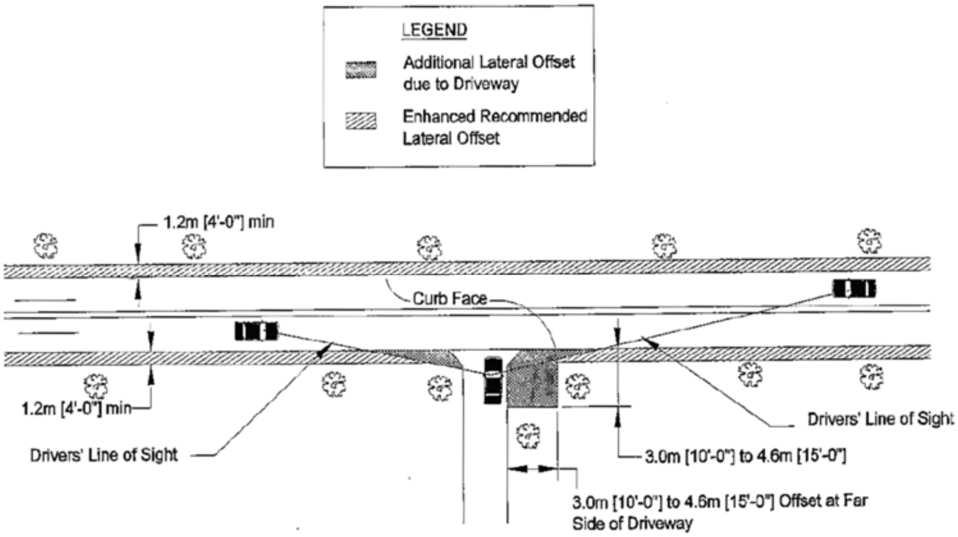
ENHANCED LATERAL OFFSET FOR CURVES IN URBAN OR RESTRICTED LOCATIONS

FIGURE 38-9.A



LATERAL OFFSET AT MERGE POINTS

FIGURE 38-9.B



ENHANCED LATERAL OFFSET AT DRIVEWAYS

FIGURE 38-9.C

38-9.04 Use of Roadside Barriers in Urban or Restricted Environments

Barriers and their end treatments within the clear zone shall be crashworthy and approved by the Department. The use of curbs with these devices may alter details of application or rule out certain systems. The selection of the appropriate test level shall be based upon the design speed of the roadway.

Many uses and competing concerns that define the urban or restricted environment also complicate selection and application of roadside barriers in these locations. When a roadside barrier is to be used, consider all of the following to evaluate the suitability of various barrier options, and placement:

- Lateral offset from the edge of pavement or curb,
- Deflection distance of the barrier,
- Terrain effects,
- Flare rate,
- Length of need,
- Corner sight distance,
- Pedestrian activity, including the needs of persons with disabilities, and
- Bicycle activity.

Generally, a barrier should be placed as far from the traveled way as possible, but it is also desirable that a uniform clearance to items such as bridge railings, retaining walls, and roadside barriers be presented to motorists.

38-9.05 Barrier Warrants

Remediation guidelines, including barrier warrants, are presented in Section 38-4.03. However, for urban or restricted environments these warrants may be less applicable due to the variety of needs addressed by these roadways. The Roadside Safety Analysis Program (discussed in Section 38-4.01) may be used to model these environments and arrive at specific warrants where questions arise. The major premise should remain that a traffic barrier should be installed only if it is expected to reduce the likelihood of severe crashes.

Innocent Bystander and Adjacent Land Use Protection. There are no set warrants or guidelines for these situations. Design judgment should be used. Consider crash history and site-specific factors.

38-9.06 Common Urban Barrier Treatments

1. Roadside and Median Barriers. Generally, median barriers will not be warranted or recommended in urban areas with street intersections, curbs, and design speeds of 45 mph (70 km/hr) or less. The use of roadside barriers will be tempered by the considerations of Section 38-9.05.

2. Crash Cushions. Crash cushions, especially those that are fully-redirective, take less space than standard roadside barrier installations. They may be more practical in many cases, especially for shielding fixed objects.

STRUCTURE PLANNING/GEOMETRICS

39-1 ADMINISTRATION

39-1.01 Introduction

The Bureau of Bridges and Structures (BB&S), the Bureau of Design and Environment (BDE), the Central Bureau of Land Acquisition (CBLA), the Central Bureau of Local Roads and Streets (CBLRS), and the Bureau of Safety Programs and Engineering (BSPE) comprise the Office of Program Development within IDOT. The BB&S provides expertise in bridge management, bridge design, and structural, hydraulic, and foundation engineering.

The Engineer of Bridges and Structures is responsible for formulating and administering policies and procedures that will ensure development of the bridge program and result in safe, economical, visually pleasing structures on the State highway system with the best use of resources for accomplishing the Department's objectives. The Bureau Chief of BB& S fulfills the role of "State Bridge Engineer" in relations with FHWA and AASHTO.

39-1.02 BB&S Functions

The functions of the Bureau of Bridges and Structures include:

- the development of policies and procedures for the administration of highway bridges and structures;
- the preparation of preliminary and final bridge and structure designs, plans, and specifications;
- the review and approval of structural work performed by consulting engineers;
- the review and approval of fabrication shop plans;
- the inspection of structural steel fabrication;
- the preparation and review of plans for bridge repairs;
- the load capacity rating and inventory of bridges on the State highway system;
- the preparation or review of retaining walls over 10 ft (3.0 m) in height;
- the directing of bridge maintenance and inspection activities; and
- the administration and technical expertise for local agencies on bridge issues.

39-1.03 BB&S Organization

To administer its responsibilities, the BB&S is organized into four sections:

- Structural Services,
- Bridge Planning,
- Bridge Design, and
- Services Development.

Organizational charts and functions of the sections are presented in the *Bridge Manual*, Section 1, "Introduction."

39-2 BRIDGE POLICIES AND DESIGN

The Bureau of Bridges and Structures (BB&S) administers policies for the design, structural details, and preparation of plans for bridges and structures on the State highway system by using a system of design specifications, standard practice manuals, standard plans, and policy memoranda. The following sections discuss these.

39-2.01 Specifications for Bridge Design

IDOT uses the AASHTO *Standard Specifications for Highway Bridges and AASHTO LRFD Bridge Design Specifications* as its principal specifications for the design of bridges and other structures. This includes all interim specifications and guide specifications when published and as directed by policy memoranda. These specifications form the basis for all bridge design by the BB&S or by an outside entity retained by the State of Illinois.

39-2.02 Specifications for Bridge Construction

The Department's *Standard Specifications for Road and Bridge Construction* govern all bridge construction contracts unless supplemented, revised, or superseded by the plans or in the special provisions for the contract documents. All bridge designs shall be prepared to be consistent with these specifications and provisions.

39-2.03 Standard Practice Manuals

The BB&S publishes a series of standard practice manuals to guide bridge and structural designs and plans in Illinois. These manuals represent a second level of control under the AASHTO *Standard Specifications for Highway Bridges and AASHTO LRFD Bridge Design Specifications,* and they present the preferred design methods, treatments, and standardized designs of the BB&S. These manuals guide the bridge designer in preparing bridge designs and plans to meet the specifications and preferences of the BB&S, but they are not intended to restrict progressive technology, innovation, or architectural improvements. Any proposed improvements other than typical designs should be thoroughly discussed with BB&S management prior to initiating any action.

The BB&S has developed the following standard practice manuals:

1. *Bridge Manual*. This *Manual* provides policies and practices for the planning and design of the component parts of bridges in general, and it guides the development of Type, Size, and Location (TS&L) plans and final plans.

2. *Prestressed Concrete Manual*. This *Manual* provides policies and design procedures for prestressed concrete bridge members and presents standard designs for prestressed concrete bridge members for use on State and local bridges.

3. *Culvert Manual*. This *Manual* provides standard design parameters for single-cell, reinforced concrete box culverts. When used within the limitations set forth, the *Manual* allows engineers and technicians outside the BB&S to prepare plans for these structures without direct structural engineering supervision.

4. *Sign Structures Manual*. This *Manual* provides standard design procedures and standard base sheets for steel and aluminum sign structures.

5. *Drainage Manual*. This *Manual* provides the drainage policies and procedures for use in the planning and design of drainage structures on the State Highway System.

6. *Structural Services Manual*. This *Manual* assists Department personnel and consulting engineers in the preparation of bridge repair plans. Information and details are provided for the types of repairs most often required for typical bridge structures.

See Chapter 60 for more information on standard practice manuals published by the BB&S.

39-2.04 Policy Memoranda

Policies of the Bureau of Bridges and Structures may be issued, amended, or supplemented by a Bridge Memorandum. These memoranda are effective the date of issuance on designs and plans not yet approved by the Engineer of Bridges and Structures, unless otherwise stated in the memorandum. Before initiating a project, bridge designers should check with the BB&S for the latest Department version of Bridge Memoranda.

39-2.05 Experimental Bridge Features

In cooperation with authorized agencies, the BB&S advises other agencies and/or develops construction plans for structures that include new products or design concepts in part or for all of the structure. These experimental projects are cataloged and periodic field inspections are made to evaluate the benefits from the experimental components.

After adequate study under actual traffic and weather conditions, the experimental products or design concepts are either included as acceptable for policy use and placed in the appropriate manual (see Section 39-2.03) or they are rejected.

39-3 BRIDGE PLANNING PROCESS

39-3.01 Bridge Improvements

39-3.01(a) Scope of Work Definitions

The scope of work for a bridge project may be any of the following:

1. Bridge Replacement. Replacement of the entire existing bridge (i.e., superstructure, substructure, and foundation).

2. Bridge Reconstruction. At a minimum, complete replacement of the superstructure and could include work on the substructure and foundation.

3. Existing Bridge to Remain in Place. If an existing bridge is structurally sound, if it meets the Department's design loading capacity, if it meets the minimum width criteria, and if it is not a high-crash location, it is unlikely to be cost effective to improve the geometrics of the bridge. When these conditions are met, an existing bridge can remain in place. In some cases, only the bridge substructure (e.g., abutments, piers) and/or foundation (e.g., footings, piles) may require rehabilitative work. These may also be considered existing bridges to remain in place for the application of geometric design criteria.

4. Bridge Rehabilitation. Major work on one or more of the components of an existing bridge (i.e., superstructure, substructure, and/or foundation).

5. Bridge Deck Rehabilitation. If the existing bridge deck is structurally deficient, it may be rehabilitated as part of a project. In addition, where the bridge deck is structurally sound but its width is inadequate (i.e., the bridge is functionally deficient), the bridge deck may be rehabilitated solely to widen the bridge deck. Bridge deck widening may then require work to the superstructure and/or substructure.

6. Bridge Deck Repair. The existing bridge deck is structurally adequate, but partial and full-depth repairs are required and an overlay is necessary to improve rideability and to maintain the integrity of the deck.

7. Bridge Rails/Transitions. For reconstructed bridges or rehabilitated bridge decks, the existing bridge rails and approaching guardrail-to-bridge-rail transitions may need upgrading to meet current Department criteria. For existing bridges to remain in place within the project limits, the Bureau of Bridges and Structures will evaluate the adequacy of the existing bridge rail to determine if it should be upgraded. The roadway designer will evaluate the adequacy of the existing approaching bridge rail transition for needed upgrading. See Chapter 38 for more information on guardrail-to-bridge-rail transitions.

Also, for 3R bridge projects, see Sections 49-3 and 50-2.

39-3.01(b) Coordination

This Section clarifies how structure information should be coordinated with the Bureau of Bridges and Structures (BB&S) and with the Bureau of Design and Environment (BDE). This coordination is through the Bridge Condition Report (Section 39-3.02) and the Proposed Structure Sketch. To indicate the bridge information necessary for completion of location study work, this Sketch is included in all Phase I reports. Complete information regarding Bridge Condition Reports can be found in the Bureau of Bridges and Structures manual *BCR Procedures and Practices*.

Bridge Condition Reports (BCR) will ensure that the scope of work proposed in a Phase I report will agree with the design in the final bridge plans. These reports accommodate early structural input into the overall planning process and, as a result, they greatly reduce the need for revisions to approved Phase I reports.

BDE must approve the typical section that shows the proposed clear roadway bridge width as a part of the Proposed Structure Sketch. This concurrence must occur before submission of the BCR by the district to the Bureau of Bridges and Structures.

A BCR and a Proposed Structure Sketch are required for every structure that is within a roadway section covered by a Phase I report or which is the subject of Phase I report by itself. Structures may fall into one of the following categories that would require a BCR or an Abbreviated BCR:

- gap the structure temporarily,
- allow structure to remain in place,
- deck repair and resurface,
- rehabilitate the structure, or
- replace the structure.

Before design approval can be granted on a roadway project that includes structures or on a bridge by itself, the BCRs on all bridges must be approved by the BB&S and concurrence must be received on all Proposed Structure Sketches.

For structures allowed to remain in place within a 3R type highway project, the Illinois Structure Information System—Master Report (S107) may be submitted in lieu of a formal BCR. In addition to the Master Report, the PONTIS Bridge Report for maintenance needs should be submitted.

Structures located within SMART and 3P projects do not require the submittal of a BCR. However, where a structure lies within the limits of such projects, coordination must be initiated with the BB&S before determining resurfacing options across the bridge.

Unless involvement is specifically requested by a district, the Bureau of Bridges and Structures does not evaluate maintenance type work on structures. However, if a project is a deck repair and overlay which is not funded with maintenance funds, it will require the submittal of an

Abbreviated BCR. If the evaluation of the deck leads to a decision to replace the deck, then normal procedures for bridge improvements must be initiated and followed.

The BCR allows BB&S concurrence on the proposed design based on the existing condition of the structure. Upon BB&S review, the Bureau will document agreement with the following geometric and structural factors:

- proposed clear roadway bridge width combined with structural feasibility,
- replacement or reuse of components,
- proposed general configuration features, and
- stage construction possibilities.

The BB&S concurrence relates to the structural adequacy and economic feasibility of the bridge improvement proposal. If appropriate, the economics of any proposal will be investigated at this time. In some instances, environmental factors may preclude economic considerations. Therefore, the Phase I report must contain sufficient information to justify recommendations concerning environmental factors.

39-3.02 Bridge Condition Reports

39-3.02(a) Definition

A Bridge Condition Report is defined as a report to establish the scope of work on the extent of repair, replacement (partial or total), and widening or other improvements. The BCR allows the Bureau of Bridges and Structures to determine the most cost-effective method of correcting the reported structural, geometric, or hydraulic deficiencies and for restoring a bridge to a structurally adequate and functionally serviceable condition.

39-3.02(b) Purpose

A BCR is required for every structure that is within a roadway section addressed in a Phase I report or which is the subject of a Phase I report by itself. The BCR, combined with the Proposed Structure Sketch (Section 39-3.02(d)), allows early structural input into the overall planning process.

Whenever the scope of anticipated rehabilitation work is limited to bridge deck and minor structural repairs without the need for widening or replacement options, only the preparation of an Abbreviated BCR is required. Because the geometrics of the structure will not be altered, this type of work normally will not require a Type, Size, and Location (TS&L) Plan (Section 39-3.04).

39-3.02(c) Applicability

The Bridge Condition Report will provide:

- a description of the physical conditions and deficiencies that mandate repair or replacement,

- a verification of the apparent soundness of any substructure elements recommended for reuse plus the economic advantage gained by their reuse,
- a statement of any geometric or hydraulic improvement requirements, and
- a recommendation for the scope of the proposed work.

The recommended scope of work should address the approximate dimensions of a replacement structure but not so precisely that configuration refinements resulting from subsequent hydraulic, soils, or structural-economic studies are restricted. The format of the BCR required by the BB&S is necessary to enable the Bureau to make accurate structural, economic, and policy decisions for the cost-effective expenditure of bridge rehabilitation funds.

With total structure replacements, a description of the conditions that led to the inclusion of the bridge in the program is usually sufficiently supportive of the replacement recommendation. However, where projects involve extensive repair of bridge components, BCRs must be supported by in-depth field inspection, physical testing, and economic analysis to determine the scope and cost-effectiveness of repairs. Before concurring with the reuse of any substructure elements, the Bureau of Bridges and Structures will verify their capacity to sustain the loads to which they will be subjected in the reconstructed bridge.

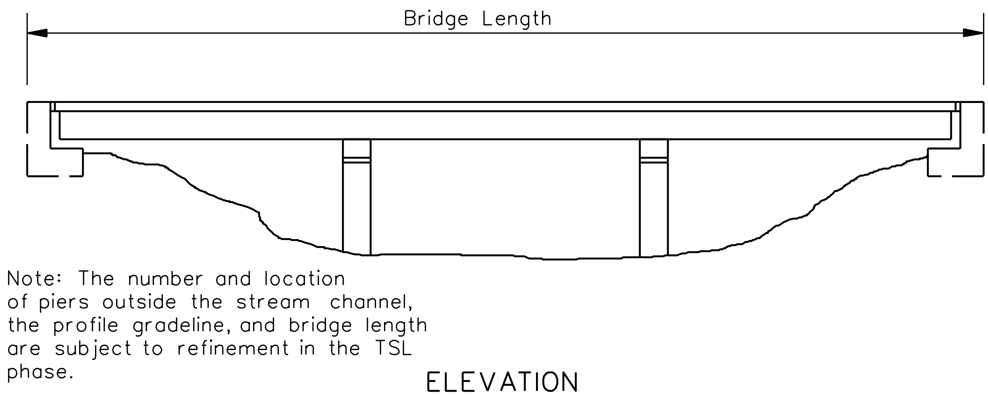
The BCR, with its comprehensive recommendation for the proposed scope of work and the support information, is submitted by the district for review and concurrence by the Bureau of Bridges and Structures. After this concurrence is obtained, the memo approving the BCR will be incorporated into or referenced in the Phase I report (see Chapter 12). After all necessary coordination with other agencies has been accomplished, the completed Phase I report and the Proposed Structure Sketch should be submitted to BDE for informational purposes.

39-3.02(d) Proposed Structure Sketches

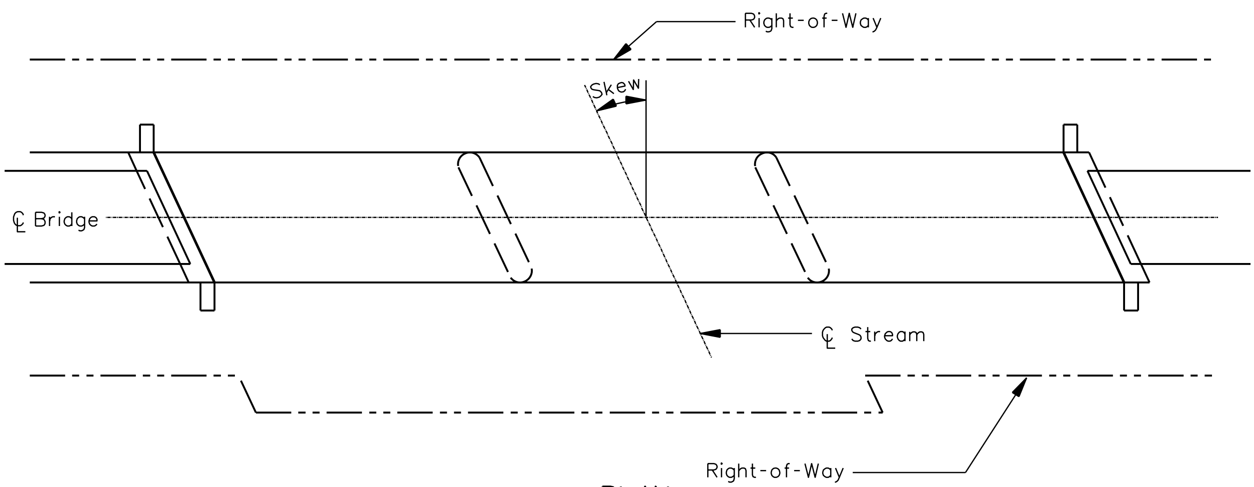
The bridge information necessary to complete the location/design study phase varies with the complexity and type of project under consideration; however, all bridge projects require the submittal of a Proposed Structure Sketch to the Bridge Planning Section for review and approval. This Sketch should be included or referenced in the Phase I report. For a typical Proposed Structure Sketch, see Figure 39-3.A.

A Proposed Structure Sketch will generally present the following information:

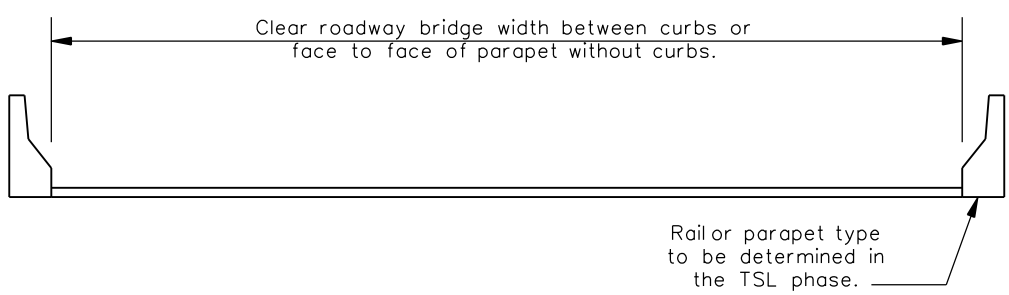
- type of bridge proposed (closed abutments vs. spill-through, existing elements to be reused, etc., but not details such as girder or deck type) and approximate structure length. A preliminary hydraulic analysis may be required to establish the appropriate structure length and vertical profile;



ELEVATION
PROPOSED STRUCTURE



PLAN
PROPOSED STRUCTURE



PROPOSED STRUCTURE WIDTH

PROPOSED STRUCTURE SKETCH

Figure 39-3.A

- approximate profile and horizontal alignment and approximate right-of-way or easement widths. The accuracy of the profile will depend upon the nature of right-of-way adjacent to the bridge project. Usually, it will be necessary to establish exact right-of-way requirements only if Section 4(f) property or other very sensitive right-of-way is affected;

- proposed skew angle of feature crossed. See Section 39-4 for further guidance on crossing angles;

- approximate pier locations proposed by the district. Comments on pier location received from the Illinois Department of Natural Resources, U.S. Fish and Wildlife Service, U.S. Army Corps of Engineers, and other affected agencies should be incorporated as appropriate;

- typical section showing the proposed clear roadway bridge width. It is not necessary to show beam locations or type; and

- the need for bikeways across the structure, bicycle railings, and pedestrian railings.

The Proposed Structure Sketch should contain the following note or variation thereof: "*The number and location of piers outside the stream channel, the profile gradeline, and the bridge length are subject to refinement in the TSL phase*." Care should be taken to make the Proposed Structure Sketch as diagrammatic as possible and no more restrictive to the final design than is necessary to gain design approval.

For rehabilitation, reconstruction, and replacement projects, the information necessary for the location/design study phase is provided in the Bridge Condition Report (BCR). The Proposed Structure Sketch is typically included with the BCR. However, only the Proposed Structure Sketch and memo from the BB&S approving each Bridge Condition Report (if required) need be included in a Phase I report. In addition for each structure location, a few color photographs or prints should be included in the Phase I report as exhibits.

For major stream crossing projects, the determinations made in the location/design study phase on the vertical and horizontal alignment are typically refined such that minor adjustments in the TS&L or design phases will not significantly affect the project impacts. Because of the potentially large variations in structure depths between major river crossing structure types, high and low vertical profile options may need to be addressed. Significant impacts caused by either the high or low profile options might lead to the elimination of certain structure types from further consideration.

Structure type evaluation at this stage should normally be limited to the determination of those structure types that are feasible for the given crossing conditions and within the same general economic range. A detailed evaluation of structure types for major stream crossings is performed during the bridge type study phase.

39-3.03 Preliminary Bridge Investigations

Before initiating Type, Size, and Location (TS&L) Plans for a structure, an investigative procedure that establishes the proper alignment and/or the scope of work to be performed is completed in the Phase I study. This procedure establishes the alignment, develops a profile gradeline, provides an environmental assessment, and addresses those factors affecting the socio-economic conditions and the overall impact of the project. It may also include a proposal for stage construction so that traffic may continue using the route during construction. The results of these procedures and studies are summarized in the Phase I report.

39-3.03(a) Bridge Type Studies

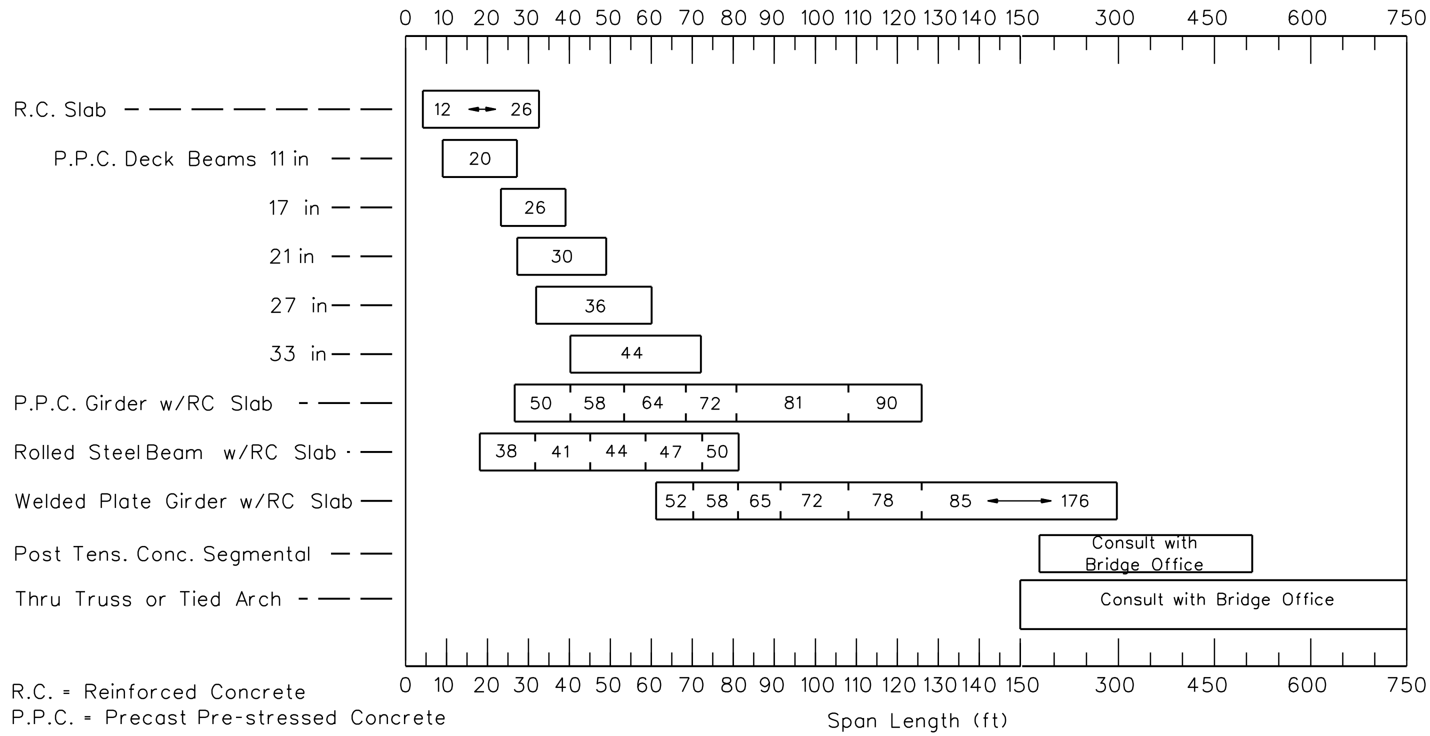
A Bridge Type Study is necessary for the preparation of a TS&L Plan. The study is the process by which the most appropriate structure type for a given location is determined, and it is a compilation of the necessary economic, aesthetic, and site evaluations that lead to that selection. A well-conceived Bridge Type Study will:

- provide hydraulic and geotechnical considerations,
- consider the structure types feasible for the site parameters or environmental commitments,
- provide the reasoning for eliminating or developing particular alternatives, and
- provide cost estimates for all alternatives considered and the rationale for the selection of the structure type chosen.

The Bridge Type Study is typically a part of the planning process that justifies the proposed bridge type and as such is not submitted for review. However, for major river crossings or when requested by BB&S, a bridge type study becomes a formal report requiring approval of the Bridge Planning Engineer before TS&L plan preparation.

39-3.03(b) Selection of a Superstructure System

For Phase I work, the designer should refer to Figure 39-3.B, which provides a list of commonly employed superstructure types; the span ranges for which they are generally applicable; and the approximate construction depth (profile grade to low beam) required for their use. The values provided are general guidelines only and should not be used for detailed TS&L determination.



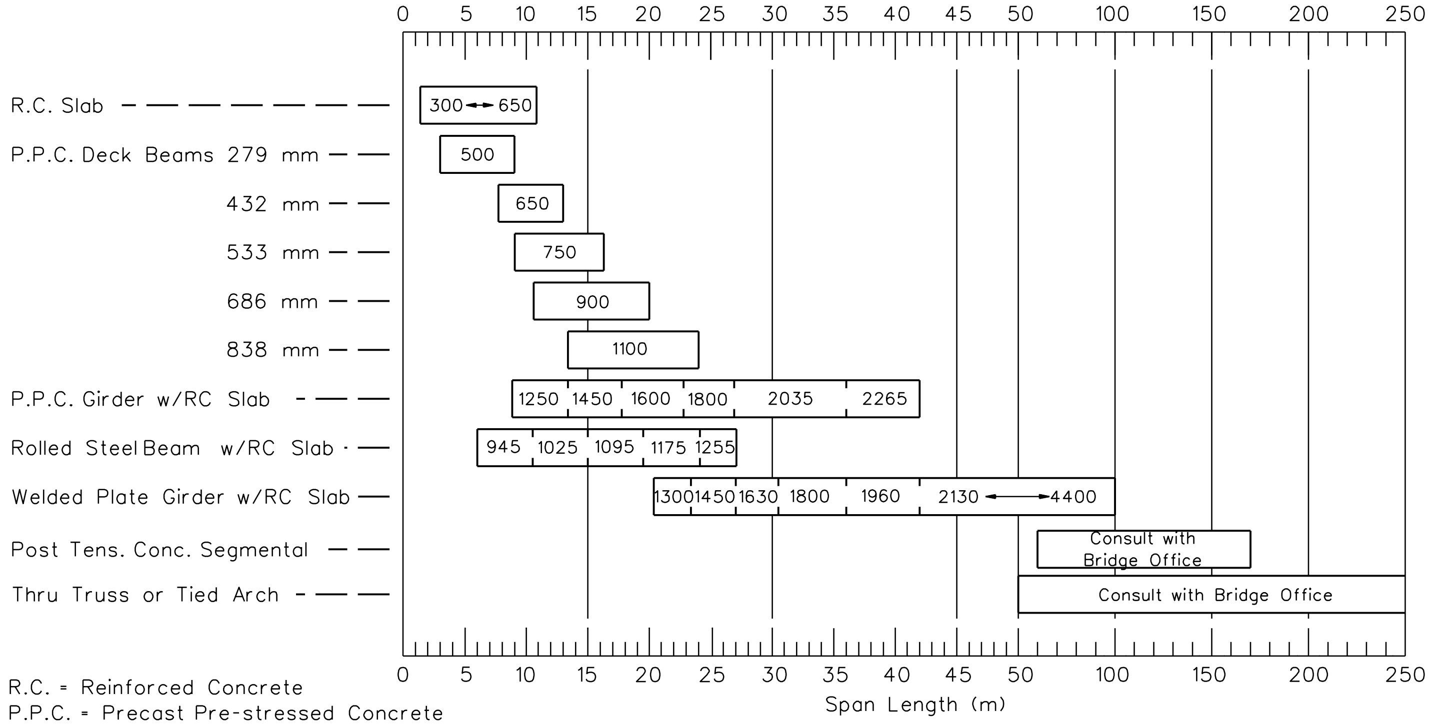
Notes:

1. *Numbers within bars denote the construction depth in inches (profile grade to low clearance point) required for a simple span structure of charted length with a 40-ft wide, normal crowned bridge roadway, and a future wearing surface allowance of 25 lbs/ft ^{2}. The values given are general guideline values and should not be used for detailed type, size, and location plans.*

2. *Span lengths for the indicated construction depths may be increased 20% to 25% for continuous beam designs.*

CONSTRUCTION DEPTH SELECTION GUIDE
(US Customary)

Figure 39-3.B



Notes:

1. *Numbers within bars denote the construction depth in millimeters (profile grade to low clearance point) required for a simple span structure of charted length with a 12-m wide, normal crowned bridge roadway, and a future wearing surface allowance of 1.2 kN/m^2. The values given are general guideline values and should not be used for detailed type, size, and location plans.*

2. *Span lengths for the indicated construction depths may be increased 20% to 25% for continuous beam designs.*

CONSTRUCTION DEPTH SELECTION GUIDE
(Metric)

Figure 39-3.B

39-3.03(c) Temporary In-Stream Work

As a part of determining the scope of work to be performed, give consideration to anticipated need for temporary in-stream work features for construction of the project (e.g., temporary stream crossings, work pads, temporary bypass channels, cofferdams). This information will need to be described in a work permit submittal to the US Army Corps of Engineers for work involving discharge of dredged or fill material into waters of the United States. To the extent that any needed temporary work features can be anticipated and addresses in the permit submittal for the bridge/culvert, it will avoid the need for having the contractor seek separate permit coverage for the temporary work in the construction phase with the associated potential for delaying construction operations while awaiting receipt of the permit authorization for the temporary work features.

39-3.04 Type, Size, and Location Plans

The bridge planning process encompasses the collection of the applicable site information, its analysis, the application of established policies and practices, and the consideration of reasonable alternatives and their economic evaluations to establish the bridge configuration that is the most cost effective and functionally, structurally, and aesthetically appropriate.

Type, Size, and Location (TS&L) Plans are detailed bridge configuration plans which are used as the basis for the development of construction plans. TS&L Plans are approved by the Bureau of Bridges and Structures only after the processing for approval of a Structure Report including an approved Hydraulics Report, an existing bridge survey, and detailed roadway data. Approved TS&L Plans may be used in lieu of a Proposed Structure Sketch in a Phase I report should their timely development so permit; however, the less detailed Proposed Structure Sketch, developed specifically for the Phase I report, will not be construed to be TS&L Plans.

The Planning Section of the *Bridge Manual* has been developed as a guide and a control for the preparation of TS&L Plans and for the promulgation of policy interpretations of the control documents. In addition, consider the following when preparing TS&L Plans:

- No new structure number should be assigned when a project involves the re-use of any existing bridge element in the rehabilitation.
- For details on Hydraulic Reports, use the *Drainage Manual.*
- A completed Structure Report and Structure Geotechnical Report must accompany any TS&L Plan submittal by a consultant.
- Boring logs are required to be submitted to the Bureau of Bridges and Structures for the development of in-house TS&L Plans.

39-4 BRIDGE SIZING/GEOMETRICS

A variety of factors determine the appropriate size of a bridge under design. Section 39-4 discusses these factors and other geometric design elements pertaining to bridge design (e.g., bridges on horizontal curves, cross slopes). Section 39-5 presents typical sections for bridge overpasses and underpasses. Section 39-6 presents tables of geometric design criteria for bridges on the rural and urban State highway system and for frontage roads.

The design criteria provided in Section 39-4 are applicable to all new or reconstructed bridges on the State highway system, except where specific policy items are governed by other Department directives. See Parts IV, Road Design Elements, and V, Design of Highway Types. Bridge widths for 3R-type improvements are included in Chapters 49 (non-freeways) and 50 (freeways).

39-4.01 Type of Highway Facility

The type of highway facility has a significant impact on bridge size. The highway facility will be defined by its:

- functional classification;
- rural or urban location;
- number of lanes (i.e., two lane or multilane);
- presence of a median (i.e., divided or undivided); and
- operational function (i.e., mainline, ramp, or frontage road).

Part V presents a comprehensive discussion on highway geometric design based on functional classification and rural/urban location. Specifically for bridges, the typical sections in Section 39-5 and the tables of design criteria in Section 39-6 are based on the type of highway facility with appropriate references to Part V, Highway Systems.

39-4.02 Bridge Widths

The bridge width will be determined by:

- the highway type;
- the approaching roadway width;
- the presence of sidewalks and/or bikeways (see Section 39-4.05);
- the presence of auxiliary lanes (e.g., acceleration lanes at interchanges); and
- for divided facilities, whether a single or dual structure is used.

See Sections 39-5 and 39-6 for bridge width criteria and application.

39-4.03 Underpass Width

The roadway section passing beneath a bridge will determine the bridge length in combination with structural design elements (e.g., abutment type). The underpass width will be based on the following roadway design elements:

- the approaching roadway width;
- the presence of sidewalks and/or bikeways (see Section 39-4.05);
- the presence of auxiliary lanes (e.g., acceleration lanes at interchanges); and
- the horizontal clearance to obstructions (i.e., the roadside clear zone).

For high unit cost bridges, the designer should consider locating abutments or piers on the right side of the roadway adjacent to the shoulder where the savings in structure cost could make the required barrier protection cost effective. All reduced clearances below the minimum horizontal clearance requirements must be economically justified and barrier protection must be provided.

The maximum practical horizontal clearance between the left edge of the roadway and pier in the median of divided highways will be realized by placing a single pier at the center of the median. Median piers should have protective barrier where warranted as discussed in Chapter 38.

39-4.04 Vertical Clearances

The vertical clearance for underpassing roadways will significantly impact the size of the overpassing structure. In some cases, the required vertical clearance may also impact the selection of the superstructure type. Sections 33-5, 39-5 and 39-6 and Part V, Highway Systems, presents the Department's vertical clearance criteria for underpassing roadways based on functional classification, project scope, and rural/urban location.

39-4.05 Sidewalks and Bikeways

If pedestrian activity is anticipated, provide sidewalks on both sides of urban structures. The standard sidewalk width on structures is 5 ft (1.5 m). See the *Bridge Manual* for sidewalk details. Also, see Section 48-2.04 for a detailed discussion on sidewalks. In addition, examine the gradeline of the sidewalks for ADA requirements (see Section 58-1). Where wider sidewalks exist on approaching roadways, sidewalk widths greater than 5 ft (1.5 m) can be considered. See the typical urban sections in Section 39-5.

Special sidewalks or bikeways, separated from the roadway by a traffic barrier, may be provided as discussed in Chapter 17. Bikeway widths will be determined from the bikeway design criteria but in no case will the width be less than 5 ft (1.5 m) for a one-way bikeway or 10 ft (3.0 m) for a two-way bikeway across a structure. For geometric combinations, see the typical sections in Chapter 17 and Section 39-5.

39-4.06 Highways Over Railroad

Where a highway bridge overpasses a railroad, the specific horizontal and vertical clearances and the bridge size will be cooperatively determined by the Department and the railroad. The Department's planner/designer shall become acquainted with 92 Ill. Admin. Code 1500.160(c), 23 C.F.R. 646.212(a-2) and (a-3) and the "Appendix to Subpart B of Part 646 – Horizontal & Vertical Clearance Provisions for Overpass and Underpass Structures" prior to any discussions with the railroad. The typical sections in Section 39-5 illustrate the typical minimum geometric design requirements for railroads.

39-4.07 Design Flood Frequency

Design flood frequency is directly related to the ratio of structure capacity to public benefit. A structure which carries large volumes of traffic on a multilane facility is expected to remain in use during extreme flood conditions. To maintain the high level of traffic service afforded by these facilities, a considerable expenditure of funds is justified to provide that service. Conversely, a structure carrying lesser traffic volumes on a lower functional classification facility does not warrant a design based on extreme flood conditions. The *Drainage Manual* and its Appendix contain detailed information on design flood frequencies. Chapter 40 also addresses general drainage issues and procedures.

Because urban highway facilities are intended to accommodate higher traffic volumes at reduced speeds, when compared to rural designs, it is apparent that optimum public benefit requires the assignment of higher flood frequency values for design to provide uninterrupted service for urban bridges. Consideration must also be given to the seriousness of flooding abutting properties that may result in property damage, possible loss of life, and adverse public reaction. Therefore, a flood frequency of 50 years is used for all designs except TWS–2 classifications.

39-4.08 Bridges on Horizontal Curves

Superelevation transitions should be avoided on bridges and their approaches. To achieve this in rural areas, the beginning of a horizontal curve should be a minimum of 400 ft (120 m) from the back of the bridge abutment. In some cases, however, superelevation transitions are unavoidable on urban bridges (e.g., because of right-of-way restraints). Where a curve is necessary on a bridge, the desirable treatment is to place the entire bridge and its approaches on a flat horizontal curve with minimum or no superelevation. In this case, a uniform superelevation rate is provided throughout (i.e., the superelevation transition is neither on the bridge nor its approaches) or the normal crown section is maintained throughout the curve.

Where a bridge is located within a superelevated horizontal curve, the entire bridge roadway is sloped in the same direction and at the same rate across the deck (i.e., the shoulders or gutters and traveled way will be in a planar section). See the typical superelevated sections in Section 39-5. This also applies to the approach traveled way and the approach shoulder pavements. The approach traveled way and approach shoulders are illustrated in the *Highway Standards*.

However, the high-side shoulder on a roadway section off the bridge should slope away from the traveled way at a rate such that the maximum shoulder rollover does not exceed 8.0%. To accomplish the longitudinal shoulder slope transition away from the bridge, the designer should refer to the applicable figure in Section 39-5. See Chapter 32 for more information on horizontal alignment.

39-4.09 Skew Angle

Crossing angles between the mainline and other roadways, railways, or waterways desirably should not be less than 60 degrees (not greater than 30 degree skew). In extreme conditions, crossing angles between waterways and roadways may be 45 degrees and, between intersecting roadways or between roadways and railways, may be 30 degrees (not greater than 60 degree skew). Where these maximums are difficult to meet, consider relocating and/or realigning the intersecting roadways/waterways.

39-4.10 Cross Slopes

The typical sections in Section 39-5 provide the cross slope criteria for bridges. Note that, on tangent sections, the shoulder cross slope on a bridge is flatter (i.e., 1/4″/ft (2%) than the typical shoulder cross slope on the approaching roadway section (i.e., 1/2″/ft (4%)).

39-4.11 Gradeline on Bridges

Where a bridge is planned for a new construction or reconstruction project and where the bridge is not within the limits of a vertical curve, the designer should strive to provide a minimum longitudinal gradient of 0.50% across the bridge. In addition, where a vertical curve cannot be avoided on the structure, a K value of 167 (51) for drainage should not be exceeded.

39-5 TYPICAL SECTIONS

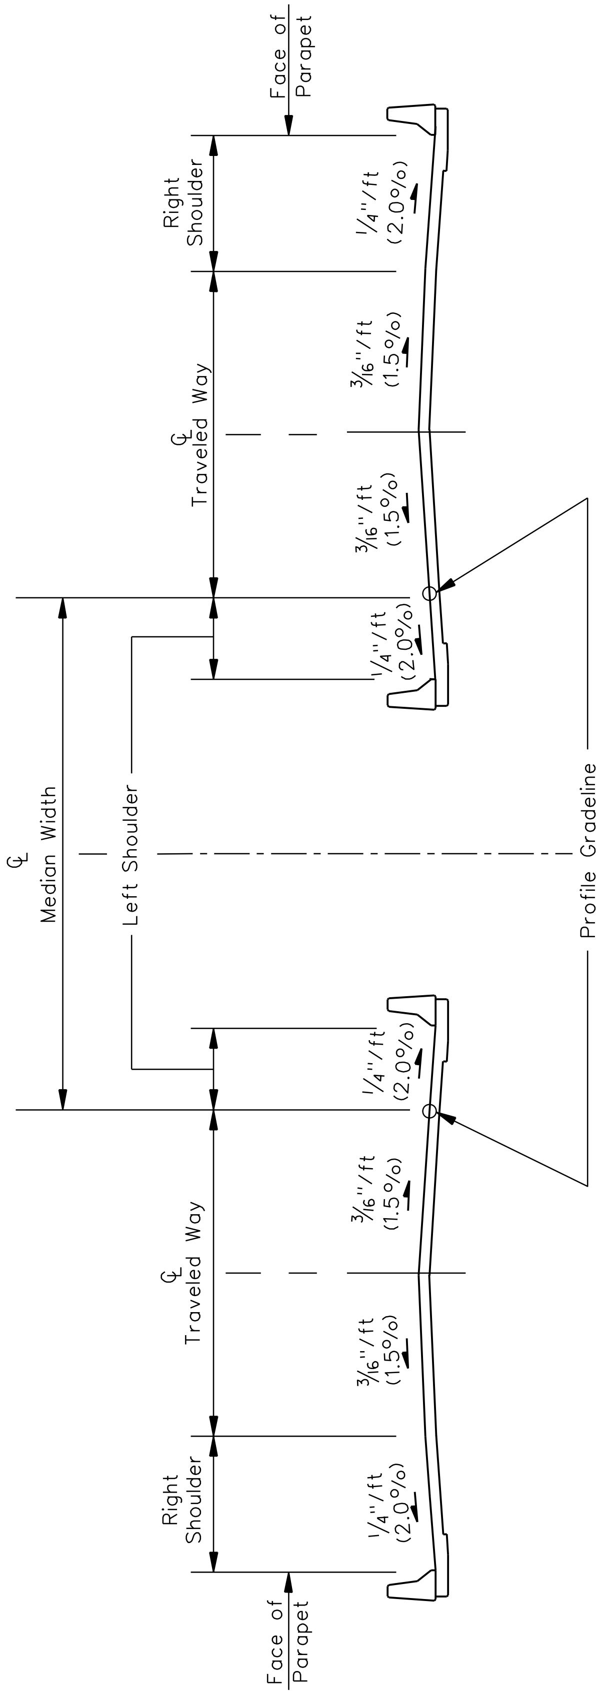
Section 39-5 presents typical sections for bridges on tangent or with superelevation, for roadways beneath bridges, and for highways passing over railroads. With the exception of cross slopes on bridges, the typical sections do not provide the numerical dimensions for the various cross section elements; i.e., these are nomenclature presentations. See Section 39-6 and the referenced chapters in the *BDE Manual* for the applicable numerical criteria.

Section 39-5 presents the following typical section figures:

- Clear Roadway Width of Bridges for New and Reconstructed Four-Lane Divided Highways (Figure 39-5.A).
- Clear Roadway Width of Bridges for New and Reconstructed Six-Lane Divided Highways (Figure 39-5.B).
- Clear Roadway Width of Bridges for New and Reconstructed Four-Lane Highways with Concrete Barrier (Figure 39-5.C).
- Clear Roadway Width of Bridges for New and Reconstructed Six-Lane Highways with Concrete Barrier (Figure 39-5.D).
- Clear Roadway Width of Bridges for New and Reconstructed Four-Lane Divided Highways with Additional Lane for Acceleration or Deceleration (Figure 39-5.E).
- Clear Roadway Width of Single-Lane Ramp Structures (Figure 39-5.F).
- Clear Roadway Width of Bridges for New and Reconstructed Rural Two-Lane Highways (Figure 39-5.G).
- Clear Roadway Width of Superelevated Bridges on Multilane Divided Highways (Figure 39-5.H).
- Clear Roadway Width of Superelevated Bridges on Multilane Highways with Concrete Barrier (Figure 39-5.I).
- Clear Roadway Width of Superelevated Bridges on Rural Two-Lane Highways (Figure 39-5.J).
- Clear Roadway Width of Bridges for New and Reconstructed Urban Highways with Raised-Curb Median (Figure 39-5.K).
- Clear Roadway Width of Bridges for New and Reconstructed Urban Highways with Bikeways (Figure 39-5.L).
- Clear Roadway Width of Bridges for New and Reconstructed Two-Lane Urban Highways (Flush/Traversable Median) (Figure 39-5.M).

- Clear Roadway Width of Superelevated Bridges on Urban Highways with Raised-Curb Median (Figure 39-5.N).
- Clear Roadway Width of Superelevated Bridges on Urban Highways with Flush/Traversable Median (Figure 39-5.O).
- Clear Roadway Width of Superelevated Bridges on Two-Lane Urban Highways (Figure 39-5.P).
- Clearances for Bridges over Divided Highways (Figure 39-5.Q).
- Clearances for Bridges over Two-Lane Highways (Figure 39-5.R).
- Highway Grade Separation over Railroad (Figure 39-5.S).

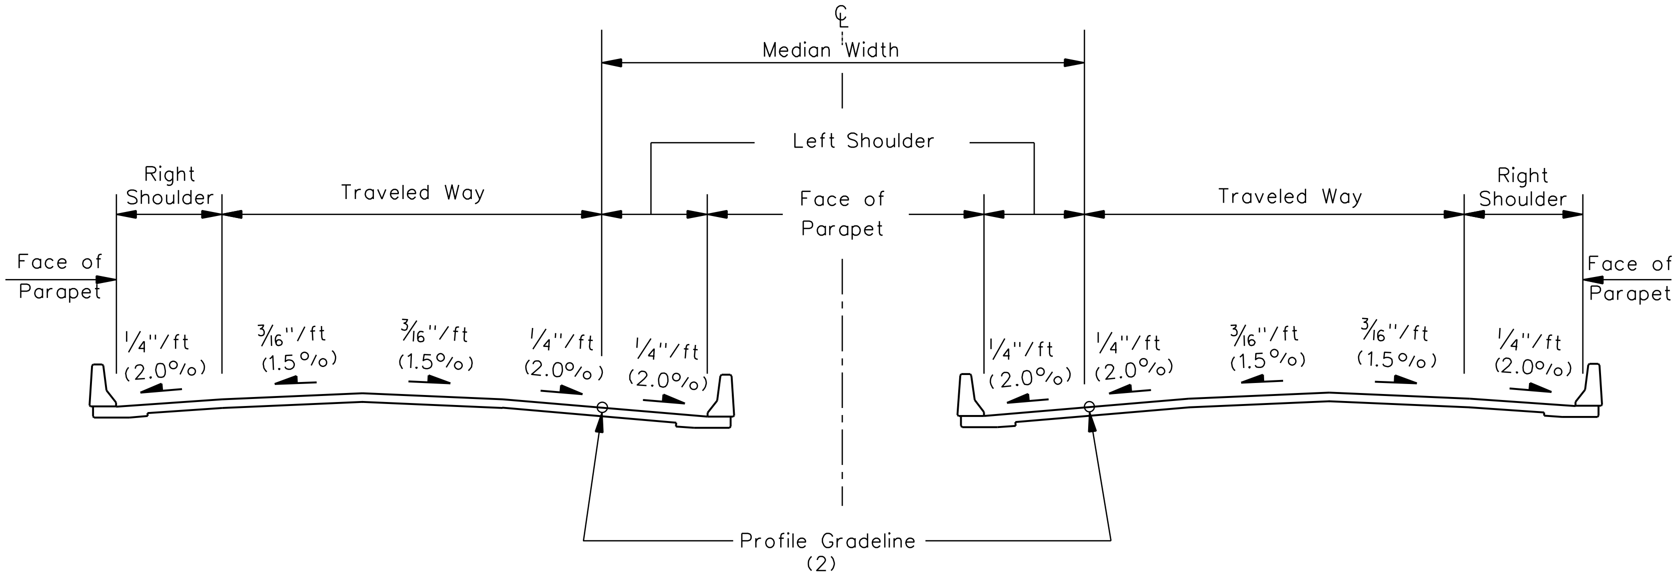
See the *Bridge Manual* for more details on bridge design.



Note: See Figure 39-6A and 39-6.C.

CLEAR ROADWAY WIDTH OF BRIDGES FOR NEW AND RECONSTRUCTED FOUR-LANE DIVIDED HIGHWAYS

Figure 39-5.A

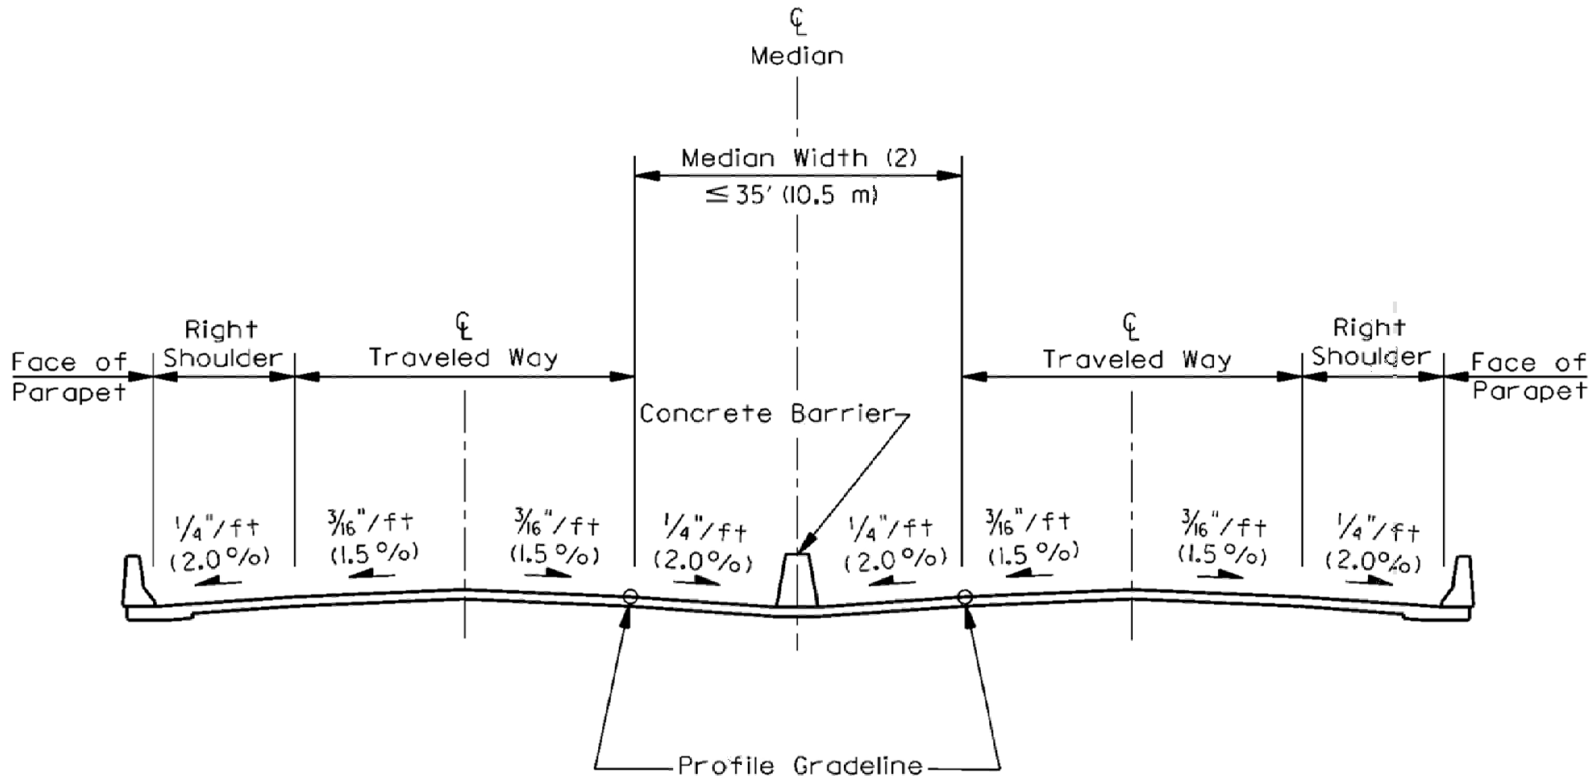


Notes:

1. *See Figures 39-6.A and 39-6.C.*
2. *Profile gradeline is set at the location shown above where the approach traveled way is initially designed for three lanes in each direction.*

CLEAR ROADWAY WIDTH OF BRIDGES FOR NEW AND RECONSTRUCTED SIX-LANE DIVIDED HIGHWAYS

Figure 39-5.B

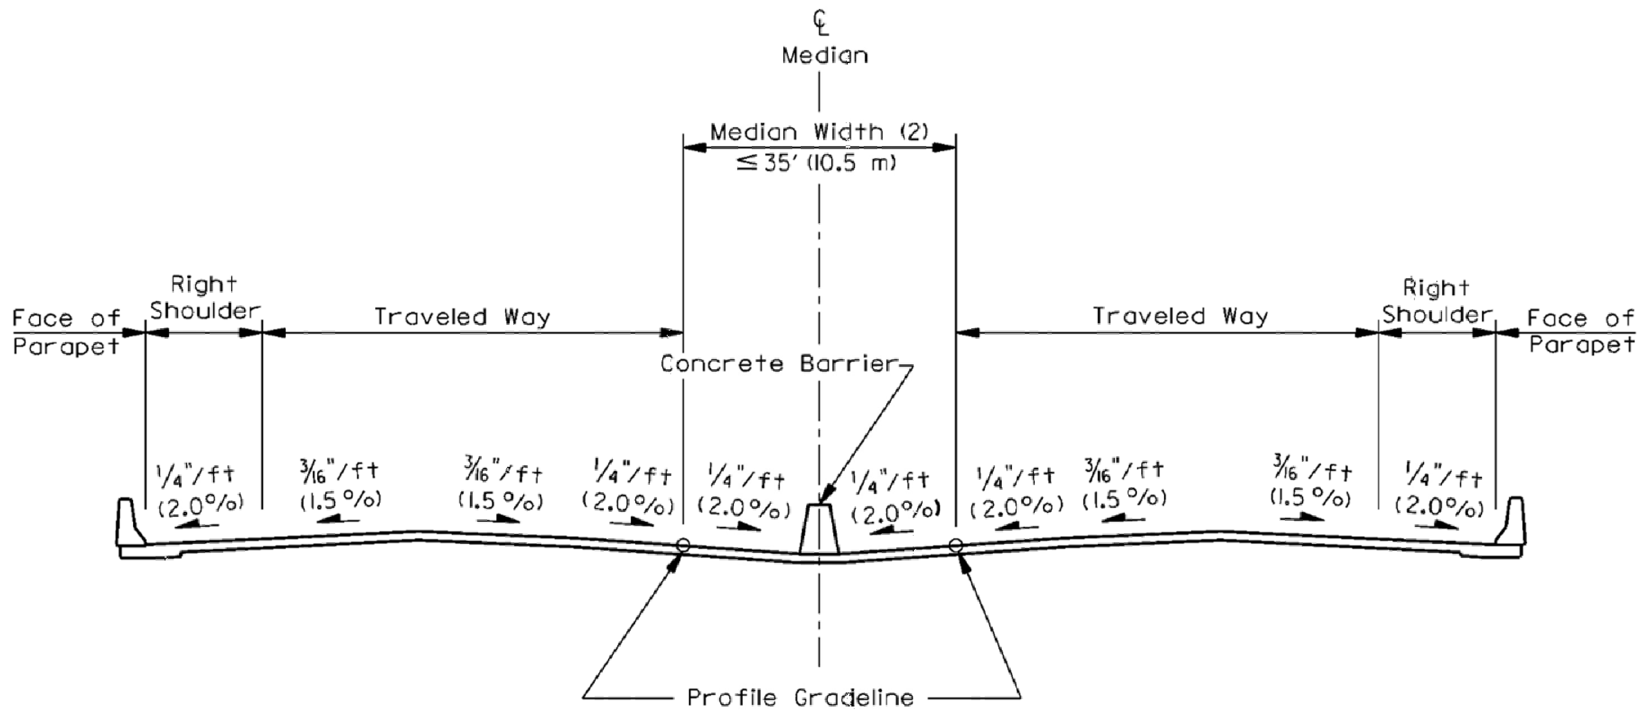


Notes:

1. *See Figures 39-6.A and 39-6.C.*
2. *In all cases, the median width on the approach roadway and the median on the bridge structure must be similar.*

CLEAR ROADWAY WIDTH OF BRIDGES FOR NEW AND RECONSTRUCTED FOUR-LANE DIVIDED HIGHWAYS WITH CONCRETE BARRIER

Figure 39-5.C

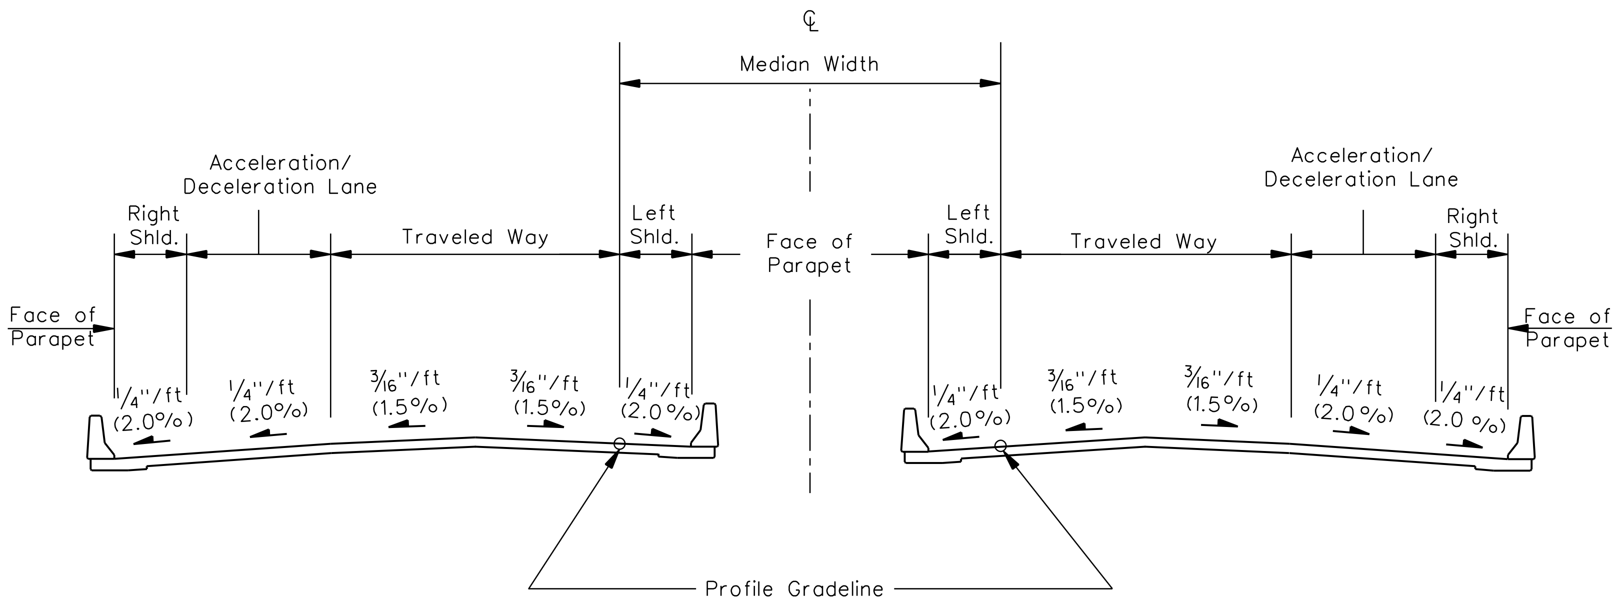


Notes:

1. *See Figures 39-6.A and 39-6.C.*
2. *In all cases, the median width on the approach roadway and the median on the bridge structure must be similar.*

CLEAR ROADWAY WIDTH OF BRIDGES FOR NEW AND RECONSTRUCTED SIX-LANE DIVIDED HIGHWAYS WITH CONCRETE BARRIER

Figure 39-5.D



Notes:

1. *See Figures 39-6.A and 39-6.C.*

2. *Where an exit terminal lies within the limits of a bridge, the cross slope of the standard exit terminal must be modified to fit the cross slope of the bridge deck. In this case, the designer should use a minimum uniform cross slope of 1/4″/ft (2%) on the terminal or, if the mainline is on a curve to the right, the designer should use the superelevation rate of the mainline for the terminal cross slope, but not greater than 5/8″/ft (5%). In both cases, the cross slope is measured perpendicular to the edge of the mainline pavement. See Section 37-6.*

CLEAR ROADWAY WIDTH OF BRIDGES FOR NEW AND RECONSTRUCTED FOUR-LANE DIVIDED HIGHWAYS

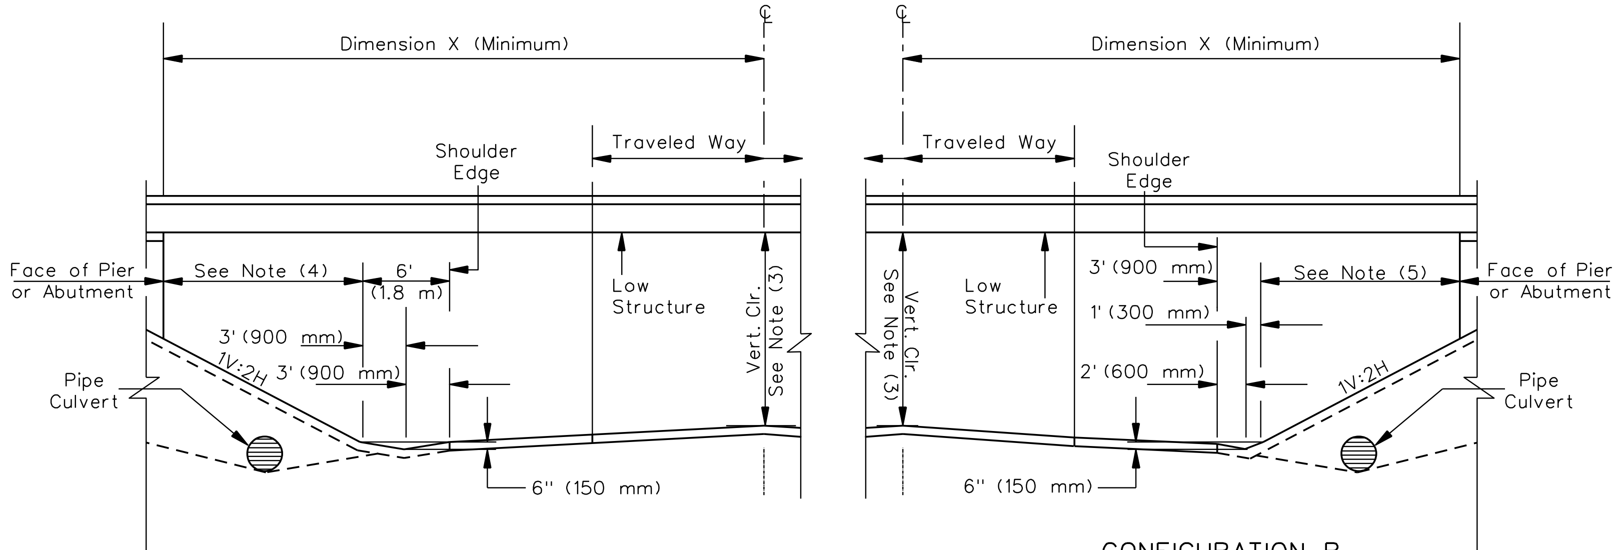
CLEARANCE CONFIGURATIONS

Notes:

1. *Locate the upstream traffic end of a through culvert outside the clear zone of the near edge of traveled way.*
2. *All horizontal dimensions are right angles.*
3. *Locate median piers, where required, on the median centerline where the median width provides less than the required clear zone width.*
4. *Locate the minimum clearance point at the least clearance point above the usable roadway under, including stabilized shoulders.*

CLEARANCES FOR BRIDGES OVER DIVIDED HIGHWAYS

Figure 39-5.Q



CONFIGURATION A CONFIGURATION B

Functional Classification of Underpassing Highway	Current ADT or 20-Year DHV	Config.	X (Min.)	Minimum Vertical Clearance
Rural Principal Arterial or Minor Arterial*	All ADT's	A	42′ (12.8 m)	16′-6″ (5.0 m) (new) 16′-0″ (4.9 m) (reconst)
Local Road or Collector	DHV over 400	A	36′ (11.0 m)	14′-9″(4.5 m)
Local Road or Collector	DHV 200-400	A	36′ (11.0 m)	14′-9″(4.5 m)
Local Road or Collector	DHV 100-200	B	30′ (9.0 m)	14′-9″(4.5 m)
Local Road or Collector	ADT 250-400	B	28′ (8.5 m)	14′-9″(4.5 m)
Local Road or Collector	ADT < 250	B	23′ (7.0 m)	14′-9″(4.5 m)
Frontage Road A	ADT over 2000	A	40′ (12.0 m)	16′-0″ (4.9 m)
Frontage Road B	ADT ≥ 750	A	32′ (10.0 m)	14′-9″(4.5 m)
Frontage Road B	ADT < 750	B	30′ (9.0 m)	14′-9″(4.5 m)
Frontage Road C	ADT < 400	B	23′ (7.0 m)	14′-9″(4.5 m)

For marked highways functional classified as collectors, use the arterial criteria.

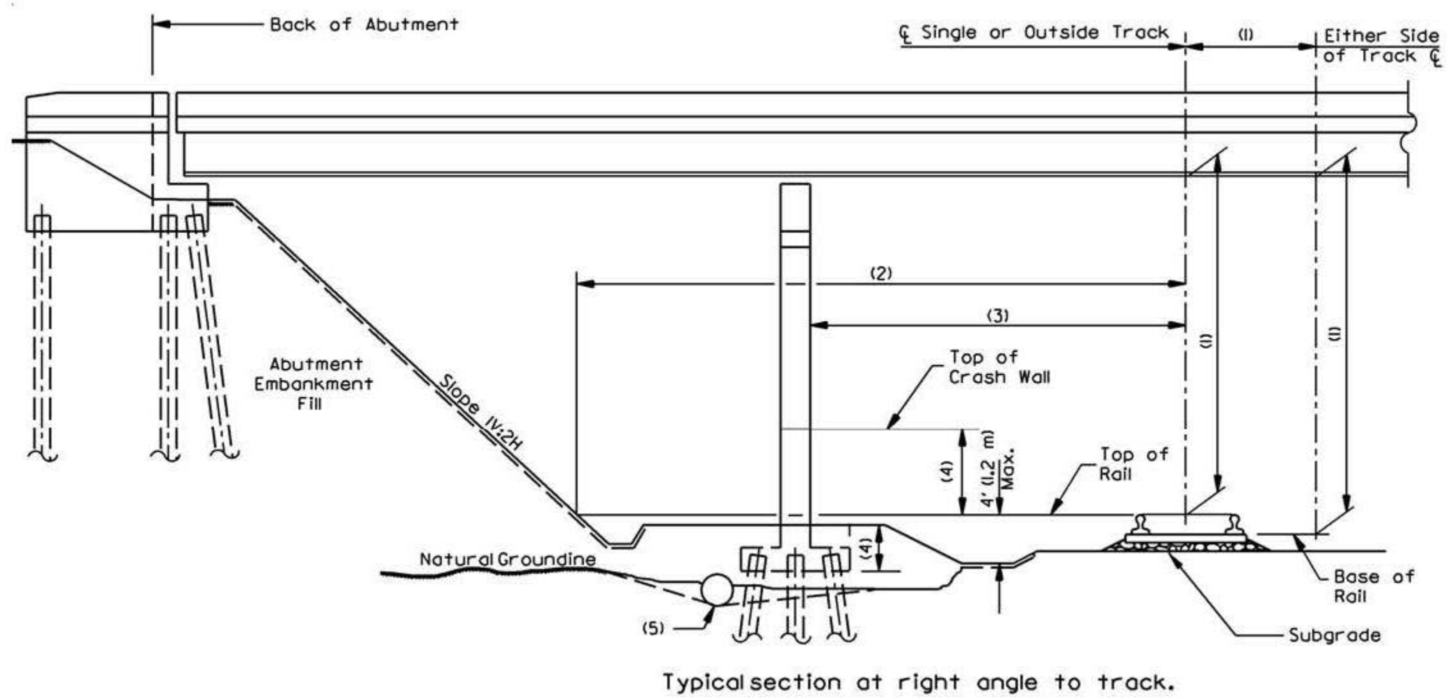
Notes:

1. *Locate the upstream traffic end of a through pipe culvert outside the clear zone of the near edge of traveled way.*
2. *All horizontal dimensions are right-angle dimensions.*
3. *Locate the minimum clearance point at the least clearance point above the usable roadway under, including stabilized shoulders.*
4. *Where DS ≥ 60 mph (100 km/h), distance is equal to 14 ft (4.2 m). For DS < 60 mph (100 km/h), distance is equal to 10 ft (3.0 m).*
5. *Where DS ≥ 50 mph (80 km/h), distance is equal to 10 ft (3.0 m). For DS < 50 mph (80 km/h) distance is equal to 6 ft (1.8 m).*

DS: Design Speed

CLEARANCES FOR BRIDGES OVER TWO-LANE HIGHWAYS

Figure 39-5.R



HIGHWAY GRADE SEPARATION OVER RAILROAD

FIGURE 39-5.S

Footnotes for Figure 39-5.S

For multiple track facilities, all dimensions apply to the centerline of the outer tracks. All horizontal dimensions are measured perpendicular to the railroad tracks.

(1) A vertical clearance of not less than 23 ft-0 in. (7.0 m) above the top of rail shall be provided for all new or reconstructed highway bridges constructed over a railroad track. Beginning at a point in the centerline of track, 23 ft-0 in. (7.0 m) above the top of the rail, the vertical clearance line shall extend thence horizontally each way to a point 9 ft, 0 in. (2.7 m) from the centerline of the track, from which points the horizontal clearance lines shall extend vertically downward to points level with the base of the rail. Illinois Commerce Commission may permit a lesser clearance if it determines that the 23 ft-0 in. (7.0 m) clearance standard cannot be justified based on engineering, operational, and economic conditions. The existing vertical clearance or 21 ft-6 in. (6.6 m), whichever is greater, is permitted for bridge rehabilitation projects that do not require pier and/or cap replacement, girder removal and/or replacement, and/or widening of the existing piers or pier caps. (92 Ill. Admin. Code 1500.160).

(2) A cross section with a horizontal distance of 20 ft-0 in. (6.1 m) measured at right angles from the centerline of track at the top of rails, to the face of the embankment slope, is permitted. The 20 ft-0 in. (6.1 m) may be increased at individual structure locations as appropriate to provide for drainage if justified by a hydraulic analysis or to allow adequate room to accommodate special conditions, such as where heavy and drifting snow is a problem. The railroad must demonstrate that this is normal practice to address these conditions in the manner proposed. This dimension may be increased by up to 8 ft (2.5 m) on one side only, as may be necessary for off-track maintenance equipment, provided adequate horizontal clearance is not available in adjacent spans and where justified by the presence of an existing maintenance road or by evidence of future need for such equipment. (92 Ill. Admin. Code 1500.160).

(3) Piers should be placed at least 9 ft-0 in. (2.8 m), measured from the nearest point along the edge of the pier, horizontally from the centerline of the track and preferably beyond the drainage ditch. (Appendix to Subpart B of Part 23 C.F.R. 646).

(4) Crash walls for piers from 12 ft to 25 ft (3.6 m to 7.6 m) clear from the centerline of track shall have a minimum height of 6 ft (1.8 m) above the top of the rail. Piers less than 12 ft (3.6 m) clear from the centerline of track shall have a minimum crash wall height of 12 ft (3.6 m) above the top of the rail. The crash wall shall be at least 2 ft, 6 in. (760 mm) thick and at least 12 ft-0 in. (3.6 m) long. When two or more columns compose a pier, the crash wall shall connect the columns and extend at least 1 ft (300 mm) beyond the outermost column parallel to the track. The crash wall shall extend at least 4 ft-0 in. (1.2 m) below the lowest surrounding grade. (Volume 2 Chapter 8 Section 2.1.5 of AREMA Manual for Railway Engineering).

(5) Intercepted drainage along railroad embankment shall be accommodated with a minimum 3 ft (900-mm) diameter culvert or carried along highway embankment.

DESIGN CRITERIA FOR NEW OR RECONSTRUCTED[1] BRIDGES
(Rural State Highway System[2])
(Metric)

Figure 39-6.A

Footnotes for Figure 39-6.A

(1) Implies reconstruction of a significant length of existing highway either on new location or on existing ROW. For reconstruction of relatively short intermittent highway segments within a project, the design criteria used, where cost-safety effective, should be consistent with the adjacent highway design, but not less than that allowed to remain in place.

(2) For marked highways functionally classified as Collectors, use the Arterial criteria.

(3) Volumes calculated with PHF = 1.0; adjust for local peak hour factors (PHF).

(4) Based on 100% MUTCD passing sight distance; adjust for actual percentage. See Chapter 31 for the assumed truck percentage.

(5) On freeways where truck traffic exceeds 250 DDHV, see Figure 44-5.A for the use of 12 ft (3.6 m) shoulders.

(6) Bridge widths for bridge rehabilitation projects are discussed in Chapters 49 and 50.

(7) Bridge widths are normally defined as the sum of the approach traveled way width and approach paved shoulder width.

(8) For reconstruction projects, where the minimum required right or left shoulder widths on a structure can only be obtained with the addition of new beams and substructure, a cost-safety evaluation should be made to determine the appropriateness of providing the required width. Significant decreases of the required widths should not be considered.

(9) Implies elements allowed to remain in place without a design exception approval when cost-effective and when safety record is satisfactory.

(10) For new freeway or expressway construction, the bottom of the superstructure shall not be below the all time high-water elevation.

(11) For reconstruction projects, the proposed low superstructure should not be below the existing superstructure unless 2 ft (600 mm) of clearance is achieved. Any proposed clearance less than 2 ft (600 mm) above design high-water elevation must be accompanied by a request for a design exception.

(12) For the Interstate System, provisions shall be made for the Alternate Military Loading.

(13) Use 14 ft-9 in. (4.5 m) for local roads and unmarked collector roads.

(14) The minimum required vertical clearance must be available over the traveled way and any paved shoulders.

(15) A vertical clearance of 17 ft-3 in. (5.25 m) shall be provided for through trusses, overhead signs, and pedestrian overpasses.

DESIGN CRITERIA FOR NEW OR RECONSTRUCTED[1] BRIDGES
(Urban State Highway System[2])
(Metric)

Figure 39-6.C

Footnotes for Figure 39-6.C

(1) Implies reconstruction of a significant length of existing highway either on new location or on existing ROW. For reconstruction of relatively short intermittent highway segments within a project, the design criteria used, where cost-safety effective, should be consistent with the adjacent highway design, but not less than that allowed to remain in place.

(2) For marked highways functionally classified as Collectors, use the Arterial criteria. For other streets on the unmarked State-maintained system, see the Bureau of Local Road and Streets Manual.

(3) Volumes calculated with PHF = 1.0; adjust for local peak hour factor (PHF).

(4) On freeways where truck traffic exceeds 250 DDHV, see Figure 44-5.A for the use of 12 ft (3.6 m) right shoulders.

(5) Bridge widths for bridge rehabilitation projects are discussed in Chapters 49 and 50.

(6) For urban bridges requiring sidewalks, the width of the sidewalks is 5 ft (1.5 m) unless a wider width is specified by the district.

(7) For new freeway or expressway construction, the bottom of the superstructure will not be below the all time high-water elevation.

(8) For reconstruction projects, the proposed low superstructure will not be below the existing superstructure unless a 2 ft (600 mm) clearance is achieved. Any proposed clearance less than 2 ft (600 mm) above design high-water elevation must be accompanied by a request for a design exception.

(9) For the Interstate System, provisions will be made for the Alternate Military Loading.

(10) The minimum required vertical clearance must be available over the traveled way and any paved shoulders.

(11) For reconstructed urban arterials, existing structures with a vertical clearance of 14 ft 0 in (4.3 m) may be allowed to remain in place. For a freeway or expressway passing through a highly developed urban area, a 15 ft 0 in (4.5 m) vertical clearance may be provided if a circumferential route is designated around the urbanized area and if the circumferential route has a minimum vertical clearance of 16 ft 0 in (4.9 m).

(12) A vertical clearance of 17 ft 3 in (5.25 m) shall be provided for through trusses, overhead signs, and pedestrian overpasses.

GENERAL DRAINAGE PROCEDURES

BUREAU OF DESIGN AND ENVIRONMENT MANUAL

Chapter Forty
GENERAL DRAINAGE PROCEDURES

Table of Contents

Chapter Forty
GENERAL DRAINAGE PROCEDURES

This Chapter provides guidance on the drainage requirements of projects designed for the State highway system. It discusses the division of responsibility between the districts and the Central Office, general drainage policies, design criteria, and the content of drainage studies for various project types.

The *IDOT Drainage Manual* provides a detailed discussion on drainage policies and procedures to be used on all design projects. This Chapter refers to the *IDOT Drainage Manual* extensively to direct the reader to specific areas of interest.

40-1 ADMINISTRATION

40-1.01 Responsibilities

The Hydraulics Unit of the Bureau of Bridges and Structures is responsible for all drainage functions completed within the Offices of Program Development and Highways Project Implementation. In District 1, the Hydraulic Engineer and support staff are located in the Bureau of Programming. In Districts 2 through 9, the Hydraulic Engineer and support staff are located in the Bureau of Program Development.

The Hydraulics Unit of the Bureau of Bridges and Structures is responsible for the development and administration of the roadway, culvert, and bridge drainage policies used by the Offices of Program Development and Highways Project Implementation within IDOT. The districts are responsible for initiating drainage and hydraulic studies, coordinating and monitoring drainage work performed by consultants, completing Phase I reports, and ensuring that the appropriate policies and procedures are followed throughout project development. Chapter 1 of the *IDOT Drainage Manual* provides a comprehensive description of drainage responsibilities of the Central Office and the districts.

40-1.02 General Overview

The critical impact of drainage decisions and their influence on plan preparation, implementation, and operation requires a continuous consideration of drainage features throughout project development. Typically, project development occurs in two phases, and drainage is a principal feature of both phases.

Drainage Studies are one of several types of Phase I studies, which are then incorporated into the Phase I report that is used to make and document design decisions. On major construction projects, it may also be necessary to prepare an Environmental Impact Statement, which uses the findings of a Drainage Study. On most projects, the district Hydraulic Engineer and the

Operations Field Engineer will examine drainage issues during Phase I and recommend needed improvements or identify items that require evaluation.

Drainage Studies are completed during Phase I to identify the drainage needs and/or problems associated with highway projects. They also provide an excellent coordination tool to consider and document local agency concerns, regulations, and needs. The complexity of the drainage study during Phase I depends on the type of project under study.

For highways on a new location, which require a Design Report or Combined Report, the Drainage Study examines the overall drainage patterns of the area, and the Study identifies the location, type, and relative size of drainage structures required for each alignment. This includes such structures as bridges, culverts, storm drains, ditches, pumping stations, or other special structures. The Study may be rather complex and assist in setting the alignment and profile of the proposed highway project. The Study will also address any special drainage problems that may be encountered by a specific alignment or any problems precipitated by a proposed alignment. The completed Drainage Study for projects on new alignment becomes a technical report to the Design Report or Combined Report.

A 3R project could involve investigating:

- the need to widen and deepen existing highway ditches;
- the hydraulics of existing bridges and culverts;
- flooding problems; and
- storm sewer capacities or the need for new storm sewers and the need for compensatory or detention storage or larger outflow facilities.

See Figure 40-1.A, which summarizes the type of drainage information needed for projects.

Type of Work Type of Project	Phase I (Location/Design Studies)	Phase II (Preparation of Construction Plans)
1. Freeway or expressway construction on new alignment.	Prepare Drainage Study that documents the overall drainage plan for project and indicates preliminary culvert sizes, highwater elevations for proposed bridges, areas of sheet flow, width of ditches for detention storage, etc. Document results in Drainage Study.	Use Drainage Study to develop a Drainage Report for project.
2. Freeway or expressway reconstruction on existing alignment.	Determine if existing drainage facilities can adequately accommodate storm water and what changes may be needed. Document results in Drainage Study. Check with field maintenance engineers and local agencies for any flooding problems. The preparation of Hydraulic Reports are necessary in this Phase.	Use Preliminary Drainage Study to develop a Drainage Report for project. Urban freeways/ expressways will have the most potential for significant drainage changes.
3. Expressway construction along existing alignment.	Prepare Drainage Study that documents the overall drainage plan for project and indicates culvert sizes, highwater elevations for existing and proposed bridges, areas of sheet flow, width of ditches for detention storage, location of any gutters and storm sewers in restricted ROW areas, etc. Document results in Drainage Study. Because of existing bridges, multiple box culverts, and other special drainage problems along an existing route, this type of project will require the preparation of Hydraulic Reports. The Hydraulic Report will be submitted in conjunction with each Bridge Condition Report.	Use Drainage Study to develop a Drainage Report for projects. In highly urbanized areas, the drainage investigations required in Phase I may be quite extensive with little work remaining to be done in Phase II.
4. Reconstruction of existing urban arterial or collector streets.	Prepare Drainage Study that documents the overall drainage plan for project and indicates preliminary storm sewer sizes, preliminary culvert sizes, highwater elevations for any bridges, detention storage needed, main outflow storm sewer locations, pump stations, etc. Document results in Drainage Study.	Use Drainage Study to develop a Drainage Report for projects. In highly urbanized areas, the drainage investigations required in Phase I may be quite extensive with little work remaining to be done in Phase II.

TYPICAL DRAINAGE INFORMATION
(Projects on the State Highway System)

Figure 40-1.A

Type of Work Type of Project	Phase I (Location/Design Studies)	Phase II (Preparation of Construction Plans)
5. Reconstruction of existing rural arterial or collector highways including any bypass around a community (could include major realignments in both the horizontal and vertical planes).	Prepare Drainage Study that will document the overall drainage plan for project. Study should indicate culvert sizes, highwater elevations for bridges, areas of sheet flow, width and depth of ditches for detention storage, etc. Document results in Drainage Study. Check with field operations engineers for any flooding problems. The preparation of Hydraulic Reports should be completed in this Phase.	Use Drainage Study to develop a Drainage Report for project. If Hydraulic Reports are not prepared in Phase I, they will have to be prepared in this Phase.
6. All 3R projects.	Check with field operations engineers and local agencies for any flooding problems. Examine the need to deepen ditches to improve highway drainage. If flooding problems occur in urban areas, determine and document causes and recommend solutions. If bridges or large box culverts exist within project, Hydraulic Reports may be prepared during this phase of work in conjunction with each Bridge Condition Report and then submitted for review and approval to the Bureau of Bridges and Structures (BB&S) or the District.	From information documented in approved Phase I Report, the designer submits a TS&L drawing to the BB&S for each major drainage structure. The approved TS&L drawing is then used to prepare the final plans for the drainage structure.
6a. Superstructure replacement on existing piers and abutments.	Project could be part of roadway improvement or a stand-alone project. Requirements as described above for Item 6 will apply.	Requirements as described above for Item 6 will apply.
6b. Complete structure replacement on existing alignment.	Project could be part of roadway improvement or a stand-alone project. Project could involve a runaround detour over waterway that would require a special hydraulics analysis. Requirements as described above for Item 6 will apply.	Requirements as described above for Item 6 will apply.
6c. Existing box culvert or bridge replaced with a multiple-barreled box culvert.	Project could be part of roadway improvement or a stand-alone project. Requirements as described above for Item 6 will apply.	Requirements as described above for Item 6 will apply.

TYPICAL DRAINAGE INFORMATION
(Projects on the State Highway System)

Figure 40-1.A
(Continued)

40-2 STUDIES

40-2.01 Introduction

Drainage Studies and Hydraulic Reports are investigations of the existing and proposed drainage patterns and the hydraulic performance of highway drainage structures. These drainage investigations are a vital component in the design of every highway project. Runoff, ponding of water, and the adequacy of the outlet must be addressed early in the project development stage to ensure that projects are designed through a process that involves consideration and balancing of a number of factors including:

- flood hazards to highway users and neighboring property owners,
- legal considerations,
- functional needs,
- environmental and social concerns,
- local stormwater management ordinances,
- costs, and
- other site conditions.

The analyses listed below are commonly conducted as a part of both a Drainage Study and a Hydraulic Report:

- hydrologic analysis;
- hydraulic analysis;
- engineering evaluation of selected alternatives; and,
- addressing Illinois Department of Natural Resources, Office of Water Resources (IDNR-OWR) permitting requirements.

The detail of analysis for either study is commensurate with the scope of work and the hydraulic risk associated with the drainage facility and other economic, engineering, social, or environmental concerns. Chapter 2 of the *IDOT Drainage Manual* provides a complete description of Drainage Studies and Hydraulic Reports.

40-2.02 Drainage Studies

A Drainage Study includes the hydraulic investigation and analysis of minor drainage facilities such as roadside and median ditches, detention ponds, storage pipes, storm sewers, and single barrel culverts. The Drainage Study becomes the basis for judging the adequacy of existing facilities, improvements needed, compliance with existing policies and standards, consideration of local stormwater management ordinances, and coordination with other agencies. The Study will typically include the analysis and evaluation of all applicable drainage features within the project reach. In District 1, the Drainage Study is completed during Phase I. However, the Drainage Study is often completed during Phase II work in Districts 2 through 9. The detailed hydraulic analysis for major drainage structures such as bridges, multi-barrel culverts, and pumping stations are contained in a separate Hydraulic Report. Where a Hydraulic Report is required, it is completed in Phase I in all districts, and the Drainage Study summarizes the findings.

The Drainage Study must begin with an investigation of existing drainage patterns to establish a basis for judging the adequacy of drainage features included in the highway project and to identify the drainage parameters that will be encountered by the highway project. Address the following specific items:

- an evaluation of floodplain impacts,
- permitting requirements,
- identification of all drainage paths,
- highest known water levels,
- reports of flooding of both adjacent property and the highway facility, and
- outlet conditions.

The Drainage Study should also identify the general type, size, and location (including right-of-way requirements) of all highway drainage facilities necessary to accommodate local conditions and design requirements, and it should contain the complete hydraulic analysis of the proposed design.

Where the project involves the replacement or rehabilitation of an existing facility, the Drainage Study should document the adequacy of the existing system during past storm events. This will include consideration for erosion and sediment control of ditches and drainage structures, storm sewer capacities, and locations of pavement flooding and adjacent property flooding. The need for drainage improvements on rehabilitation projects is determined from the investigation of existing conditions and the evaluation of problems or inadequacies encountered. A theoretical hydraulic analysis is performed to determine the proposed changes.

However, if the theoretical analysis indicates the need for major changes but the Drainage Study reveals that no problems have been encountered during past flood events, the theoretical analysis may be determined by the engineer to be overly conservative and not representative of local conditions. The experience of problems with the existing facility, as identified by district Operations personnel, adjacent property owners, or local agencies that maintain State Routes by agreement is normally required to justify major drainage improvements to existing facilities on 3R projects.

When the final Drainage Study is scheduled to be completed with Phase II work, a Preliminary Drainage Study is prepared in Phase I. This Study defines existing drainage features and identifies the type and relative size of drainage structures required to complete the project. The Preliminary Drainage Study should contain mapping or USGS quadrangle maps that identify drainage patterns, adjacent land usage, and the location of affected structures. The Study should include a centerline profile, an adjacent groundline profile, existing and proposed roadway templates, right-of-way or easement requirements, and the relative size and configuration of existing and proposed drainage structures. It should identify known problems such as pavement flooding, ditch erosion, bridge or culvert scour, concerns of other agencies, and complaints by property owners.

The Preliminary Drainage Study, when finalized and approved, becomes the Drainage Report for the project. The final Drainage Report should identify all changes made to the preliminary study affecting the number, type, size, and location of drainage structures.

40-2.03 Hydraulic Reports

A Hydraulic Report is similar to a Drainage Study, except that it typically focuses on a single structure location because of the greater volume of computations and support data required for the structure involved. Hydraulic Reports are required for bridges, multiple-barrel culverts, single-barrel culverts that are identified by the district as requiring a special study, pumping stations, and all special or unusual drainage structures. For all projects where the structural design will be reviewed by the district Hydraulic Engineer, Hydraulic Reports must be prepared and submitted to the Central Office with the submittal of a Bridge Condition Report. The content of a Hydraulic Report is similar to a Drainage Study in that it includes an evaluation of existing conditions, hydraulic calculations of the proposed design, details of structure type and size, and all supporting data. Bridge and culvert crossings should also be investigated for problems associated with scour and siltation, debris and ice blockage, stream alignment, highwater clearances, headwater and tailwater elevations, and complaints of flooding.

Early in the Hydraulic Report preparation, it should be determined if the project will require a construction permit from the IDNR, Office of Water Resources. See Chapter 28. If a permit is required, the type of permit and the permit requirements should be identified, and the proposed design must be evaluated for those requirements. Where local conditions dictate a higher design standard than the permit requirement, the Hydraulic Report must identify and document these conditions in accordance with the Floodplain Encroachment Policy in Section 1-302 of the *IDOT Drainage Manual*. The jurisdictional limits and the permit requirements of the Office of Water Resources are described in Section 1-400 of the *IDOT Drainage Manual*. The design decisions of projects that do not require a construction permit should be based on a cost evaluation of alternatives which satisfy the project design criteria, local site conditions, legal requirements, and project objectives. These conditions and decisions must also be documented in accordance with the Floodplain Encroachment Policy.

40-3 DESIGN CONSIDERATIONS

40-3.01 Introduction

Section 40-3 addresses the types of design considerations that relate to the drainage aspects of a highway project. There are often numerous design features that will satisfy the design objectives of the project and, therefore, many tasks and requirements must be considered during the early phases of project development to ensure the selection of the most cost-effective and beneficial design features.

Coordination among the various Central Bureaus and the district is a very important function. Also, notification of proposed projects must be made to other agencies and the public, and the permits and regulations of other agencies applicable to the project should be identified and documented as soon as practical. Often project delays are due to the legal process. Problems that may arise during design, construction, or maintenance should be considered in Phase I studies.

The above factors and other considerations may not always allow items to be separated into the planning phase and the design phase. Often, there will be overlap, and sometimes the separation of work between the phases will be indistinct. Therefore, it is essential that the design concepts developed in Phase I be evaluated for their constructability. This includes right-of-way needs, because this consideration reduces the likelihood that Phase I decisions will be revisited during Phase II. When Phase II work is allowed to proceed before Phase I studies are complete, many problems are exacerbated and conflicts between the various parties and schedules often occur. The district is responsible for coordination and guidance on these issues. This ensures that project schedules are maintained.

40-3.02 Storm Drainage Facilities

40-3.02(a) General

Highway storm drainage facilities collect stormwater runoff and convey it along and/or away from highway right-of-way to adequately drain the roadway and minimize the potential for flooding and the erosion to properties adjacent to the right-of-way. Stormwater includes the runoff from precipitation falling within the right-of-way and the surface runoff from adjacent properties which flows into the roadside ditches or the storm drainage system. Storm drainage facilities consist of curbs, gutters, inlets, storm drains, ditches, and culverts. The placement and hydraulic capacities of storm drainage structures and conveyances should be designed to avoid/minimize damage to adjacent property and to secure a low degree of risk of traffic interruption by flooding. Interruption by flooding should commensurate with the importance of the road, the design traffic service requirements, and available funds.

There are two basic types of roadway sections to be considered for pavement drainage—a rural section and a curbed section. A rural section consists of a crowned pavement that drains laterally to the shoulders and down the embankment slope to a roadside ditch or that continues as sheet flow down slope from the right-of-way. The ditches are sloped to carry the runoff to the nearest natural outlet. A curbed section consists of a sloped pavement that drains to a curb and gutter system. The curb and gutter channels the flow to a series of inlets which capture the runoff and outlet into a storm drain. Both section types may include a median to separate traffic. The rural section is normally more cost effective and is the section of choice where other factors are equal, because it allows the unhindered drainage of the pavement without concern for encroachment on the traveled way. Costs of the rural section include wider right-of-way, longer/wider cross drainage structures, and the maintenance costs of mowing, debris pickup, and ditch erosion repairs. Curbed sections are required in urban settings where sidewalks, storefronts, residential lawns, and/or intersections do not allow room for roadside ditches and the wider right-of-way required for a rural section. The policies and procedures for the design of storm drain systems are presented in Chapter 8 of the *IDOT Drainage Manual*.

40-3.02(b) Rural Cross Sections

Because rural sections usually require wider right-of-way, the scheduling of widening or reconstruction projects must include sufficient time for the purchase of additional right-of-way and the right-of-way requirements must be determined early in project development. Actual right-of-way required is determined by roadway geometrics and drainage needs. Existing drainage conditions and the design highwater elevation plus the freeboard requirements (see Chapter 1 of the *IDOT Drainage Manual*) may control the roadway profile. Basic geometrics with consideration of key drainage elements are established first and then detailed drainage needs and type and size of drainage facilities are determined. These are based on the roadway geometrics and the runoff from adjacent properties. If drainage problems are encountered, it may be necessary to review geometric design decisions and/or to use special drainage structures.

Drainage considerations for rural sections include the discharge to be carried, typical ditch sections and gradients, ditch erosion protection requirements, and suitable outlet conditions. The source of discharge must consider the width of pavements, appurtenant vegetation and/or paved areas of the right-of-way, and adjacent property. Ditch sections must conform to acceptable side slopes and depth to accommodate errant vehicles and mowing equipment. The width, depth, and gradient of ditches may need adjustment to accommodate the design discharge and minimum depth requirements. Chapter 9 of the *IDOT Drainage Manual* presents complete design procedures for roadside ditches.

40-3.02(c) Curbed Cross Sections

Curbed sections are normally more expensive than rural sections because of the number of appurtenant structural items involved. These include the curb and gutter section, inlets, laterals, storm drains, manholes, and outlet structures. A major consideration in the design of a curbed section is the location of the main storm drain. Locations outside the pavement structure are preferred because they provide easier access for maintenance and repairs, and they do not involve the expense of special backfill required for storm drains placed beneath the pavement structure. However, potential conflicts with utilities must be fully evaluated and often will influence the location of storm drains. The most cost-effective design is determined by an analysis considering a balance of sizes, slopes, and depths of storm drains that satisfy the storm drain policies and drainage needs of the project. Chapter 34 discusses the drainage of selected medians (raised-curb, traversable, or flush). The drainage of each median considers the traffic safety concerns with additional cross flow, and it also considers minimizing ice melt flowing onto and refreezing on the traveled way.

Inlet types are selected from the *IDOT Highway Standards* based on the location and situation to be served by the inlet. Spacing of inlets is determined by analysis to control the spread of water onto the traveled way and at predetermined locations such as at sag vertical curves, intersections, and pedestrian cross walks. These details are normally addressed during Phase II work.

The Drainage Study prepared with Phase I work must address proposed hydraulic improvements for existing conditions such as the conversion of open ditches to a storm drainage system including the suitability of outfalls, pumping stations, and detention basins. Both the functionality and constructability of these changes must be addressed, and impacts such as right-of-way needs, environmental impacts, agency coordination, and permit requirements considered.

40-3.02(d) Joint Participation

Many highway projects involve joint participation in both the use and funding of storm drain systems. Joint participation normally involves a municipality or a county in conjunction with the Department. This may result in either the State connecting to a local agency storm drain because there is no other feasible outlet or the local agency tying into a State storm drain. The possibility of joint participation should be determined early in project development to allow an investigation of the full area to be served by the system and a determination of the storm drain size. Also, adequate time must be allowed for negotiations and development of an agreement between the Department and the local agency involved. Chapter 5 of the *BDE Manual* discusses the policies on Joint Participation.

40-3.03 Stormwater Management

Stormwater management is defined as the control of runoff to satisfy a predetermined objective. The Department’s policy on stormwater management is found in the Department’s *Storm Water Management Plan*. The basic objective is to ensure that runoff from a highway project does not result in any detrimental effects to upstream or downstream property and flooding conditions. The primary tool in reducing runoff for stormwater management is detention storage; however, it is also possible to reduce runoff rates by lengthening flow paths, flattening slopes, and using open ditches instead of enclosed storm drains. Where storage is necessary, it may be provided in any one of several locations (e.g., medians, roadside ditches, open basins, oversized storm drains). A roadway project may involve a combination of storage features and methods to reduce runoff.

Stormwater management considerations in accordance with Department policies must be analyzed on all projects to ensure that drainage problems are not increased and all legal obligations are satisfied. The stormwater management ordinances of local agencies must also be considered and incorporated into a project design when feasible and cost-effective.

40-3.04 Bridges and Culverts

Highways which cross a watercourse are often referred to as a transverse encroachment. The cross drainage to the highway, whether by swale, stream, or river system, must be carried across the highway to preserve the natural and existing drainage courses. A hydraulic investigation and analysis of both the upstream and downstream reaches of the watercourse is necessary to determine the best location, size, and elevation of the proposed crossroad structure, whether a culvert or a bridge. The investigation should ensure that any highway structure or roadway embankment that encroaches on or crosses the floodplain of a watercourse will not cause a significant adverse effect to the floodplain and will be capable of withstanding the flood flow with minimal damage. The analysis should also clearly indicate the path and approximate elevations of flow and existing conditions at any location where water comes to or leaves a proposed project. To ensure that adequate attention is provided to this aspect of design, all construction plans submitted for approval shall show the magnitude, frequency, and pertinent water surface elevations for the design flood, the 100-year flood, and the overtopping or 500-year flood for all structures in accordance with the criteria in the *IDOT Drainage Manual.*

Where hydraulic structure sizes can affect the selection of alignments or grades, a detailed hydraulic analysis should be performed with Phase I work, and included in a Hydraulic Report. Likewise, 3R projects that have experienced hydraulic problems (severe scour, inundation, debris, flooding complaints, etc.) require a detailed hydraulic analysis in Phase I to identify any necessary countermeasures or drainage features that should be incorporated into the design. This is pursuant to the policy on Documentation of Floodplain Encroachment Designs in Section 1-302 of the *IDOT Drainage Manual.* Abbreviated Hydraulic Reports can be completed for some minor projects which have no impact on the hydraulic performance as described in Section 1-303.

Proposed designs for replacement bridge and culvert structures may be considered acceptable for hydraulic design during location studies provided the proposed replacement does not cause more restriction to flood flows than the existing structure and provided the existing structure will not cause significant flood damage during a normally anticipated flood event up to and including the 100-year frequency flood. A Hydraulic Report is required to verify that these conditions are met.

The selection of a bridge versus a culvert structure will be based on a cost comparison of equal hydraulic alternatives considering acceptable levels of backwater, structure clearance, debris and ice, foundation stability, overtopping flows, scour potential, and local site conditions. The normal break point for considering a culvert alternative is approximately 300 ft^2 (28 m^2) of opening; however, site conditions will allow the use of larger culverts in some situations. The bridge and culvert alternatives must reasonably conform to the shape of the stream channel section to minimize the occurrence of siltation. Consideration of construction staging and the benefits of precast versus cast in place (culvert or bridge) may also influence the selection of structure type.

Projects involving a Regulatory Floodplain of the IDNR-OWR must consider the compensatory storage requirements of the permit rules. Any fill material placed in a designated floodway must be compensated for at the approximate elevation of the fill. If a highway fill is placed between the normal water elevation and the 10-year flood elevation, it must be compensated for between the normal and 10-year elevation. Likewise, for fill material placed between the 10-year and the 100-year flood elevations, this must be compensated for between the 10-year and 100-year flood elevations. The Drainage Study must address the issue of compensatory storage and identify suitable locations for providing adequate storage.

The policies and procedures for the hydraulic design of culverts are presented in Chapter 6 and those for bridges are presented in Chapter 7 of the *IDOT Drainage Manual.*

40-3.05 Longitudinal Encroachments

Longitudinal encroachments are those where the highway is within the boundary of the stream and its floodplain and runs along the stream approximately parallel to the floodplain. This contrasts with a transverse encroachment which crosses the channel from one side of the floodplain to the other. The policies and procedures for flood plain encroachments are in Section 1-302 and Chapter 3 of the *IDOT Drainage Manual*.

Avoid longitudinal encroachments, especially those that encroach upon the floodway. Where a longitudinal encroachment cannot be avoided, the degree of encroachment should be minimized. Longitudinal encroachments can have a critical impact on floodplain conveyance and storage requiring additional right-of-way and excavation for compensatory storage and enhancement of conveyance sections. Where required, compensatory storage will be provided in accordance with Section 40-3.04. Environmental and highway impacts must be evaluated and mitigated. Highway impacts include overtopping flows, erosive velocities, accumulation of debris, and migrating channel bends. The obvious disadvantages of an encroaching location are the increased flood risk, potential for damaging the highway, cost to protect the facility, environmental impacts, and permit requirements.

40-3.06 Pump Stations

Stormwater pump stations are necessary to remove stormwater from highway sections that cannot be drained by gravity. Because of high costs and the potential problems associated with pump stations, their use is recommended only where other systems are not feasible. Where operation and maintenance costs are capitalized, a considerable expenditure can be justified for a gravity system.

Pump station design presents the designer with a challenge to provide a cost-effective drainage system that meets the needs of the project. Considerations in pump station design include:

- location,
- wet-pit vs. dry-pit,
- type of pumps,
- number and capacity of pumps,
- pump cycling sequence,
- peak flow vs. storage,
- force main vs. gravity,

- above grade vs. below grade,
- site and location of receiving water,
- outlet restrictions,
- monitoring systems,
- backup systems, and
- maintenance requirements.

The procedures recommended for the hydraulic design of pumping stations are found in Chapter 13 of the *IDOT Drainage Manual.*

40-3.07 Pipe Culverts and Storm Sewers

Section 40-3.07 establishes design guidelines for the use of pipe culverts and storm sewers.

40-3.07(a) Diameter Limitations

The following limitations apply:

1. Reinforced Concrete Pipe may be used for diameters up to 108 in. (2700 mm) and equivalent, round sizes up to 72 in. (1800 mm).

2. Corrugated Steel Pipe may be used for diameters up to 144 in. (3600 mm) and equivalent, round sizes up to 120 in. (3000 mm).

3. Corrugated Aluminum Alloy Pipe may be used for diameters up to 120 in. (3000 mm) and equivalent, round sizes up to 120 in. (3000 mm).

4. Polyvinyl Chloride (PVC) Pipe and Corrugated PVC Pipe with a Smooth Interior may be used for diameters up to 36 in. (900 mm). PVC Profile Wall Pipe may be used for diameters up to 48 in. (1200 mm).

5. Polyethylene (PE) Pipe may be used for diameters up to 48 in. (1200 mm).

40-3.07(b) End Treatments

For all pipe culverts, with the exception of entrance culverts, a non-plastic end treatment must be specified. An end treatment for entrance culverts, which can protect the culvert ends from being crushed and allow for proper grading of the transverse slopes, will be at the designers' option.

40-3.07(c) pH Limitations

When the soil pH levels are outside the range of 5 to 9, the designer should consult the Central Bureau of Materials for the appropriate material type to use.

40-3.07(d) Class of Pipe Culverts and Storm Sewers

The classes of pipe culverts and storm sewers are defined in Figures 40-3.A and 40-3.B. In the plans, the designer should specify the appropriate pipe class and allow the contractor to bid the most cost effective material type. To specify, any one particular material type must be examined as a design exception and supported by proper justification.

Figure 40-3.A presents the class of pipe culvert to be specified for specific conditions. See Section 542 of the *Standard Specifications for Road and Bridge Construction* for a listing of pipe materials allowed in each class.

Figure 40-3.B presents the class of storm sewer to be specified for specific conditions. See Section 550 of the *Standard Specifications for Road and Bridge Construction* for a listing of pipe materials allowed in each class.

Conditions	Class
Entrances, regardless of ADT; and Roadways with ADT < 4000	D
Roadways with 4000 ≤ ADT < 10000	C
Roadways with ADT ≥ 10000	A

PIPE CULVERT CLASSES

Figure 40-3.A

Conditions	Class
Roadways with ADT < 10000; or pipe location is > 12 ft (3.6 m) from the edge of traveled way	B
Roadways with ADT ≥ 10000 and pipe location is ≤ 12 ft (3.6 m) from the edge of the traveled way	A

STORM SEWER CLASSES

Figure 40-3.B

40-3.07(e) Minimum Permissible Diameter of Pipe Culverts and Storm Sewers

Figure 40-3.C presents the minimum permissible diameter for pipe culverts.

The minimum permissible size for storm sewer is 12 in. (300 mm). However, the *IDOT Drainage Manual* contains additional information on sizing and a discussion of possible exceptions.

Functional Class	Minimum Diameter
Entrances	15 in. (375 mm)
All roadways except arterials	18 in. (450 mm)
All arterials	24 in. (600 mm)

MINIMUM PERMISSIBLE DIAMETER FOR PIPE CULVERTS

Figure 40-3.C

40-4 DOCUMENTATION

40-4.01 Introduction

The definition of hydrologic and hydraulic documentation as used in this chapter is the compilation and preservation of the design and related details and all pertinent information on which the design and decisions were based. Appropriate documentation for the design of any hydraulic facility is essential because of:

- the importance of public safety;
- justification of expenditure of public funds;
- future reference by engineers (when improvements, changes, or rehabilitations are made to the highway facilities);
- information leading to the development of defense for litigation;
- public information;
- IDNR-OWR rule and regulatory conformance (where appropriate); and
- local agency concerns/criticism.

Documentation permits evaluation of the performance of structures after flood events to determine if the structures performed as anticipated or to establish the cause of unexpected performance, if such is the case. In the event of a failure, documentation may aid in the identification of contributing factors that can be avoided or mitigated to prevent recurring damage after repairs or reconstruction.

The documentation shall include drainage area and other maps, field survey information, source references, photographs, methodology, engineering calculations and analyses, other data, and flood history including narratives from newspapers and individuals such as highway maintenance personnel and local residents who witnessed or had knowledge of a significant flood event.

There are three basic types of documentation that shall be considered—preconstruction, design, and construction or operation. The following discusses each type:

1. Preconstruction. This documentation includes the following if available or within the constraints of the project:

    - aerial photographs;
    - contour mapping;
    - watershed map or plan including:

        + flow directions,
        + watershed boundaries,
        + watershed areas, and

    + natural storage areas;

- surveyed data reduced to include:

    + existing hydraulic facilities;
    + existing horizontal and vertical controls;
    + profiles (roadway, channel, driveways); and
    + cross sections (roadway, channels, faces of structures);

- flood insurance studies and FEMA maps;
- Natural Resources Conservation Service soil maps;
- field trip report(s) which may include:

    + video cassette recordings,
    + audio tape recordings,
    + still camera photographs,
    + movie camera films, and
    + written analysis of findings with sketches; and

- reports from other agencies (local, State, or Federal), IDOT personnel, newspapers, and abutting property owners.

2. <u>Design</u>. This documentation includes all information used to justify the design, including:

    - reports from other agencies,
    - drainage study,
    - hydrological report,
    - hydraulic report, and
    - permits and approvals.

3. <u>Construction/Operation</u>. This documentation includes:

    - plans;
    - revisions;
    - as-built plans and subsurface borings;
    - photographs; and
    - record of operation during flood events, complaints, and resolutions.

It is important to prepare and maintain, in a permanent file, the as-built plans for every drainage structure to document subsurface foundation elements (e.g., footing types, (driven) tip elevations). There may be other information that should be included or may become evident as the design or investigation develops.

40-4.02 Purpose

The major purpose of providing good documentation is to define the design procedure that was used and to show how the final design and decisions were determined. Documentation should be viewed as the record of reasonable and prudent design analysis based on the best available technology. Documentation can provide the following:

- evidence that reasonable and prudent actions were, in fact, taken;
- identification of the situation at the time of design;
- documentation that rationally accepted procedures and analyses were used at the time of the design which were commensurate with the perceived site importance and flood hazard;
- identification of the criteria and considerations used in design and evidence that they were adhered to;
- a continuous site history to facilitate future reconstruction;
- the file data necessary to quickly evaluate any future site problems that might occur during the facilities' service life;
- an expedition of plan development by clearly providing the reasons and rationale for specific design decisions; and
- identification and an explanation for design variations from standard policy, practice, and procedures.

40-4.03 Documentation Procedures

A complete hydrologic and hydraulic design and analysis file for each drainage feature shall be maintained by the Section responsible for design approval. Figure 40-4.A provides a tabulation of the items to be included in the documentation file for the various types of drainage facilities. Although the Department's documentation requirements for existing and proposed drainage facilities are similar, the data retained for existing facilities are often slightly different than that for proposed facilities. The intent is not to limit the data to only those items listed except to establish a minimum requirement consistent with the hydraulic design procedures as outlined in the *IDOT Drainage Manual.*

Documentation of hydraulics analyses and studies for pump stations and bridges are included in the approved Hydraulic Reports. These reports are retained in the district files and/or in the Bureau of Bridges and Structures files. Documentation of hydraulic analyses and studies for culverts are included in the Hydraulic Reports approved by the districts and retained in district files.

Other drainage studies and analyses prepared during Phase I become part of the Phase I report(s) and are retained in the district and in the Bureau of Design and Environment.

Detailed design calculations for drainage work, prepared during Phase II, are placed in the district files for each project.

If circumstances are such that the drainage facility is sized by other than normal procedures or if the size of the facility is governed by factors other than hydrologic or hydraulic factors, a narrative summary detailing the design basis shall appear in the documentation file. Additionally, include the file items not listed in Figure 40-4.A but which are useful in understanding the analysis, design information, findings, and final recommendations. The preparer should initial and date all calculations, methods used, and work. Identify the engineer (P.E.) who directed or completed the work.

Item	Bridges	Culverts	Open Channels	Roadside & Median Ditches	Storm Drains	Pump Stations

CONSTRUCTION SITE STORM WATER POLLUTION CONTROL

41-1 INTRODUCTION

41-1.01 Background

Storm water runoff occurs naturally as part of the hydrologic cycle. Site development alters the drainage characteristics and patterns of the landscape through increased imperviousness, restructured contours, altered soils and vegetation, etc. These impacts include changes to the quantity, quality, and timing of storm water being discharged from the altered landscape; increased flooding; and increased concentrations of pollutants in lakes, rivers, streams, and reservoirs. For decades, these impacts have been addressed using storm water detention facilities designed to capture and detain runoff from the site post construction.

Recently, however, more focus has been given to improving the quality of storm water being discharged during the construction process. Significant pollutant loads have been shown to contribute to the degradation of water quality during site development due to the temporary vulnerability of the exposed soils to erosion before permanent stabilization is achieved.

41-1.02 Purpose, Scope, and Organization

Chapter 41 provides guidance in meeting State and Federal requirements for controlling pollution of waterways, the roadway and associated rights-of-way, adjacent properties, and sensitive environmental resources (e.g., floodplain, wetlands and riparian areas, habitat of threatened and endangered species) during highway construction projects. Comprehensive pollution prevention involves thorough planning and proper selection, implementation, and maintenance of pollution prevention best management practices (BMPs) that are designed to reduce or eliminate the introduction of target pollutants from construction sites to receiving waters. Design information is provided to assist in the BMP selection process. Section 41-4 provides guidance for developing the design portion of a site-specific Storm Water Pollution Prevention Plan (SWPPP), as per National Pollutant Discharge Elimination System (NPDES) requirements.

SCP. Sediment Control Practices
Standard Specifications. *Standard Specifications for Road and Bridge Construction*
STD. Standard Drawing
SWPPP. Storm Water Pollution Prevention Plan (Form BDE 2342)
TRM. Turf Reinforcement Mat
USEPA. United States Environment Protection Agency

41-1.04 Regulatory Framework

41-1.04(a) Federal Requirements

The National Pollutant Discharge Elimination System (NPDES) is a Federal program, under Section 402 of the *Clean Water Act*, designed to improve the quality of the nation's surface water resources. The NPDES program controls water pollution by regulating the discharge of pollutants into waters of the United States. The NPDES program is administered by the US Environmental Protection Agency (USEPA) or authorized States.

One component of the NPDES program targets storm water discharges from municipal and industrial sites, including discharges associated with construction activities. The program seeks to reduce pollutants found in storm water runoff by prohibiting the discharge of pollutants unless a NPDES permit is obtained and the site maintains compliance with the permit conditions.

41-1.04(b) State Requirements and IDOT Responsibilities

In Illinois, the NPDES storm water permitting program is administered by the Illinois Environmental Protection Agency (IEPA). IEPA issues two general NPDES permits for the discharge of storm water — ILR10 and ILR40 (see Appendix A). The ILR10 is a general permit that provides requirements for storm water discharges from construction site activities that meet or exceed the threshold for permit applicability (e.g., one acre of disturbed land area), while the ILR40 is a general permit for storm water discharges from small municipal separate storm sewer systems (MS4). Individual NPDES permits may be required by IEPA for extensive construction activities that discharge to critical receiving waters or as otherwise deemed necessary by IEPA.

This Chapter provides design guidance for pollution prevention strategies consistent with the requirements of the ILR10 general permit. Individual permits may require design guidance beyond the scope of this Chapter. Meeting the conditions of the general permits covered within Chapter 41 tend to cost less and require less effort than individual permits.

The main components of the ILR10 permit are the required preparation of a SWPPP (Form BDE 2342) (See Section 41-4) and submittal of a Notice of Intent (NOI). The SWPPP identifies potential sources of pollution associated with the construction site activity and describes the pollution prevention BMPs that will be used to reduce the likelihood of those pollutants being discharged from the site. The NOI includes a brief description of the project, estimates of the number of acres (hectares) of the site on which soil will be disturbed, and a certification that a SWPPP will be prepared prior to the start of construction.

The ILR40 permit requires operators of small MS4s to develop a Storm Water Management Program for the management of storm water within their jurisdiction. The term MS4 has a broad application that applies to universities, local sewer districts, hospitals, military bases, parks, and prisons, as well as State departments of transportation and municipally owned storm sewer systems. The *Code of Federal Regulations* defines a MS4 as a conveyance or a system of conveyances, which includes roads with drainage systems, municipal streets, catch basins, curbs, gutters, ditches, man-made channels, or storm drains that are owned or operated by a State, city, town, borough, county, parish, district, association, or other public body.

While IDOT is not a municipality, its extensive storm sewer system functions similarly to the MS4s of small municipalities and, therefore, requires coverage under the NPDES ILR40 permit. IDOT's Storm Water Management Program (Plan) has been developed and is maintained by the Department's Storm Water Committee. This plan addresses the following six minimum control measures:

1. public education and outreach on storm water impacts,
2. public involvement/participation,
3. illicit discharge detection and elimination,
4. construction site storm water runoff control,
5. post-construction storm water management in new development and redevelopment, and
6. pollution prevention/good housekeeping for municipal operations.

Upon submittal of a NOI, any MS4 covered by the ILR40 permit is also granted automatic coverage under the ILR10 for the discharge of storm water associated with construction site activities. The permittee must comply with the requirements of the ILR10 for all construction projects.

The focus of Chapter 41 is to address construction and post-construction site storm water runoff control (Minimum Control Measure #4 and #5, respectively). Regarding these minimum control measure, the ILR40 permit states that the Plan must include the development and implementation of, at a minimum:

1. an ordinance or other regulatory mechanism to require erosion control practices (ECP) and sediment control practices (SCP) and sanctions to ensure compliance to the extent allowable under State or local law;

2. requirements for construction site operators to implement appropriate ECPs and SCPs;

3. requirements for construction site operators to control waste (e.g., discarded building materials, concrete truck washout, chemicals, litter, sanitary waste at the construction site) that may cause adverse impacts to water quality;

4. require all regulated construction sites to have a SWPPP that meets the requirements of Part IV of the NPDES permit ILR10 including management practices, controls, and other provisions at least as protective as the requirements contained in the *Illinois Urban Manual*.

5. procedures for site plan review that incorporate consideration of potential water quality impacts and review of individual preconstruction site plans to ensure consistency with local sediment and erosion control requirements;

6. procedures for receipt and consideration of information submitted by the public; and

7. procedures for site inspections and enforcement of control measures.

Sections 41-2 and 41-3 provide guidance on selection and implementation of ECPs and SCPs. Section 41-4 provides guidance for developing a SWPPP for IDOT construction projects. The nature and extent of the control measures should be appropriate to address the specific conditions involved and the measures must be properly maintained to ensure continued effective operation.

41-1.04(c) Applicability and Exemptions

IDOT must comply with the requirements of the current ILR10 permit or individual permit for all applicable State highway projects. Provided the proposed project meets the ILR10 permit applicability criteria, IDOT submits a NOI and develops and implements a SWPPP for applicable projects. Unless notified by IEPA to the contrary, IDOT is authorized to discharge storm water from construction sites 30 days after the date the NOI is received by IEPA. This requirement should be considered when developing a construction schedule for time-sensitive projects. ILR10 permit applicability extends to storm water discharges associated with construction activities on sites that:

1. disturb 1 acre (0.4 ha) or more of total land area;

2. disturb less than 1 acre (0.4 ha) of total land but are part of a larger common plan of development or sale if the larger common plan will ultimately disturb one or more acres (0.4 ha or more hectares) of total land area; or

3. disturb less than 1 acre (0.04 ha) of total land and are designated by IEPA to have the potential for contribution to a violation of water quality standards or significant contribution of pollutants to waterways. This includes waters designated by the IEPA as "impaired waters" pursuant to Section 303(d) of the *Clean Water Act*; see Section 26-21. This designation may be determined during the process of acquiring a water quality certification.

Construction projects not meeting any of the above and those that do not involve clearing and grubbing, excavation, stockpiling of topsoil, borrow, or construction of embankments will generally not require a SWPPP or Erosion and Sediment Control Plan sheets (ESCP). However, the design is to include any applicable pollution prevention BMPs necessary to minimize the potential for pollutants to enter IDOT's MS4 or other waters of the State. The following projects are examples of construction activities that will not require development of a SWPPP or ESCP:

- installation of lighting, signage, traffic signals, or guardrails;
- herbicide application;
- pavement marking;
- seal coating;
- bituminous resurfacing;
- pavement patching; and
- planting of woody landscaping materials.

41-1.05 <u>Typical Construction Activity Related Pollutants</u>

41-1.05(a) Overview

Construction activities involving earthwork (e.g., clearing and grubbing, grading, importing fill material, utility installation) disturb the soil that when the protective vegetation is removed the soil becomes exposed and vulnerable to excessive erosion. This makes the sediment the most common pollutant associated with construction activities. Sediment can be detrimental to aquatic life by interfering with photosynthesis, respiration, growth, reproduction, and oxygen exchange in waterways. In addition, sediment particles can transport other pollutants that are attached to them including nutrients, trace metals, and hydrocarbons. Sediment particles (e.g., silts, clays) are the primary components of total suspended solids, a common water quality parameter.

Construction activities involving building materials, vehicular use, and landscaping have the potential to contribute pollutants to storm water. Common pollutants related to these construction activities include vehicle fluids, curing compounds, solvents, paints, emulsions, oil and grease, metals, organics, pesticides, nutrients, trash, debris, and floatables, as well as other miscellaneous waste.

41-1.05(b) Erosion and Sedimentation

Erosion is the process of soil particle detachment from the land surface by the forces of wind, water, or gravity. After the soil particles have been detached (eroded), the suspended soil particles in transport are referred to as sediment. Sedimentation occurs where suspended sediment settles out and is deposited. Note that gravels and sands tend to drop out of suspension more rapidly than finer particles (e.g., silts, clays) due to differences in size, density, and shape.

Where soil is cleared or disturbed, erosion occurs at a much higher rate due to direct exposure to erosive forces (e.g., raindrop impacts, sheet erosion, rill erosion). Land clearing disturbances can also alter the natural structure of soil and weaken the reinforcing matrix of plant roots and organic compounds. USEPA estimates that unprotected construction sites can experience erosion at over one hundred times the natural rate. As result, primary emphasis should be placed on ECPs as they are preventative source controls, while SCPs are secondary measures designed to contain sediment after it is in transport, preventing it from leaving the site.

41-1.05(c) Types of Erosion

1. Erosion from Raindrop Impact. The dislodgement of soil particles by falling raindrops is a primary agent of erosion, particularly on soils with sparse vegetative cover. Individual soil particles can be splashed over 1.5 ft (500 mm) in height and 5 ft (1.5 m) to the side.

2. Sheet Erosion. Splashed soil particles are moved in a semi-suspended layer uniformly over the land surface. The distance of sheet flow depends on slope, soil roughness, type of vegetative cover, and rainfall intensity.

3. Rill and Gully Erosion. As runoff concentrates, tiny channels form that are termed rills. Rill erosion is the form that produces the greatest amount of soil loss worldwide. Rills are channels small enough to be smoothed by normal tillage. As the runoff accumulates in the rills, they erode further, causing gullies to form. Gullies are so large that they cannot be smoothed by normal tillage. The rate of rill erosion can easily be one hundred times greater than that of sheet flow, and the rate of gully erosion can easily be one hundred times greater than rill erosion. Due to the significant amount of sediment generated by rill and gully erosion, these types of erosion must be given top priority for elimination, reduction, and control.

41-1.06 The BMP Approach/Limitations to Addressing Water Quality Problems

The goal of the Department’s NPDES Storm Water Permit Program is to improve water quality by reducing the amount of pollutants in storm water runoff that are conveyed to receiving waters. The Department’s program is using the BMP approach to meet this goal.

A pollution prevention BMP is a technique, measure, or structural control that is used for a given set of site conditions to manage the rate, quantity, and quality of storm water runoff in a cost-effective manner. No single BMP can address all pollutants associated with construction activities. Sections 41-2 and 41-3 explores two categories of BMPs — ECPs and SCPs. Independently, these BMPs serve different purposes. Erosion control is a preventative strategy that uses techniques to stabilize the soil, thereby minimizing the occurrence of erosion. Sediment control is a backup strategy that incorporates structural measures to contain sediment on site in the event that erosion does occur. While functionally different, these BMPs should be selected and implemented in a complimentary manner in order to maximize pollution prevention effectiveness.

Each type of BMP has certain limitations based on drainage area served, available land space, cost, pollutant removal efficiency, as well as a variety of site-specific factors (e.g., soil types, slopes, depth of groundwater table). Careful consideration of these factors is necessary in order to select the appropriate BMP or group of BMPs for a particular location. The success of the program relies on the assumption that proper implementation of appropriate pollution prevention BMPs will achieve and maintain applicable water quality standards and protect designated uses. However, additional measures (e.g., treatment of polluted runoff) may be required in the future if these BMPs fall short of the program goals.

Chapter 41 provides guidance for selecting appropriate BMPs to mitigate water pollution as a result of construction activities. Designers are to use the IDOT specification listed for each BMP. If an IDOT specification is not listed, use the associated *Illinois Urban Manual* specification to develop a special provision for the project.

Section 41-4 provides guidance for completing the design portion of the SWPPP (BDE 2342).

41-1.07 <u>Notice of Intent (NOI)</u>

IEPA requires all Notices of Intent (NOIs) to be submitted online through the Central Data Exchange (CDX). Instructions on applying through the CDX platform and can be found on the IEPA website.

The following documents are required for the NOI:

41-1.07(a) BDE 2342 (Stormwater Pollution Prevention Plan)

BDE 2342 comprises the majority of the required “Contents of Plan” from the ILR10 permit. This form is the narrative portion of the SWPPP.

41-1.07(b) Erosion and Sediment Control Details

This plan sheet is discussed in Section 63-4.09 and serves as the site map described in the ILR10 permit.

41-1.07(c) BDE 2342a (Contractor Certification Statement)

BDE 2342a identifies the contractor and every subcontractor for the project. In addition, this form certifies the contractors and all subcontractors will comply with the requirements of the ILR10 permit.

41-1.07(d) Supporting Documentation

The following additional documents are also required as part of the NOI:

41-1.07(d)1 *Threatened and Endangered Species Clearance*

To obtain documentation that can be uploaded into the IEPA CDX system for threatened and endangered species, the district should utilize BDE 2710 (See Section 27-1.05(a)1) or submit the Natural Resource Review (NRR).

41-1.07(d)2 *Section 106 Clearance*

To obtain documentation that can be uploaded into the IEPA CDX system for Section 106 resources, see Section 27-1.05(a)2.

41-2 EROSION CONTROL PRACTICES (STABILIZATION)

All erosion control practices (ECP) selected should consider seasonal influences on BMP effectiveness, installation, and maintenance throughout the duration of the project. For example, stabilization practices that may be effective in the summer may not be sufficient for the winter season (e.g., vegetation establishment).

41-2.01 Vegetation

Vegetation-related BMPs are some of the most effective and economic methods of soil stabilization. Vegetative cover protects soils from raindrop impacts, rill and sheet erosion, and wind erosion. Vegetation also provides a reduction in velocities, valuable filtration and adsorption of pollutants, and can reduce runoff volumes by enhancing infiltration.

41-2.01(a) Incorporate Existing Vegetation

1. Definition and Purpose. Measures taken to use existing vegetation as part of erosion control throughout construction activities. The purpose of this practice is to preserve areas that have value for erosion control.

2. Applications. Existing vegetation is appropriate for the following applications:

    - projects where grading can be phased,
    - projects where existing vegetation can be temporarily preserved and used for erosion control,
    - areas along the perimeter of the site, and
    - areas where upstream tributary sheet flow enters the site.

3. Design Considerations.

    - Minimize disturbance along the project where no construction activity is planned or will occur at a later stage/phase/date. If greater than 10 acres (4 ha) are to be disturbed at any one time to properly construct a project, a special provision will be required to modify Section 280.03 of the *Standard Specifications*.
    - Construction activities, heavy equipment, vehicular traffic, or storage of construction materials are prohibited within the vegetated areas designated for erosion control.
    - Use of existing vegetation for erosion control requires planning and may limit the area available for construction activities.

- See Sections 59-6.03 and 59-6.04 for further information on incorporating existing vegetation for erosion control.

4. Specifications. See Sections 201 and 280 of the *Standard Specifications*.

41-2.01(b) Establish New Vegetation

1. Definition and Purpose. Establishing temporary or permanent vegetative cover to stabilize disturbed or exposed areas in order to reduce erosion from these areas and create a landscape that enhances soil permeability and the filtering of runoff pollutants.

2. Applications.

   a. Temporary. Temporary locations include the following:

   - all cleared, non-vegetated, or sparsely vegetated soil surfaces where vegetative cover is necessary for less than one year (e.g., diversions, dams, temporary sediment basins, temporary road banks, topsoil stockpiles, any other exposed areas of a construction site);
   - sites that will not be brought to final grade within seven days or are likely to be re-disturbed;
   - cut and fill slopes under construction;
   - soil storage areas and stockpiles; and
   - where development of cover or nursery crops are necessary to assist with establishment of perennial grasses.

   b. Permanent. Permanent locations include the following:

   - disturbed areas where long-lived vegetative cover is needed to stabilize the soil,
   - rough graded areas that will not be brought to final grade for a year or more,
   - final graded or cleared areas where permanent vegetative cover is needed to stabilize the soil, and
   - drainage channels or waterways designed to be protected with channel liners.

3. Design Considerations.

- Rapidly growing annuals and legumes are recommended examples of temporary vegetation for disturbed soils.
- Erosion may occur during the establishment stage; therefore, areas that fail may need to be re-seeded or seeded in conjunction with additional stabilization practices; see Section 41-2.02.
- Consider the state of the project as the growing season ends.
- Perform seeding during the appropriate season in order to ensure rapid establishment of vegetation. Sufficient moisture conditions may not be present at time of seeding to support timely germination of the seed. If unusually dry (drought) conditions are predicted, a special provision for supplemental watering may need to be included in the contract.
- Sod can provide a quick, but relatively expensive, method for establishing vegetation.
- For seeding and sodding design guidance, see Section 59-7, Section 280.04(f) of the *Standard Specifications*, and Figure 41-2.A.
- Calculate the quantity of temporary erosion control seeding for weekly seeding of estimated acreage (hectares) of disturbance.
- In the event that temporary or permanent vegetation cannot be established prior to winter shutdown, include erosion control measures (e.g., installation of mulch or ECBs on any exposed soil, slopes, and around the perimeter of the site) in the contract. Also, include measures to maintain these areas over the winter.

4. Specifications. See Sections 250, 252, and 280 of the *Standard Specifications*.

41-2.02 Mulch, Erosion Control Blankets, and Turf Reinforcement Mats

Mulch, erosion control blankets, and turf reinforcement mats are ECPs that can be employed in situations requiring stabilization of exposed soils before and during establishment of vegetation. These BMPs protect against raindrop impact and enhance vegetative establishment by retaining soil moisture, preventing erosion and seed washout, controlling weedy species, and protecting seeds from wildlife consumption. See Figure 41-2.A for appropriate applications.

Treatment	Recommended Use	Flow Velocity for Ditch (ft/sec)	Max. Slope Gradient (V:H)	Approx. C Factor[1] at Max. Grade	Approx. Max. Shear Stress (lbs/sq ft)
Sod	Stabilizing slopes, shallow channels, exposed soil	2 - 7 (0.6-2.1 m/s)	1:4	0.01	1.0 - 3.0 (47.8-143.6 Pa)
Straw Mulch (Method 1)	Stabilizing flat areas	N/A	1:10	0.90	N/A
Stabilized Straw Mulch (Method 2)	Stabilizing slopes and exposed soil	N/A	1:4	0.25	N/A
Hydraulic Mulch (Method 3)	Stabilizing slopes and exposed soil	N/A	1:3	0.25	N/A
Compost w/ Stabilizer (Method 4)	Stabilizing slopes and exposed soil	N/A	1:4	0.25	N/A
ECB	Stabilizing slopes, channels, exposed soil	2 - 7 (0.6-2.1 m/s)	1:3	0.15	1.5 (71.8 Pa)
Heavy Duty ECB	Stabilization of slopes, mulches, and areas to be vegetated; suitable for low flow channel stabilization and steeper slopes	2 - 7 (0.6-2.1 m/s)	1:2	0.25	2.25 (107.7 Pa)
TRM	Long term stabilization and reinforcement of vegetation, especially in highly erosive, hydraulic conditions	7 - 22 (2.1-6.7 m/s)	1:3 or steeper	Varies	10.0 (478.8 Pa)
Hard Armament	Where other practices are inadequate, and for highly erosive, concentrated flows or steep slopes	22+ (6.7+ m/s)	1:2 or steeper	Varies	12.0+ (574.6+ Pa)

[1] *C Factor = ratio of soil loss from protected slope to ratio of soil loss from unprotected slope in large-scale testing, per ECTC and ASTM Standards. Used to compare the effects of different soil management techniques on erosion.*

[2] *Adapted from ECTC* Standard Specifications for Rolled Erosion Control Products.

SUMMARY OF DITCH LINING AND SLOPE TREATMENTS[2]

Figure 41-2.A

41-2.02(a) Straw Mulch (Mulch Methods 1 and 2)

1. Definition and Purpose. Application of straw fibers to exposed soil as a protective, insulating layer. Straw mulch stabilizes exposed soil and slopes from erosive forces (e.g., wind, water), promotes retention of soil moisture, and encourages the establishment of vegetation.

2. Applications. Consider the following for straw mulch applications:

   - appropriate for disturbed areas that require temporary protection until permanent stabilization is achieved;
   - on slopes 1V:10H and flatter, appropriate with straw mulch alone;
   - on slopes 1V:4H and flatter, appropriate with stabilized straw mulch;
   - not for use in areas of concentrated flow; and
   - in combination with seeding strategies; see Section 41-2.01(b).

3. Design Considerations.

   - Straw mulch may be used for immediate stabilization (unlike hydraulic mulch that requires a drying time).
   - The use of straw mulch may be limited by seasonal availability.
   - The potential exists for introduction of unwanted species.
   - If using a straw blower, disturbed areas should be accessible to vehicles and spreading equipment.
   - If wind or displacement by traffic is a potential problem, straw mulch will need to be anchored; see Mulch Method 2 in Section 251 of the *Standard Specifications*.
   - Straw mulches are biodegradable and should be replaced if decomposition has compromised the stabilizing properties of the product.

4. Specifications. See Section 251 of the *Standard Specifications*.

41-2.02(b) Hydraulic Mulch (Mulch Method 3)

1. Definition and Purpose. Application of degradable fibers or hydraulic matrix combined with a stabilizing tackifier. Hydraulic mulches insulate exposed soils and slopes from erosive forces (e.g., wind, water), promote retention of soil moisture, and encourage establishment of vegetation.

2. Applications. Consider the following for hydraulic mulch applications:

    - appropriate for disturbed areas that require temporary protection until permanent stabilization is achieved;
    - appropriate for areas where there will be re-disturbance following an extended period of inactivity;
    - appropriate for areas where straw mulch is ineffective due to wind, slopes, or ground surface;
    - appropriate for low traffic areas;
    - not appropriate for slopes steeper than 1V:3H; and
    - not to be applied to frozen ground.

3. Design Considerations.

    - Hydraulic mulch typically requires 12 to 24 hours to dry before product is effective, so other erosion control practices (e.g., straw mulch, erosion control blankets, turf reinforcement mats) should be implemented when immediate stabilization is required.
    - A second application may be required in order to remain effective for an entire season, so additional quantities may need to be included in plans.

4. Specifications. See Section 251 of the *Standard Specifications*.

41-2.02(c) Compost Combined With Binder/Stabilizer (Mulch Method 4)

1. Definition and Purpose. Application of compost combined with a performance additive designed to bind/stabilize the compost and prevent erosion of soil during turf establishment.

2. Applications. Consider the following for compost combined with binder/stabilizer applications:

- appropriate for disturbed areas that require temporary protection until permanent stabilization is achieved,
- appropriate for areas where there will be re-disturbance following an extended period of inactivity,
- appropriate for areas where vegetative establishment may be hindered by hard ground surface or poor soil nutrient content,

- not appropriate for slopes steeper than 1V:4H (see Section 41-2.02), and
- do not use in areas of concentrated flow.

3. Design Considerations. Where practical, track (compact) perpendicular to contours on the slope using a bulldozer before applying compost combined with binder/stabilizer.
4. Specifications. See Section 251 of the *Standard Specifications*.

41-2.02(d) Erosion Control Blankets and Turf Reinforcement Mats

Erosion Control Blankets (ECB) and Turf Reinforcement Mats (TRM) are manufactured BMPs consisting of nets and textiles. These products provide effective and immediate stabilization of slopes and channels before, during, and after the establishment of vegetation. ECBs and TRMs enhance the development of vegetation and TRMs provide for permanent reinforcement.

1. Definition and Purpose. The placement of ECBs and TRMs stabilize disturbed soil and protect from wind and water erosion. The purpose of this practice is to protect the soil surface from raindrop impacts and overland flow during the establishment of grass or other vegetation and to reduce soil moisture loss due to evaporation.
2. Applications. ECBs and TRMs are appropriate for the following applications:
    - generally used on steep slopes (e.g., 1V:3H and steeper) or soils with a high erosion hazard rating, as determined by USDA Soil Survey;
    - areas inaccessible to other BMPs;
    - channels to be vegetated;
    - slopes and shorelines adjacent to waterways or environmentally sensitive areas;
    - adjacent to shoulders where traffic may blow away other mulches; and
    - areas free from large rocks that could damage or affect the performance of the product.
3. Design Considerations.
    - ECBs and TRMs provide immediate stabilization of disturbed soil regardless of temperature and precipitation, unlike other erosion control practices that require an ideal temperature or curing time in order to become effective (e.g., hydraulic mulches, soil binders).
    - Blankets and mats are generally not suitable for excessively rocky sites.

- When used adjacent to shoulders, the blanket should extend through the ditch line or 25 ft (7.5 m) from the edge of pavement, whichever is greater, in order to mitigate blowing conditions caused by traffic.
- ECBs are biodegradable and should be replaced if decomposition has compromised the stabilizing properties of the product.
- Unlike ECBs designed to biodegrade, some TRMs may be considered semi-permanent or permanent and, therefore, may be implemented in situations requiring long-term stabilization (e.g., longer than one growing season).
- See Figure 41-2.A to determine the proper ECB or TRM to be used.

4. Specifications. See Section 251 of the *Standard Specifications*.

41-2.03 Soil Binders (Stabilization Polymers)

Soil binders consist of spray-on chemical soil amendments designed to provide temporary soil stabilization in low-traffic areas. Some soil binders may be incorporated into the soil medium after their effective use has expired, so they are useful in short-term situations where further disturbance will soon occur (e.g., on stockpiles or areas soon to be graded/paved). Soil binders are composed of chemical blends that penetrate the topsoil and bind the soil particles together, thereby, minimizing wind and runoff erosion. They are used to stabilize the soil and as an erosion control agent. See Figure 41-2.B for appropriate applications.

Attributes	Plant Material Based (Short Lived)	Plant Material Based (Long Lived)	Polymeric Emulsion Blends	Cementitious-Based Binders
Resistance to Leaching	High	High	Low to Moderate	Moderate
Resistance to Abrasion	Moderate	Low	Moderate to High	Moderate to High
Compatibility with Existing Vegetation	Good	Poor	Poor	Poor
Mode of Degradation	Biodegradable	Biodegradable	Photodegradable/ Chemically Degradable	Photodegradable/ Chemically Degradable
Liquid/Powder	Powder	Liquid	Liquid/Powder	Powder

Adapted from California Department of Transportation BMP Handbook.

PROPERTIES OF SOIL BINDERS FOR EROSION CONTROL

Figure 41-2.B

1. Definition and Purpose. Water soluble polyacrylamide (PAM) or other comparable compounds that are applied to exposed soils. Soil binders provide temporary protection from wind and water erosion in low traffic areas.

2. Applications. Consider the following for soil binders applications:

   - appropriate for areas requiring short-term temporary stabilization;
   - appropriate for areas where grading activities will soon resume;
   - appropriate for temporary stabilization of cut and fill areas and on stockpiles;
   - appropriate for tacking wood fiber or straw;
   - appropriate for where over-spray onto the traveled way, sidewalks, lined drainage channels, and existing vegetation can be avoided;
   - where appropriate, in areas supporting existing vegetation (review product specifications for compatibility);
   - appropriate for soils made up primarily of fine silts, clay, and colloids;
   - not suitable for areas receiving concentrated flow;
   - not suitable for frozen soil conditions or when surface ice is present;
   - not suitable for slopes greater than 1V:3H as a stand-alone practice; and
   - not suitable for areas with pedestrian or vehicular traffic.

3. Design Considerations.

   - Soil binders may require a curing time of up to 24 hours, so other erosion control practices (e.g., straw mulch, ECBs, TRMs) should be implemented when immediate stabilization is required.
   - Because cationic PAM is toxic to aquatic life, only anionic PAM may be used.
   - Stabilization effectiveness increases if PAM is combined with the application of seed and mulch.
   - Soil binders are temporary in nature and may need reapplication. Reapplication is considered maintenance and should be included as a special provision.
   - Some soil binders may not perform well with low relative humidity or in low temperatures. Refer to manufacturer’s suggested optimal ambient conditions.

- Under rainy conditions, some agents may become slippery or leach out of the soil.

- Soil binders do not have the capabilities of organic mulches to insulate the soil or retain soil moisture; see Section 41-2.02(d).

4. Specifications.

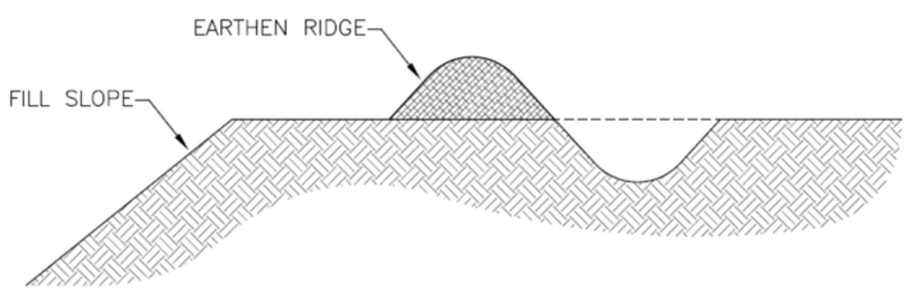
- District Special Provision will be required.
- Refer to manufacturer's specification for particular product.

41-2.04 Concentrated Flow Controls

Concentrated flow control BMPs prevent erosion by redirecting potentially erosive flows along a stabilized path and away from areas that have not yet been stabilized.

41-2.04(a) Diversion Dikes, Drainage Swales, and Lined Ditches

1. Definition and Purpose. Temporary berm of compacted soil with an excavated channel at the upstream toe or temporary drainage ditches (e.g., vegetated, reinforced). Diversion dikes, drainage swales, and lined ditches are designed to divert and convey clean or sediment laden water from upstream tributary areas away from construction activities and exposed soil; see Figure 41-2.C.



DIVERSION DIKE AND DRAINAGE SWALE

Figure 41-2.C

2. Applications. Diversion dikes, drainage swales, and lined ditches are appropriate for the following applications:

- upslope of disturbed areas (including cut or fill slopes) to prevent surface runoff from entering,
- across slopes to reduce slope length,
- on the down slope side of a construction site to prevent sediment-laden runoff from leaving the site by diverting it to sediment trapping facilities and stabilized outlets, and
- to intercept runoff from paved surfaces.

3. Design Considerations.

- Acquisition of additional right-of-way for diversions may be necessary and may require more time and additional permits.
- Ensure that concentrated flow controls do not become barriers to the movement of construction equipment.
- Design all concentrated flow controls to safely convey the 10-yr, 24-hr storm event.
- Ensure diverted runoff from undisturbed areas is conveyed and discharged to undisturbed areas at non-erosive velocities.
- The minimum height of diversion dikes and berms should be twice the height of the outlet pipe diameter.
- Ensure concentrated flow controls are stabilized prior to use to prevent erosion of exposed soils; see Sections 41-2.02(d) and 41-2.02.
- Consider the additional earthwork costs to remove berms at the end of the project when designing concentrated flow controls.
- Concentrated flow controls are not suitable as sediment-trapping devices.
- It may be necessary to use other soil stabilization and sediment controls in conjunction to prevent scour (e.g., temporary ditch checks); see Section 41-3.03.
- Controls should be constructed of soils that are not easily eroded.
- All ditch, swale, and diversion outlets should be sufficiently stabilized; see Sections 41-2.03(b) and 41-2.05(a).

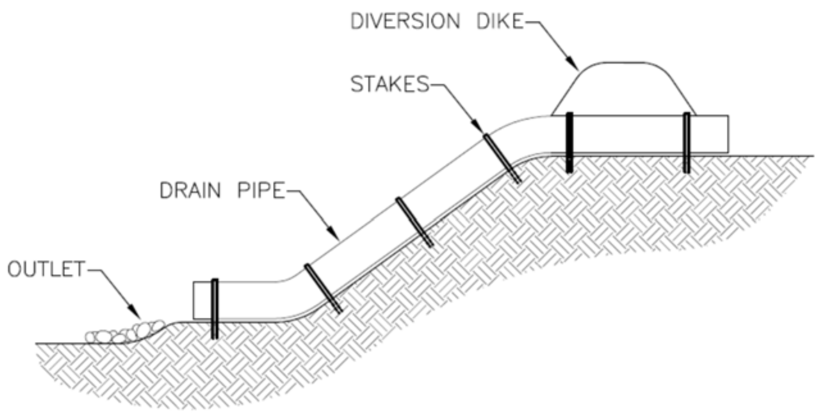
4. Specifications.

- District Special Provision will be required.
- See ISTHA Standard Drawing K1.

Note: Use IDOT pay items when incorporating ISTHA Standards.

41-2.04(b) Slope Drains

1. Definition and Purpose. A flexible tubing or rigid pipe, generally used in conjunction with a diversion dike or channel, to convey concentrated runoff down the face of a cut or fill slope without causing erosion on or at the base of the slope; see Figure 41-2.D.



SLOPE DRAIN

Figure 41-2.D

2. Applications. Slope drains are appropriate for the following applications:

   - where concentrated flow of surface water must be conveyed down a slope without erosion,
   - where runoff is intercepted upstream of a newly graded cut or fill section that has not achieved permanent stabilization, and
   - as an emergency spillway for a sedimentation basin.

3. Design Considerations.

   - The maximum allowable drainage area is 1.5 acres (0.61 ha) per 18 in (457 mm) slope drain. Ensure pipe sizes are adequate to convey flows from upstream tributary area without overtopping impoundment structures (e.g., diversion dikes, silt fence).
   - The maximum slope of slope drains is generally limited to 1V:2H, as energy dissipation below steeper slopes is difficult.

- For areas larger than 1.5 acres (0.61 ha) or slopes steeper than 1V:2H, it may be necessary to use aggregate-lined channels or additional drains; See Section 283 of the *Standard Specifications*.

- Severe erosion may result if slope drain fails.

- Install reinforced stakes and cables at least every 10 ft (3 m) to secure conduit.

- To prevent stress and failure, install drains perpendicular to slope contours.

- Place slope drains on compacted soil that is covered with Class B geotextile filter fabric.

- Slopes drains should always drain directly, or indirectly to sediment traps or sedimentation basins; see Section 41-3.04.

- Protect the area around inlet with appropriate inlet sediment controls and outlet area with velocity dissipater; see Sections 41-3.02 and 41-2.05(a).

4. Specifications.

- District Special Provision will be required.
- See ISTHA Standard Drawing K1.

Note: Use IDOT pay items when incorporating ISTHA Standards.

41-2.05 Outlet Protection Controls

Outlet protection controls prevent erosion by slowing the velocity of concentrated flows. These measures are to be employed wherever concentrated flows are conveyed at erosive velocities (e.g., in steep swales, at pipe outlets); See Figures 41-2.E and 41-2.F.

41-2.05(a) Velocity Dissipaters

1. Definition and Purpose. An area or apron of rock, concrete rubble, or gabions placed at the outlet of a drainage system, intended to prevent erosion and reduce velocity of the storm water outflow.

2. Applications. Use velocity dissipaters where the discharge velocity and energy at an outlet will cause erosion to the receiving channel or area, including:

- outlets of pipes, drains, culverts, slope drains, diversion ditches, swales, and channels (concentrated flows);

- outlets carrying a continuous flow of water;

- outlets subject to short, intense flows;
- outlets to sedimentation basins; and
- points where lined channels discharge to unlined channels or natural waterways.

IDOT Gradation	Maximum Rock Size (lb)*	Equivalent Diameter (spherical) (in) *	Minimum Bedding Thickness (in)	Minimum Thickness (in)
RR-3	50 (22.5 kg)	10 (300 mm)	—	8 (200 mm)
RR-4	150 (67.5 kg)	15 (400 mm)	6 (150 mm)	16 (400 mm)
RR-5	400 (180 kg)	21 (500 mm)	8 (200 mm)	22 (600 mm)
RR-6	600 (270 kg)	24 (600 mm)	10 (250 mm)	26 (700 mm)
RR-7	1000 (450 kg)	28 (700 mm)	12 (300 mm)	30 (800 mm)

* *Assumes a minimum specific gravity of 2.450 and minimum unit weight of 153 lb/ft^3 (2,450 kg/m^3).*

ROCK RIPRAP SIZE AND THICKNESS

Figure 41-2.E

Culvert Diameter (in)	Minimum Tailwater				Maximum Tailwater			
	Max Conduit Velocity = 5 fps (1.5 mps)		Max Conduit Velocity = 10 fps (3.1 mps)		Max Conduit Velocity = 5 fps (1.5 mps)		Max Conduit Velocity = 10 fps (3.1 mps)	
	IDOT Gradation	Apron Length (ft)	IDOT Gradation	Apron Length (ft)	IDOT Gradation	Apron Length (ft)	IDOT Gradation	Apron Length (ft)
12 (0.3 m)	RR-3	10 (3.1 m)	RR-3	12 (3.7 m)	RR-3	12 (3.7 m)	RR-3	15 (4.6 m)
18 (0.5 m)	RR-3	14 (4.3 m)	RR-4	16 (4.9 m)	RR-3	12 (3.7 m)	RR-3	16 (4.9 m)
24 (0.6 m)	RR-3	16 (4.9 m)	RR-4	20 (6.1 m)	RR-3	14 (4.3 m)	RR-4	17 (5.2 m)
30 (0.8 m)	RR-3	18 (5.5 m)	RR-4	22 (6.7 m)	RR-3	16 (4.9 m)	RR-4	20 (6.1 m)
36 (0.9 m)	RR-4	20 (6.1 m)	RR-5	24 (7.3 m)	RR-3	16 (4.9 m)	RR-4	22 (6.7 m)
48 (1.2 m)	RR-4	24 (7.3 m)	RR-6	28 (8.5 m)	RR-4	20 (6.1 m)	RR-4	24 (7.3 m)
60 (1.5 m)	RR-5	32 (9.8 m)	RR-6	36 (10.9 m)	RR-4	22 (6.7 m)	RR-5	26 (7.9 m)
72 (1.8 m)	RR-6	40 (12.2 m)	RR-6	44 (13.4 m)	RR-5	24 (7.3 m)	RR-5	29 (8.8 m)

96 (2.4 m)	RR-7	50 (15.2 m)	RR-7	54 (16.5 m)	RR-5	26 (7.9 m)	RR-5	32 (9.8 m)

Notes:

1. *If tailwater depth from the pipe invert is less than half of diameter of the pipe, then minimum tailwater conditions exist. Otherwise, maximum tailwater conditions exist.*
2. *Adapted from the* Illinois Urban Manual*.*

MINIMUM IDOT ROCK SIZES AND APRON LENGTH FOR MAXIMUM AND MINIMUM TAILWATER CONDITIONS

Figure 41-2.F

3. Design Considerations.

   - Velocity dissipaters are not adequate to stabilize discharges occurring at the top of a cut or a slope steeper than 1V:10H; see Section 41-2.04.
   - Large storms may wash away rock or concrete, leaving the area susceptible to erosion.
   - Consider using a riprap-stilling basin or plunge pool where velocities exceed 10 fps (3 mps) or where the velocity requires an apron of an excessive length.
   - Riprap, gabions, or slope mattresses placed over filter fabric are the general materials used to provide temporary outlet protection. See Figure 41-2.C.

4. Specifications. See Sections 281 and 284 of the *Standard Specifications*.

41-2.06 Erosion Control Reference Table

Figure 41-2.G references all ECPs discussed in Section 41-2. This figure may be used by the designer as a supplemental tool to ensure that all BMP options have been considered. Note that multiple BMPs may be required from each category in order to provide comprehensive stabilization of the site.

ECP Category	Specific ECP	Appropriate Application	Section
Vegetation	Incorporate Existing Vegetation	Wherever feasible	41-2.01(a)
	Establish New Vegetation	All projects where temporary or permanent stabilization is required; when existing vegetation is removed	41-2.01(b)
Mulch, ECBs and TRMs	Straw, Hydraulic, and Compost Mulches	Temporary stabilization; concurrent with seeding or turf establishment	41-2.02
	ECBs and TRMs	Stabilization of slopes, mulches, and areas to be vegetated; suitable for channel stabilization	41-2.02(d)
Soil Binders	Plant-Material Based, Polymeric Emulsion Blends, and Cementitious-Based Binders	Short- to long-term stabilization of low traffic areas (cut/fill areas, stockpiles, areas to be graded soon)	41-2.03
Concentrated Flow Controls	Diversion Dikes	Upslope and down slope of disturbed areas and across slopes where runoff must be intercepted	41-2.04(a)
	Drainage Swales	Upslope and down slope of disturbed areas, adjacent to paved areas	41-2.04(a)
	Lined Ditches	Upslope and down slope of disturbed area, across slopes, where erosive conditions may exist	41-2.04(a)
	Slope Drains	Where concentrated flows must be conveyed down an unstable slope	41-2.04(b)
Outlet Protection Controls	Velocity Dissipaters	All outlets and points of discharge, where lined channels drain to unlined channels	41-2.05(a)

EROSION CONTROL PRACTICES REFERENCE TABLE

Figure 41-2.G

41-3 SEDIMENT CONTROL PRACTICES (CONTAINMENT)

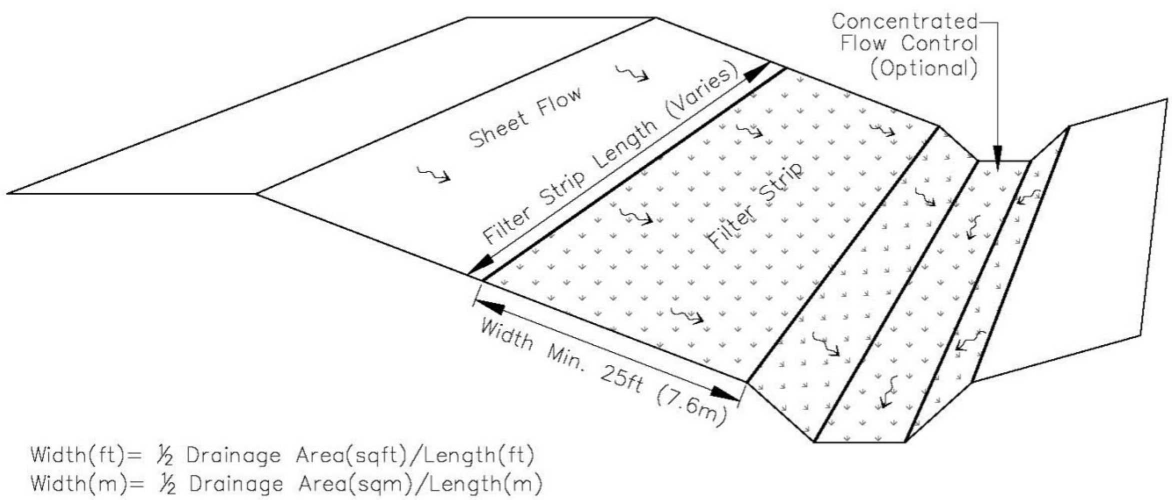
Sediment-laden waters generated on-site should be routed through at least one sediment control practice (SCP) prior to discharge. In some instances, multiple SCPs will be necessary to protect against the discharge of suspended sediment. Install all SCPs in combination with ECPs, using a treatment train approach.

41-3.01 Perimeter Controls

Perimeter control BMPs are methods of containing sediment within the boundaries of the project site. Where containing sediment on site, always install perimeter controls in conjunction with ECPs. Do not use perimeter control as a stand-alone BMPs. Perimeter control BMPs prevent the discharge of sediment by filtering and dissipating the energy of sediment laden sheet flow runoff. Consider all site characteristics when selecting appropriate perimeter control BMPs.

41-3.01(a) Perimeter Vegetated Buffers

1. Definition and Purpose. An existing or proposed area of vegetation designed to remove sediment and other pollutants and enhance infiltration of surface runoff. See Figure 41-3.A.



VEGETATION BUFFERS

Figure 41-3.A

2. Applications. Preservation of existing vegetated buffers should always be considered. Perimeter vegetated buffers are appropriate for the following applications:

- projects where grading can be phased and vegetation can be temporarily preserved and used for sediment control;
- urban areas where surface runoff is discharged as sheet flow;
- adjacent to roadways, parking lots, and other impervious surfaces to filter runoff before discharge to storm sewers, swales, and waterways; and
- areas where upstream tributary sheet flow enters site.

3. Design Considerations.

- Vegetation selection varies depending on climate, soil type, topography, land use, available light (e.g., shade tolerance), aesthetics, and planned use of the area.
- The maximum drainage area to a vegetated buffer should be 5 acres (2 ha).
- Vegetated buffer slope should be 1V:6H or flatter if used as a stand-alone perimeter control.
- The width (e.g., dimension parallel to flow path) of the vegetated buffer can be calculated using the equation:

  Width (ft (m)) = Half of the Drainage Area to Buffer ÷ Buffer Length*

  * *Buffer length is the dimension perpendicular to the flow path.*

- The minimum width (e.g., dimension parallel to flow) should be 25 ft (7.62 m).
- Vegetation should be established prior to runoff being directed onto it from impervious areas. If this is not possible, install sodding in the buffer area.
- Avoid concentrated flows through the vegetated buffer. If potential exists for concentrated flows, employ other sediment control measures upstream of the buffer.
- Locate protection measures at the boundary of the existing or proposed vegetated buffer area or 1 ft (300 mm) outside the perimeter of the leaf canopy if a stand of trees is to be protected.
- Install all required protection measures prior to the commencement of any site development activity. Protective measures should remain in place year round and in working, functional order until all site development activities have ceased or the surrounding area has been stabilized.

- Prohibit construction activities, heavy equipment, vehicular traffic, or storage of construction materials within the vegetated buffer area.

4. Specifications.

- See Sections 250, 252, and 280 of the *Standard Specifications*.

- Where existing vegetation is used, delineate the area as a “No Intrusion Area” on the ESCP sheets and note the area in the SWPPP. Temporary fencing and/or signage can be used to delineate this BMP.

- Where proposed vegetation is to be used, note the timing of the installation in the SWPPP. A schedule will be required to designate the widths of vegetation to be used as a buffer.

- See *Illinois Urban Manual* STD 835 (Filter Strip).

- See *Illinois Urban Manual* STD IL-535.

Note: Use IDOT pay items when incorporating Illinois Urban Manual Standards.

41-3.01(b) Perimeter Silt Fence Barriers

1. Definition and Purpose. A temporary permeable barrier of entrenched filter fabric used to contain sediment within a site. Perimeter silt fence barriers promote sedimentation of sheet-flow runoff prior to discharge from the construction site. They intercept and detain small amounts of sediment resulting from disturbed areas (e.g., construction sites) and prevent sediment from leaving the site.

2. Applications. Perimeter silt fence barriers are appropriate for the following locations:

- along the perimeter of a project,
- around temporary soil stockpiles and spoil areas,
- along perimeter of streams and channels,
- downslope of exposed erodible soil areas, and
- below the toe of exposed and erodible slopes.

3. Design Considerations.

- Do not install silt fence barriers in areas of concentrated flow (e.g., streams, channels, drain inlets).

- Do not use silt fence barriers as mid-slope protection on slopes steeper than 1V:4H; see Section 41-3.03.

- Do not install silt fence barriers where ponding water behind the silt fence may cause flooding or fence failure.

- Silt fence barriers should not make dips that intercept slope contours because flows will be concentrated and blowouts may occur.

- The maximum drainage area for sheet-flow runoff to a silt fence should not exceed 0.5 acre per 100 ft (0.2 ha per 30 m) of fence.

- Install silt fence barriers with a “J”-Hook at intervals of at least 200 ft (61 m).

4. Specifications.

- See Section 280 of the *Standard Specifications*.
- See IDOT Highway Standard 280001.

Note: Contractor will have choice of materials unless a District Special Provision is included.

41-3.01(c) Perimeter Straw Bale Barriers

1. Definition and Purpose. A temporary barrier of entrenched and anchored straw bales used to contain sediment within a site. Perimeter straw bale barriers promote sedimentation of sheet-flow runoff prior to discharge from a construction site.

2. Applications. Perimeter straw bale barriers are appropriate for the following locations:

- along the perimeter of a project,
- around temporary soil stockpiles and spoil areas,
- down-slope of exposed erodible soil areas, and
- below the toe of exposed and erodible slopes.

3. Design Considerations.

- Do not install straw bale barriers in areas of concentrated flow (e.g., streams, channels).

- This control can only be used for installations less than three months, because straw bales tend to rapidly degrade.

- Straw bales can introduce non-native, undesirable plants.

- The maximum drainage area for sheet-flow runoff to a straw bale barrier should not exceed 0.5 acre per 100 ft (0.1 ha per 30 m) of barrier.

4. Specifications.

- See Section 280 of the *Standard Specifications*.
- See IDOT Highway Standard 280001.

Note: Contractor will have choice of materials unless a District Special Provision is included.

41-3.01(d) Perimeter Rolled Barriers

1. Definition and Purpose. Rolled and bound wood excelsior or equivalent placed around the site perimeter or stockpiles. Rolled barriers decrease the velocity and erosive force of sheet flows, and contain sediment by detaining and filtering runoff.

2. Applications. Perimeter rolled barriers are appropriate for the following locations:

   - along the perimeter of a project;
   - around temporary stockpiles and spoil areas;
   - at the top, face, and toe of erodible and exposed slopes;
   - at grade breaks on erodible and exposed slopes; and
   - down slope of any exposed soil areas.

3. Design Considerations. Install rolled excelsior barriers at the same elevation (e.g., along the same contour line) to prevent erosion.

4. Specifications.

   - See Section 280 of the *Standard Specifications*.
   - See ISTHA Standard Drawing K1.

   Note: Contractor will have choice of materials unless a District Special Provision is included.

41-3.02 Inlet Controls

Inlet controls prevent the movement of sediment and other pollutants into the storm sewer network. Consider all site and storm sewer characteristics when selecting an appropriate BMP. Sheet flow draining to drop inlets and shallow concentrated flow draining to culvert inlets require different methods of treatment, so it is important to select a BMP best suited to accommodate the expected velocity, shear stress, and sediment load of site runoff.

41-3.02(a) Drop Inlet Filter Bags

1. Definition and Purpose. A manufactured inlet filtration bag that is custom-fitted for insertion under virtually any type of drop drainage structure casting. An inlet filter can significantly reduce the ingress of sediment into the storm sewer system.

2. Applications. Drop inlet filter bags are appropriate for the following locations:

- inlets within paved areas, and
- drop inlets receiving runoff from 0.5 acre (0.2 ha) or less.

3. Design Considerations. Common curb-and-gutter and parking lot installations are available. The designer should ensure availability before specifying in other locations.

4. Specifications. See Section 280 of the *Standard Specifications*.

41-3.02(b) Drop Inlet Silt Fence Barriers

1. Definition and Purpose. A temporary silt fence secured around a drop inlet. Silt fence barriers impound water behind the barrier allowing sediment to drop out before the water enters the inlet.

2. Applications. Drop inlet silt fence barriers are appropriate for the following applications:

   - only for drop inlets in unpaved areas where the base of barrier can be trenched; and

   - for relatively small, flat areas (e.g., less than 1 acre (0.4 ha) per inlet; flatter than 5% slopes) with shallow sheet flows not exceeding 1 cfs (0.03 cms).

3. Design Considerations.

   - Slopes immediately surrounding silt fence barrier should not exceed 1% and must remain accessible for removal of accumulated sediment.

   - Verify flooding will not impact surrounding land.

4. Specifications.

   - See Section 280 of the *Standard Specifications*.
   - See IDOT Highway Standard 280001.

   Note: Contractor will have choice of materials unless a District Special Provision is included.

41-3.02(c) Drop Inlet Straw Bale Barriers

1. Definition and Purpose. A sediment control barrier consisting of entrenched and staked straw bales surrounding a drop inlet. Straw bale barriers impound water behind the barrier allowing sediment to drop out before the water enters the inlet.

2. Applications. Drop inlet straw bale barriers are appropriate for the following applications:

- only for drop inlets in unpaved areas; and

- in relatively small, flat areas (e.g., less than one acre per inlet; flatter than 5% slopes) with shallow sheet flows not exceeding 0.5 cfs (0.01 cms).

3. Design Considerations.

- Straw bale barriers are effective for three months or less.

- Slopes immediately surrounding straw bale barrier should not exceed 1% and must remain accessible for removal of accumulated sediment.

- Straw bales can introduce non-native, undesirable plants.

4. Specifications.

- See Section 280 of the *Standard Specifications*.
- See IDOT Highway Standard 280001.

Note: Contractor will have choice of materials unless a District Special Provision is included.

41-3.02(d) Drop Inlet Rolled Barriers

1. Definition and Purpose. Rolled and bound wood excelsior or equivalent surrounding a drop inlet. Rolled barriers impound water behind the barrier allowing sediment to drop out before the water enters the inlet.

2. Applications. Drop inlet rolled barriers are appropriate for the following applications:

- around drop inlets in unpaved areas, especially where other inlet controls are not feasible; and

- in relatively small, flat areas (e.g., less than one acre (0.4 ha) per inlet; flatter than 5% slopes) with shallow sheet flows not exceeding 0.5 cfs (0.01 cms).

3. Design Considerations.

- Rolled barriers should be staked and trenched in to a depth of 3 in (762 mm) to prevent displacement by high flows.

- Slopes immediately surrounding rolled barrier should not exceed 1% and must remain accessible for removal of accumulated sediment.

4. Specifications.

- District Special Provision will be required.
- See ISTHA Standard Drawing K1.

Note: Use IDOT pay items when incorporating ISTHA Standards.

41-3.02(e) Drop Inlet Prefabricated Barriers

1. Definition and Purpose. Manufactured, temporary sediment control barriers constructed of geosynthetic fabric and foam or equivalent. Drop inlet prefabricated barriers are installed around drop inlets in order to intercept and pond sediment-laden runoff prior to entering the storm sewer. Ponding the water reduces the velocity of any incoming flow and allows most of the suspended sediment to settle and be intercepted. After the water height reaches the top of the barrier, it flows over the dike and into the inlet.

2. Applications. Drop inlet prefabricated barriers are appropriate for the following applications:

   - in relatively small, flat areas (e.g., less than one acre (0.4 ha) per inlet; flatter than 5% slopes) with shallow sheet flows not exceeding 0.5 cfs (0.01 cms); and

   - where temporary upstream ponding will not adversely affect roadways or construction.

3. Design Considerations

   - Slopes immediately surrounding prefabricated barrier should not exceed 1% and must remain accessible for removal of accumulated sediment.

   - Place prefabricated barriers directly around the perimeter of the inlet.

   - Place two full sections against opposite sides of the inlet, and extend both sections beyond the drop sides of the inlet.

   - Where multiple barriers are installed, the sleeve end of fabrics should overlap at the joints and ends and be stapled to prevent bypass of storm water.

   - Prefabricated barriers can be cleaned, moved, and reused multiple times.

4. Specifications. District Special Provision required.

41-3.02(f) Above Grade Drop Inlet Filters

1. Definition and Purpose. Filter fabric-covered, polyethylene-framed barriers that are installed over area drains. Above grade inlet filters protect storm drains from ingress of sediment during construction activities.

2. Applications. Above grade drop inlet filters are appropriate for the following applications:

   - only for drop inlets in sump conditions;
   - for relatively small, flat areas (e.g., one acre (0.4 ha) or less) draining to each inlet; and
   - where sediment laden water is capable of clogging conventional inlet filters.

3. Design Considerations. None.

4. Specifications. See BDE Special Provision for "Above Grade Inlet Filter" (to be incorporated into Section 280 of *Standard Specifications* at a later date).

41-3.02(g) Pipe (Culvert) Inlet Vegetated Buffers

1. Definition and Purpose. A preserved or created area of vegetation at a culvert inlet that filters runoff prior to drainage. A vegetated buffer helps prevent sediment, mulch, and other pollutants from entering the storm sewer system before permanent seeding has become established in the tributary area of the storm inlet.

2. Applications. Pipe (culvert) inlet vegetated buffers are appropriate for the following applications:

   - in areas surrounding pipe inlets, especially culverts; and
   - in conjunction with other SCPs; see Section 41-3.04.

3. Design Considerations.

   - Ensure all feasible efforts are used to preserve existing vegetative buffers during construction.
   - See Section 41-3.01(a) for sizing of vegetated buffers. The minimum length is 25 ft (7.62 m).
   - Designate vegetative buffers as no entry areas by use of signage and/or temporary fence.
   - If removal of existing vegetation cannot be avoided, sod may be used as a buffer. Place the sod level with the surrounding ground surface and extend it at least 25 ft (7.62 m) from inlet.

4. Specifications.

- See Sections 250, 252, and 280 of the *Standard Specifications*.
- Where existing vegetation is used, delineate the area as a “No Intrusion Area” on the ESCP sheets. Also, note this area in the SWPPP. Temporary fencing and/or signage can be used to delineate this BMP.
- Where proposed vegetation is used, note the timing of the installation in the SWPPP. Include a schedule to designate the widths of vegetation to be used as a buffer.
- See *Illinois Urban Manual* practice STD 862 (Inlet Protection-Sod Filter).
- See *Illinois Urban Manual* STD IL-562.

Note: Use IDOT pay items when incorporating Illinois Urban Manual Standards.

41-3.02(h) Pipe (Culvert) Inlet Silt Fence Barriers

1. Definition and Purpose. A temporary permeable barrier of entrenched filter fabric used to protect a pipe inlet. A pipe (culvert) inlet silt fence barrier promotes the deposition of sediment from sediment-laden runoff prior to discharge from the construction site.
2. Applications. Use a pipe (culvert) inlet silt fence barrier for sediment control around pipe and culvert inlets where other methods of inlet protection and sediment control cannot be implemented in a timely manner. See Sections 41-3-.02(g), 41-3.03, and 41-3.04.
3. Design Considerations. Filter fabric may cause storm water backup and flooding of adjacent areas.
4. Specifications.
   - See Section 280 of the *Standard Specifications*.
   - See IDOT Highway Standard 280001.

41-3.02(i) Pipe (Culvert) Inlet Straw Bale Barriers

1. Definition and Purpose. A temporary barrier consisting of entrenched straw bales placed at a pipe inlet. Pipe (culvert) inlet straw bale barriers promote sedimentation and filtration of runoff prior to discharge from the construction site.
2. Applications. Use pipe (culvert) inlet straw bale barriers for short term (e.g., less than three months), sediment control around pipe and culvert inlets where other methods of inlet protection and sediment control cannot be implemented in a timely manner. See Sections 41-3-.02(g), 41-3.03, and 41-3.04.

3. Design Considerations.

- Straw bales may cause storm water backup and flooding of adjacent areas.
- Straw bales decompose and disintegrate rapidly; therefore, may be inefficient and expensive to maintain.
- Straw bales can introduce unwanted plant species and can contribute organic matter to waterways if improperly installed.

4. Specifications. See Section 280 of the *Standard Specifications*.

41-3.03 Temporary Ditch and Slope Checks

41-3.03(a) Aggregate Ditch Checks

1. Definition and Purpose. A small rock barrier constructed perpendicular to the flow path in drainage ditches and swales. Aggregate ditch checks reduce the velocity of surface water, which reduces scouring and allows sedimentation to occur. Ditch checks also promote infiltration where suitable soils are present.

2. Applications. Aggregate ditch checks are appropriate for the following applications:

- most economical choice for steep swales or ditches with velocities exceeding 4.9 ft/s (1.5 m/s),
- during the establishment of grassy-linings in swales or ditches (both temporary and permanent), and
- in temporary swales where erosion control lining is not warranted due to their short service time.

3. Design Considerations.

- Maximum recommended drainage area to each ditch check should not exceed 10 acres (4 ha).
- Maximum spacing between the ditch checks should be such that the toe of the upstream ditch check is at the same elevation as the top of the rock at the center of the downstream ditch check; see Figure 41-3.B.
- If scouring occurs on downstream side of aggregate ditch check, install ECBs, or TRMs to prevent further erosion; see Section 41-2.02.

% Slope	Height at Center/Overflow Pt. of Ditch Check (ft)	Spacing of Ditch Check (ft)
8%	1.0 (0.3 m)	13 (3.9 m)
	1.5 (0.5 m)	20 (6.1 m)
	2.0 (0.6 m)	26 (7.9 m)
7%	1.0 (0.3 m)	14 (4.27 m)
	1.5 (0.5 m)	21 (6.40 m)
	2.0 (0.6 m)	28 (8.5 m)
6%	1.0 (0.3 m)	17 (5.2 m)
	1.5 (0.5 m)	26 (7.9 m)
	2.0 (0.6 m)	34 (10.4 m)
5%	1.0 (0.3 m)	20 (6.1 m)
	1.5 (0.5 m)	30 (9.1 m)
	2.0 (0.6 m)	40 (12.2 m)
4%	1.0 (0.3 m)	25 (7.6 m)
	1.5 (0.5 m)	38 (11.6 m)
	2.0 (0.6 m)	50 (15.2 m)
3%	1.0 (0.3 m)	33 (10.1 m)
	1.5 (0.5 m)	50 (15.2 m)
	2.0 (0.6 m)	66 (20.1 m)
2%	1.0 (0.3 m)	50 (15.2 m)
	1.5 (0.5 m)	75 (22.9 m)
	2.0 (0.6 m)	100 (30.5 m)
1% and below	1.0 (0.3 m)	100 (30.5 m)
	1.5 (0.5 m)	150 (45.7 m)
	2.0 (0.6 m)	200 (60.9 m)

Notes:

1. *For applications not addressed in this figure, spacing should be equal to the height of ditch check divided by the slope. This ensures that the base of the upstream check is at the same elevation as the crest of the downstream check.*

2. *Adapted from the* Illinois Urban Manual*.*

SPACING OF TEMPORARY DITCH CHECKS

Figure 41-3.B

- Aggregate ditch checks are not recommended for slopes greater than 20%. When steeper than 20%, stabilize channels and drain to a SCP; see Section 41-2.03(a) and Section 41-3.04.

4. Specifications. See Sections 28 and 283 of the *Standard Specifications*.

41-3.03(b) Prefabricated Ditch Checks

1. Definition and Purpose. Manufactured temporary ditch checks are placed perpendicular to flow in shallow drainage ditches. The purpose of temporary ditch checks is to reduce the velocity of flowing water, thereby, reducing scour and channel erosion, encouraging deposition of sediment and filtration, and promoting infiltration where suitable soils are present.

2. Applications. Prefabricated ditch checks are appropriate for the following applications:

   - in shallow swales or ditches with slopes less than 8%,
   - during establishment of vegetation, and
   - in temporary swales where erosion control lining is not warranted due to short service time.

3. Design Considerations.

   - Product should not cause flooding of adjacent areas or roadways.
   - Place ditch checks perpendicular to the flow path.
   - Space ditch checks according to Figure 41-3.B.

4. Specifications. See Section 280 of the *Standard Specifications*.

41-3.03(c) Rolled Barrier Slope Checks

1. Definition and Purpose. Rolled and bound wood excelsior or equivalent placed on the face of slopes, installed perpendicular to the flow path. Slope checks decrease the velocity and erosive force of sheet flows by reducing slope length and contain sediment near its source by detaining and filtering runoff.

2. Applications. Roller barrier slope checks are appropriate for the following applications:

   - at the top, face, and toe of erodible and exposed slopes;
   - at grade breaks on erodible and exposed slopes;
   - down slope of any exposed soil areas; and
   - not to be used on steep slopes susceptible to slumping or creeping.

3. Design Considerations.

- Rolled barriers should be staked and trenched in to a depth of 3 in (762 mm) to prevent displacement by high flows.

- Space rolled barriers in accordance with the following:

  + slope inclination of 1V:4H or flatter = 20 ft (6.1 m) apart,
  + slope inclination of 1V:4H to 1V:2H = 15 ft (4.6 m) apart, and
  + slope inclination 1V:2H or greater = 10 ft (3.0 m) apart.

- Install temporary slope checks at the same elevation (along the same contour line) to prevent erosion.

4. Specifications.

- District Special Provision will be required.
- See ISTHA Standard Drawing K1.

Note: Use IDOT pay items when incorporating ISTHA Standards.

41-3.04 Sediment Traps and Basins

These sediment controls use excavated or impounded areas to temporarily detain sediment-laden water to promote settling of suspended particles prior to discharge. The outlets of these sediment controls should be stabilized (see Sections 41-2.04 and 41-2.05) so that treated water does not become re-contaminated, and should receive secondary treatment by means of inlet control BMPs (see Section 41-3.02) prior to drainage to a storm sewer. Designs should allow for adequate retention time to ensure maximal sedimentation for the anticipated sediment loads.

41-3.04(a) Sediment Traps

1. Definition and Purpose. A small, temporary ponding area either excavated or impounded by embankments. A sediment trap detains runoff for a sufficient period of time to allow sediment to drop out of suspension prior to discharge through a stabilized spillway. These practices are optimal for draining small disturbed areas comprised of coarse textured soils.

2. Applications. Sediment traps are appropriate for the following applications:

- for removal of medium to large-sized sediment particles (e.g., sands, coarse silts). For finer textured soils (e.g., silts, clays), see Section 41-3.04(b);

- at the outlets of small disturbed soil areas draining less than 5 acres (2 ha). If the contributing drainage area is greater than 5 acres (2 ha), see Section 41-3.04(b);

- for installations lasting less than 18 months;
- as a supplemental control to provide additional protection for waterways and drainage systems;
- at the perimeter of the site, at the outlet of any runoff conveyance that will discharge sediment-laden water, or along the flow path of runoff being conveyed through the site;
- where failure of the sedimentation trap will not result in injury, loss of life, damage to homes, buildings, roads, or other public infrastructure or service utilities; and
- not in live waterways or streams.

3. Design Considerations.

- Design the sediment trap to provide enough storage to accommodate the settling process (e.g., live storage) in addition to the accumulated sediment (e.g., dead storage).
- Live storage volume should, at a minimum, accommodate 3600 ft^3 of runoff per acre (101.9 m^3 per ha) tributary to each sediment trap.
- Design the dead storage to store the estimated sediment load generated from the site over the duration of the construction period. Ensure it is below the permeable fill.
- Total storage may consist of only live detention storage; however, a more frequent schedule for sediment removal will be required.
- Larger surface areas provide more effective settling than smaller areas.
- Larger length-to-width ratios provide protection against short-circuiting; therefore, the length of the trap should be at least twice the width as measured from inlet to outlet.
- If trap is formed by an embankment, maximum height should not exceed 5 ft (1.5 m).
- Side slopes should be no steeper than 1V:2H and be stabilized with vegetation, ECB, or TRM; see Section 41-2.02.
- Sediment should be removed and trap restored to original dimensions when accumulation reaches ½ the design depth of dead storage. If only live storage is used, then sediment should be removed after each sediment generating storm event.

- For situations where particle size or wind turbulence impedes settling within recommended timeframe, chemical treatment may be considered; see Section 41-3.05(b).

- Multiple traps and/or additional volume may be required to accommodate site-specific rainfall and soil conditions.

- Outlet design should ensure sediment is contained and erosion of outlet does not occur. Outflows should discharge to fully stabilized channels at non-erosive velocities; see Section 41-2.05.

- For outlets with a discharge point onto or cut into natural ground, the outlet width (ft (m)) should be equal to six times the drainage area (acres (ha)). If an embankment is used, the outlet should be at least 1 ft (300 mm) below the top of the embankment.

- For outlets consisting of a coarse aggregate and riprap section, locate the stone at the low point of the trap and extend vertically to 1 ft (300 mm) below the top of the embankment. Place coarse aggregate (CA-3) on the upstream side of outlet, separated by filter fabric from riprap (RR-3) on downstream side of outlet; see Section 41-3.03(a). Outlet width (ft (m)) should be equal to six times the drainage area (acres (ha)).

- Provide a maintenance access-way for sediment removal and disposal.

- Sediment traps require construction safety fencing around perimeter.

4. Specifications.

    - District Special Provision and detailed drawing will be required.

    - See ISTHA Standard Drawing K1.

    - See *Illinois Urban Manual* practice STD 960 (Temporary Sediment Trap).

    - See *Illinois Urban Manual* STD Drawing IL-660 (Temporary Sediment Trap) as a plan sheet.

Note: Use IDOT pay items when incorporating ISTHA and Illinois Urban Manual Standards.

41-3.04(b) Sediment Basins

1. Definition and Purpose. A temporary ponding basin (i.e., larger than a Sediment Trap), either excavated or impounded by earthen embankments with a controlled release. A sedimentation basin detains runoff for a sufficient period of time to allow sediment to

drop out of suspension prior to discharge through a control structure. These practices are optimal for draining large disturbed areas comprised of finer textured soils.

2. Applications. Sediment basins are appropriate for the following applications:

- for removal of medium to small sized sediment particles (e.g., silts, clays);
- at the outlets of large disturbed soil areas;
- generally for areas between 5 and 10 acres (2 and 4 ha), but not for drainage areas greater than 75 acres (30 ha);
- at the perimeter of the site, at the outlet of any runoff conveyance that will discharge sediment-laden water, or along the flow path of runoff being conveyed through the site;
- where sediment basins are to remain in place after construction is completed as permanent structures (e.g., for storm water detention purposes);
- where failure of the sedimentation basin will not result in injury, loss of life, damage to homes, buildings, roads, or other public infrastructure, or service utilities; and
- not in live waterways or streams.

3. Design Considerations.

- Design the basin to provide enough storage to accommodate the settling process (live storage) in addition to the accumulated sediment (dead storage).
- Multiple basins and/or additional volume may be required to accommodate site-specific rainfall and soil conditions.
- Design the live storage volume for the runoff from a 2-year, 24-hour storm event draining into the basin under maximum runoff conditions, or 3600 ft^3 of runoff per acre (101.9 m^3 per ha) tributary to the basin, whichever is greater.
- Dead storage should be sized to store the estimated sediment load generated from the site over the duration of the construction period, or 3600 ft^3 of runoff per acre (101.9 m^3 per ha) tributary to the basin, whichever is greater.
- Ensure the dead storage is below the permeable fill.
- Larger surface areas provide more effective settling than smaller areas.
- Larger length-to-width ratios provide protection against short-circuiting; therefore, the length of the basin should be at least twice the width as measured from inlet to outlet.

- Basin should have a minimum depth of 3 ft (900 mm) and a maximum of 5 ft (1.5 m) in order to maximize safety and efficiency.
- Side slopes should be no steeper than 1V:2H and be stabilized with vegetation, ECB, or TRM; see Section 41-2.02.
- Sediment should be removed and basin restored to original dimensions when accumulation reaches ½ the design depth of dead storage.
- Calculate the elevation of sediment cleanout level and clearly mark the level on the riser.
- Sediment clean-out level should never exceed 1 ft (300 mm) below the top of riser.
- For situations where particle size or wind turbulence impedes settling within recommended timeframe, chemical treatment may be considered; see Section 41-3.05.
- Basin sizes may be limited based on available right-of-way.
- In restrictive right-of-way areas, the basin may be designed to store 1800. ft^3 per acre (125 m^3 per hectare) of contributing drainage area.
- Where reduced sized basins will be used, more frequent clean out intervals will be required.
- Design the outlet to drain the basin within 24 to 72 hours in order to provide adequate time for sediment to settle out of suspension and protection against mosquito concerns.
- Recommended outlet types are a single orifice outlet or a perforated riser.
- Outlet should consist of corrugated metal, high-density polyethylene (HDPE) or reinforced concrete riser pipe with dewatering holes.
- Attach an anti-vortex device and trash rack to the top of the riser to prevent the discharge of floatables and to protect outlet from obstruction.
- Minimize erosion using stabilization controls (e.g., ECB) at the inlet and outlet using velocity dissipation devices; see Section 41-2.05.
- The design should include features to accommodate overflow or bypass flows that exceed the design storm event.
- The overflow should consist of an open spillway over undisturbed material or properly compacted fill and be appropriately stabilized with vegetation or riprap.

- The level portion of the spillway at the highest elevation in the channel (control section) should be a minimum of 20 ft (6.1 m) in length.

- Provide a maintenance access-way for sediment removal and disposal.

- The perimeter of the basin requires construction safety fencing.

4. Specifications.

   - See Section 280 of the *Standard Specifications*.
   - ISTHA Standard Drawing K1 for basin dewatering details.

   Note: Use IDOT pay items when incorporating ISTHA Standards.

41-3.05 Flocculant Polymers/Treatment Chemical

Per the ILR10 permit, when flocculants are used on a Department project the following shall documented in BDE 2342 (SWPPP):

- Identify the use of all flocculants or treatment chemicals at the site;

- Dosage of treatment chemicals shall be identified along with any information from any Material Safety Data Sheet;

- Describe the location of all storage areas for chemicals. Include any information from the manufacturer's specifications;

- Treatment chemicals must be stored in areas where they will not be exposed to precipitation; and

- The SWPPP must describe procedures for use of treatment chemicals and staff responsible for use/application of treatment chemicals must be trained on the established procedures.

41-3.05(a) Batch Treatment

1. Definition and Purpose. The process of applying chemical compounds to sediment-laden bodies of water (e.g., sediment traps, sedimentation basins) to reduce turbidity by causing fine sediments to settle out. The compounds are generally buffered alum, polyacrylamide (PAM), and ferric chloride (or ferrous sulfate), which promote settling of fine, suspended particles through the process of flocculation. Flocculation occurs when small, charged soil particles become attached to the chemical compounds and aggregate into larger masses, which then settle out of suspension.

2. Applications. Batch treatment is appropriate for the following applications:

- where turbid discharges cannot be avoided using other SCPs, see Section 41-3.05; and

- only in conjunction with other sedimentation controls, see Section 41-3.04.

3. Design Considerations.

- Anionic PAM is the most commonly used treatment for flocculation of suspended colloids, clays, and metals. PAM is soil specific and should, therefore, be tested on soils and water from the site to ensure adequate performance.

- Do not use cationic PAM, which is highly toxic to aquatic life.

- Perform toxicity and pH testing to ensure that flocculants meet water quality standards.

- Dilute granular flocculants in water to form stock solutions, which is applied hydraulically to the water surface.

- Flocculation effectiveness is highly dependent on the compound being thoroughly dissolved and mixed with the turbid water.

- In general, application rate should yield 1 ppm in the final volume. The application rate is specific to runoff constituents, site conditions, and flocculent compounds.

4. Specifications.

- District Special Provision will be required.
- Refer to manufacturer's specification for chosen product.

41-3.05(b) Flow-Through Treatment (Flocculent Logs, Polymer Treated Structures)

1. Definition and Purpose. The process of bringing concentrated flows (e.g., diversion channels, dewatering discharges, ditches, swales) of sediment-laden runoff in contact with flocculent-treated materials in order to promote settling of suspended particles; see Section 41-3.05(a).

2. Applications. Flow-through treatments are appropriate for the following applications:

- where turbid discharges cannot be avoided by sole use of other SCPs, see Section 41-3.04;

- turbid discharges associated with dewatering, pipe discharges, channelized or concentrated flow paths, storm sewer conveyance and collection systems, temporary diversions, and bypass channels; and

- only for concentrated flows draining to a sediment trap or sedimentation basin, see Section 41-3.04.

3. Design Considerations.

- Semi-hydrated polymer blocks (e.g., floc logs) may be placed within sediment-laden concentrated flow paths as a “pretreatment” to remove fine, suspended solids (e.g., silts, clays, colloids) prior to discharge to a sediment trap or sediment basin.

- Effluent from flow-through treatments should not drain directly into natural water bodies or storm sewer.

- Anionic PAM is the most commonly used treatment for flocculation of suspended colloids, clays, and metals. PAM is soil specific and should, therefore, be tested on soils and water from the site to ensure adequate performance.

- Do not use cationic PAM, which is highly toxic to aquatic life.

- Flocculation effectiveness is highly dependent on the compound being thoroughly dissolved and mixed with the turbid water.

- Perform toxicity and pH testing to ensure that flocculants meet water quality standards.

- Securely stake flocculent logs and other polymer-treated structures along the flow path based upon manufacturers’ specifications and site characteristics.

4. Specifications.

- District Special Provision will be required.
- Refer to manufacturer’s specification for chosen product.

41-3.06 Entrance/Exit Controls

Entrance/exit control BMPs prevent the tracking of sediment attached to equipment and vehicles offsite. The design of entrance/exit control measures will depend upon the site conditions. Generally, these BMPs are not a pay item as the contractor is required to install and maintain per NPDES permits. If the district feels the necessity to require this item in a specific location, a District Special Provision will be required.

41-3.06(a) Stabilized Construction Entrance/Exits

1. Definition and Purpose. A stabilized pad of coarse aggregate, underlain with geotextiles or a commercially available prefabricated unit designed to vibrate accumulated sediment from tires and under chassis. BMPs are located at any point where traffic will be entering

and leaving a construction site. Stabilized construction entrances and exits reduce or eliminate the tracking of sediment (e.g., mud, dirt) onto public right-of-way or streets by construction vehicles.

2. Applications. At all points of construction ingress/egress where sediment can be tracked onto public roads.

3. Design Considerations.

- Stabilized construction entrances can be expensive to construct and maintain, so it will be necessary to limit the number of access points to the construction site.
- Design stabilized entrances and exits for the heaviest vehicles and equipment loads.
- Construct stabilized entrances and exits on level or slightly sloping ground.
- Aggregate entrances and exits may require periodic top dressing.
- Route runoff from the entrance through a sediment-trapping device.
- If site conditions are such that the entrance does not remove sufficient amounts of sediment from vehicle and equipment tires, then tire washing may also be required; see Section 41-3.06(b).
- A temporary pipe culvert may be needed beneath the entrance as to not impede ditch or surface flow towards the entrance.

4. Specifications.

- Generally not a pay item as the contractor is required to install and maintain per NPDES permits. If the district feels the necessity to require this item in a specific location, include a District Special Provision.
- See *Illinois Urban Manual* practice STD 930 (Stabilized Construction Entrance).
- See *Illinois Urban Manual* STD Drawing IL-630 (Stabilized Construction Entrance Plan) as a plan sheet.

Note: Use IDOT pay items when incorporating Illinois Urban Manual Standards.

41-3.06(b) Tire Wash Stations

1. Definition and Purpose. A designated area where sediment may be washed from equipment tires and chassis prior to exiting the site via a stabilized construction exit. Sediment is collected in a receptacle and disposed of at an approved location. Tire wash stations reduce or eliminate the tracking of sediment (e.g., mud, dirt) onto public right-of-

way or streets by construction vehicles and ensure appropriate discharge of sediment-laden wash water.

2. Applications. Tire wash stations are appropriate for the following applications:

- on sites where conditions are such that a stabilized construction entrance alone does not remove all sediment from vehicle and equipment tires; and
- in combination with grated wash rack (e.g., cattle guard).

3. Design Considerations.

- Wash stations require a supply of wash water.
- Where wash areas are used, provide a construction entrance with two lanes (e.g., to avoid having incoming vehicles drive through the wash area) or have a turnout area.
- Drain wash water away from the construction entrance and adjacent pavement towards a sediment trapping facility; see Section 41-3.04.
- If wash rack is used, have the manufacturer design the wash rack to handle the heaviest anticipated traffic loads.

4. Specifications.

- Generally not a pay item as the contractor is required to install and maintain per NPDES permits. If the district feels the necessity to require this item in a specific location, include a District Special Provision. Ensure the wash area has a stabilized construction entrance.
- See *Illinois Urban Manual* practice STD 930 (Stabilized Construction Entrance).
- See *Illinois Urban Manual* STD Drawing IL-630 (Stabilized Construction Entrance Plan) as a plan sheet.

Note: Use IDOT pay items when incorporating Illinois Urban Manual Standards.

41-3.07 Sediment Control Reference Table

Figure 41-3.C summarizes the SCPs that were discussed in Section 41-3. The figure may be used by the designer as a supplemental tool to ensure that all BMP options have been considered. It should be noted that multiple BMPs may be required from each category in order to provide comprehensive sediment management on the site.

SCP Category	Specific SCP	Appropriate Application	Section
Perimeter Controls	Perimeter Vegetated Buffers	Filtration of all overland sheet flow before discharge to storm sewer, swales, or State waters.	41-3.01(a)
	Perimeter Silt Fence Barriers	Along perimeter of construction sites, streams, channels, and stockpiles; at toe of slopes.	41-3.01(b)
	Perimeter Straw Bale Barriers	Along perimeter of construction sites, streams, channels, and stockpiles; at toe of slopes.	41-3.01(c)
	Perimeter Rolled Barriers	Along perimeter of site, on face and toe of slopes, at grade breaks on exposed soils.	41-3.01(d)
Inlet Controls	Drop Inlet Filter Bags	Drop inlets at grade, especially in paved areas.	41-3.02(a)
	Drop Inlet Silt Fence Barriers	Drop inlets draining up to 1 acre (0.4 ha) of flat land, inlets receiving less than 1 cfs (0.03 cms) shallow sheet flow.	41-3.02(b)
	Drop Inlet Straw Bale Barriers	Drop inlets draining up to 1 acre (0.4 ha) of flat land, inlets receiving less than 0.5 cfs (0.01 cms) shallow sheet flow.	41-3.02(c)
	Drop Inlet Rolled Barriers	Drop inlets draining up to 1 acre (0.4 ha) of flat land, inlets receiving less than 0.5 cfs (0.01 cms) shallow sheet flow.	41-3.02(d)
	Drop Inlet Prefabricated Barriers	Drop inlets draining up to 1 acre (0.4 ha) of flat land, inlets receiving less than 0.5 cfs (0.01 cms) shallow sheet flow.	41-3.02(e)
	Above Grade Inlet Filters	Drop inlets draining small up to 1 acre (0.4 ha) during construction.	41-3.02(f)
	Pipe (Culvert) Inlet Vegetated Buffers	Open grated culvert inlets in areas undergoing permanent seeding, areas up to 1 acre (0.4 ha).	41-3.02(g)
	Pipe (Culvert) Inlet Silt Fence Barriers	Only when timely inlet protection and sediment control by other methods is not possible.	41-3.02(h)
	Pipe (Culvert) Inlet Straw Bale Barriers	Only when timely inlet protection and sediment control by other methods is not possible.	41-3.02(i)

SEDIMENT CONTROL PRACTICES REFERENCE TABLE

Figure 41-3.C

SCP Category	Specific SCP	Appropriate Application	Page
Temporary Ditch and Slope Checks	Aggregate Ditch Checks	In small open swales or ditches with a tributary area of 10 acres (4 ha) or less, steep swales or ditches with velocities exceeding 4.9 ft/s (1.5 m/s), during the establishment of grassy-linings in temporary or permanent swales or ditches.	41-3.03(a)
	Prefabricated Ditch Checks	In shallow swales or ditches with slopes less than 8%, during establishment of vegetation, in temporary swales where erosion control lining is not warranted due to short service time.	41-3.03(b)
	Rolled Barrier Slope Checks	Along the face of erodible and exposed slopes.	41-3.03(c)
Sedimentation Controls	Sediment Traps	Where sediment laden water is discharged from small areas (<5 acres (<2 ha)); supplemental treatment.	41-3.04(a)
	Sediment Basins	Where sediment laden water is discharged from large areas (>5 acres (>2 ha)); supplemental treatment.	41-3.04(b)
Flocculent Polymers	Batch Treatment	Where extreme turbidity exists and where sediment basin alone is insufficient.	41-3.05(a)
	Flow-Through Treatment	As pretreatment for sediment-laden water before draining to sediment trap or sediment basin.	41-3.05(b)
Entrance/Exit Controls	Stabilized Construction Entrance/Exits	All points of site egress/ingress.	41-3.06(a)
	Tire Wash Stations	Where stabilized entrances/exits are not sufficient to remove all sediment.	41-3.06(b)

SEDIMENT CONTROL PRACTICES REFERENCE TABLE

Figure 41-3.C
(Continued)

41-4 GUIDANCE ON THE NPDES PERMIT NUMBER ILR10

The National Pollutant Discharge Elimination System (NPDES) permit Number ILR10 is a general permit issued by the Illinois Environmental Protection Agency (IEPA) to authorize storm water discharges from Department construction projects that disturb one (0.4 ha) or more acres of land either as a single project or a group of projects under a common development plan.

The authority for this permit comes from the United States Environmental Protection Agency (USEPA) which has delegated the IEPA to issue NPDES permits under Section 402 of the Clean Water Act.

The ILR10 has numerous components that the Department must comply with, and those components are discussed below.

41-4.01 Definitions

1. 303(d) listed receiving water. 303(d) refers to Section 303(d) of the Clean Water Act where impaired streams are listed by the IEPA.

2. Impaired Stream. An Impaired stream is a waterway listed on the IEPA Section 303(d) List due to nonattainment of applicable water quality standards and/or designated uses. Listing a waterway as impaired is a requirement for developing a Total Maximum Daily Load for a specific pollutant for that waterbody.

3. Biologically Significant Stream. A stream that has a Biological Stream Rating System score of “A” either for Diversity or Integrity based on data from at least two taxonomic groups. These streams are unique resources in the State and are considered to be the highest quality streams.

4. Designated Use. The designated use of a water body includes aesthetic quality, aquatic life, fish consumption, indigenous aquatic life, primary contact (i.e. recreation), and public and food processing water supply.

5. Incidence of Noncompliance (ION). An ION occurs when during an inspection, a violation of the SWPPP is observed, or for any violation of any condition of this permit. The ION (which is a IEPA form) addresses the noncompliance with a corrective action and is submitted to the IEPA. In itself, the ION is not a punitive action (See Part IV (D)(4)(e) of the IRL10).

6. Final Stabilization. Final stabilization means that all soil disturbing activities at the site have been completed and either of the two following conditions have been met:

    a. a uninform (e.g. evenly distributed, without large bare areas) perennial vegetative cover with a density of 70 percent of the native background vegetative cover for the area has been established on all unpaved areas and area not covered by permanent structures, or

b. equivalent permanent stabilization measures (such as the use of riprap, gabions, or geotextiles) have been employed.

7. Municipal Separate Storm Sewer System (MS4). An MS4 is conveyance or system of conveyances that is:

- owned by a state, city, town, village, or other public entity that discharges to waters of the U.S.,
- designed or used to collect or convey stormwater (e.g., storm drains, pipes, ditches),
- not a combined sewer, and
- not part of a sewage treatment plant, or publicly owned treatment works (POTW).

8. Notice of Intent (NOI). The NOI is a package of information submitted to the IEPA and essentially declares that the project is covered under the ILR10. Contents of the NOI are described in Part II. C of the ILR10.

9. Notice of Termination (NOT). The NOT serves to notify the IEPA that Final Stabilization has been reached for the project.

10. Steep slope. A steep slope is defined as a slope that has a slope gradient of 1V:3H or steeper.

11. Total Maximum Daily Load (TMDL). A TMDL is the greatest amount of a given pollutant that a water body can receive without violating water quality standards and designated uses.

41-4.02 Notice of Intent

The Notice of Intent (NOI) is a notice to the IEPA that a Department project meets the conditions of the ILR10 permit. The Department utilizes the following forms and plans to comply with the NOI requirements.

- BDE 2342 Storm Water Pollution Prevention Plan (SWPPP)
- BDE 2342a Contractor Certification Statement
- Erosion and Sediment Control Detail (See Section 63-4.09)

41-4.03 BDE 2342 (SWPPP)

BDE 2342 is broken down into the following parts:

1. Part I. Site Description

2. Part II. Waters of the US

3. Part III. Water Quality

4. Part IV. Temporary Erosion and Sediment Controls

5. Part V. Other Conditions

6. Part VI. Permanent (i.e., Post- Construction) Storm Water Management Controls

7. Pat VII. Additional Practices Incorporated from Local Ordinance(s)

8. Part VIII. Unexpected Regulated Substances/Chemical Spill Procedures

9. Part IX. Contractor Required Submittals

10. Part X. Maintenance

11. Part XI. Inspections

12. Part XII. Incidence of Noncompliance

13. Part XIII. Corrective Actions

14. Part XIV. Retention of Records

15. Part XV. Failure to Comply

16. Part XVI. Keeping the SWPPP ("Plan") Current

17. Part XVII. Notifications

18. Part XVIII. Notice of Termination

Each of these parts will be explained below

Note: Parts I through VII are filled out during Design. Parts VIII to XVIII are the responsibility of either the Contractor or Construction.

41-4.03(a) SWPPP Signature Page

The first page of BDE 2342 is the signature page. The form shall be signed by a representative of the Department delegated by the Regional Engineer to approve the SWPPP.

41-4.03(b) SWPPP Notes

This section provides information in relation to preparing the SWPPP as well as requirements for the Notice of Intent (NOI).

41-4.03(c) Part I. Site Description

This first section describes the nature and scope of the project.

1. Describe the project location; include latitude and longitude, section, town, and range.

2. Describe the nature of the construction activity or demolition work

3 . Describe the intended sequence of major activities which disturb soils for major portions of the site (e.g. clearing, grubbing, excavation, grading, on-site or off-site stockpiling of soils, on-site or off-site storage of materials).

4. The total area of the construction site is estimated to be acres.

5. The total area of the site estimated to be disturbed by excavation, grading or other activities is acres.

6. Below, determine an estimate of the runoff coefficient of the site after construction activities are completed and existing data describing the soil or the quality of any discharge from the site (See Drainage manual)

7. Provide the existing data describing the soil or the quality of any discharge from the site.

8. Erosion and Sediment Control Plan (i.e., ILR10 site map) is included in the contract.
☐ Yes ☐ No

9. List all soils found within project boundaries; include map unit name, slope information, and erosivity.

10. List of all MS4 permittees in the area

<u>Note</u>: For sites discharging to an MS4, a separate map identifying the location of the construction site and the location where the MS4 discharges to surface water must be included.

41-4.03(d) Part II. Waters of the US

The following section discuss any Waters of the US in the project area. These are waters that fall under Federal jurisdiction of the Clean Water Act of 1972.

1. List the nearest named receiving water(s) and ultimate receiving waters.

2. Are wetlands present in the project area?
☐ Yes ☐ No

If yes, describe the areal extent of the wetland acreage at the site.

3. Natural buffers:
For any storm water discharges from construction activities within 50 feet of a Waters of the United States, except for activities for water-dependent structures authorized by a Section 404 permit, the following shall apply:

(i) A 50-foot undisturbed natural buffer between the construction activity and the Waters of the United States has been provided

☐ Yes ☐ No; and/or

(ii) Additional erosion and sediment controls within that area has been provided
☐ Yes No; and Describe:

41-4.03(e) Part III. Water Quality

41-4.03(e)1 *Water Quality Standards Background*

Water Quality Standards are set by the Illinois Pollution Control Boards. These standards are published in Title 35: Environmental Protection, Subtitle C: Water Pollution, Chapter 1: Pollution Control Board, Part 302 Water Quality Standard. This publication should be reviewed as there are general use waters, which apply to all waterways, and specific standards that apply to certain waterways, such as Lake Michigan Basin as well as descriptions of other chemicals not described below.

41-4.03(e)2 *Definitions*

1. Acute Toxicity means the capacity of any substance or combination of substances to cause mortality or other adverse effects in an organism resulting from a single or short-term exposure to the substance.

2. Adverse Effect means any gross or overt effect on an organism, including reversible histopathological damage, severe convulsions, irreversible functional impairment, and lethality, as well as any non-overt effect on an organism resulting in functional impairment or pathological lesions that may affect the performance of the whole organism, or that reduces an organism's ability to respond to an additional challenge.

3. Chronic Toxicity means the capacity of any substance or combination of substances to cause injurious or debilitating effects in an organism that result from exposure for a time period representing a substantial portion of the natural life cycle of that organism, including the growth phase, the reproductive phases, or such critical portions of the natural life cycle of that organism.

4. Criterion means the numerical concentration of one or more toxic substances derived in compliance with the procedures in Subpart F that, if not exceeded, would assure compliance with the narrative toxicity standard of Section 302.210.

5. "Early Life Stages" of fish means the pre-hatch embryonic period, the post-hatch free embryo or yolk-sac fry, and the larval period, during which the organism feeds. Juvenile fish, which are anatomically similar to adults, are not considered to be an early life stage.

6. "Hardness" means a water quality parameter or characteristic consisting of the sum of calcium and magnesium concentrations expressed in terms of equivalent milligrams per liter as calcium carbonate. Hardness is measured in compliance with methods specified in 40 CFR 136, incorporated by reference in 35 Ill. Adm. Code 301.106.

7. "Mixing Zone" means a portion of the waters of the State identified as a region within which mixing is allowed under Section 302.102(d).

8. “Thermocline” means the plane of maximum rate of decrease of temperature with respect to depth in a thermally stratified body of water.

9. "Total Residual Chlorine" or "TRC" means those substances that include combined and uncombined forms of both chlorine and bromine and that are expressed, by convention, as an equivalent concentration of molecular chlorine. TRC is measured in compliance with methods specified in 40 CFR 136, incorporated by reference in 35 Ill. Adm. Code 301.106.
"Toxic Substance" means a chemical substance that causes adverse effects in humans, or in aquatic or terrestrial animal or plant life. Toxic

substances include those substances listed in 40 CFR 302.4, incorporated by reference in 35 Ill. Adm. Code 301.106, or any "chemical substance" as defined by the Illinois Chemical Safety Act [430 ILCS 45]

10. "ZID" or "Zone of Initial Dilution" means a portion of a mixing zone, identified pursuant to Section 302.102(e), within which acute toxicity standards need not be met.

41-4.03(e)3 *General use Standards*

The following are general use water quality standards from the Illinois Pollution Control Board.

- pH
- Phosphorus
- Dissolved Oxygen
- Radioactivity
- Numeric Standards for Chemical Constituents
- Fecal Coliform
- Other Toxic Substances
- Temperature
- Total Ammonia Nitrogen

Below, in BDE 2342, is a table of common chemicals used on Department construction sites as referenced in Standard Specifications for Road and Bridge Construction. This table is not an exhaustive list. Each contract should be reviewed for other chemicals that could cause an issue with Water Quality if spilled and those additional chemicals shall be added to the table as appropriate.

1. Water Quality Standards

As determined by the Illinois Pollution Control Board, Illinois waters have defined numeric limits of pollutants under the umbrella term “Water Quality Standards.” In the following table are commonly used chemicals/practices used on a construction site. These chemicals if spilled into a waterway, could potentially contribute to a violation of a Water Quality Standard. If other chemicals that could contribute a violation of a Water Quality Standard, add as needed,

☐	Fertilizer (check as appropriate)		☐	
	☐	Nitrogen	☐	Petroleum (gas, oil, kerosene, hydraulic oil / fluids)
	☐	Phosphorous, and/or	☐	Wastewater for concrete washout station
	☐	Potassium	☐	Coal Tar Pitch Emulsion
☐		Herbicide	☐	Other (Specify)

Table 41-4.A Common chemicals/potential pollutants used during construction

Comparing the general use water quality standards and Table 41-4A. we can see that phosphorus and nitrogen used as a fertilizer per Article 250.04 in the spec book could be two chemicals that can cause an issue if allowed to enter a waterway. However, both fertilizers are applied as a dry product and the likelihood of a spill is low and is reinforced by the Department's Pollution Prevention practices as described in the Department's ILR40 permit.

After determining if any chemicals can pose an issue if spilled into a waterway, the following check boxes can be filled out in the SWPPP.

If no boxes are checked in the table above, check the following box:

☐ There are no chemicals on site that will exceed a Water Quality Standards if spilled.

If any of the boxes are checked in the table, check the following box and statement:

☐ There are chemicals on site that if spilled could potentially cause an exceedance of a Water Quality Standard. The Department shall implement Pollution Prevention/Good Housekeeping Practices as described in the Department's ILR40 Discharge for Small Municipal Separate Storm Sewer Systems (MS4) reiterated below and Part VIII. Unexpected Regulated Substances/Chemical Spill Procedures:

The following discusses pollution prevention practices utilized by the Department.

Pollution Prevention

The Department will design, and the contractor shall, install, implement, and maintain effective pollution prevention measures to minimize the discharge of pollutants from construction activities. At a minimum, such measures must be designed, installed, implemented, and maintained to:

a) Minimize the discharge of pollutants from equipment and vehicle washing, wheel wash water, and other wash waters. Wash waters must be treated in a sediment basin or alternative control that provides equivalent or better treatment prior to discharge;

b) Minimize the exposure of building materials, building products, construction wastes, trash, landscape materials, fertilizers, pesticides, herbicides, chemical storage tanks, deicing material storage facilities and temporary stockpiles, detergents, sanitary waste, and other materials present on the site exposed to precipitation and to storm water;

c) Minimize the discharge of pollutants from spills, leaks and vehicle and equipment maintenance and repair activities and implement chemical spill and leak prevention and response procedures;

d) Minimize the exposure of fuel, oil, hydraulic fluids, other petroleum products, and other chemicals by storing in covered areas or containment areas. Any chemical container with a storage of 55 gallons or more must be stored a minimum of 50 feet from receiving waters, constructed or natural site drainage features, and storm drain inlets. If infeasible due to site constraints, store containers as far away as the site permits and document in your SWPPP the specific reasons why the 50-foot setback is infeasible and how the containers will be stored;

e) The contractor is to provide regular inspection of their construction activities and Best Management Practices (BMPs). Based on inspection findings, the contractor shall determine if repair, replacement, or maintenance measures are necessary in order to ensure the structural integrity, proper function, and treatment effectiveness of structural storm water BMPs. Necessary maintenance shall be completed as soon as conditions allow to prevent or reduce the discharge of pollutants to storm water or as ordered by the Engineer. The Engineer shall conduct inspections required in Section XI Inspections, and report to the contractor deficiencies noted. These Department conducted inspections do not relieve the contractor from their responsibility to inspect their operations and perform timely maintenance; and

f) In addition, all IDOT projects are screened for Regulated Substances as described in Section 27-3 of the BDE Manual and implemented via Section 669: Removal and Disposal of Regulated substances in the Standard Specifications for Road and Bridge Construction.

Approved alterations to the Department’s provided SWPPP, including those necessary to protect Contractor Borrow, Use and Waste areas, shall be designed, installed, implemented and maintained by the Contractor in accordance with IDOT Standard Specifications Section 280.

2. 303(d) Impaired Waterways

Note: Information on 303(d) impaired waterways can be found at the following website: IEPA 2020/2022 Integrated Report Web App (Interactive Map)

Does the project area have any 303(d) impaired waterways with the following impairments?

- suspended solids
- turbidity, and or
- siltation.

☐Yes ☐No

If yes, list the name(s) of the listed water body and the impairment(s)

303(d) waterbody	Impairment(s)

In addition, It is paramount that the project does not increase the level of the impairment(s) described above. Discuss which BMPs will be implemented to reduce the risk of impairment increase:

3. Total Maximum Daily Load (TMDL)

Note: Information on TMDL's can be found on the IEPA's website

Does the project include any receiving waters with a TMDL for sediment, total suspended solids, turbidity or siltation?

☐ Yes ☐ No

If yes, List TMDL waterbodies below and describe associated TMDL)

TMDL waterbody	TMDL

Provide a description of the erosion and sediment control strategy that will be incorporated into the site design that is consistent with the assumptions and requirements of the TMDL:

If a specific numeric waste load allocation has been established that would apply to the project's discharges, provide a description of the necessary steps to meet that allocation:

41-4.03(f) Part IV. Temporary Erosion and Sediment Controls

The following section of the SWPPP provides and overview of erosion and sediment control practices implemented for the project and ILR10 permit requirements for these practices.

Stabilization efforts must be initiated within 1 working day of cessation of construction activity and completed within 14 days. Areas must be stabilized if they will not be disturbed for at least 14 calendar days. Exceptions to this time frame include:

(i) Where the initiation of stabilization measures is precluded by snow cover, stabilization measures must be initiated as soon as practicable,

(ii) On areas where construction activities have temporarily ceased and will resume after 14 days, a temporary stabilization method can be used (temporary stabilization techniques must be described), and

(iii) Stabilization is not required for exit points at linear utility construction site that are used only episodically and for very short durations over the life of the project, provided other exit point controls are implemented to minimize sediment track-out.

Additionally, a record must be kept with the SWPPP throughout construction of the dates when major grading activities occur, when construction activities temporarily or permanently cease on a portion of the site, and when stabilization measures are initiated.

At a minimum, controls must be coordinated, installed and maintained to:

1. Minimize the amount of soil exposed during construction activity;

2. Minimize the disturbance of steep slopes;

3. Maintain natural buffers around surface waters, direct storm water to vegetated areas to increase sediment removal and maximize storm water infiltration, unless infeasible;

4. Minimize soil compaction and, unless infeasible, preserve topsoil

Note: For practices below, consult relevant design criteria in Section 41-2 and Section 41-3 and maintenance criteria in the Erosion and Sediment Control Field Guide for Construction.

1. Erosion Control

The following are erosion control practices which may be used on a project (place a check by each practice that will be utilized on the project, add additional practices as needed):

☐	Mulch	☐	Temporary Turf Cover Mixture (Class 7)
☐	Erosion Control Blanket	☐	Turf Reinforcement Mat
☐	Geotextile Fabric	☐	Permanent seeding (Class 1 – 6)
☐	Preservation of existing vegetation	☐	Other (specify)
☐	Sodding	☐	Other (specify)
		☐	Other (specify)

2. Sediment Control

The following sediment control devices will be implemented on this project:

☐	Ditch Checks	☐	Perimeter Erosion Barrier
☐	Inlet and Pipe protection	☐	Rolled Excelsior
☐	Hay or Straw bales	☐	Urethane foam/geotextiles
☐	Silt Filter Fence	☐	Other (specify)
☐	Above grade inlet filters (fitted)	☐	Other (specify)
☐	Above grade inlet filters (non-fitted)	☐	Other (specify)
☐	Inlet filters	☐	Other (specify)

3. Structural Practices:

Provided below is a description of structural practices that will be implemented:

☐	Aggregate Ditch	☐	Rock Outlet Protection
☐	Articulated Block Revetment Mat	☐	Stabilized Construction Exits
☐	Barrier (Permanent)	☐	Stabilized Trench Flow
☐	Concrete Revetment Mats	☐	Sediment Basin
☐	Dewatering Filtering	☐	Sediment Trap
☐	Gabions	☐	Slope Walls
☐	In-Stream or Wetland Work	☐	Storm Drain Inlet Protection
☐	Level Spreaders	☐	Other (Specify)
☐	Paved Ditch	☐	Other (Specify)
☐	Permanent Check Dams	☐	Other (Specify)
☐	Precast Block Revetment Mat	☐	Other (Specify)
☐	Riprap	☐	Other (Specify)
☐	Retaining Walls	☐	Other (Specify)

4. Polymer Flocculants

Note: Polymer Flocculants may only be used by district special provision. If used for a project, the following must be adhered to and described below:

- Identify the use of all polymer flocculants at the site.
- Dosage of treatment chemicals shall be identified along with any information from any Material Safety Data Sheet.
- Describe the location of all storage areas for chemicals.
- Include any information from the manufacturer's specifications.
- Treatment chemicals must be stored in areas where they will not be exposed to precipitation.
- The SWPPP must describe procedures for use of treatment chemicals and staff responsible for use/application of treatment chemicals must be trained on the established procedures.

41-4.03(g) Part V. Other Conditions

The following describes requirements for dewatering as described in the ILR10 permit. In addition, dewatering is addressed on the following form: BC 2259 Storm Water Pollution Plan and Sediment Control Inspection Report

1. Dewatering

Will dewatering be required for this project?

☐Yes ☐No

If yes, the following applies:

- Dewatering discharges shall be routed through a sediment control (e.g., sediment trap or basin, pumped water filter bag) designed to minimize discharges with visual turbidity;
- The discharge shall not include visible floating solids or foam;
- The discharge must not cause the formation of a visible sheen on the water surface, or visible oily deposits on the bottom or shoreline of the receiving water. An oil-water separator or suitable filtration device shall be used to treat oil, grease, or other similar products if dewatering water is found to or expected to contain these materials;
- To the extent feasible, use well-vegetated (e.g., grassy or wooded), upland areas of the site to Infiltrate dewatering water before discharge;
- You are prohibited from using receiving waters as part of the treatment area;

- To minimize dewatering-related erosion and related sediment discharges. use stable. erosion-resistant surfaces (e.g., well-vegetated grassy areas, clean filler stone, geotextile underlayment) to discharge from dewatering controls. Do not place dewatering controls, such as pumped water filter bags, on steep slopes (15% or greater in grade);
- Backwash water (water used to backwash/clean any filters used as part of storm water treatment) must be properly treated or hauled off- site for disposal;
- Dewatering treatment devices shall be properly maintained; and
- See Part XI (Inspections) for inspection requirement.

41-4.03(h) Part VI. Permanent (i.e., Post-Construction) Storm Water Management Controls

Provided below is a description of measures that may be installed during the construction process to control volume and therefore the amount pollutants in storm water runoff that can occur after construction operations have been completed.

Practices may include but are not limited to the following:

- Aggregate ditch checks;
- bioswales,
- detention pond(s),
- infiltration trench;
- retention pond(s),
- open vegetated swales and natural depressions,
- treatment train (sequential system which combine several practices).
- Velocity dissipation devices (See Structural Practices above)

Describe these practices below:

41-4.03(i) Part VII. Additional Practices Incorporated from Local Ordinance(s)

In some instances, an additional practice from a local ordinance may be included in the project. If so, describe below (Note: the Department is not subject to local ordinances)

41-4.03(j) Part VIII. Unexpected Regulated Substances/Chemical Spill Procedures

When Unexpected Regulated Substances or chemical spills occur, Article 107.19 of the Standard Specifications for Road and Bridge Construction shall apply. In addition, it is the contractor's responsibility to notify the Engineer in the event of a chemical spill into a ditch or waterway, the Engineer will then notify appropriate IEPA and IEMA personnel for the appropriate cleanup procedures.

41-4.03(k) Part IX. Contractor Required Submittals

Prior to conducting any professional services at the site covered by this plan, the Contractor and each subcontractor responsible for compliance with the permit shall submit to the Resident Engineer a Contractor Certification Statement, BDE 2342A.

1. The Contractor shall provide a construction schedule containing an adequate level of detail to show major activities with implementation of pollution prevention BMPs, including the following items:

- Approximate duration of the project, including each stage of the project
- Rainy season, dry season, and winter shutdown dates
- Temporary stabilization measures to be employed by contract phases
- Mobilization time-frame
- Mass clearing and grubbing/roadside clearing dates
- Deployment of Erosion Control Practices
- Deployment of Sediment Control Practices (including stabilized construction entrances and exits to be used and how they will be maintained)
- Deployment of Construction Site Management Practices (including concrete washout facilities, chemical storage, refueling locations, etc.)
- Paving, saw-cutting, and any other pavement related operations
- Major planned stockpiling operation
- Time frame for other significant long-term operations or activities that may plan non-storm water discharges as dewatering, grinding, etc.
- Permanent stabilization activities for each area of the project

2. During the pre-construction meeting, the Contractor and each subcontractor shall provide, as an attachment to their signed Contractor Certification Statement, a discussion of how they will comply with the requirements of the permit in regard to the following items and provide a graphical representation showing location and type of BMPs to be used when applicable:

- Temporary Ditch Checks - Identify what type and the source of Temporary Ditch Checks that will be installed as part of the project. The installation details will then be included with the SWPPP.
- Vehicle Entrances and Exits - Identify type and location of stabilized construction entrances and exits to be used and how they will be maintained.
- Material Delivery, Storage and Use- Discuss where and how materials including chemicals, concrete curing compounds, petroleum products, etc. will be stored for this project. Specifically, any chemical stored in a 55 gallon drum provided by the contractor.
- Stockpile Management - Identify the location of both on-site and off-site stockpiles. Discuss what BMPs will be used to prevent pollution of storm water from stockpiles.
- Waste Disposal - Discuss methods of waste disposal that will be used for this project.
- Spill Prevention and Control - Discuss steps that will be taken in the event of a material spill.
- Concrete Residuals and Washout Wastes - Discuss the location and type of concrete washout facilities to be used on this project and how they will be signed and maintained.
- Litter Management - Discuss how litter will be maintained for this project (education of employees, number of dumpsters, frequency of dumpster pick-up, etc.).
- Vehicle and Equipment Fueling - Identify equipment fueling locations for this project and what BMPs will be used to ensure containment and spill prevention.
- Vehicle and Equipment Cleaning and Maintenance - Identify where equipment cleaning and maintenance locations for this project and what BMPs will be used to ensure containment and spill prevention.
- Dewatering Activities - Identify the controls which will be used during dewatering operations to ensure sediments will not leave the construction site.

Additional measures indicated in the plan.

41-4.03(l) Part X. Maintenance

It will be the Contractor's responsibility to attain maintenance guidelines for any manufactured BMPs which are to be installed and maintained per manufacture's specifications. However, when requested by the Contractor, the Resident Engineer will provide general maintenance guides (e.g., IDOT Erosion and Sediment Control Field Guide) to the Contractor for the practices associated with this project. Any damage or undermining shall be repaired immediately.

Below, describe procedures to maintain in good and effective operating conditions:

41-4.03(m) Part XI. Inspections

Qualified personnel shall inspect disturbed areas of the construction site that have not been finally stabilized, structural control measures, and locations where vehicles enter or exit the site at least once every seven calendar days and within 24 hours of the end of a storm or by the end of the following business or workday that is 0.50 inches or greater or equivalent snowmelt (except as allowed for Frozen Conditions).

In addition, all areas where storm water typically flows within the site should be inspected periodically to check for evidence of pollutants entering the drainage system, as well as all locations where stabilization measures have been implemented to ensure they are operating correctly.

Inspections shall be documented on the form BC 2259 (Storm Water Pollution Prevention Plan Erosion Control Inspection Report).

The Erosion and Sediment Control Field Guide for Construction Inspection shall be consulted as needed.

Dewatering Inspections:

For site(s) discharging dewatering water, an inspection during the discharge shall be done once per day on which the discharge occurs and record the following in a report within 24 hours of completing the Inspection:

(i) The inspection date;

(ii) Names and titles of personnel performing the inspection;

(iii) Approximate times that the dewatering discharge began and ended on the day of inspection;

(iv) Estimates of the rate (in gallons per day) of discharge on the day of inspection;

(v) Whether or not any of the following indications of pollutant discharge were observed at the point of discharge: a sediment plume, suspended solids. unusual color, presence of odor, decreased clarity, or presence of foam; and/or a visible sheen on the water surface or visible oily deposits on the bottom or shoreline of the receiving water.

Frozen Conditions

Inspections may be reduced to once per month when all construction activities have ceased due to frozen conditions. Weekly inspections will recommence when construction activities resume, either temporarily or continuously, or if there is 0.5” or greater rain event, or a discharge due to snowmelt occurs.

Flooding or unsafe conditions

Areas that are inaccessible during required inspections due to flooding or other unsafe conditions must be inspected within 72 hours of becoming accessible.

41-4.03(n) Part XII. Incidence of Noncompliance (ION)

The Department shall notify the appropriate Agency Field Operations Section office by email as described on the IEPA ION form, within 24 hours of any incidence of noncompliance for any violation of the storm water pollution prevention plan observed during any inspection conducted, or for violations of any condition of this permit.

The Department shall complete and submit within 5 days an "Incidence of Noncompliance" (ION) report for any violation of the storm water pollution prevention plan observed during any Inspection conducted, or for violations of any condition of this permit. Submission shall be on forms provided by the IEPA and include specific information on the cause of noncompliance, actions which were taken to prevent any further causes of noncompliance, and a statement detailing any environmental impact which may have resulted from the noncompliance. Corrective actions must be undertaken immediately to address the identified non-compliance issue(s}.

Illinois Environmental Protection Agency

Division of Water Pollution Control Compliance Assurance Section

1021 North Grand Avenue East

Post Office Box

19276

Springfield, Illinois

62794-9276

41-4.03(o) Part XIII. Corrective Actions

Corrective actions must be taken when:

- A storm water control needs repair or replacement;
- A storm water control necessary to comply with the requirements of this permit was never installed, or was installed incorrectly;
- Discharges are causing an exceedance of applicable water quality standards; or
- A prohibited discharge has occurred.

Corrective Actions must be completed as soon as possible and documented within 7 days in an Inspection Report or report of noncompliance. If it is infeasible to complete the installation or repair within 7 calendar days, it must be documented in the records why it is infeasible to complete the installation or repair within the 7 day timeframe and document the schedule for installing the storm water control(s) and making it operational as soon as feasible after the 7-day timeframe. In the event that maintenance is required for the same storm water control at the same location three or more times, the control must be repaired in a manner that prevents continued failure to the extent feasible, and it must be documented the condition and how it was repaired in the records. Alternatively, it must be documented why the specific reoccurrence of this same issue must continue to be addressed as a routine maintenance fix.

41-4.03(p) Part XIV. Retention of Records

The Department must retain copies of the SWPPP and all reports and notices required by this permit, records of all data used to complete the NOI to be covered by this permit, and the Agency Notice of Permit Coverage letter for at least three years from the date that the permit coverage expires or is terminated. the permittee must retain a copy of the SWPPP and any revisions to the SWPPP required by this permit at the construction site from the date of project initiation to the date of final stabilization. Any manuals or other documents referenced in the SWPPP must also be retained at the construction site.

41-4.03(q) Part XV. Failure to Comply

Failure to comply with any provisions of this Storm Water Pollution Prevention Plan will result in the implementation of a National Pollutant Discharge Elimination System/Erosion and Sediment Control Deficiency Deduction against the Contractor and/or penalties under the Permit ILR10 which could be passed on to the contractor (See Article 105.03 Conformity with Contract)

41-4.03(r) Part XVI. Keeping the SWPPP (“Plan”) Current

IDOT shall amend the plan whenever there is a change in design, construction, operation, or maintenance, which has a significant effect on the potential for the discharge of pollutants to Waters of the United States and which has not otherwise been addressed in the plan or if the plan proves to be ineffective in eliminating or significantly minimizing sediment and/or pollutants identified under paragraph Part II. Water Quality or in otherwise achieving the general objectives of controlling pollutants in storm water discharges associated with construction site activity.

In addition, the plan shall be amended to identify any new contractor and/or subcontractor that will implement a measure of the plan. Amendments to the plan may be reviewed by the IEPA the same manner as the SWPPP and Erosion and Sediment Control Plan (ESCP) submitted as part of the Notice of Intent (NOI). The SWPPP and site map must be modified within 7 days for any changes to construction plans, storm water controls or other activities at the site that are no longer accurately reflected in the SWPPP.

In addition, the NOI shall be modified using the CDX system for any substantial modifications to the project such as:

- address changes,
- new contractors,
- area coverage,
- additional discharges to Waters of the United States, or
- other substantial modifications (e.g. addition of dewatering activities.

The notice of intent shall be modified within 30 days of the modification to the project,

41-4.03(s) Part XVII: Notifications

In addition to the NOI submitted to IEPA, all MS4 permittees identified in Part I. Site Description shall receive a copy of the NOI.

41-4.03(t) Part XVIII. Notice of Termination

Where a site has completed final stabilization and all storm water discharges from construction activities that are authorized by this permit are eliminated, the permittee must submit a completed Notice of Termination (NOT) that is signed in accordance with ILR10 permit.

Method of Measurement: NPDES Compliance shall not be measured for payment separately. Measurement for payment for Temporary Erosion and Sediment Control shall be in accordance with Section 280 or as otherwise provided in the contract. Permanent BMPs necessary to comply with this provision shall be measured for payment in accordance with their respective provisions in the contract.

Basis of Payment: NPDES Compliance shall not be paid for separately. Payment for Temporary Erosion and Sediment Control shall be in accordance with Section 280 or as otherwise provided in the contract. Permanent BMPs necessary to comply with this provision shall be paid for in accordance with their respective payment provisions in the contract.

Chapter Forty-three
HIGHWAY SYSTEMS

The proper application of road design criteria depends in part on the various highway system classifications that have been developed, especially the functional classification system. Chapter 43 discusses these highway systems, which include the:

- functional classification system,
- urban subcategories,
- Federal-aid funding categories,
- highway jurisdictions, and
- the National Truck Network.

43-1 FUNCTIONAL CLASSIFICATION SYSTEM

43-1.01 General

43-1.01(a) Definitions

Functional classification is the process by which highways and streets are grouped into classes or systems based on the character of service they are intended to provide.

Urban areas are those places identified by the U.S. Bureau of Census as having a population of 50,000 or more (urbanized areas) or 5,000 or more but less than 50,000 (small urban areas); all places outside of urbanized and small urban areas are rural areas. The urban area boundaries are established by the State, in cooperation with the Metropolitan Planning Organizations (MPOs) and other appropriate local officials. The boundaries must be approved by FHWA.

43-1.01(b) Background

The *Intermodal Surface Transportation Efficiency Act (ISTEA) of 1991* required that every State functionally reclassify its public roads and streets. The database is also used to identify routes for the National Highway System (NHS), for administering the Federal-aid programs, and for assessing the extent, conditions, and performance of the highway system. Figure 43-1.A presents the Department's functional classification terminology.

43-1.01(c) Relationship to Roadway Design

The functional classification concept is one of the most important determining factors in roadway design. The concept recognizes that the public highway network in Illinois serves two basic and often conflicting functions—access to property and travel mobility. Each road or street will

Rural	Urban
Principal Arterial System • Interstates • Other Principal Arterials (OPA)	Principal Arterial System • Interstates • (Non-Interstate) Freeways and Expressways • Other Principal Arterials (OPA)
Minor Arterials*	Minor Arterials
Collector Roads • Major Collectors* • Minor Collectors	Collector Streets
Local Roads	Local Streets

* *Upgrade rural Minor Arterial to Urban OPA and upgrade rural Major Collector to urban Minor Arterial when these routes enter an urbanized area.*

IDOT FUNCTIONAL CLASSIFICATION TERMINOLOGY

Figure 43-1.A

provide varying levels of access and mobility, depending upon its intended service. The overall objective of the functional classification system, when viewed in its entirety, is to yield an optimum balance between its access and mobility functions. When achieved, the benefits to the traveling public will be maximized.

The functional classification system provides the foundation for highway planning functions and the framework for determining the geometric design of individual roadways and streets. Once the function of the highway facility is defined, the designer can select an appropriate design speed, roadway width, roadside safety elements, amenities, and other design values. All of Part V and much of Part IV of this *Manual* are based upon this systematic concept to determining roadway design.

Before initiating project work, the designer should review the most recent highway functional classification maps for the proposed project in the district or in the Central Office.

43-1.02 General Functional Classification Categories

The following identifies the basic characteristics of the three general categories within the functional classification system:

1. Arterial. Arterial highways are generally characterized by their ability to quickly move relatively large volumes of traffic, but often with restricted capacity to serve abutting

properties. The arterial system typically provides for high travel speeds and the longest trip movements. The rural and urban arterial systems are connected to provide continuous through movements at approximately the same level of service.

2. Collector. Collector routes are characterized by a relatively even distribution of access and mobility functions. Traffic volumes and speeds are typically lower than those of arterials.

3. Local. All public roads and streets not classified as arterials or collectors are classified as local roads and streets. Local roads and streets are characterized by the many points of direct access to adjacent properties and the relatively minor value in accommodating mobility. Speeds and volumes are usually low and trip distances short.

The following sections more explicitly describe the characteristics of these three general categories for rural and urban areas.

43-1.03 Rural Functional Classification Categories

43-1.03(a) Principal Arterial System

The rural principal arterial system provides connections between the major urban areas and OPAs and provides a level of service suitable for statewide or interstate travel. The system provides integrated, continuous movements without the need for stub connections. The rural principal arterial system is divided into the following subcategories:

1. Interstates. The Interstate system consists of a connected rural network of continuous routes designated as part of the National System of Interstate and Defense Highways. They are fully access controlled and constructed for higher design speeds. All Interstates are required components of the National Highway System (NHS) (see Section 43-3).

2. Other Principal Arterials (OPAs). These facilities consist of a connected rural network of continuous routes having the following designations and characteristics:

    - serve to interconnect various regions of the State not served by the Interstate system with either a non-Interstate freeway, expressway (partial access control), or high-type two-lane highway;
    - should connect with routes of the same functional classification in adjacent States;
    - should provide a design with high overall travel speeds and with minimum interference to through movements; and
    - could be part of the National Highway System (NHS); however, note that not all OPAs are on the NHS (see Section 43-3).

43-1.03(b) Minor Arterials

Rural minor arterials should form a network having the following characteristics:

- should form an integrated network of routes connecting to the OPAs and should provide interregional or intercounty service. Stub sections are seldom justified;
- should interconnect and serve areas of the State not served by the principal arterial system;
- should connect with routes of the same function in adjacent states;
- are located at such intervals to provide an average spacing of approximately 12 miles to 15 miles (20 km to 25 km) between all arterial routes;
- should serve virtually all county seats and small towns with populations of 1,000 or more or equivalent type traffic generators; and
- should provide a design with relatively high overall travel speeds with minimum interference to through movements. Partial access control should be considered and investigated on these routes as they approach urbanized areas.

43-1.03(c) Collector Roads

The rural collector road system generally includes those routes where the predominant travel distances are shorter than trips on arterial routes, but greater than the short trips characteristic of the local road system. To more clearly define the characteristics of rural collector roads, these facilities have been subdivided into two separate functional classifications:

1. Major Collectors. These are characterized as follows:
   - provide service to any county seats not on an arterial route;
   - serve the more important intracounty or intraregional travel corridors not served by higher route classifications;
   - serve larger towns not directly served by higher route classifications nor other traffic generators of equivalent intracounty importance. Such routes link nearby larger cities or other routes of higher classification;
   - serve most small towns with populations of 500 or more. Such small towns are either served by a major collector or higher classified route;
   - form an integrated network; however, stub sections are not uncommon. Consolidated school districts, shipping points, recreational areas, or other equivalent traffic generators can be used to justify the inclusion of such stubs in this classification;

- are located at intervals with an average spacing between collectors and other routes with higher classifications of approximately 6 miles to 10 miles (10 km to 15 km); and
- provide all-weather service for reliable and safe travel, considering both access and mobility.

2. Minor Collectors. These are characterized as follows:
   - provide service to any remaining small communities with populations of 100 or more and which are not served by a higher classified route;
   - are located at intervals, consistent with population density, to collect traffic from local roads and to connect all developed areas within a reasonable distance from a collector route. The average spacing between minor collectors and other routes with higher classifications should be approximately 3 miles to 6 miles (5 km to 10 km);
   - include more stub sections than the major collector classification; and
   - are designed for relatively reliable and year-around safe travel, with more emphasis on property access than mobility.

Projects for improvements on roads with a rural minor collector functional classification are not eligible for Surface Transportation Program (STP) funds.

43-1.03(d) Local Roads

The roads functionally classified as rural local roads generally have the following characteristics:

- constitute the rural mileage not designated as part of higher classifications;
- serve primarily to provide access to abutting property and connections to higher classified routes;
- provide service to motorists who travel relatively short distances as compared to collectors or other higher classified routes;
- commonly include stub sections; and
- reflect minimal design criteria with primary consideration to access needs.

Projects for improvements on roads with a rural local road functional classification are not eligible for Surface Transportation Program (STP) funds.

43-1.04 <u>Urban Functional Classification Categories</u>

43-1.04(a) Principal Arterial System

In general, the urban principal arterial system carries the highest traffic volumes and accommodates the greatest trip lengths. Because of the nature of the travel served by this system, almost all fully and partially access-controlled facilities will be part of the principal arterial system. However, this system is not restricted to access-controlled routes. To preserve the identification of access-controlled facilities, the principal arterial system is segregated as follows:

1. <u>Interstates</u>. The Interstate system consists of a connected urban network of continuous routes designated as part of the National System of Interstate and Defense Highways. They are fully access controlled and constructed for higher design speeds. All Interstates are required components of the National Highway System (NHS); see Section 43-3.

2. <u>Non-Interstate Freeways and Expressways</u>. Non-Interstate freeways and expressways may be connecting links in the urban area, and they may be extensions of rural OPAs. These routes may traverse the urban area from one boundary to another or may simply connect to another connecting link. Also, non-Interstate freeways and expressways may provide access to circumferential routes around the city or provide links to the central city. Additional links may be necessary to provide system continuity in urbanized areas with a population greater than 50,000.

   Non-Interstate freeways and expressways consist of facilities that have the following general characteristics:

   - should serve traffic coming from rural other principal arterials or other traffic with interregional demand;
   - should provide continuity within the urban area and for all rural freeways and expressways that intercept the urban boundary;
   - serve the major economic activity centers of an urban area, the highest traffic volume corridors, or the longest regional and intra-urban trips; and
   - should carry a high proportion of the total urban area travel on a minimum of mileage (kilometers) and should serve the major portion of trips entering and leaving the urban area and the majority of through movements desiring to bypass the central city.

3. <u>Other Principal Arterials</u>. These routes consist of a connected urban network of continuous routes having the following designations and characteristics:

   - provide service to, through, or around urban areas from rural minor arterial routes and may be connecting links;

- serve generally as an extension of a rural minor arterial highway and could be an expressway design, a major two-way city street, or a one-way couple system;

- may warrant management of access to the highway;

- serve long distance traffic within a city by connecting major regional activity centers not served by connecting links;

- in urbanized areas (50,000 population or greater), should provide for significant urban and suburban travel demands. Such trips would be between central business districts and outlying residential areas, between major inner city communities, or between major suburban centers;

- in urbanized areas, are located at spacings which are closely related to the trip-end density characteristics of specific portions of the urban area. The spacing may vary from 1 mile (1.5 km) between routes in the densely developed central business district areas to 6 miles (10 km) or more in the sparsely developed urban fringes;

- in smaller urban areas (under 50,000 but greater than 5,000 population), may be limited in the number and extent of routes. The importance of such routes is primarily to serve the central business district and to accommodate through travel at an appropriate level of service;

- could be part of the National Highway System (NHS) (see Section 43-3) and/or a Strategic Regional Arterial (SRA) route in District 1 (see Chapter 46); however, it should be noted that not all OPAs are on the NHS; and

- provide for an integrated network serving the entire urban area.

43-1.04(b) Minor Arterials

When compared to the principal arterial system, urban minor arterials may provide lower travel speeds and accommodate shorter trip lengths and lower traffic volumes, but they provide more access to property. These routes have the following general characteristics:

- interconnect and supplement the urban principal arterial system;

- provide service for trips of moderate length and at a somewhat lower level of mobility than urban principal arterial routes;

- may carry local bus routes and provide intracommunity continuity (but will not, for example, penetrate neighborhoods);

- may be urban extensions of rural major collector routes; and

- considered together with all urban arterial routes, are located from 2 miles to 3 miles (3 km to 5 km) between routes in suburban fringes and as close as 1 mile (1.5 km) in fully developed areas. Within the central business district, a spacing of 650 ft to ½ mile (200 m to 800 m) is typical.

43-1.04(c) Collector Streets

In urban areas, collector streets serve as intermediate links between the arterial system and points of origin and destination. These facilities typically have the following characteristics:

- provide both access and traffic circulation within residential neighborhoods and commercial and industrial areas;
- may penetrate residential neighborhoods or commercial/industrial areas to collect and distribute trips to and from the arterial system;
- in the central business district, may include the streets which are not classified as arterials;
- have spacing of routes dependent on the density of development. In fully developed areas, spacing together with higher classifications should provide approximately ½ mile (800 m) between routes and, within the central business district, a spacing of 650 ft to ½ mile (200 m to 800 m); and
- may be urban extensions of rural minor collector routes.

43-1.04(d) Local Streets

The streets functionally classified as urban local streets generally have the following characteristics:

- constitute the urban mileage (kilometers) not designated as part of a higher classification,
- serve primarily to provide direct access to abutting land and higher order systems,
- offer the lowest level of mobility and usually contain no bus routes, and
- discourage through traffic movements.

Projects for improvements on streets with an urban local street functional classification are not eligible for Surface Transportation Program (STP) funds.

43-1.05 Illinois System

The percent of miles (kilometers) traveled nationally in each category is documented in the US DOT/Federal Highway Administration manual *Highway Functional Classification—Concepts, Criteria and Procedures*. Current Illinois statistics are published annually in *Illinois Travel Statistics*. In addition, roadway information is collected on all public highways and is stored on computer files as documented in the *Roadway Information and Procedure Manual*. The Illinois Roadway Information System (IRIS) is used to compile information for two principal reasons:

- to determine if a specific project is eligible for a certain type of funding, and
- to assist in prioritizing highway improvement needs.

43-2 URBAN SUBCATEGORIES

43-2.01 General

The functional classification system described in Section 43-1 is divided into urban and rural categories. However, the "urban" designation is not sufficiently specific to determine the appropriate roadway design. The urban design classification is divided into "suburban" and "urban" based on the extent of roadside development. These categories are further subdivided as discussed in the following sections. This refinement to the highway design process allows the project to be tailored to the constraints of the surrounding environment. The following briefly discusses these urban subcategories.

43-2.02 Urban

Urban areas are those places identified by the US Bureau of Census having a population of 5,000 or more. For design purposes, urban areas are further subdivided as follows:

1. Central Business Districts (CBD). On streets in the CBD or downtown area, abutting building development often prohibits space for off-street parking and entrances for individual businesses. Right-of-way is usually very limited. The streets may include high-density commercial or residential development (e.g., apartment complexes, row houses). Access to property is the primary function of the street network in CBDs. The designer often must select the cross-sectional criteria that will fit into the existing right-of-way. Pedestrian and bicycle considerations may be as important as vehicular considerations, especially at intersections.

   Because of the high density of development in CBD areas, the distinction between the functional classes (local, collector, arterial) becomes less significant in design. The primary distinction among the three functional classes is often the relative traffic volumes and, therefore, the number of lanes needed. As many as half of the intersections may be signalized; posted speed limits typically range between 25 mph and 30 mph.

2. Fringe Area/Outlying Business District (FRNG/OBD). These areas generally have off-street parking and driveway entrances that usually are quite numerous. Right-of-way may be restricted and will typically limit the practical options for roadway improvements. The extent of roadside development will have a significant impact on the selected speeds of drivers. Pedestrian and bicycle activity is common and warrants significant consideration in design.

   Local and collector streets in FRNG/OBD areas typically have posted speed limits between 30 mph and 45 mph. The frequency of signalized intersections is substantially higher than in suburban areas. An arterial in FRNG/OBD areas will often have strip commercial development along its roadside, and posted speed limits will range between 40 mph and 45 mph.

43-2.03 Suburban

These areas connote a degree of development greater than that of a rural area, but less than that of an urban area. The predominant character of the surrounding environment is usually residential, but it may also include a considerable number of commercial establishments and a few industrial parks. On suburban roads and streets, drivers usually have considerable freedom of maneuverability; nonetheless, they must devote some of their attention to entering and exiting vehicles. Roadside development is characterized by low to moderate density. Pedestrian and bicycle activity is usually not a design factor. Right-of-way may be available for roadway improvements.

Local and collector streets in suburban areas are typically located in residential areas, but may also serve a commercial area. Posted speed limits typically range between 30 mph and 45 mph. The majority of intersections will have stop or yield control, but there will be an occasional traffic signal. A typical suburban arterial will have strip commercial development and perhaps a few residential properties. Posted speed limits usually range between 35 mph and 50 mph, and there will be a few signalized intersections along the arterial.

Suburban areas are further divided into two subclassifications (closed and open). For definition, the area adjacent to urban conditions is noted as “closed suburban” and the area adjacent to rural conditions as “open suburban.” Some judgment is necessary to define the boundaries between these two suburban subclassifications, as described below.

43-2.03(a) Closed Suburban

Closed suburban areas will generally follow urban policies for capacity and lane requirements and will generally have the following characteristics:

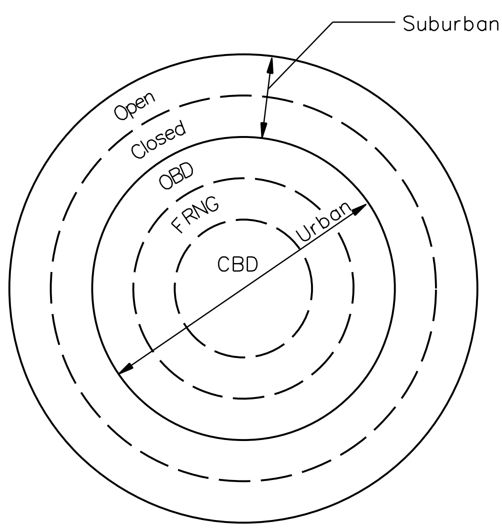
- combination of intermittent strip development, intermittent street network, and open-space segments;
- some high-volume traffic generators;
- isolated signalized intersections;
- some two-way and four-way stop-controlled intersections;
- outside curb and gutter cross sections with a closed drainage system;
- average posted speeds of 35 mph to 45 mph;
- high potential for considerable land development within approximately five years following the highway improvement; and
- adherence to restricted spacing for route access.

43-2.03(b) Open Suburban

Open suburban designs will generally follow the rural policies for capacity purposes and lane requirements and will generally have the following characteristics:

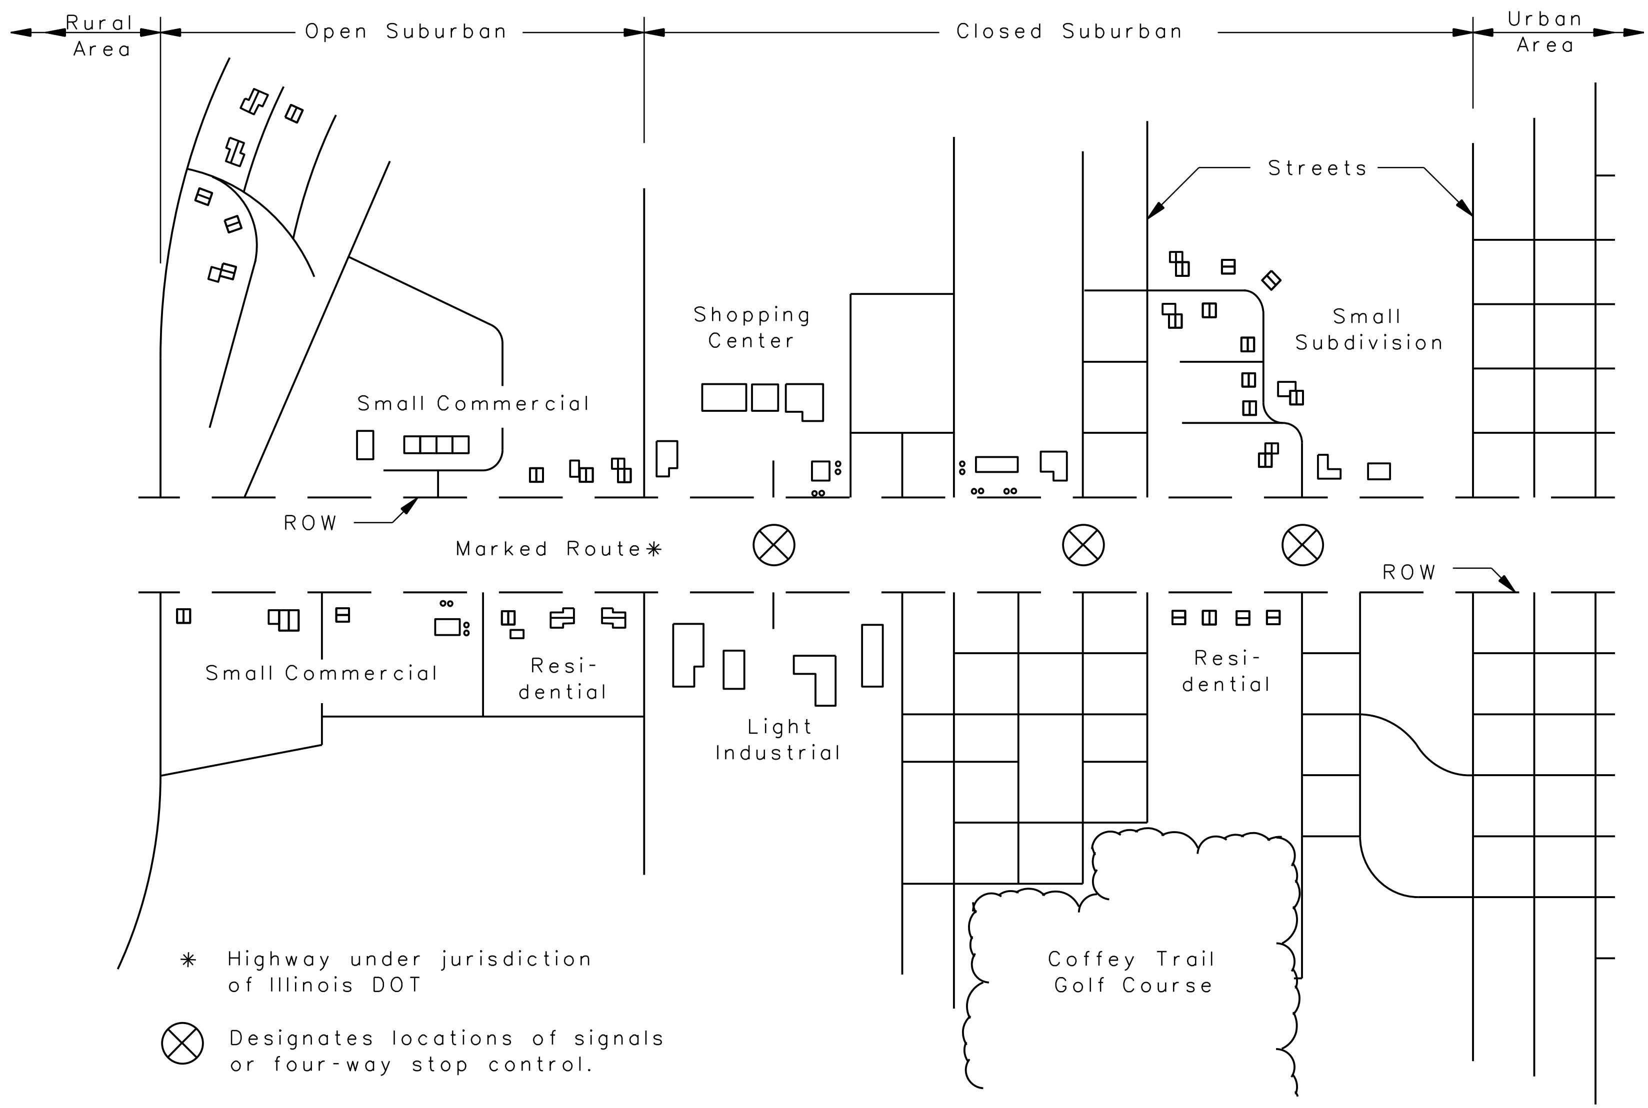
- no established street network;
- local road intersections spaced at approximately 1320 ft – 1600 ft (400 m – 500 m) apart;
- some residential and small commercial properties;
- generally free-flowing traffic on mainline roadways;
- average posted speeds of 45 mph to 50 mph;
- with depressed medians, the cross section usually includes outside shoulders and outside ditch drainage;
- good potential for considerable land development within about 10 to 15 years following the highway improvement; and
- adherence to ¼ mile (400 m) spacing for route access.

Figure 43-2.A presents the relationship between urban and suburban subcategories for design. Figure 43-2.B schematically illustrates the general type of cultural development and roadway networks within suburban areas.



URBAN AND SUBURBAN CATEGORIES
(For Design)

Figure 43-2.A



INTERSECTION SIGHT DISTANCE CONTROLS

Figure 43-2.B

43-3 FEDERAL-AID FUNDING CATEGORIES

There are three basic Federal-aid funding categories:

- the National Highway System (NHS),
- the Interstate System, and
- the Surface Transportation Program (STP).

Funding options for projects or improvements should be identified because some roadway functional classification categories are not eligible to receive STP funding (e.g., all rural and urban local roads and streets).

43-3.01 National Highway System

The National Highway System (NHS) is a network of principal arterial routes identified as essential for international, interstate, and regional commerce and travel, national defense, and the transfer of people and goods to and from major intermodal facilities. It consists of selected Other Principal Arterials, the Strategic Highway Network (STRAHNET), major STRAHNET connectors, and selected major intermodal connectors. The NHS represents approximately 4% to 5% of the total public road mileage in the United States. Specifically, the NHS includes the following subsystems (note that in a few cases a specific highway route may be on more than one subsystem):

1. Interstate. The current Interstate system of highways retains its separate identity within the NHS. There are also provisions to add mileage to the existing Interstate subsystem.

2. (Selected) Other Principal Arterials (OPA). These are selected highways in rural and urban areas that provide access between an arterial and a major port, airport, public transportation facility, or other intermodal transportation facility.

3. Strategic Highway Network (STRAHNET). This is a network of highways that are important to the United States' strategic defense policy and which provide defense access, continuity, and emergency capabilities for defense purposes. In Illinois, the STRAHNET is the entire marked Interstate system (including toll facilities marked as Interstate routes).

4. Major Strategic Highway Network (STRAHNET) Connectors. These are roads and highways that provide access between major military installations and highways that are part of the Strategic Highway Network (Interstate system).

5. Major Intermodal Connectors. These are selected streets and highways (primarily in urban areas) that provide access between another NHS designated route (Interstate or OPA) and a designated major port, airport, public transportation facility, freight facility, or other intermodal transportation facility.

The NHS (with the exception of the major intermodal connectors) was approved by the *National Highway System Designation Act* in 1995. As of January 1, 1997, the major intermodal connectors are pending formal approval.

To properly manage the NHS, ISTEA initially mandated that each State highway agency develop and implement several management systems and one monitoring system for those facilities on the NHS. These include management systems for pavements, bridges, traffic congestion, safety, public transportation facilities/equipment, traffic monitoring, and intermodal transportation facilities/systems. However, the *NHS Act* of 1995 has relaxed the requirements for these management systems.

43-3.02 Surface Transportation Program

The Surface Transportation Program (STP) is a block-grant program that provides Federal funds for any public road not functionally classified as a rural minor collector or a rural or urban local road/street. The basic objective of the STP is to provide Federal-aid for improvements to facilities not considered to have significant national importance and to minimize the Federal requirements for funding eligibility. The Federal funds allocated to the STP are comparable to those funds previously designated for use on the former Federal-aid primary, Federal-aid urban, and Federal-aid secondary systems. The functional classification of a route is a major factor in determining eligibility for Federal-aid. In addition, bridge projects are eligible for STP funds on any public road. Transit capital projects are also eligible under the STP program.

43-3.03 Highway Bridge Program

The Highway Bridge Program (HBP), formerly known as the Highway Bridge Rehabilitation and Replacement Program, provides funds for eligible bridges located on any public road. The HBP is the cornerstone of FHWA's efforts to correct, on a priority basis, deficient bridges throughout the nation.

HBP funds can be used for total replacement or for rehabilitation. HBP funds can also be used for a nominal amount of roadway approach work to tie the new bridge in with the existing alignment or to tie in with a new gradeline. HBP funds cannot be used for long approach fills, causeways, connecting roadways, interchanges, ramps and other extensive earth structures.

43-4 HIGHWAY JURISDICTIONS

The network of public highway and streets in Illinois has been divided into several jurisdictional systems: —the State, County, Municipal, and Township/Road District highway systems. Jurisdiction is defined as the authority and obligation to administer, control, construct, maintain, and operate a highway subject to the provisions of the *Illinois Highway Code*.

Jurisdictional transfers are usually initiated by an agency that identifies a need for an improvement of a specific roadway or structure; however, certain transfers of jurisdiction can occur without an improvement. Negotiations for a jurisdictional transfer of State unmarked routes should begin when an improvement is being formulated and should be documented with a letter of intent (accepting or refusing the jurisdictional transfer) and signed by the local agency. Subsequently, a Joint Agreement with all affected agencies (State, county, and/or municipality) must be executed before the jurisdictional transfer occurs. For more information, refer to Section 14 of the Office of Planning and Programming's "Multi-Year Guidelines" (updated annually), the Central Bureau of Local Roads and Streets' publication, *Jurisdictional Transfer Guidelines for Highways and Street Systems*, and Chapter 5 of the *BDE Manual*.

43-4.01 <u>State Highway System</u>

The State highway system consists of all highways under the jurisdiction of the Illinois Department of Transportation. This system contains all Interstate highways, all other marked State and US routes, and some unmarked routes. In general, the marked routes are the most important highways in the State, carry the greatest traffic volumes, and operate at the highest speeds. The Department uses either a combination of Federal funds and State funds or State-only funds for improvements on the State highway system.

43-4.02 <u>County Road System</u>

The county governments are responsible for all roads within their boundaries that are not on the State or township/road district highway systems and are not the responsibility of the incorporated municipalities within the county. IDOT is responsible for administering Federal funds that are available for highway improvements on eligible county routes and the rehabilitation of bridges carrying county roads over the State system. The maintenance responsibilities for these structures can vary and depends on the terms of the structure maintenance agreement.

43-4.03 <u>Municipal Street System</u>

The municipal system includes public roads and streets within the corporate limits of municipalities, except those on the Federal, State, county and toll highway systems. The extension of these routes outside the corporate limits, but still within an urbanized or small urban area, is the responsibility of the county. IDOT is responsible for administering Federal funds that are available for improvements on eligible municipal streets.

43-4.04 Township/Road District System

The township/road district system consists of all remaining rural (outside corporate limits and outside urban area boundaries) routes, excluding other jurisdictions described in Section 43-4.05.

43-4.05 Other Systems

These include other private routes under the jurisdiction of other State agencies (e.g., Illinois Department of Natural Resources), Federal agencies, and the toll authorities or toll commissions. A route may also have joint jurisdictional responsibility (e.g., county and State).

43-5 NATIONAL TRUCK NETWORK

43-5.01 National Legislation

The *Surface Transportation Assistance Act* (STAA) of 1982 required the U.S. Secretary of Transportation, in cooperation with the State highway agencies, to designate a national network of highways to allow the passage of trucks of specified minimum dimensions and weight. The objective of the STAA was to promote uniformity throughout the nation for legal truck sizes and weights on a National Truck Network. The Network includes all Interstate highways and significant portions of the former Federal-aid primary system (before the 1991 ISTEA) built to accommodate large-truck travel. In addition, the STAA required that "reasonable access" be provided along other designated routes for STAA vehicles to travel from the National Truck Network to terminals and to facilities for food, fuel, repair, and rest and, for household goods carriers, to points of loading and unloading.

43-5.02 State Legislation

As a result of STAA, the Illinois legislature passed Public Act 83-12, which permits larger and heavier trucks on Illinois highways. As a result, a "Designated State Truck Route System for Large Vehicles and Combinations" was developed and implemented. This system governs the mobility and accessibility of these vehicles and is illustrated on a State map issued annually by the Central Bureau of Operations.

In 1995, additional State legislation was passed governing the length of tractor/semitrailer units. This legislation allows even longer trucks on most State highways. See Section 36-1 for the critical design vehicles corresponding to the appropriate truck route classes within the Designated State Truck Route System.

Chapter Forty-four

RURAL AND URBAN FREEWAYS

Freeways are functionally classified as Principal Arterials and are constructed with full control of access. Freeways are intended to provide high levels of safety and efficiency in moving high volumes of traffic at high speeds. The operational efficiency, capacity, safety, and cost of the highway facility are largely dependent upon its design. Chapter 44 provides guidance in the design of freeways including specific design criteria, frontage roads, lane drops, justification for grade separations, access control along the freeway, and safety. Information that is also applicable to freeways is included in the following chapters:

- Chapter 11 discusses the procedures for determining the freeway location.
- Chapter 15 discusses interchange type and design studies.
- Chapters 31, 32, 33, 34, and 39 provide guidance on the geometric design elements that are also applicable to freeways.
- Chapter 35 provides guidelines for access control along interchange crossroads. It also discusses the procedures for preparing access control plans.
- Chapter 37 discusses the type, location, and design of interchanges.
- Chapter 38 provides guidelines on roadside safety issues that are also applicable to freeways.

44-1 GENERAL

44-1.01 Establishing a Freeway

Highways are established as freeways where they either comprise a portion of a system (e.g., National System of Interstate and Defense Highways) or where there is a need for access control over the entire or a portion of the highway. According to 605 ILCS 5/8-101 of the *Illinois Highway Code*, once it has been determined to control the access on a particular highway, it will be necessary to designate and establish the highway as a freeway. This action is initiated after the design of the freeway is approved and once approval is received on environmental reports.

When establishing a freeway, the district will need to prepare an Order Establishing a Freeway; see Chapter 12. The Order Establishing a Freeway is a legal declaration made by the Department designating a highway as a freeway and delineating the extent of the freeway. The Order contains a legal description of the freeway referenced to section corners, townships, and ranges. The Order must also include the limits along the mainline and specific limits on all crossroads at interchanges. The Order Establishing a Freeway is approved by the Secretary of the Department and attested by the Director of Program Development.

In addition to filing an Order Establishing a Freeway, the district should also consider filing a Corridor Protection Map. The procedures for this process are discussed in the *Land Acquisition Policies and Procedures Manual*.

44-1.02 Design Studies

Chapter 11 discusses the procedures for designing the freeway's alignment and profile through a corridor. When developing a freeway alignment, first determine the type and location of interchanges. Then develop the freeway alignment between the interchanges. Other factors that determine the freeway alignment include:

- the location of grade separations, including major river crossings;
- access control along the freeway and along interchange crossroads;
- topography;
- environmental restrictions; and
- property lines and right-of-way restrictions.

44-2 DESIGN ELEMENTS

44-2.01 Design Speed

Figures 44-5.A, 44-5.B, and 44-5.C provide the range of design speeds for freeways. This range is dependent upon whether the project is rural or urban, new construction or reconstruction, or if the design element can remain in place. See Figures 44-5.B and 44-5.C and Figure 50-2.B for guidance on curves to remain-in-place.

44-2.02 Alignment

Designed for high-volume and high-speed operations, freeways should have smooth-flowing horizontal and vertical alignments. Proper combinations of curvature, tangents, grades, variable median widths, and separate roadway elevations all combine to enhance safety and aesthetics of freeways. When laying out freeway alignments, consider the following guidelines:

1. Horizontal Alignment. Consider the following guidelines when laying out the horizontal alignment:

   - Use large radius curves.
   - Only use minimum radii where it is necessary due to restricted conditions.
   - Avoid alignments that require superelevation transitions on bridges or bridge approach slabs. See Section 32-3.07 for additional guidance on the location of horizontal curves near bridges.

2. Vertical Alignment. Even though the profile may satisfy all design controls, the use of minimum criteria may appear forced and angular. Therefore, with freeways, use values greater than the minimum criteria to produce a smoother, more aesthetically pleasing alignment.

3. Horizontal and Vertical Combinations. Consider the relationship between horizontal and vertical alignments simultaneously to obtain a desirable condition. Chapter 33 discusses this relationship in detail and its effect on aesthetics and safety.

4. Freeway River Crossings. During the development of freeways, the alignment may need to cross major rivers or streams. In selecting the location for a bridge site, consider the following guidelines:

   a. Crossing Angle. Cross the river at a nearly right angle to minimize the length of the main span.

   b. Bluffs. If a bluff exists adjacent to the river, attempt to locate one of the abutments on a bluff closest to the river. This will minimize the overall length of the bridge and, therefore, reduce the cost of the structure.

c. River Bends. Avoid locating the bridge on a bend in the river. Locating a bridge on a bend may result in unnecessarily long spans and may increase the chance of the main river piers being hit by barges.

d. Freeway Alignment. Examine how the freeway alignment will tie into the ends of the bridge. Approach horizontal and vertical alignments can significantly improve the aesthetics of the bridge location. Make every effort to avoid placing horizontal curves and superelevation transitions on the bridge.

e. Foundation Conditions. Investigate the soil conditions at each bridge abutment and the depth of bedrock at each pier location. Poor foundation conditions may limit possible bridge sites.

f. Existing Structures. Existing structures may limit the location of a new bridge. Provide sufficient separation between structures to avoid logjams during spring flooding, ice jams in the winter, accommodate barge traffic, and ease construction.

g. Environmental Considerations. Avoid or minimize environmentally or historically sensitive areas wherever practical in conjunction with the above guidelines.

5. Interchanges. When developing the alignment and profile of freeways near proposed interchanges, see Section 37-2.14 for detailed guidelines.

6. Climbing Lanes. For most freeways, climbing lanes will not be warranted. However, if the drop in the level of service is significant, a climbing lane may be required. Section 33-3 discusses the warrants and design criteria for climbing lanes.

44-2.03 Cross Sections

44-2.03(a) Lane and Shoulder Widths

Section 44-5 provides the minimum lane and shoulder widths for freeways. Under very restricted conditions and with an approved design exception, the designer may consider the following:

1. Widths. Lane widths of 11 ft (3.3 m) may be acceptable for reconstruction projects.

2. Shoulders to Travel Lanes. Converting shoulders to travel lanes for additional capacity through short sections may reduce congestion-related crashes. However, converting shoulders to travel lanes for several miles (kilometers) generally does not reduce crashes. Where shoulders are converted to travel lane(s), use of the left shoulder is preferable to the right shoulder.

3. Shoulder Widths. Where reduced shoulder widths are provided, consider incorporating the following mitigation factors:

- adding advisory and regulatory signing,
- constructing frequent emergency pull-outs,
- using changeable overhead message signs,
- providing continuous lighting,
- incorporating truck-lane restrictions, and/or
- setting up dedicated service patrols and other incident management measures.

44-2.03(b) Typical Sections

Figures 44-2.A through 44-2.F illustrate typical cross sections for various freeway designs. Figure 44-2.G illustrates two options for converting a freeway from two lanes in each direction to four lanes in each direction.

44-2.04 Medians

44-2.04(a) General

Freeway medians should be as wide as economic, operational, and environmental considerations will permit. See for Section 34-3 for guidance on medians. Freeways generally have depressed medians in rural areas and in urban areas where right-of-way is restricted, flush medians with concrete barriers. Section 44-5 provides the minimum median width criteria for freeways. Median widths of 100 ft (30 m) or more allow for the development of independent alignments.

For reconstruction projects with narrow medians, a median barrier usually will be required between the roadways. See Section 38-7 for guidelines for median barrier selection and warrants.

44-2.04(b) Median Crossovers

Permanent crossovers are only provided on freeways for emergency and/or maintenance purposes. During the development of the design study, the district should coordinate with the Bureau of Operations, the State Police, and the district maintenance personnel to determine where crossovers will be required. For guidance on determining the location and design of crossovers, see the Bureau of Operations *Manual of Maintenance Policies*.

For guidance on retaining construction median crossovers, see Section 55-2.12.

44-2.05 Frontage Roads/Service Drives

44-2.05(a) General

A frontage road is a public street or road, adjacent to, and normally located parallel to a freeway or expressway and connected to a public street or road at both ends. Its purpose is to maintain local road continuity and to provide for controlling of access. Frontage roads serve numerous functions, depending on the type of facility served and the character of the surrounding area. They may be used to control access to the facility, to function as a street serving adjoining property, and to maintain circulation of traffic on each side of the freeway. Frontage roads segregate local traffic from the higher speed through traffic and serve driveways of residences and commercial establishments along the freeway. Connections between the freeway and frontage roads are provided at interchanges. Thus, the flow of the freeway traffic is unaffected by subsequent development. To determine the location of frontage roads at crossroads, see Figures 44-3.B and 44-3.D, Chapter 36, and the access control figures in Chapter 35.

Service drives, as opposed to frontage roads, connect with a public street or road at one end only and normally are constructed to provide access to properties that would otherwise be landlocked or denied access. Service drives adjacent to freeways are usually constructed when an investigation reveals that the cost of construction and right-of-way is less than the cost of mitigation of damages to the properties. Because maintenance of a service drive may become the responsibility of the State, maintenance costs will also need to be considered in the economic analysis.

44-2.05(b) Design Criteria

The selection of the appropriate design criteria is based on the type and ADT of the frontage road, see Figures 44-2.H and 44-2.I. Once the frontage road type has been determined, the appropriate design speed, lane and shoulder widths, etc., can be selected. When designing the frontage road alignment, consider the following:

- In rural areas, design the horizontal curvature according to Chapter 32.
- In urban areas, design the horizontal curvature according to Chapter 48.
- Where horizontal curves approach and tie into a crossroad, see the guidelines in Section 36-1.05(b) for reducing the superelevation rate near the intersection.

For service drives, the design functional classification should be a local road or street. For service drives where the current ADT is 10 or less and the drive serves a single property, a minimum surface width of 12 ft (3.6 m) may be used. Where the ADT is greater than 10 or the drive serves more than one property or is relatively long, consider providing a surface width of 16 ft (5.0 m) or wider to permit passing of opposing vehicles. A roadway surface of a higher type than typically used may be provided when replacing an existing facility in kind.

GEOEMTRIC DESIGN CRITERIA FOR URBAN FRONTAGE ROADS
(New Construction/Reconstruction)
(Metric)

Figure 44-2.I

(1) Design Speed. To determine the minimum design speed to remain in place, see Section 45-2.02.

(2) Remain In Place. Minimum design criteria allowed to remain in place for existing design elements are shown in parenthesis.

(3) Clear Zone. The clear zone will vary according to design speed, traffic volumes, side slopes, and horizontal curvature.

(4) Ditch Bottom Width. Provide a wider outside ditch bottom where detention storage of storm water is a consideration.

(5) Back Slope. Where the height of cut exceeds 10 ft (3 m), consider using a 1V:2H back slope beyond the clear zone. Also, for heights greater than 30 ft (9 m), consider the use of benching.

(6) Fill Slope. For fill heights greater than 30 ft (9 m), use a 1V:2H uniform slope with a roadside barrier. Also, for heights greater than 30 ft (9 m), consider the use of benching.

(7) New and Reconstructed Bridge Widths. Clear roadway bridge widths are measured from face to face of parapets or rails. Bridge widths are normally defined as the sum of the approach traveled way width and the width of the paved shoulders.

(8) Existing Bridge Widths to Remain in Place. Clear roadway bridge widths are measured from face to face of parapets or rails. Implies elements allowed to remain in place without a design exception approval when cost effective and when safety record is satisfactory.

(9) Vertical Clearance (Frontage Road Under).

a. The clearance must be available over the traveled way and any paved shoulders.
b. Table value includes allowance for future overlays.

GEOEMTRIC DESIGN CRITERIA FOR RURAL/URBAN FRONTAGE ROADS
(New Construction/Reconstruction)

Footnotes to Figures 44-2.H and 2.I

44-2.05(c) One-Way/Two-Way

Two-way frontage roads are used in suburban or rural areas where the adjoining street system is so irregular or so disconnected that one-way operation would introduce considerable added travel distance and cause undue inconvenience. Two-way frontage roads are also used in many urban situations.

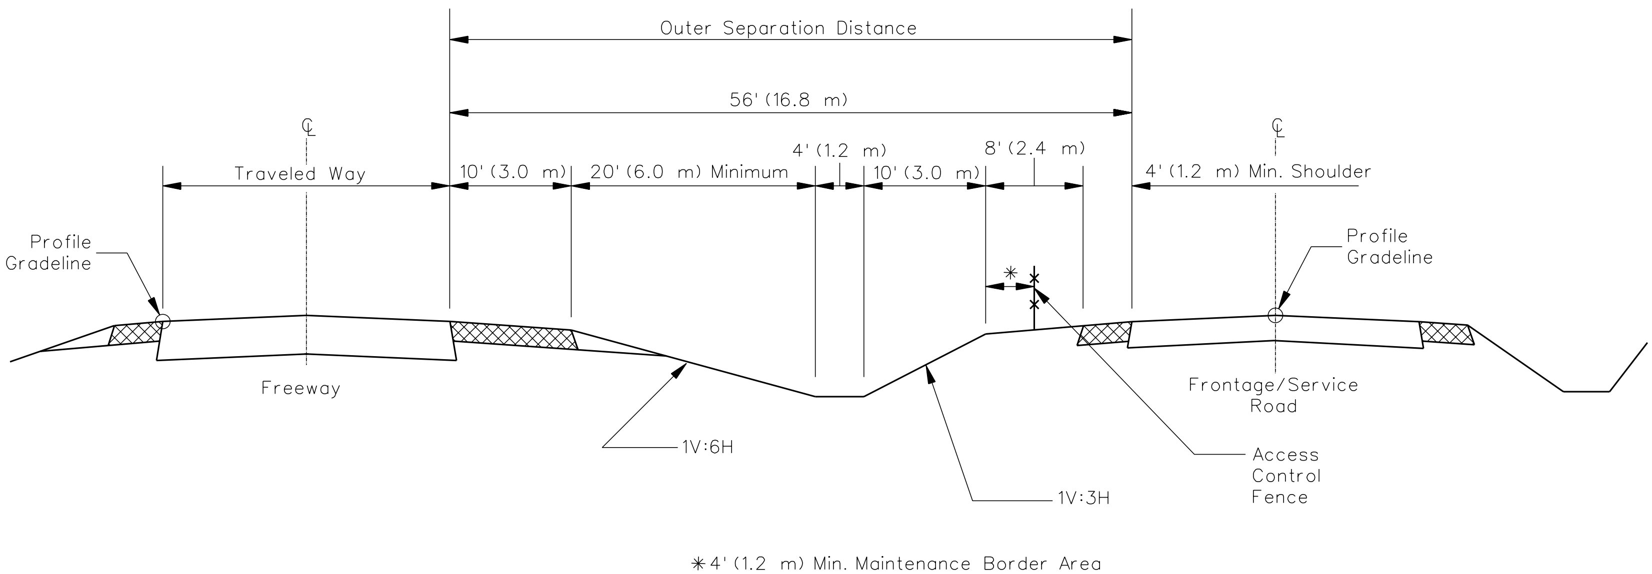
From an operational and safety perspective, one-way urban frontage roads are preferred to two-way. One-way operations may inconvenience local traffic to some extent, but the advantages in reducing vehicular and pedestrian conflicts at intersecting streets often fully compensates for this inconvenience. Two-way frontage roads at high-volume, urban intersections may complicate crossing and turning movements. Off ramps (e.g., slip ramps) joining two-way frontage roads should not be used because of the potential for wrong-way entry. See Section 37-5.02 for the design of one-way frontage roads with slip ramps.

44-2.05(d) Outer Separation

The area between the traveled way of the freeway and a frontage road or street is designated as the outer separation distance. This separation functions as a buffer between the through traffic on the freeway and the local traffic on the frontage road. This separation also provides space for shoulders, drainage, and ramp connections to or from the through facility where slip ramps are used. The wider the outer separation, the less influence local traffic will have on the freeway through traffic. Wider separations also lend themselves to landscape treatments that enhance the appearance of both highways and the adjoining property. In urbanized areas, wide separations may also be used for noise walls or noise berms.

The width of an outer separation is based upon the sum of the shoulder widths for the freeway and frontage road, an appropriate border area, and earth slopes. On curvilinear alignments, also consider the clear zone along the outside of horizontal curves when determining the width of the border area. Figure 44-2.J illustrates a typical separation between a rural freeway and frontage road where both roadways have the same profile elevation. The width of this outer separation would have to be increased accordingly for differences in roadway profile elevations. Figure 44-2.K illustrates two typical separations between an urban freeway and a frontage road.

At interchanges, connect the frontage road with the crossroad outside of the access control limits as shown in Chapter 35. For grade separated crossings, the frontage road is typically flared out to account for geometric restrictions (e.g., sight distance restrictions, embankments). This design is illustrated in Figures 44-3.B, 44-3.D, and 36-1.F. Figure 36-1.G also illustrates where the frontage road passes under the crossroad and is connected to the crossroad with a buttonhook design.



Note: Both roadways are assumed to be at the same profile elevation.

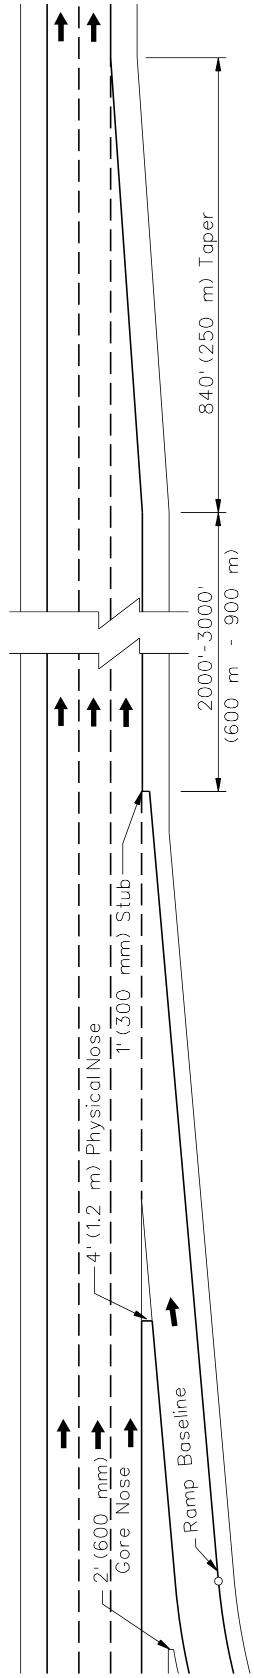
TYPICAL CROSS SECTION FOR URBAN OUTER SEPARATION
(Restricted ROW Conditions)

Figure 44-2.K

44-2.06 Lane Drops

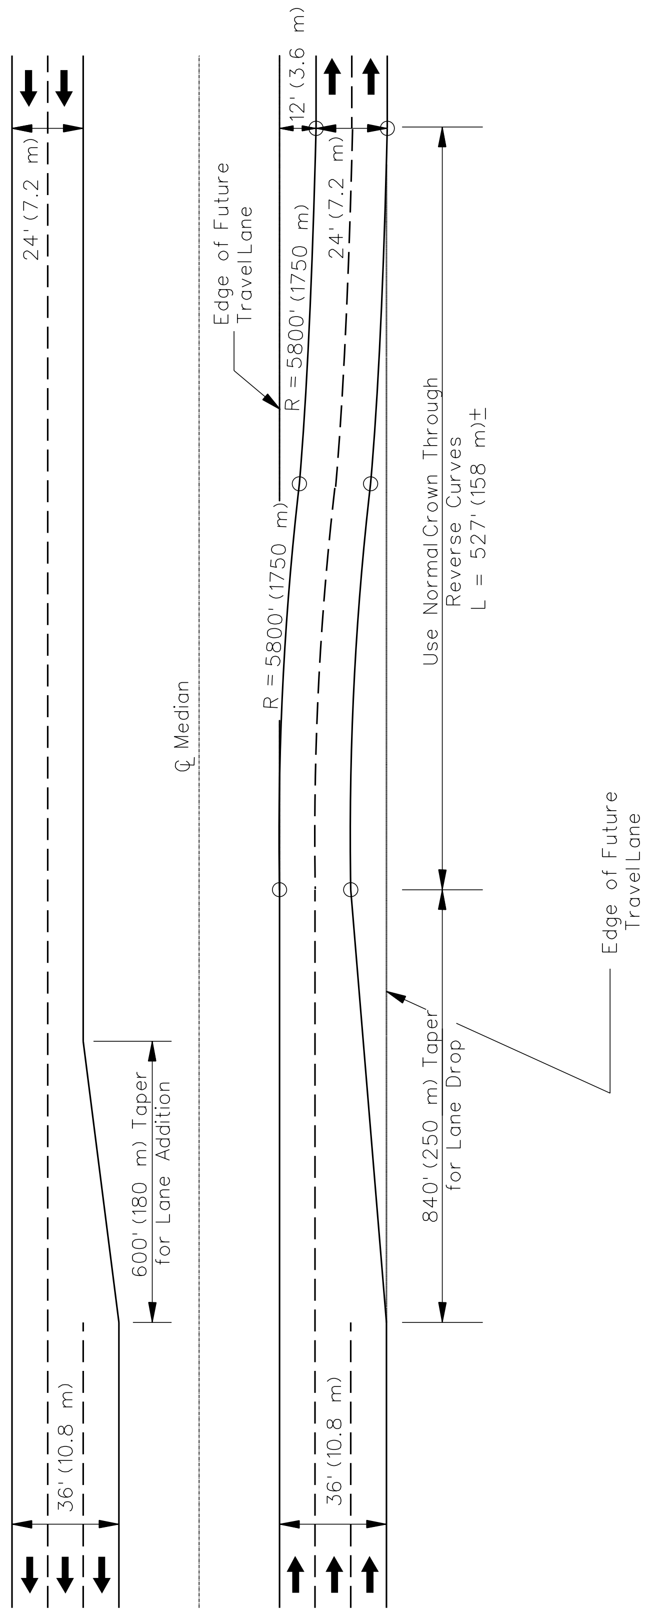
Freeway lane drops, where the basic number of lanes is reduced, should normally occur on the freeway mainline away from any other turbulence (e.g., interchange exits and entrances). Figure 44-2.L illustrates the recommended design of a lane drop beyond an interchange where there is a high probability of no additional through lanes being needed on the freeway in the near future. Where the addition of a through lane is highly likely in the near future (i.e., four to six years), consider providing a median or left-side lane drop; see Item 4 below. Because left-side lane drops do not meet normal driver expectations, provide advance supplemental signing, longer taper lengths, and 12 ft (3.6 m) wide paved left shoulders beyond the area of the proposed lane drop. In addition, consider the following criteria when designing a freeway lane drop:

1. Location. The following discusses the appropriate locations for lane drops:
    a. Rural. Desirably, the lane drop should occur approximately 2000 ft–3000 ft (600 m-900 m) beyond the end of a standard entrance terminal. This distance allows for adequate signing and driver adjustments from the interchange, but yet is not so far downstream that drivers become accustomed to the number of lanes and are surprised by the lane drop. A lane drop should not occur on a horizontal curve or where other signing is required (e.g., an upcoming exit).
    b. Urban. Where interchanges are closely spaced, it may be necessary to drop a freeway lane at an exit. This decision is made on a case-by-case basis and an evaluation of operations of the traffic volume exiting versus the through traffic volume. It is preferable to drop the freeway lane at a major divergence or two-lane exit rather than at a single-lane exit. Lane drops at exit ramps are further discussed in Section 37-6.
2. Tapers. The minimum taper length at the end of a lane drop is 840 ft (250 m).
3. Sight Distance. Decision sight distance (DSD) should be available to any point within the entire lane transition. See Section 31-3.02 for applicable DSD values. This criterion would favor, for example, placing a freeway lane drop within a sag vertical curve rather than just beyond a crest or at a location where the freeway lies on an upgrade.
4. Right-Side versus Left-Side Drop. Right-side freeway lane drops are preferred due to the merging of slower vehicles and normal driver expectations. In the situation where the left lane is to be continued in the median in the future, the right-side lane drop is still preferred. In this case, the mainline is designed for a right-side lane drop and the traveled way is shifted through a set of flat reverse curves. Figure 44-2.M illustrates this design.
5. Shoulders. Maintain the full-width right shoulder through a right-side lane drop. If a left-lane drop is used, maintain the full 10 ft or 12 ft (3.0 m or 3.6 m) paved left shoulder for a distance of 350 ft (100 m) beyond the lane drop. This will provide a recovery area for those drivers who missed the lane drop.
6. Lane Addition. Figure 44-2.M illustrates a typical example for adding a lane to a freeway.



TYPICAL FREEWAY LANE DROP
(Right Side)

Figure 44-2.L



TYPICAL FREEWAY LANE DROP AND ADDITION
(Median Lanes to be Continued in the Future)

Figure 44-2.M

44-2.07 Roadside Safety

Chapter 38 discusses the design of clear zones, roadside barriers, breakaway sign supports, median barriers, and impact attenuators that are also applicable to freeways. In addition, the following criteria will apply to freeways:

1. Curbs. Curbing should not be used on freeways. However, where deemed necessary, only use M-4.24 (M-10.60) curb and gutter. Do not locate the curb and gutter any closer than the outer edge of the shoulder.

2. Utilities. Utility easements running parallel to the freeway should be outside the access control line. Generally, provide access to these easement strips from outside of the freeway right-of-way. This includes both the freeway mainline and ramps.

3. Landscaping. Proper landscaping of the freeway can contribute to the safe operation of the freeway by indicating changes in road and ramp alignments, reducing glare from oncoming vehicles, and controlling snow drifting. Plan the landscaping so that when it matures it will not become an obstacle itself or will not restrict sight distance.

44-2.08 Branch Connections/Major Forks

Where two freeways diverge or converge, a major divergence or convergence design will be required. Section 37-6 provides the design criteria for major diverges and converges.

44-2.09 Overhead Signing

Proper interchange operations depend partially on the compatibility between its geometric design and the traffic control devices at the interchange. Freeway signing should be planned concurrently with the geometric design. The proper application of signs and pavement markings increases the clarity of the path to be followed and the safety and operational efficiency of the freeway. For many freeways, overhead signing is used to increase this clarity. Due to sight distance limitations and spacing logistics, signing along a highway segment also impacts the minimum acceptable spacing between adjacent interchanges. Section 37-2.16 provides minimum distances between interchange terminals based on operational and signing requirements. For additional information on the use of overhead signing, the designer should review the *Illinois MUTCD* and/or contact the Bureau of Operations.

44-3 OTHER DESIGN FEATURES

44-3.01 Access Control

44-3.01(a) General

A controlled access highway is defined as a highway where the right of owners or occupants of abutting land to access, light, air, or view, in conjunction with a highway design, is controlled by a public authority. For freeways, the access is controlled by the Department and is limited to interchanges. Direct access to property along the freeway is prohibited. Indirect access may be provided to these properties by means of frontage or service roads constructed adjacent and parallel to the freeway or by existing roads that intersect other public roads, which then connect to an interchange. Section 37-1 discusses the Department's criteria for adding or changing access points (interchanges) along the freeway.

44-3.01(b) Access Control Line

The extent of access control on any freeway is indicated by the access control line. This line is placed on the access control plans included with a Phase I engineering report and on the right-of-way and construction plans. It clearly delineates the extent of access control and provides a permanent record. The access control line is defined as a line established by the Department across which ingress to or egress from a freeway is prohibited. This line is generally coincident with or parallel to the right-of-way line of the normal roadway section and is continuous along the freeway. The access control line must assume various configurations at grade separation structures and bridges and, is extended along those highways interchanging with the freeway. Access control along the crossroad provides for smooth flow of traffic and proper signing distances. The following access control criteria will apply to freeways:

1. Interchanges. Chapter 35 presents the Department's access control criteria along interchange crossroads.

2. Grade Separated Structures. The access control lines at grade separation structures (without an interchange) must be located to permit the movement of traffic over or under the freeway and preclude direct access to the freeway. The locations of access control lines at grade separation structures are indicated in Figures 44-3.A through 44-3.F.

3. Bridges and Culverts. The location of the access control line at bridges and at culverts, having a clear height of 6 ft (1.8 m) or greater or a definite stream channel will necessitate fencing being installed around the culvert wing wall. This is illustrated in Figure 44-3.G. Where the culvert has a clear height less than 6 ft (1.8 m) and no definite stream channel, the access control line is continuous as illustrated in Figure 44-3.H.

44-3.02 HOV Lanes

44-3.02(a) General

High occupancy vehicle (HOV) lanes are those dedicated, for a portion of the day, to provide priority treatment for HOV's (e.g., carpools, vanpools, buses). HOV facilities provide efficiencies for maximizing person flow while minimizing overall person delay. Therefore, in general, HOV lanes are congestion-dependent improvements and produce substantial benefits where extreme congestion occurs regularly on freeways. HOV facilities should be considered in these situations to encourage motorist to shift from single occupancy vehicles (SOV) to high occupancy vehicles.

Management of HOV operations may be accomplished by a range of technological and manpower means. The level of control needed will depend upon the user demand, system size, HOV lane type, geometric design, hours of operation, and operational costs. Surveillance, communications, and control are vital components with respect to, 2+ versus 3+ occupancy requirements, incident management strategies, and enforcement requirements. HOV facilities should be part of a complete ridesharing program that includes the provision of support facilities and programs (e.g., park-and-ride lots, park and pool lots), and information services to facilitate both bus and rideshare needs.

44-3.02(b) Types of HOV Lanes

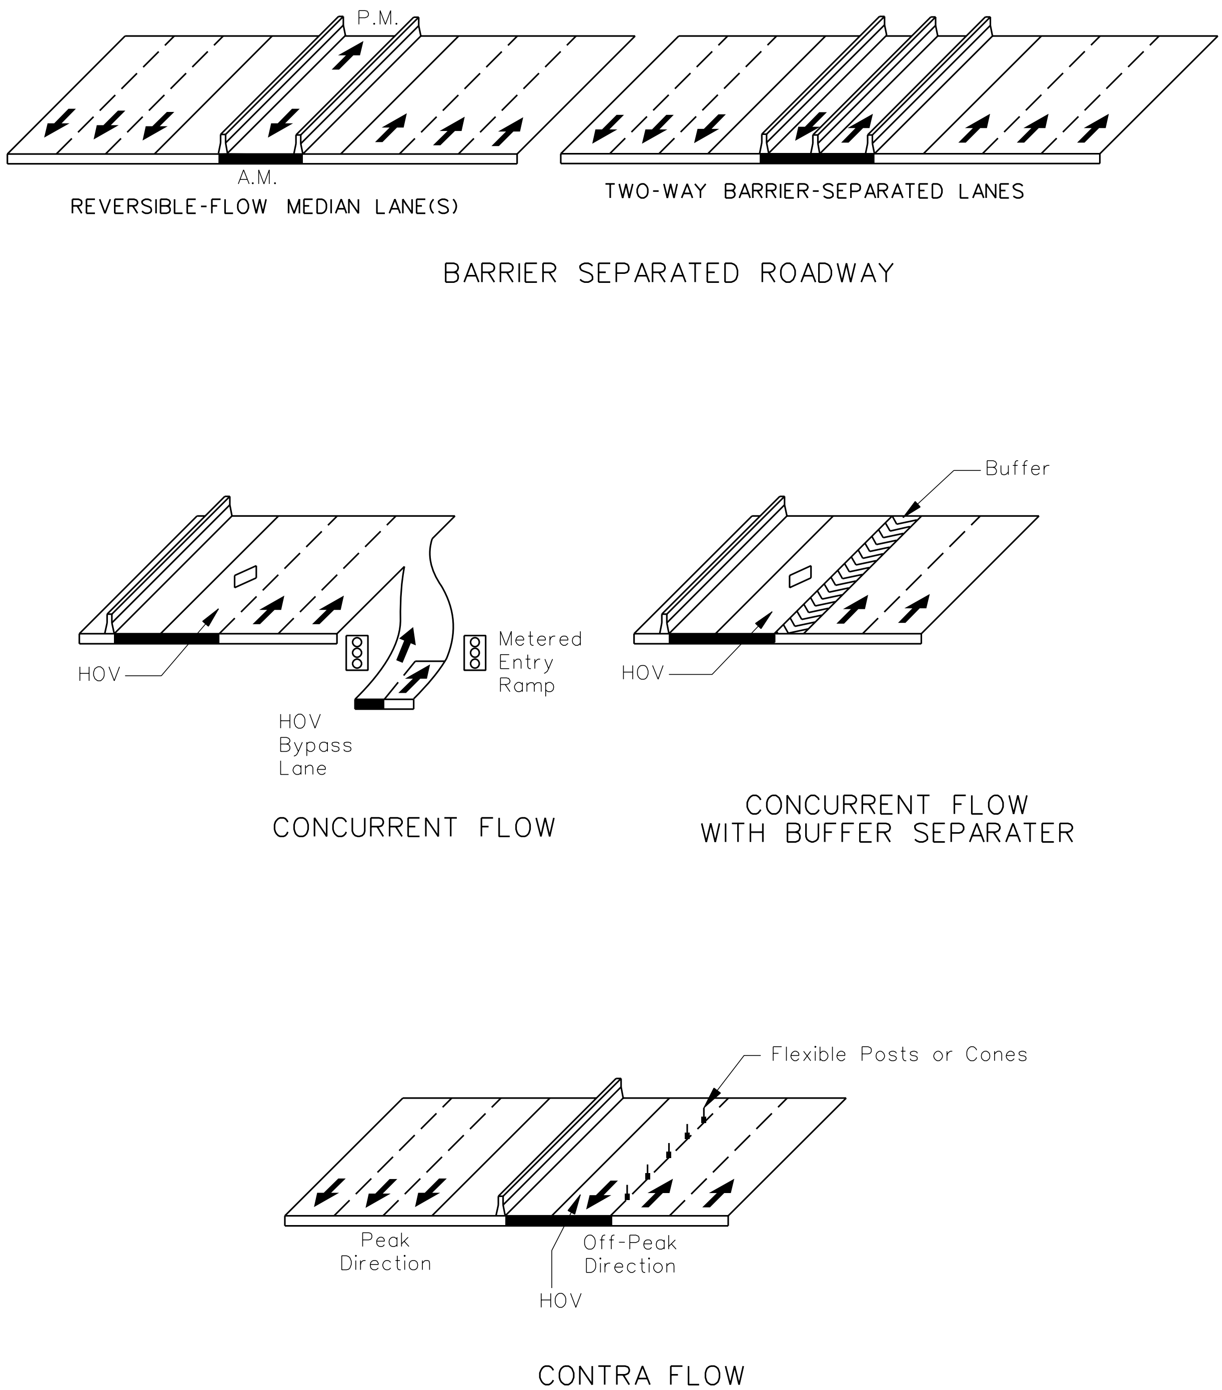
Within an existing freeway corridor, there are at least three types of HOV lanes—separated roadway, concurrent-flow lane, and contra-flow lane. These are illustrated in Figure 44-3.I and are further discussed as follows:

1. Separated HOV Roadway. Figures 44-3.J and 44-3.K illustrate separated HOV facilities. Consider the following:

    a. Location. Separated HOV roadways may be located in the median of the freeway, adjacent to the freeway, or on an independent alignment depending on available space. Consideration should be given to factors such as traffic operations in interchange areas and ramps, access to intermodal facilities, access to and from the facility, and traffic management during construction.

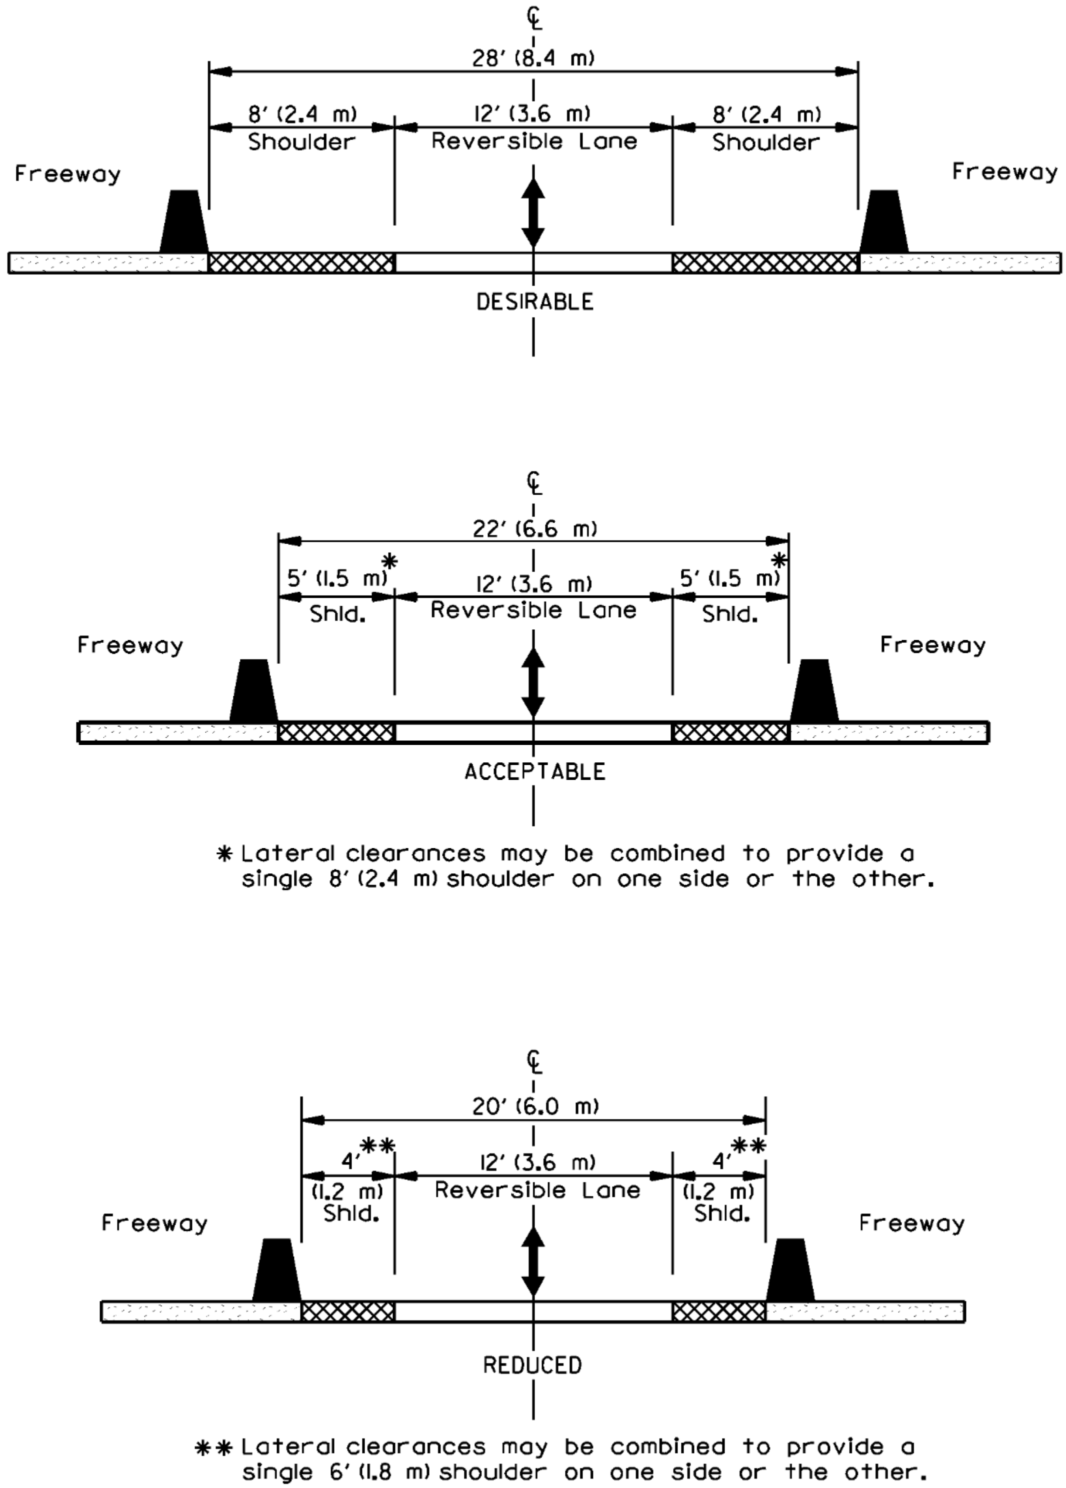
    b. Design Criteria. Design criteria for separated HOV roadways are typically high by the very nature of the commitment of funds and time to implement and are considered a long-term solution.

    c. Enforcement. The enforcement needs for a barrier-separated HOV facility can be lessened somewhat because access along the facility is largely controlled at selected breaks in the barrier, as a result, violators are deterred.



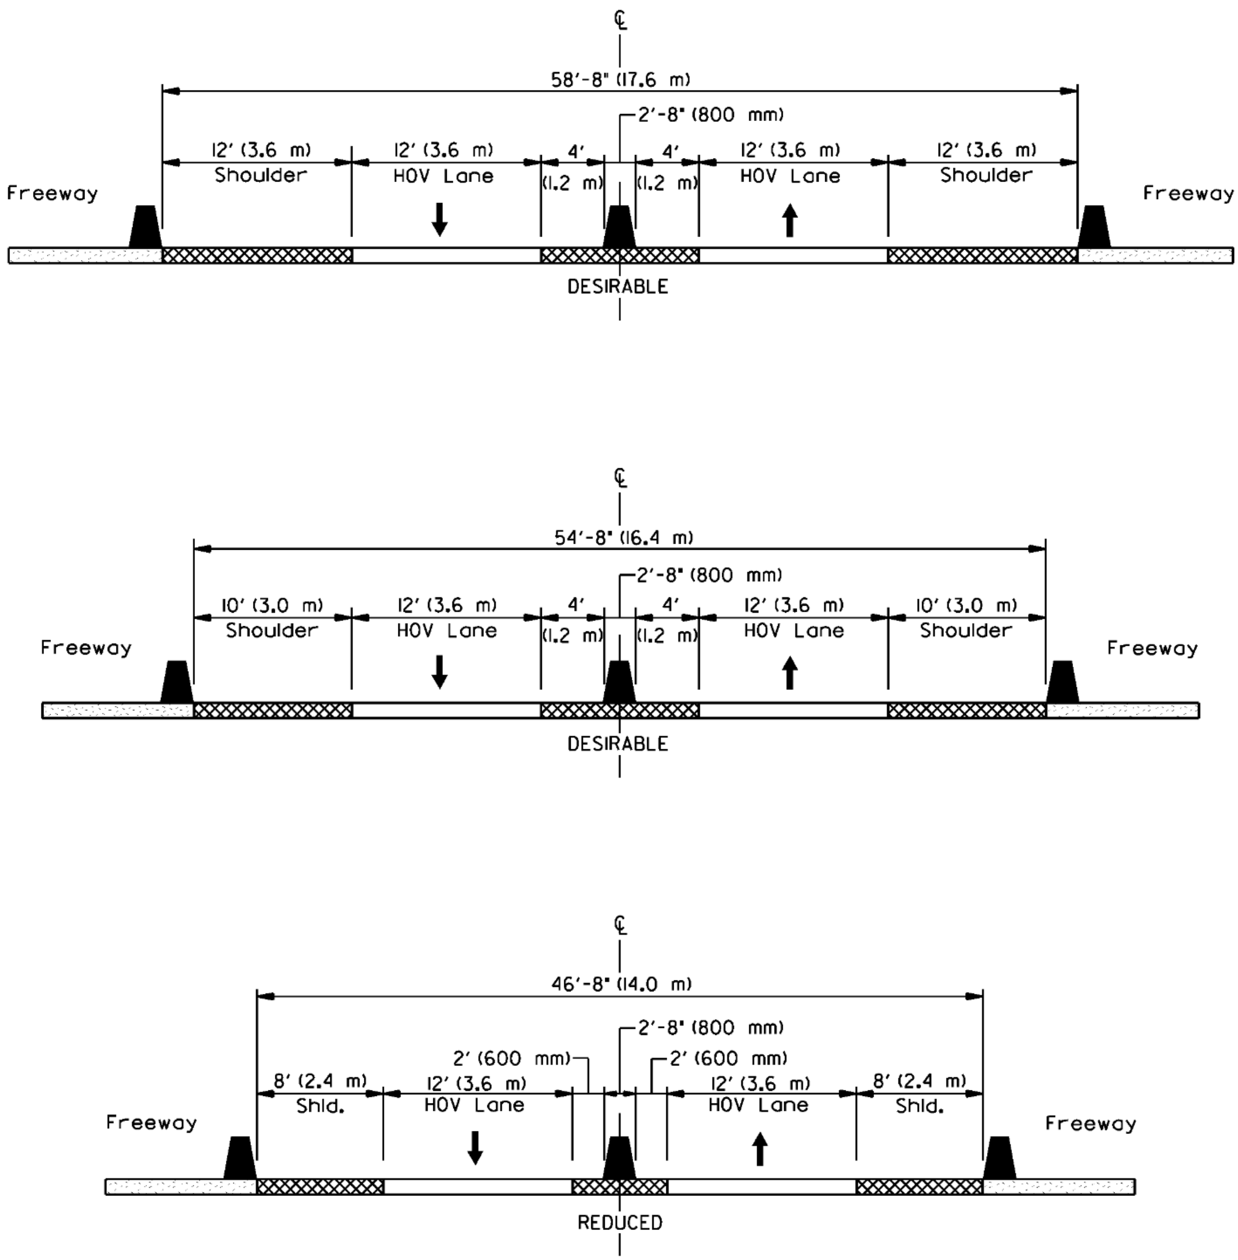
HOV CONCEPTS

Figure 44-3.I



BARRIER SEPARATED HOV FACILITY CROSS SECTIONS
(Single-Lane Reversible Flow)

Figure 44-3.J



BARRIER SEPARATED HOV FACILITY CROSS SECTIONS
(Two-Way Flow)

Figure 44-3.K

d. Access. Entering and exiting from an HOV to an interchange requires weaving across mixed-flow traffic lanes. To avoid this friction, access may be provided directly to the HOV, which can save users additional travel time. Ramps can be dropped down/up from a crossroad (low speed) or with a fly-over ramp (high speed).

2. Concurrent-Flow HOV Lanes. In contrast to barrier-separated facilities, concurrent-flow HOV lanes provide no more than a paint stripe or painted buffer adjacent to the through lanes; see Figure 44-3.L. Concurrent-flow HOV lanes can be implemented as interim retrofit by reducing the inside shoulder width and widening shoulders over time to enhance safety. Consider the following:

   a. Access. Concurrent-flow HOV lanes provide for frequent access and are suited for HOV operations that can revert back to general purpose lanes while barrier separated facilities are more applicable to 24-hour HOV operation.

   b. Enforcement. The lack of a physical barrier and ease of access increases the need for enforcement when compared to a separated HOV roadway; therefore, design treatments for enforcing concurrent flow HOV's is critical. Where a minimum 10 ft (3.0 m) wide shoulder cannot be provided contiguously adjacent to the HOV lane, enforcement will be difficult and violators may reach such proportions that HOV's may lose their time savings. Where narrow inside shoulders exist, it is possible to accommodate enforcement pockets by narrowing the median shoulder on alternating sides of the center barrier.

   c. Incident Management. Incident management for HOV's are normally handled in the same manner as applied to freeways. Narrow inside shoulders also require real-time incident response.

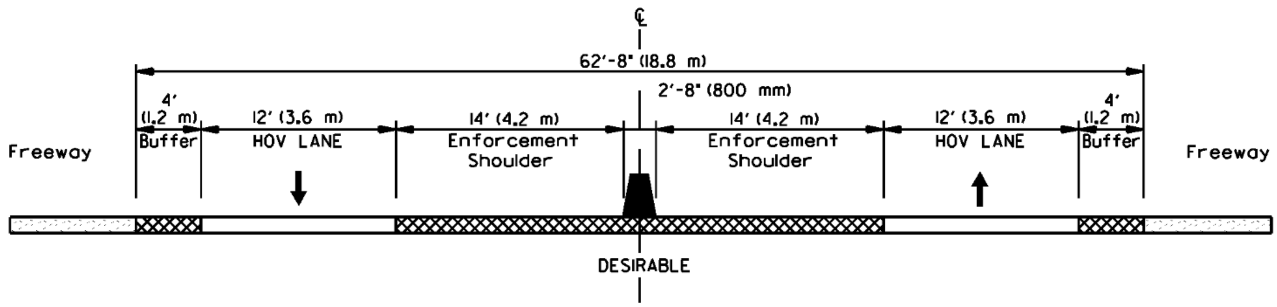
3. Contra-flow Lanes. Contra-flow lanes provide an exclusive lane for HOV's traveling in the peak direction by removing a lane from service in the off-peak direction in cases where the level of service will not be seriously affected; see Figure 44-3.I. Contra-flow lanes are often reserved for buses only; however, vanpools and taxis have been successfully introduced through special training and licensing.

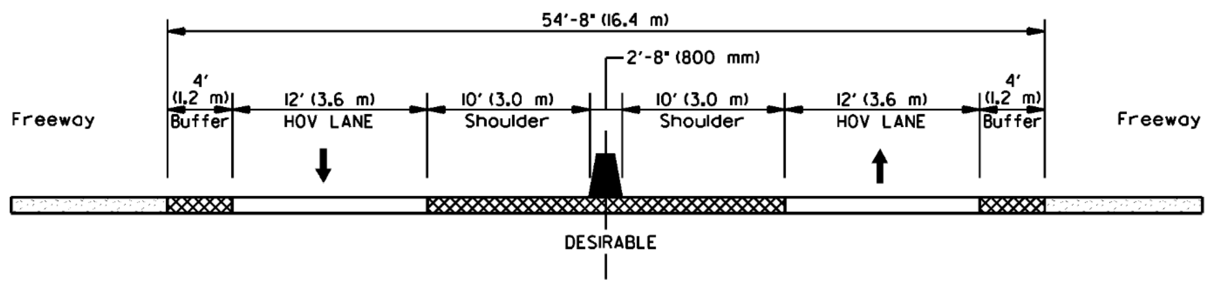
44-3.02(c) Design

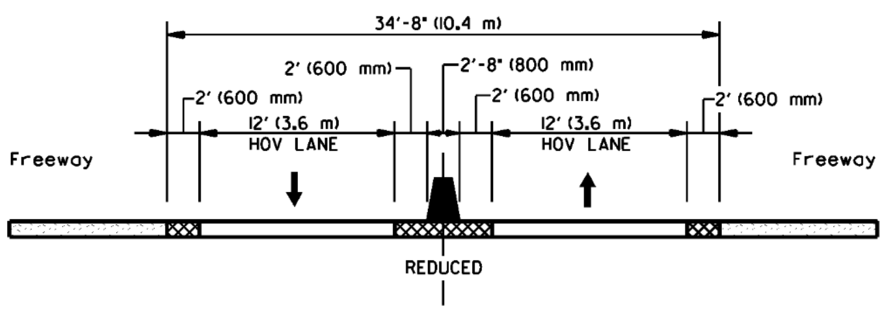
When designing HOV lanes, consider the following:

1. HOV Types. Section 44-3.02(b) discusses the common HOV types used by the Department.

2. Design Criteria. In general, the same criteria for urban freeways also apply to HOV facilities (e.g., 12 ft (3.6 m) lanes, horizontal alignment, vertical alignment, cross slopes). Urban freeway criteria are presented in Section 44-5.







BARRIER SEPARATED HOV FACILITY CROSS SECTIONS
(Two-Way Concurrent Flow)

Figure 44-3.L

3. Shoulder Widths. Where barrier separated HOV facilities are provided (e.g., two-way flow), desirably at least one shoulder next to the HOV lane should be 10 ft (3.0 m) wide for emergency stops and at a minimum 8 ft (2.4 m). At a minimum, provide 2 ft (600 mm) offset to the median barrier.

4. Sight Distance. Where concrete barrier is used to separate the HOV lanes from adjacent and/or opposing lanes, give special consideration to any sight distance restrictions that may be caused by a concrete barrier through horizontal curves.

5. Separation. Where an HOV lane is adjacent to the through freeway lanes (i.e., no median barrier), desirably provide a 2 ft to 4 ft (600 mm to 1.2 m) buffer, or spatial separation, between the HOV lane and adjacent through lane. In general, it is more desirable to provide a narrow right-side clearance between the HOV lane and the through traffic lanes plus a wide left-side shoulder than to have a wide common shoulder as the buffer. The wide left shoulder also facilitates enforcement, which is key to the success of an HOV facility.

6. Access Ramps. Access to the HOV lane will vary according to the type of HOV facility used and space available. Access may be obtained by shared ramps, dedicated access ramps, and/or slip ramps from the mainline or crossroads. In general, design HOV ramps using the same criteria as for interchange ramps. However, consider the following:

    a. Design Vehicle. The design vehicle for HOV lanes will typically be a bus. The absence of trucks may allow for narrower widths and reduced vertical clearances.

    b. Signing. Advance signing and pavement markings are critical to ensure proper operation of the HOV ramps.

7. Incident Management. Special consideration must be given to incident management to ensure the HOV facility continues to operate after an incident (e.g., crash, disabled vehicle).

8. Additional Guidance. For additional guidance on determining candidate HOV freeway segments and design of HOV lanes, see the AASHTO publication *Guide for the Design of High-Occupancy Vehicles*.

44-3.03 Lighting

Nighttime traffic volumes, nighttime crashes, and geometric complexity will significantly influence the need for freeway lighting. In addition to the following, Chapter 56 provides further guidance on highway lighting:

1. Urban. Urban freeways with closely spaced interchanges and substantially developed adjacent areas are generally illuminated. The geometric and traffic complexities are such that drivers need to detect and react to conditions 500 ft to 1200 ft (150 m to 350

m) in front of their vehicle. Also, vehicle headlamps cannot be relied on to provide adequate lateral visibility on very wide roadways.

2. Suburban. On suburban freeways without lighting, a reduction in visual sensitivity due to transient adaptation effects can also result from the spillover of lighting from adjacent development. This ambient illumination is distracting to the driver, causes veiling glare, and reduces attention to freeway signs. In areas where the surrounding areas are brightly illuminated, freeway lighting is typically warranted.

3. Rural. In rural areas, lighting is sometimes deemed justified at interchanges, especially those with complex geometry or multiple merging traffic points. Energy availability and routine maintenance costs are important factors that influence the decisions to provide a lighting system.

4. Interchanges. Because interchanges have the greatest probability for traffic conflict requiring quick driver decisions, lighting at high-density, complex freeway interchanges can be a useful tool with a high potential for crash reduction. Two designs of interchange lighting systems are commonly warranted—complete interchange lighting and partial interchange lighting. Complete interchange lighting provides considerably better driver performance and traffic operations than partial interchange lighting. Partial interchange lighting is sometimes used based on the premise that it provides some of the benefits attributable to complete interchange lighting at a lower operating cost. In partial interchange lighting, only the freeway gore area, major changes in ramp alignment, and the area where the ramp joins the crossroad are lighted.

44-3.04 Landscaping

The highway should be designed to blend into its environment, see Chapter 59. This may involve landscaping the roadside, either during the construction or later as an improvement. Proper use of landscaping can contribute to the safe operation of freeways by reducing glare from oncoming vehicles, indicating changes in road and ramp alignments, and controlling snow drift. At the same time, ensure that any additions do not sacrifice available operational and safety features. Also, consider the following guidelines:

- Locate tree and shrub plantings so that adequate sight distance will be maintained when mature growth is achieved.
- Give special consideration to selecting flora that will not mature into large or multiple trunks that can halt or snag a vehicle.
- Plant small trees at least 10 ft (3 m) away from other small trees and breakaway devices (e.g., sign supports) to reduce the possibility of a vehicle striking two objects at essentially the same time.
- Do not plant trees and shrubbery in front of barriers and other safety devices.

- Before planting trees on the inside of a curve, consider the restriction they might impose on the sight distance, especially when they mature.

44-4 INTERCHANGES/GRADE SEPARATIONS

On fully access-controlled facilities, each intersecting highway must be terminated, rerouted, or provided with a grade separation or interchange. The importance of the continuity of the crossing road, the feasibility of alternative routes, traffic volumes, construction costs, environmental impacts, etc., must be evaluated to determine which option is the most cost effective.

44-4.01 Interchanges

Section 37-1 discusses several guidelines that must be considered in determining whether or not an interchange should be provided. In general, interchanges are provided on freeways at:

- all freeway-to-freeway crossings;
- all marked highways, unless determined inappropriate; and
- other highways based on the anticipated demand for regional access.

Section 37-1 also discusses the procedures for adding or revising an interchange access point to the freeway system.

44-4.02 Grade Separations

44-4.02(a) Justification

For each crossroad along the freeway, which is not an interchange, a determination must be made whether the crossroad should be closed, rerouted, or provided with a grade separation. This justification is made primarily by comparing the respective cost and social factors for each alternative. Section 44-4.03 discusses the process for determining the feasibility of closing a facility or providing a grade separation. Although cost is a primary factor, also review the following considerations:

1. Operations. Grade separations should be of sufficient number and adequate capacity to accommodate crossroad traffic, traffic diverted to crossroads from other roads and streets terminated by the freeway, and the traffic generated by access connections to and from the mainline.

2. Rural/Urban Locations. In rural areas, the location of grade separation structures is determined by the access and feasibility study. For urban areas, usually grade separation structures are provided every three to four blocks for continuity.

3. Local Considerations. Closing the crossroad can have a significant effect on local users and the overall local road system integrity, due primarily to changes in travel patterns. These may include:

    a. School Bus Routes. The effect of a road closure on the bus route system can be two-fold. There may be an increase in the operating cost due to longer buses routes and an increase in the travel time for school children.

b. Emergency Personnel. The financial effect of the longer detour route on emergency vehicles is generally not a concern. However, the extra response time could adversely affect the health and safety of local citizens.

c. Mail Routes. Mail delivery is normally a minor consideration. Although there may be extra financial burdens, these are generally minor because most routes can be rearranged.

d. Businesses/Farms. Evaluate access to businesses and farms to ensure that these operations can continue without severe economic hardship. For businesses, the road closure can significantly affect their deliveries and the number of customers they receive (e.g., customers may be unwilling to travel the extra distance). For farmers, the road closure may require the transportation of large, slow-moving farm equipment along busy alternative facilities.

e. Social Factors. Parks, churches, cemeteries, public facilities, and other areas or buildings of social concern generally cannot be relocated. Limited access to these facilities may create undue hardship if a specific road is closed.

f. Land Use Planning. Consider future land use within a suburban environment to ensure adequate access and reciprocation factors are available.

44-4.02(b) Design

When designing grade separations, the following guidelines will be applicable:

1. Design Criteria. Section 33-5, Chapter 39, and Part V, Highway Systems, provide geometric design criteria for structures including clear roadway bridge widths, vertical clearances, horizontal clearance, shoulder widths, etc.

2. Over versus Under. The decision on whether the freeway should be over or under the crossroad is normally dictated by topography and cost. If the topography does not favor one profile over the other, use the following guidelines to decide which highway should cross over the other:

    a. Cost-Effectiveness. The designer should consider which alternative will be more cost effective to construct. Some elements to consider are the amount of embankment and excavation required, span lengths, angle of skew, gradients, sight distances, alignment, vertical clearances, constructability, traffic control, right-of-way, drainage, soil conditions, and construction costs.

    b. Classification. Select the alternative that provides the highest design level for the mainline road. Typically, the crossroad has a lower design speed and, therefore, the minor road can be designed with steeper gradients, lesser roadway widths, steeper side slopes, etc.

    c. Future Crossings. Plan future crossings and/or structures as overpasses over the mainline. Overpasses are easier to install and will be less disruptive to the freeway when they are constructed in the future.

3. Vertical Clearance. The allowable vertical clearance for rural and urban interstate projects is 16 ft 09 in for new construction/reconstruction. For urban interstates within the single routing with a 16 ft 09 in vertical clearance, 15 ft 00 in is permitted. Refer to the figures in Section 44-6 for maps of single routing in the urban areas of Peoria, the Quad Cities, the Metro-east St. Louis, and the Chicago metropolitan. See Figure 33-5.A for vertical clearance requirements. If these vertical clearances cannot be met, a design exception must be sought. Refer to Section 31-7.04(c) for directions to process a design exception for vertical clearances over interstates.

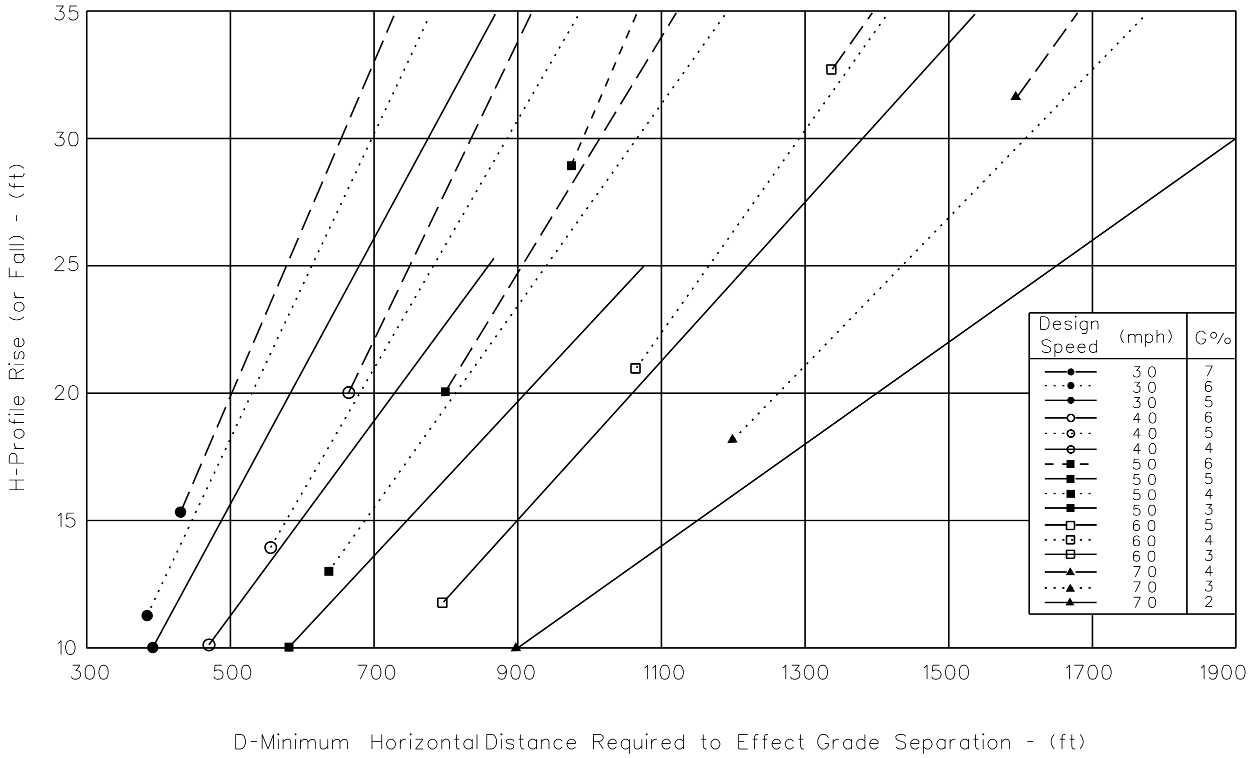
4. Horizontal Distance. The distance required for adequate design of a grade separation depends on the design speed, the roadway gradient, and the amount of rise or fall necessary to affect the separation. Figure 44-4.A can be used during Phase I to quickly determine whether a grade separation is feasible for a given set of conditions, what gradients may be involved, and what profile adjustments may be necessary on the crossroad. Also, carefully study sight distance requirements because these will often dictate the required horizontal distance along the crossroad. When using Figure 44-4.A, consider the following:

    a. Minimum Horizontal Distances. The plotted lines on Figure 44-4.A are derived assuming the same approach gradient on each side of the structure. However, values of "D" from the figure also are applicable to combinations of unequal gradients. Distance "D" is equal to the length of the initial vertical curve, plus one-half the central vertical curve, plus the length of tangent between the curves. Lengths of vertical curves are based on the stopping sight distance. However, longer vertical curves are desirable from an aesthetic and safety standpoint. Conversely, longer curve lengths may be costlier due to increased earthwork quantities. However, these additional costs may be a less important consideration if crossroads or access points exist near the grade separation structure.

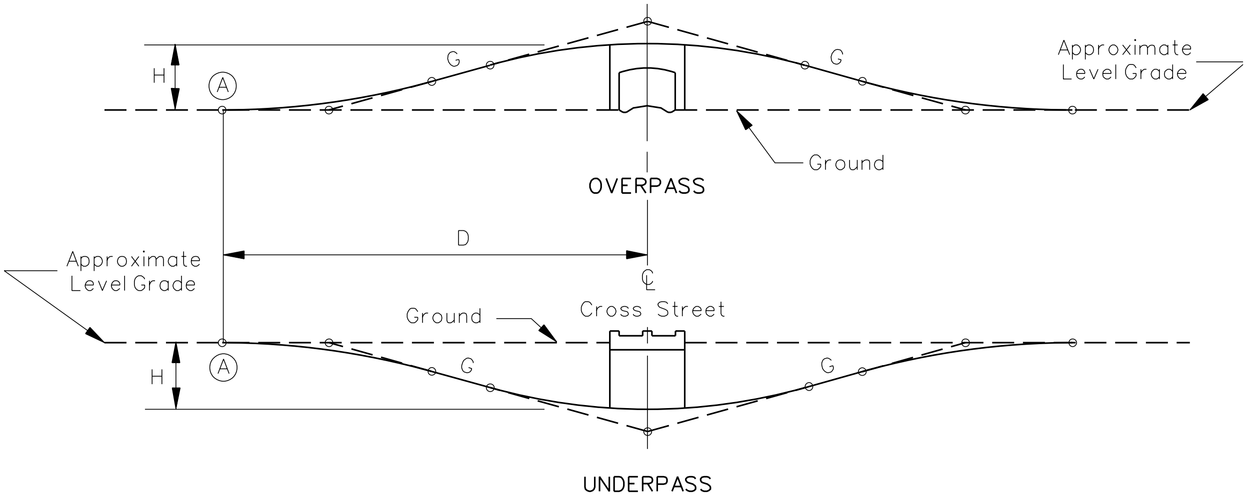
    b. Maximum Gradient. The lower terminal point of each gradient line on Figure 44-4.A, marked by a small symbol, indicates the distance where the tangent between the curves is zero and below which a design for the given grade is not feasible (i.e., a profile condition where the minimum central and end curves for the gradient would overlap).

    c. Restricted Gradients. For the usual profile rise or fall required for a grade separation ("H" of 25 ft (7.5 m) or less), do not use gradients greater than 3% for a design speed of 70 mph (110 km/h), 4% for 60 mph (100 km/h), 5% for 50 mph (80 km/h), and 6% for 40 mph (60 km/h). For values of "H" less than 25 ft (7.5 m), use flatter gradients.

    d. Relationship. For a given "H" and design speed, distance "D" is only shortened a negligible amount by increasing the gradient. However, the distance "D" varies to a greater extent for a given "H" and "G" with respect to the design speed.

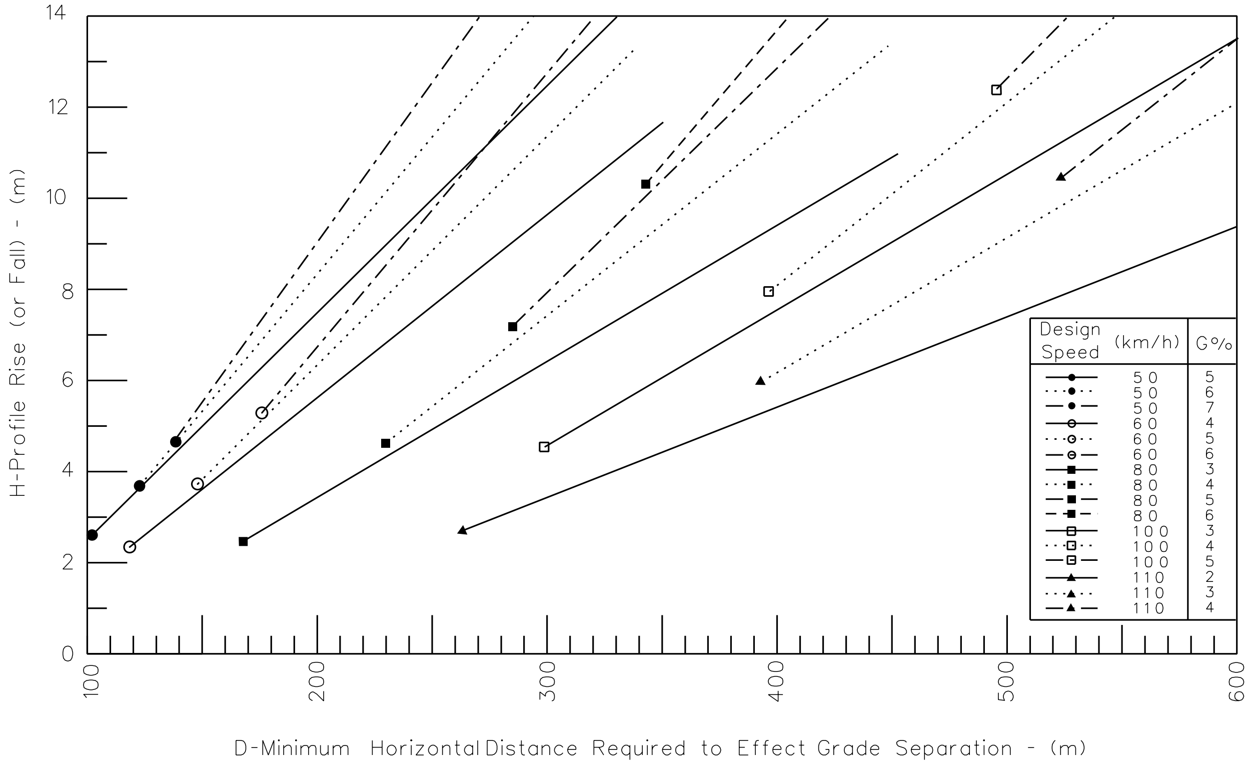


Note: Symbols on ends of lines indicate the point below which the grade is not feasible, necessitating the use of next flatter curve.

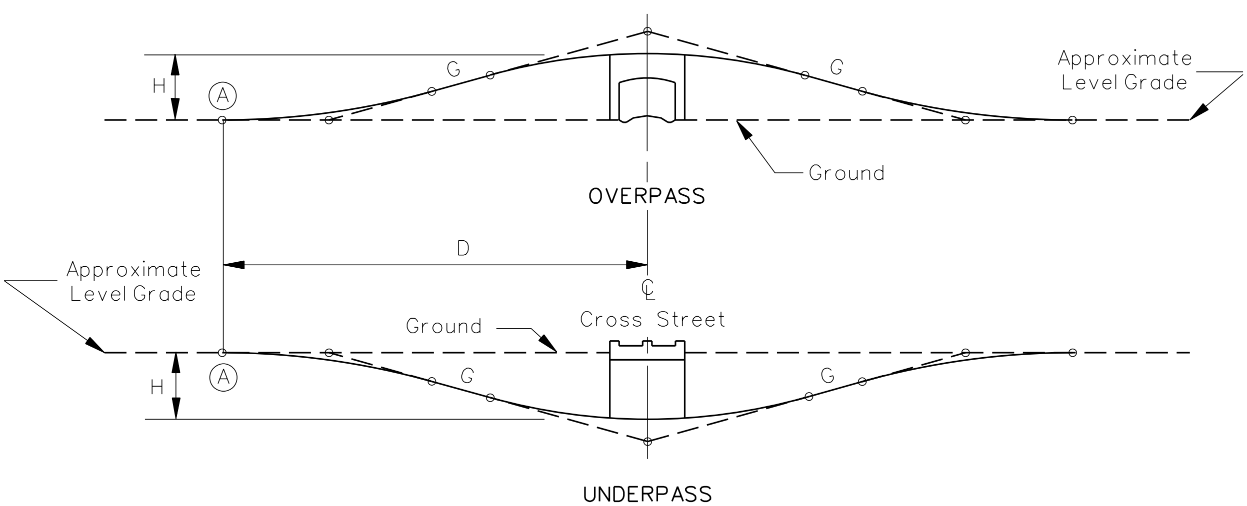


GRADE SEPARATION DETERMINATION
(US Customary)

Figure 44-4.A



Note: Symbols on each line indicate the point below which the grade is not feasible, necessitating the use of the next flatter grade.



GRADE SEPARATION DETERMINATION (Metric)

Figure 44-4.A

e. Elevation. Considering the vertical clearance and structural depth, an elevation distance of “H” is typically between 23 ft and 25 ft (7.0 m and 7.5 m) for the grade separation of two highways. “H” is typically the same for a freeway under a railroad. For a railroad facility under a freeway, “H” is typically 30 ft to 31 ft (9.2 m to 9.4 m).

f. Design Speed. To provide additional safety at rural grade separations where the crossroad passes over the freeway, consider designing the crest vertical curve with a design speed of 55 mph (90 km/h) or greater.

44-4.03 Feasibility Analysis

44-4.03(a) Procedure

When determining the feasibility of closing a crossroad or providing a grade separation on the crossroad, a cost analysis must be completed. This will include comparing the additional road user costs for closing the facility against the amortized annual cost of building a grade separation. The following steps will apply in making this analysis:

1. Data Gathering. The first step is to gather all the necessary data for the cost analysis. This includes a map showing the location of other possible crossings, traffic volumes, construction costs, unit prices, service life for various construction elements, possible detour routes, length of alternative routes, a field review of the area, and possibly meeting with farmers, businessmen, the local postmaster, and local school officials.

2. Road Closure. The cost of the road closure is based on the increase in cost for road users to travel the additional distance to reach their destination. The computation of these costs is based on traffic volumes, distribution of vehicular types (e.g., passenger cars, trucks, buses), additional detour distance, and variable operating costs. Figure 44-4.B provides a form that can be used in the road closure analysis. The following steps will apply to Figure 44-4.B:

   a. Traffic Volume/Composition. Use the latest data available for traffic volumes and vehicle composition. For local roads, this information can be obtained from the district and/or Chicago Area Transportation System. Adjust the traffic volumes for the design year (e.g., 20 years). For most analyses, the crossroad traffic will typically be the single most important element in influencing the cost analysis for grade separations.

   b. Alternative Route Distances. Determine the most practical route that will be taken and measure these distances from a local map. The most practical route will typically be obvious. However, in some cases, it may be beneficial to talk with the appropriate local officials (e.g., county officials, emergency personnel, local school district).

1. Daily Increase in Road User Costs:								$
2. Annual Increase in Road User Costs (Item 1 x 365):								$

JUSTIFICATION FOR GRADE SEPARATION STRUCTURE
(Part 1)

Figure 44-4.B

c. Road User Costs. Road user costs are based on the variable operating cost of operating a vehicle. Do not include the fixed (ownership) costs. The latest road user costs can be obtained from BDE. Variable operating costs consist of:

- nonscheduled repairs and maintenance,
- gasoline,
- oil,
- tires,
- gasoline tax (State and Federal),
- oil tax (Federal),
- tire tax (Federal), and
- parking and tolls.

d. Alternative Route Costs. The daily road user costs for the alternative route can be determined by multiplying each vehicular cost per mile (kilometer) by the distance of the detour. Do this for each vehicular type and add the total costs together.

e. Open Road Costs. Determine the daily road user costs for each vehicular type assuming the road will remain open by multiplying the distance of the existing route by the road user costs.

f. Final Costs. Determine the increase in road user costs by subtracting the non-detoured costs from the road closure costs. Multiply this number by 365 to determine the annual cost.

3. Grade Separation Structure. For comparison purposes, determine the annualized costs for constructing the grade separation. These include right-of-way acquisition, construction costs, and other mitigating items (e.g., environmental factors). Figure 44-4.C provides a form that may be used to determine these annualized costs. The following steps apply to Figure 44-4.C:

a. Base Cost. Estimate quantities or use a generalized quantity (e.g., cost per square foot (square meter) of bridge deck, cost per square foot (square meter) of pavement). Use these quantities in conjunction with the average weighted unit prices to develop the overall grade separation costs. Also, include the cost for any necessary mitigation measures (e.g., relocating businesses, environmental factors, wetland mitigation, compensatory storage) that may be involved with providing a grade separation. Chapters 12, 64, and 65 provide additional guidance in determining quantities and cost estimates for Phase I reports.

b. Service Life. Determine the service life for the various construction items. These can be found in Chapter 11.

Recommendation and Comments:

JUSTIFICATION FOR GRADE SEPARATION STRUCTURE
(Part 2)

Figure 44-4.C

c. Annual Costs. Amortization factors are based on the service life of the construction item and the assumed discount rate for capital improvements, typically 3% or 4%. Amortization factors are available in most engineering economic textbooks. Annualized costs are computed by multiplying the base or total cost of the various construction elements by the amortization factor for capital recovery.

d. Total Costs. Sum the annual costs for each element to determine the total annual cost for providing the grade separation.

4. Comparison. Compare the annual road user costs from Step 2 with the annual grade separation costs determined in Step 3. If the value from Step 3 is larger, then the grade separation is not cost effective. If the value from Step 2 is larger, than the grade separation is considered cost effective.

5. Miscellaneous Considerations. If a structure is justified based on costs, then no other analysis will be required. However, if the closure cost to road users is less than the cost of the grade separation structure, then consider the factors listed in Section 44-4.02(a).

6. Summary Sheet. Figure 44-4.D can be used to summarize the results for all the crossings of each alternative affected by the proposed freeway.

44-4.03(b) Example Problem

The following is an example calculation to determine whether to close a crossroad or provide a grade separation over a new freeway.

****

Example 44-4.1

Given: New Rural Freeway
Design Year Crossroad Traffic Volumes — 80 ADT (2022)
Traffic Distribution — 90% passenger cars, 10% SU vehicles
Existing Route Length — 1.74 miles
Alternative Route Length — 5.16 miles
Variable Operating Costs — passenger cars - $0.31/mile, SU - $1.05/mile, MU - $1.21/mile
Discount Factor — 4%
Proposed Roadway Cross Section — 20 ft traveled way, 3 in Class I Surface, 8 in Aggregate Base, 4 ft Earth Shoulders

Problem: Determine whether to close the crossroad (TR79) or provide a grade separation.

Solution: Use the procedures in Section 44-4.03(a).

FREEWAY ALTERNATIVE: ______________________

Crossroad	GENERAL CONDITIONS				COST — ROAD CLOSED			COST — ROAD OPEN		PROPOSED ACTION	
		Public Service Adversity									
	( ) ADT	Mail (mile) (km)	School Bus (no./mile) (no./km)	Emerg. Veh. (mile) (km)	Alternative Crossing	Adverse Travel (mile) (km)	Annual User Cost	Constr. Cost	Annual Cost	Recommendations	Remarks

SUMMARY OF GRADE SEPARATION/ROAD CLOSURE INVESTIGATIONS

Figure 44-4.D

Step #1: Gather data. Quantities for the grade separation are shown in Figure 44-4.F.

Step #2: Determine the cost for closing the road. These calculations are shown in Figure 44-4.E. The extra distance for the detour is 3.42 miles. The average annual cost for closing the road is $37,675.

Step #3: Determine the cost for the grade separation structure. Service lives for the various construction items can be found in Chapter 11 and are shown in the table. Amortization factors for a 4% discount rate can be obtained from an engineering economics textbook. Use the capital recovery factor. The annual cost for providing a grade separation is $38,776. These calculations are shown in Figure 44-4.F.

Step #4: Comparing the annual grade separation costs ($38,776) against the road closure cost ($37,675), the grade separation cannot be justified economically.

Step #5: The road closure would cause significant delays to school bus and emergency vehicle travel times; see Section 44-4.02(a). When considering these factors and the closeness of the annual costs (i.e., less than 5%), a grade separation can be justified for this location.

Step #6: This process would be completed for each crossroad that intersects with the freeway to determine if a grade separation structure should be provided or the road closed. The results can be summarized in a table similar to Figure 44-4.D. In some cases, it may be appropriate to propose building a frontage road or service drive between two adjacent roads.

Annual Grade Separation Cost if Road is Kept Open .... $ 38,776

Proposed Roadway Cross Section:

Recommendation and Comments:

JUSTIFICATION FOR GRADE SEPARATION STRUCTURE
(Example 44-4.1)

Figure 44-4.F

44-5 TABLES OF DESIGN CRITERIA

Figures 44-5.A, 44-5.B, 44-5.C, and 44-5.D present the Department's design criteria for freeway projects. The designer should realize that some of the cross section elements included in the figures (e.g., flush concrete barrier median) are not automatically warranted in the project design. The values in the figures only apply after the decision has been made to include the element in the highway cross section.

Design Element				Manual Section	Rural One-Way DHV: 2300 - 3400 (1) Urban One-Way DHV: 2800 – 4300 (1)	Rural One-Way DHV: Under 2300 (1) Urban One-Way DHV: Under 2800 (1)

GEOMETRIC DESIGN CRITERIA FOR FREEWAYS
(New Construction/Reconstruction)
(Metric)

Figure 44-5.A

(1) Traffic Volumes. The design hourly volumes (DHV) are calculated assuming base conditions (except for 16% heavy vehicles) and a PHF = 1.0. Adjust these values using local factors.

(2) Design Speed. In rolling terrain, a minimum design speed of 60 mph (100 km/h) may be considered with study and justification.

(3) Level of Service. In major urban areas, a level of service D may be considered with study and justification.

(4) Shoulder Width (Right). Where the directional distribution of trucks exceeds 250 DDHV, consider providing a 12 ft (3.6 m) paved shoulder.

(5) Shoulder Width (Left). Where there are three or more lanes in one direction and the directional distribution of trucks exceeds 250 DDHV, consider providing a 12 ft (3.6 m) paved shoulder.

(6) Travel Lane Cross Slope. For each additional lane away from the crown lanes, increase the cross slope by 1/16″/ft (0.5%) per additional lane up to a maximum of 5/16″/ft (2.5%).

(7) Flush Median Width. Consider providing wider medians where required for snow storage.

(8) Clear Zone. The clear zone will vary according to design speed, traffic volumes, side slopes, and horizontal curvature.

(9) Ditch Bottom Width. Provide a wider outside ditch bottom where detention storage of storm water is a consideration.

(10) Back Slope. Where the height of cut exceeds 10 ft (3 m), consider using a 1V:2H back slope beyond the clear zone. Also, for heights greater than 30 ft (9 m), consider the use of benching.

(11) Fill Slope. For fill heights greater than 30 ft (9 m), use a 1V:2H uniform slope with a roadside barrier. Also, for heights greater than 30 ft (9 m), consider the use of benching.

(12) New and Reconstructed Bridge Widths. Clear roadway bridge widths are measured from face to face of parapets or rails. Bridge widths are normally defined as the sum of the approach traveled way width and the width of the paved shoulders.

(13) Bridge Width. Where the directional distribution of trucks exceeds 250 DDHV, consider providing 12 ft (3.6 m) right and left shoulders. Total width equals 60 ft (18.0 m).

(14) Existing Bridge Widths to Remain in Place. Clear roadway bridge widths are measured from face to face of parapets or rails. Implies elements allowed to remain in place without a design exception approval when cost effective and when safety record is satisfactory.

(15) Vertical Clearance (freeway under).

a. The clearance must be available over the traveled way and any paved shoulders.
b. Make allowances to maintain 16 ft- 0 in (4.9 m) minimum vertical clearance in anticipation of for future overlays.
c. In urban areas, a 15 ft 0 in (4.5 m) clearance may be used where a single routing interstate with a 16 ft 0 in (4.9 m) clearance is available. See Section 44-6 for maps of the single routing in urban areas of Illinois.

GEOMETRIC DESIGN CRITERIA FOR EXISTING CROSS-SECTION ELEMENTS TO REMAIN IN PLACE ON RURAL FREEWAYS[1]
(Reconstruction)
(Metric)

Figure 44-5.B

(1) Design Criteria. The minimum cross-section elements in this figure are allowed to remain in place for reconstruction of an existing freeway provided it is cost effective and the safety record is satisfactory.

(2) Traffic Volumes. The design hourly volumes (DHV) are calculated assuming base conditions (except for 16% heavy vehicles) and a PHF = 1.0. Adjust these values using local factors.

(3) Design Speed. Existing alignment elements may be allowed to remain in place, provided the comfortable operating speed for level and rolling terrain is a minimum of 65 mph (105 km/h) and 60 mph (100 km/h) respectively.

(4) Traveled Way Width. In existing 22′ (6.7 m) traveled way width may be allowed to remain with concurrence of a design exception.

(5) Shoulder Width (Right). Where the directional distribution of trucks exceeds 250 DDHV, consider providing a 12 ft (3.6 m) paved shoulder.

(6) Shoulder Width (Left). Where there are three or more lanes in one direction and the directional distribution of trucks exceeds 250 DDHV, consider providing a 12 ft (3.6 m) paved shoulder.

(7) Travel Lane Cross Slope. For each additional lane away from the crown lanes, increase the cross slope by 1/16″/ft (0.5%) per additional lane up to a maximum of 5/16″/ft (2.5%).

(8) Depressed Median Width. Median width based on paved shoulder width 1V:6H median slope, and 2 ft (600 mm) ditch bottom width.

(9) Flush Median Width. Only use flush medians with concrete barrier where right-of-way or topography restricts the use of a depressed median. Consider providing wider medians where required for snow storage.

(10) Clear Zone. The clear zone will vary according to design speed, traffic volumes, side slopes, and horizontal curvature.

(11) Ditch Bottom Width. Provide a wider outside ditch bottom where detention storage of storm water is a consideration.

(12) Back Slope. Where the height of cut exceeds 10 ft (3 m), consider using a 1V:2H back slope beyond the clear zone. Also, for heights greater than 30 ft (9 m), consider the use of benching.

(13) Fill Slope. For fill heights greater than 30 ft (9 m), use a 1V:2H uniform slope with a roadside barrier. Also, for heights greater than 30 ft (9 m), consider the use of benching.

(14) Existing Bridge Widths to Remain in Place. Clear roadway bridge widths are measured from face to face of parapets or rails. Implies elements allowed to remain in place without a design exception approval when cost effective and when safety record is satisfactory.

(15) Vertical Clearance (Freeway Under).

a. The clearance must be available over the traveled way and any paved shoulders.
b. Make allowances to maintain 16 ft- 0 in (4.9 m) minimum vertical clearance in anticipation of future overlays.
c. In urban areas, a 15 ft 0 in (4.5 m) clearance may be used where a single routing interstate with a 16 ft 0 in (4.9 m) clearance is available. See Section 44-6 for maps of the single routing in urban areas of Illinois.

GEOMETRIC DESIGN CRITERIA FOR EXISTING CROSS-SECTION ELEMENTS TO REMAIN IN PLACE ON URBAN FREEWAYS(1)
(Reconstruction)
(Metric)

Figure 44-5.C

(1) Design Criteria. The minimum cross-section elements in this figure are allowed to remain in place for reconstruction of an existing freeway provided it is cost effective and the safety record is satisfactory.

(2) Traffic Volumes. The design hourly volumes (DHV) are calculated assuming base conditions (except for 16% heavy vehicles) and a PHF = 1.0. Adjust these values using local factors.

(3) Design Speed. With restricted conditions, a minimum design speed of 55 mph (90 km/h) may be considered to remain-in-place with study and justification. Also, consider the existing posted speed limits.

(4) Level of Service. In major urban areas, a level of service D may be considered on a reconstruction project with study and justification.

(5) Traveled Way Width. In existing 22 ft (6.7 m) traveled way width may be allowed to remain with concurrence of a design exception.

(6) Shoulder Width (Right). Where the directional distribution of trucks exceeds 250 DDHV, consider providing a 12 ft (3.6 m) paved shoulder.

(7) Shoulder Width (Left). Where there are three or more lanes in one direction and the directional distribution of trucks exceeds 250 DDHV, consider providing a 12 ft (3.6 m) paved shoulder.

(8) Travel Lane Cross Slope. For each additional lane away from the crown lanes, increase the cross slope by 1/16″/ft (0.5%) per additional lane up to a maximum of 5/16″/ft (2.5%).

(9) Depressed Median Width. Median width based on 1V:4H median slope, and 2 ft (600 mm) ditch bottom width (3 – Lanes/Direction) or 4ft. (1.2 m) ditch bottom width (2-Lanes/Direction).

(10) Flush Median Width. Only use flush medians with concrete barrier where right-of-way or topography restricts the use of a depressed median. Consider providing wider medians where required for snow storage.

(11) Clear Zone. The clear zone will vary according to design speed, traffic volumes, side slopes, and horizontal curvature.

(12) Cut Section. In restricted right-of-way, the typical design will have mountable curb and gutter behind the shoulder and an enclosed drainage system.

(13) Back Slope. Where the height of cut exceeds 10 ft (3 m), consider using a 1V:2H back slope beyond the clear zone. Also, for heights greater than 30 ft (9 m), consider the use of benching.

(14) Fill Slope. For fill heights greater than 30 ft (9 m), use a 1V:2H uniform slope with a roadside barrier. Also, for heights greater than 30 ft (9 m), consider the use of benching.

(15) Existing Bridge Widths to Remain in Place. Clear roadway bridge widths are measured from face to face of parapets or rails. Implies elements allowed to remain in place without a design exception approval when cost effective and when safety record is satisfactory.

(16) Vertical Clearance (Freeway Under).

a. The clearance must be available over the traveled way and any paved shoulders.
b. A 15 ft 0 in (4.5 m) clearance may be used where a single routing interstate with a 16 ft 0 in (4.9 m) clearance is available.
c. In urban areas, a 15 ft 0 in (4.5 m) clearance may be used where a single routing interstate with a 16 ft 0 in (4.9 m) clearance is available. See Section 44-6 for maps of the single routing in urban areas of Illinois.

	Urban		Desirable: 0.5% Minimum: 0.3% (with Curb and Gutter) **(6)**		

* Controlling design criteria (see Section 31-8).

(1) Stopping Sight Distance. Table values are for passenger cars on level grade.

(2) Decision Sight Distance. Table values are for the avoidance maneuver (speed/path/direction change).

(3) Minimum Radii/Superelevation Rates. Values are only allowed for remain-in-place elements.

(4) Horizontal Sight Distance. For a given design speed, the necessary middle ordinate will be determined by the radius of curve and the required sight distance.

(5) Maximum Grade.

a. Rural. With wide medians where two roadways are on independent alignments, downgrades may be 1% steeper.
b. Urban. Grades 1% steeper may be used for restricted conditions.

(6) Minimum Grades. Where curb and gutter is required due to restricted right-of-way, use M-4.24 curb and gutter and locate it no closer than the outer edge of shoulder.

Figure 44-5.D

44-6 SINGLE INTERSTATE ROUTING FOR SELECT URBAN AREAS

The integrity of the Interstate System for national defense purposes shall be maintained to meet AASHTO policy as stated in AASHTO's "A Policy on Design Standards - Interstate System." IDOT requires vertical clearances on new construction/reconstruction Interstate sections in rural areas and single routing through or around urban areas to be no less than 16 ft 09 in (5.1 m). The clear height of structures over other urban interstate routes shall not be less than 15 ft 00 in (4.5 m). This clearance is required over the full roadway width (travel lanes and usable shoulders), including ramps and collector-distributor roadways within Interstate-to-Interstate interchanges.

The FHWA allows a minimum 16 ft 00 in (4.9 m) in rural areas and along the single routing in urban areas. The minimum vertical clearance in other urban areas shall be no less than 14 ft 00 in (4.3 m). The extra clearance IDOT requires allows for future overlays. The urban areas in Illinois where single routing occurs and the figures showing maps of the routing are:

- the Chicago urban area[1]; Figure 44-6.A
- Metro-east St. Louis urban area; Figure 44-6.B
- Peoria urban area, Figure 44-6.C
- Quad Cities; and Figure 44-6.D

The Federal Highway Administration (FHWA) and the Surface Deployment and Distribution Command Transportation Engineering Agency (SDDCTEA), previously the Military Traffic Command Transportation Engineering Agency, have cooperated to meet the demands of the military traffic on the Interstate System, particularly in the area of vertical clearance. The coordination and reporting with the SDDCTEA on all design exceptions for vertical clearance is to ensure the Department of Defense is aware of the locations of nonstandard clearances on the Interstate System in the event a defense emergency arises. The military continues to have a need for the 16-ft (4.9m) clearance. While the size of future equipment that may use the Interstate System is unknown, the SDDCTEA needs to ensure options remain for the routing of military equipment.

1. The map for the Chicago metropolitan area is the most current available. The SDDCTEA have added the section of I-355 between I-80 and I-55 to the single routing since this map was released.

Chapter Forty-five
EXPRESSWAYS (New Construction/Reconstruction)

Table of Contents

Section **Page**

Chapter Forty-five

EXPRESSWAYS (New Construction/Reconstruction)

Expressways are functionally classified as Other Principal Arterials and are constructed with partial control of access. Expressways are intended to provide high efficiency, safety, and move high volumes of traffic at high speeds. The operational efficiency, capacity, safety, and cost of the highway facility are largely dependent upon its design. Intersections are an integral feature of an expressway design. Chapter 45 provides guidance in the design of expressways including specific design criteria, frontage roads, median openings, service drive connections, public road connections, and transitions. Information that is also applicable to expressways is included in the following chapters:

- Chapter 11 discusses the design of expressway alignment and profile.
- Chapter 14 discusses intersection design studies.
- Chapter 15 discusses interchange type and design studies.
- Chapters 31, 32, 33, 34, and 39 provide guidance on the geometric design elements that are also applicable to expressways.
- Chapter 35 provides guidelines on the access control around interchanges and intersections on expressways. It also discusses the procedures for preparing access control plans.
- Chapter 36 provides information on the design of intersections including left- and right-turn lanes, channelization, and intersection sight distance. Certain alternative intersection types can often be considered along expressway facilities; see 36-1.03(b).
- Chapter 37 discusses the type, location, layouts, and design of interchanges.
- Chapter 38 provides guidelines on roadside safety issues.
- Chapter 44 discusses the procedures for designing freeways, which require full control of access. New-alignment expressway bypasses may include sections with full control of access.

45-1 GENERAL

45-1.01 Design Studies

Chapter 11 discusses the procedures for determining the location of expressways within a corridor. Factors that determine an expressway alignment include:

- existing roadway alignment (many rural expressways will involve constructing a travel way adjacent and parallel to an existing two-lane highway);
- logical and effective locations for proposed interchanges;
- locations of structures over railroads, streams, and river crossings;
- access control along the expressway and crossroads at interchanges and intersections;
- access to property and right-of-way restrictions;
- topography; and
- environmental restrictions.

45-1.02 Establishing An Expressway

When a highway is designated and designed as an expressway, the district must prepare and file an Order Establishing a Freeway sometime after receiving design approval but before construction plans are finalized. The details of this procedure are discussed in Chapter 12. The Order must include the access control limits along the mainline, the location of access breaks for field and private entrances, and the limits of access control along each crossroad.

In addition to filing an Order Establishing a Freeway, the district should also consider filing a Corridor Protection Map. The procedures for this process are described in the *Land Acquisition Policies and Procedures Manual*.

45-1.03 Crossroads

With expressways crossroads usually remain open and are designed as intersections, but also consider opportunities to relocate lower-volume routes. At some locations, a grade separation and/or interchange may be proposed at a crossroad. The following Sections provide guidance for making these decisions.

45-1.03(a) Interchanges/Intersections

For rural expressways, full-access or alternative-access intersections are provided with most public crossroads. When reconstructing urban expressways, limit the number of such connections and space them according to Section 45-2.06(b). Chapter 36 provides the design criteria for intersections that are also applicable to expressways.

Accurate traffic projections based on reasonable estimates of local and regional growth are very important in the planning of expressways. Over-estimation of growth may result in excessive right-of-way acquisition for unnecessary interchanges; underestimation of growth can create future operational concerns at the at-grade intersections. Interchanges may be constructed or planned at state marked routes or high-volume county highways. Apply the following guidelines in decision making:

- Consider constructing an interchange initially where traffic signals are expected to be warranted within nine years of construction.
- Where projected traffic volumes show a warrant for traffic signals within 10 to 20 years, initially provide a traditional or alternative intersection. Depending on the analysis of future operations, consider a design that can be adapted to accommodate a future interchange. This will include purchasing the access rights for approximately 1000 ft to 1200 ft (300 m to 350 m) along each leg of the crossroad.
- If traffic signals are not warranted within the 20-year design life, construct a two-way stop-controlled traditional or alternative intersection.
- Where a low-volume marked route exists within 2 miles (3 km) of another parallel marked route or high-volume crossroad, consider relocating the low-volume route and only provide one interchange to serve both routes.

Signalized intersections along high-speed roadways can create safety concerns in part because drivers do not expect them. Therefore, when an interchange is not appropriate, a two-lane roundabout should be considered when signal warrants are met at any time within the 20-year design period. Consider the safety of all users in assessing a two-lane roundabout design option wherever two-way stop control will not be effective in handling projected traffic volumes and where local constraints or costs make an interchange impractical. Although roundabouts will increase travel time slightly versus a free-flow mainline condition, the resulting safety benefits as well as operational improvements for side road traffic and non-motorized users can often be substantial.

45-1.03(b) Grade Separations

Grade separations should be considered at all railroad crossings, sites where terrain contours favor the separation of grades, and at high-volume crossroads near an urbanized area where the crossroad connects with a marked route.

45-2 GEOMETRIC DESIGN FEATURES

45-2.01 Design Speed

Figures 45-4.A and 45-4.B provide the range of design speeds for expressways between 50 mph (80 km/h) and 70 mph (110 km/h). Most expressways are classified as rural and will have a 70 mph (110 km/h) design speed. Existing geometric design features may be allowed to remain in place in accordance with Section 45-2.02. For additional guidance on selecting design speeds for existing facilities, see Chapter 49 and consider the following:

- whether a new or existing alignment is proposed for the expressway,
- access restrictions and the level of access control that can be achieved,
- whether signalized intersections will be required initially or in the future, and
- construction costs.

45-2.02 Alignment

Expressways should have smooth-flowing horizontal and vertical alignments. Proper combinations of curvature, tangents, grades, and median types all combine to enhance the safety and aesthetics of expressways. When designing expressway alignments, consider the following:

1. Horizontal Alignment. In rural areas, use curve radii which yield consistent superelevation (SE) rates in the range of 3-4%. SE rates in this range are efficient, meet driver expectations, and minimize the design challenges at intersections/entrances.

   Also design alignments to avoid SE transitions on bridges or bridge approach slabs. In urbanized areas where right-of-way is restricted, it may not be practical to avoid SE transition on bridges. See Section 32-3.07 for guidance on the location of horizontal curves near bridges.

   Existing horizontal curves may remain in place provided they have a comfortable operating speed within 10 mph (15 km/h) of the design speed if there is no historical pattern of crashes within the curves. See Section 49-3 for guidance on comfortable operating speeds.

2. Vertical Alignment. For the vertical alignment, use design values in the "desirable" range to produce a smooth, aesthetically pleasing alignment. For existing alignments, the following will apply:

   a. Sag Vertical Curves. Existing sag vertical curves may remain in place if they have a design speed within 20 mph (30 km/h) of the design speed if there is no historical pattern of crashes.

   b. Crest Vertical Curves. Existing crest vertical curves may remain in place if they have a design speed within 15 mph (25 km/h) of the design speed if there is no historical pattern of crashes.

3. Horizontal and Vertical Combinations. Consider the relationship between horizontal and vertical alignments simultaneously to obtain a desirable condition. Chapter 33 discusses these relationships and their effect on aesthetics and safety.

45-2.03 Typical Sections

The tables in Section 45-4 provide the minimum criteria for lane widths, shoulder widths, median widths, and other cross section elements that should be used on expressways. Figures 45-2.A through 45-2.E illustrate schematic typical sections for various expressway designs.

45-2.04 Access Control

Access to expressways must be located at points that will enable vehicles to enter and exit without creating undue safety concerns. The controls governing the location of access points have some degree of flexibility to meet traffic needs, to fit terrain features, and to be cost effective. Locating access points must be done within the purpose and intent of partial access control. As part of locating access points designers must address safety performance and operational concerns with a goal of allowing mainline traffic to flow without excessive delay.

The types of access allowed on expressways (e.g., partial control, full control on new bypasses, entrances) are discussed throughout Section 45-2 and Chapter 35. Any major access changes should be discussed at district coordination meetings with both BDE and FHWA. When expressways are not on the National Highway System (NHS) exceptions to Department access criteria are reviewed and handled by BDE.

Chapter 35 provides the procedures for preparing access control plans during Phase I studies.

TYPICAL SECTION FOR SUPERELEVATED EXPRESSWAY
(Flush Median with Concrete Barrier)

Figure 45-2.E

45-2.05 Intersections

Chapter 36 provides the criteria for the design of intersections. In addition, the following will apply to expressways:

1. Definitions. The following definitions will apply to the crossroad:

   a. Major Public Roads. These are facilities with ADT's of 1500 or greater.
   b. Minor Public Roads. These are facilities with ADT's less than 1500.

2. Turn Lane Warrants. In addition to the turn lane warrants presented in Section 36-3.01, the following will apply to expressways:

   a. Left-Turn Lanes. Provide left-turn lanes at all public road intersections and at any other locations where U-turns regularly occur.

   b. Right-Turn Lanes. Provide right-turn lanes at all major public road intersections and at minor public road intersections where the ADT is greater than or equal to 250. At minor public road intersections where the ADT is less than 250, the use of right-turn lanes will be determined on a case-by-case basis.

3. Tapered Offset Left-Turn Lanes. For the design of tapered offset left-turn lanes, see Section 36-3.03(c).

4. Parallel Left-Turn Lanes. For the design of parallel left-turn lanes without an offset, see Section 36-3.03(b). Safety concerns arise with this type of design if they could create visibility constraints with opposing left-turning traffic.

5. Signalized Intersections. Signalized intersections on expressways typically are used only in urban and suburban areas. Due to the safety concerns presented by their "unexpected stop" conditions other options should always be considered. Provide interchanges where traffic signals are warranted; see Section 45-1.03(a). Also investigate alternative intersection designs that may best address operational and safety concerns; see Section 36-1.03(b).

6. Superelevation of Intersections. See Section 36-1.05(b) for intersection details on curves.

7. Design Speeds. In rural areas, use a 70 mph (110 km/h) design speed to design turn lanes on the expressway at major public road intersections and a 50 mph (80 km/h) design speed for turn lanes at minor public roads. In urban areas, use the mainline design speed, typically 50 mph (80 km/h) and also consider storage requirements to determine overall turn-lane lengths.

8. Lighting. Consider providing partial lighting at all major intersections. See Chapter 56 for information on highway lighting.

45-2.06 Medians

45-2.06(a) General

Expressway medians should be as wide as economic, operational, and environmental considerations will permit. Consider the following in the design of medians:

1. Median Selection. Section 34-3 discusses the purpose of medians, types of medians, and guidelines for their selection. Rural expressways generally will have depressed medians. In more urbanized areas where right-of-way is restricted, flush medians with concrete median barriers are typically used. Raised curb medians may only be used where design speeds will be 45 mph (70 km/h) or less, so they are rarely used along expressways.

2. Widths. Section 45-4 provides the minimum median width criteria. The designer should note the following:

   - Median widths of at least 50 ft (15 m), and preferably 64 ft (19 m), are recommended where a large number of trucks are turning or crossing.

   - In rural areas, median widths of 100 ft (30 m) or more may be appropriate when using independent alignments and based on engineering or aesthetic goals. These wider medians accommodate two-stage left turns and typically will not create operational or safety issues if well signed and marked.

   - Provide minimum 50 ft (15 m) wide medians where school buses may store within the median when performing left turning and crossing movements.

3. Median Openings. Section 36-4.04 provides the criteria for designing and laying out the median openings (crossovers) that are provided for full access intersections.

4. Median Barriers. Within narrow medians where the design speed is greater than or equal to 50 mph (80 km/h) a median barrier is required between the directional roadways. See Section 38-7 for guidelines on median barriers. Also, see Figure 36-3.M for how to terminate a median barrier at intersections.

5. Illustrations. Figures 45-2.A and 45-2.B illustrate a typical depressed median. Figure 45-2.C illustrates a typical flush median with a concrete median barrier.

45-2.06(b) Access and Crossover Spacing and Design

Paved median openings (crossovers) for U-turns, crossing and full-access entering/exiting movements along expressways should be constructed only where operationally necessary and where adequate sight lines can be provided. Initial and future crossover locations should be discussed and determined, to the extent practicable, during project planning stages and shown in a Phase I report. Provide the minimum number of median openings necessary to serve the existing road network during the initial construction. Additional crossovers may be considered later as the need arises. In addition to crossovers at many township roads, most county highways, and most State highways, crossovers may also be considered:

- to permit full access to and from frontage roads and public service drives;
- to minimize the adverse travel from agricultural or residential entrances;
- where property, held under one ownership and used for farming, is severed by an expressway, and;
- to accommodate U-turn movements, often in conjunction with RCUT or other alternative intersections. Where U-turns are expected, median widths of less than 64 ft (19 m) will require the inclusion of outside “loon” areas to allow for tractor-semitrailer movements.

Space median crossovers on expressways according to the following:

1. Rural New Alignment. Space median crossovers, including those for intersecting public highways, an average of 1 mile (1600 m) as measured between adjacent intersections. However, closer spacing may be provided for severed farm tracts.

2. Rural Existing Alignment. Where the new roadway is constructed parallel and adjacent to the existing highway, the average crossover spacing may be reduced to ½ mile (800 m). A detailed study and analysis should document any recommendation to reduce the average spacing to ½ mile (800 m).

3. Urban New Alignment. Where a rural expressway is extended into an urbanized area and where a bypass alignment is feasible, design the bypass with full control of access. This eliminates cross traffic conflicts, stopping through traffic due to traffic signals, lower running speeds, and the potential for rear-end and right-angle crashes.

4. Urban Existing Alignment. Where an expressway design has been extended from a rural area through a developing urban area with restricted right-of-way and where reconstruction of an existing arterial is proposed to six lanes, space median crossovers on the average ¼ mile to ½ mile (400 m to 800 m) apart. Where reconstruction of an existing arterial is proposed to four lanes, space median crossovers no closer than 500 ft (150 m) and desirably 1320 ft to 1800 ft (400 m to 550 m) apart. At these distances, consider closing some median openings and only allowing right in and right out on the side street. Signalized intersections will exist and signal progression must be considered and investigated for the above designs.

5. Interchanges. The location of the first median crossover beyond the end of an interchange entrance ramp terminal will be dependent on the design speed of the expressway. See Chapter 35 for the applicable spacing criteria.

6. Near Bridges. Do not locate crossovers within 750 ft (225 m) of overhead bridge structures or within 750 ft (225 m) from the ends of mainline bridges. Provide adequate stopping sight distance on each side of the proposed crossover.

45-2.07 Future Public Road or Street Connections

Chapter 605 ILCS 5/8-107 of the *Illinois Highway Code* allows the Department, county, or municipality to give, withhold consent, or fix conditions on any request for connecting a new highway or other public way to an expressway. When reviewing a request for public road connections to an expressway, consider the following:

1. Applications. Permit applications must be presented by and issued in the name of the local public agency that will be responsible for the maintenance of the facility upon completion of construction. For a determination of financial responsibilities with public road connections, see the Department's *Joint Agreements Policy and Procedure Manual*.

2. Spacing. Limit the connections according to the median crossover spacing requirements noted in Section 45-2.06.

3. System Design. Evidence must be presented that the proposed public road or public service drive will become an integral part of an existing or definitely planned public road system. The access should not be merely a provision for internal circulation within a particular property.

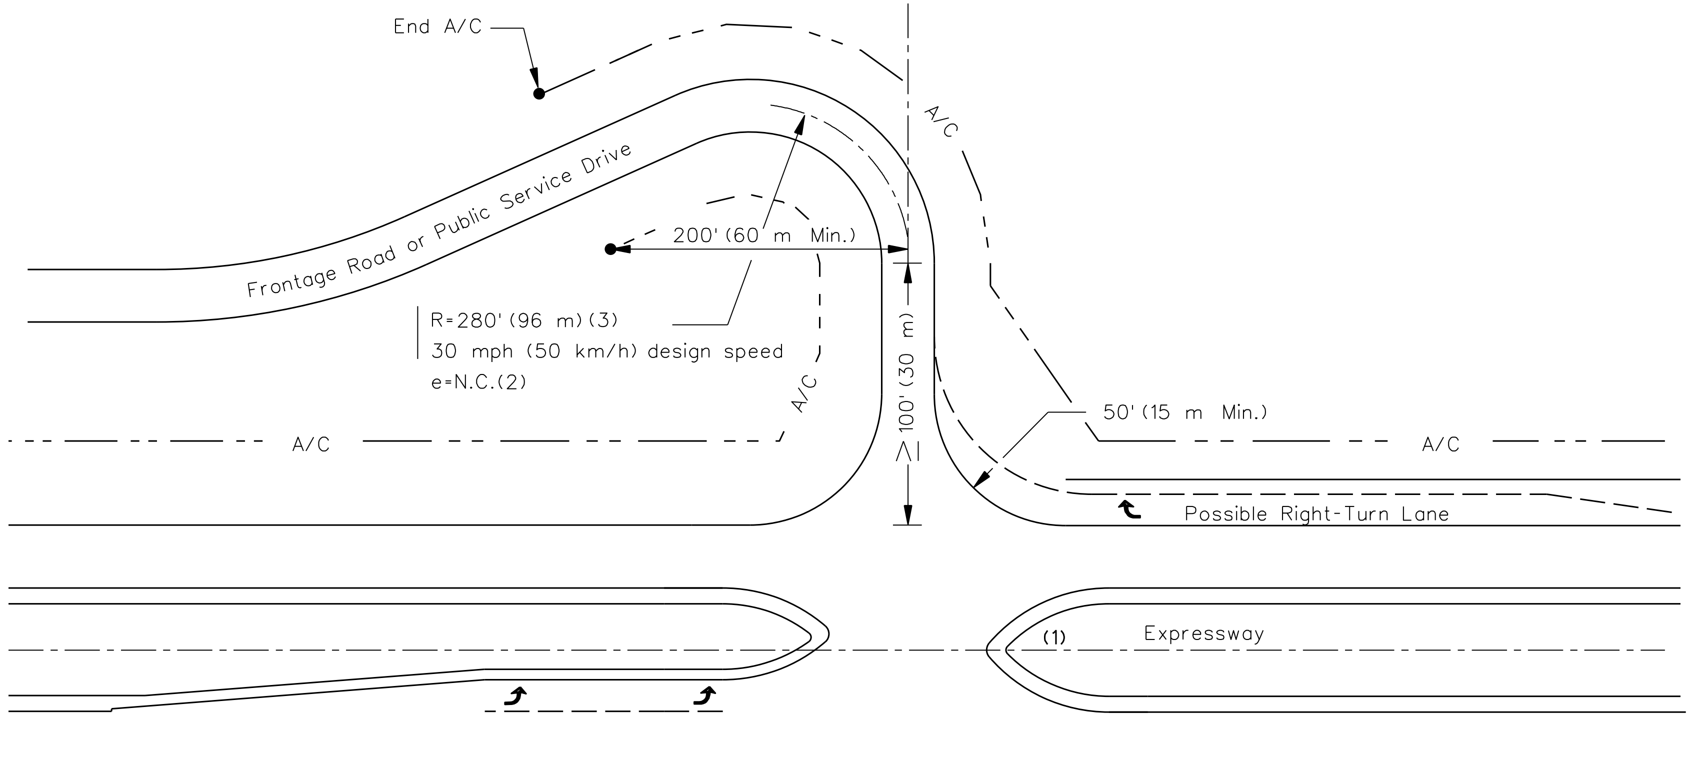
4. Access. See Chapter 35 to determine location of the first point of access allowed along a proposed new connection. According to the *Illinois Highway Code,* the Department is authorized to define these first points of access adjacent to an expressway considering safety and traffic operations.

45-2.08 Frontage Roads/Service Drives

Access to expressways from frontage roads and public service drives is only permitted opposite median crossovers and should be designed according to Figures 45-2.H and 45-2.I. Space median crossovers according to Section 45-2.06(b). For expressways, the following definitions apply:

1. Frontage Roads. A public street or road normally located alongside of and parallel to an expressway. Its purpose is to maintain local road continuity and to provide for access. A frontage road is connected to public roads or streets at both ends. In some cases, it may be connected to a public road at one end and the expressway at the other.

2. Service Drive. Similar to a frontage road except that a service drive is normally connected to a public road or street at only one end. A private service drive is one that is maintained by the property owner(s) served.



Notes:

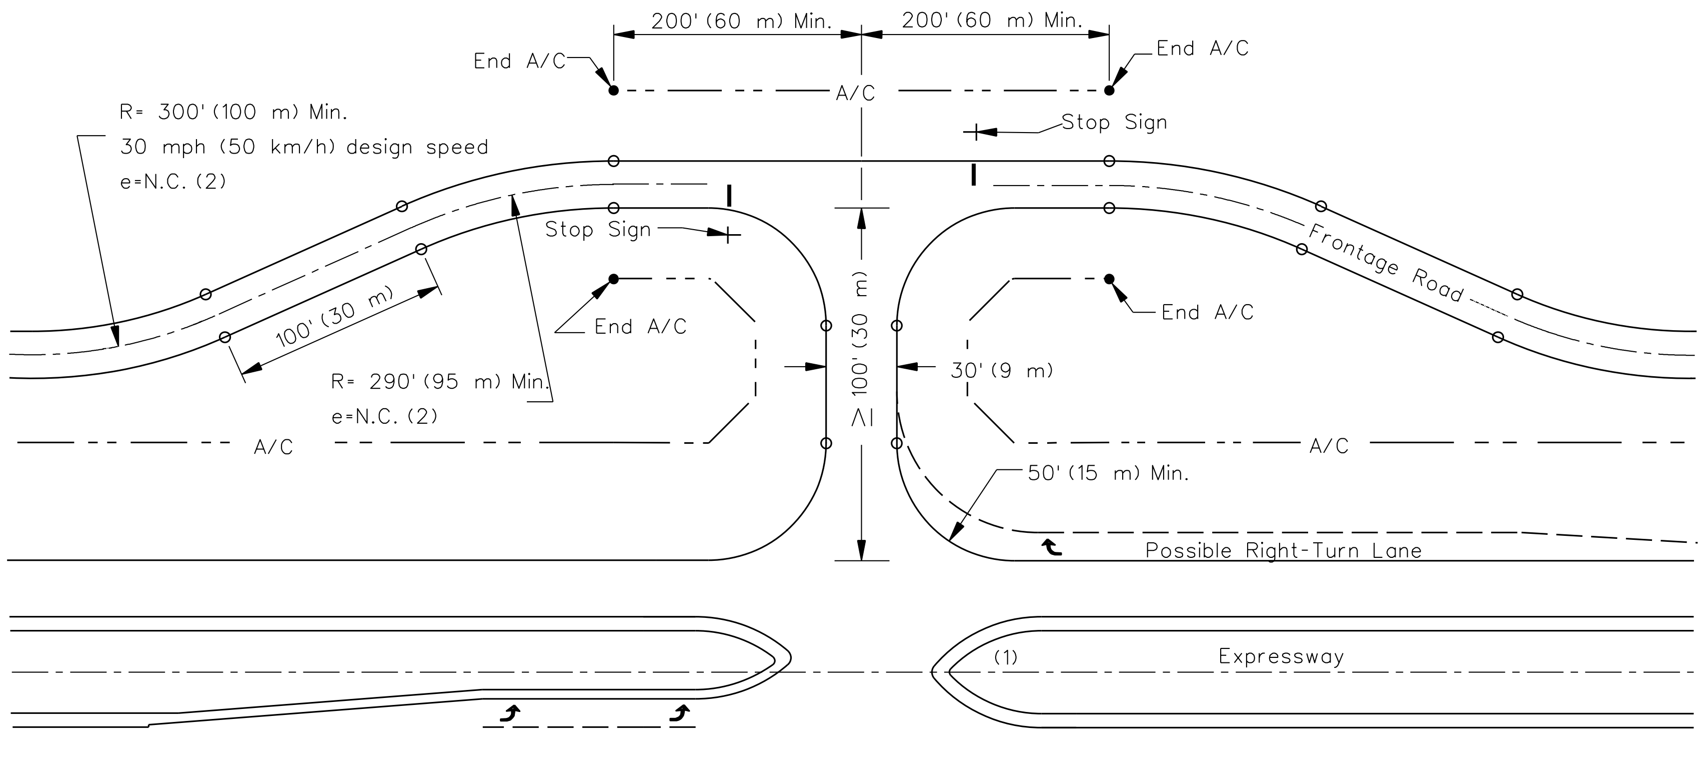
1. *With a median crossover as shown typically include a left turn lane. There may be a need to add a loon area for U-turn movements opposite the left-turn lane.* Considerations in determining design details include *the expected number of U-turns per day, safety, and the level of service on the expressway in the design year.*

2. *Use AASHTO Method 2 for the distribution of superelevation on curves; see Section 48-5. Normal crown is 3/16″ /ft (1.5%).*

3. *If physical space is not available to provide a 280 ft (96 m) radius, use as large of radius as practical, but not less than the minimum radius required for the selected design vehicle. If the radius is selected for the design vehicle, widen the pavement through the curve to accommodate the design vehicle.*

TYPICAL FRONTAGE ROAD OR PUBLIC SERVICE DRIVE DESIGN AT AN ACCESS POINT

Figure 45-2.H



Notes:

1. With a median crossover as shown typically include a left turn lane. There may be a need to add a loon area for U-turn movements opposite the left-turn lane. *Considerations in determining design details include the expected number of U-turns per day, safety, and the level of service on the expressway in the design year.*

2. *Use AASHTO Method 2 for the distribution of superelevation on curves; see Section 48-5. Normal crown is 3/16″ /ft (1.5%).*

TYPICAL FRONTAGE ROAD DESIGN AT AN ACCESS POINT

Figure 45-2.I

The design criteria for frontage roads and public service drives adjacent to freeways as presented in Section 44-2.05 also applies to these facilities along expressways. In addition, Figure 45-2.J illustrates a cross section view with a service drive adjacent to an expressway where restricted right-of-way conditions exist.

45-2.09 <u>Entrances</u>

45-2.09(a) Agricultural and Residential Entrances

Direct access may be provided to an expressway from an abutting property if it is used solely for farming purposes or for one single-family residence. For these locations, only consider points of direct access where other means of access require unreasonable adverse travel, have excessive construction costs or damages, and where the point of direct access will not interfere with the operational safety of the expressway. Agricultural and single residential entrances are subject to the following specific restrictions:

1. <u>Interchanges</u>. See Chapter 35 to determine the required spacing of an entrance from the end of the speed change taper of an interchange ramp. The calculated composite distances are also provided in Chapter 35.

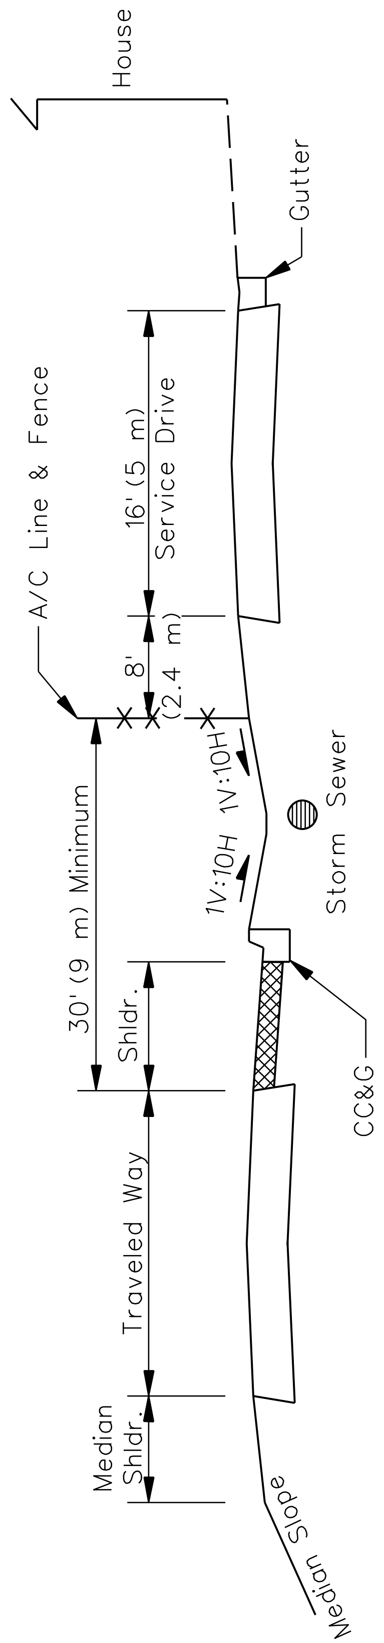
2. <u>Median Crossovers</u>. Do not provide an entrance within 300 ft (90 m) of a median crossover if the entrance is not located directly opposite the crossover.

3. <u>Number and Spacing</u>. Limit the number and spacing of agricultural or residential entrances to a desirable average of one per ¼ mile (400 m) on each side of the expressway. The minimum distance between two residential entrances on the same side of an expressway should be 500 ft (150 m). Where practical, consider combining two or more entrances into one service drive.

4. <u>Field Entrances</u>. Where a field entrance exists to an agricultural property and where the property extends to a nearby public road, make every effort to relocate the field entrance to the adjacent public road.

5. <u>Suburban Entrances</u>. In rare cases, additional entrances to an expressway can be approved on a case-by-case basis by a highway permit. Specifically this may occur where an expressway traverses areas that are “suburban” in nature, has a 50 mph (80 km/h) design speed, and traverses abutting land with development that is not sufficient to warrant continuous frontage roads.. Such access must incorporate a design similar to that of a service drive as a future consideration.

6. <u>Design</u>. Design entrances for agricultural or residential purposes according to the criteria in the *Handbook for the Policy on Permits for Access Driveways to State Highways* (92 *Illinois Administrative Code* 550).



SERVICE DRIVE ADJACENT TO EXPRESSWAY
(Restricted Right-of-Way Conditions))

Figure 45-2.J

45-2.09(b) Entrances Other Than Agricultural or Residential

All land uses other than agricultural or single-dwelling residential are considered commercial. Direct access from commercial developments to an expressway is not permitted. The suburban access allowance may provide an occasional exception as noted in the previous section. Plan for indirect access to commercial properties via adjacent crossroads, service drives, or frontage roads.

45-3 OTHER DESIGN FEATURES

45-3.01 Lane Transitions

Careful consideration must be provided to the design of transitions from multilane facilities to two-lane facilities. These are complex decision-making areas for a driver who may not be expecting the lane reduction and lane shift. Therefore, decision sight distance should be provided to and throughout the transition area. When designing transitions, consider the following:

1. Transitions on Tangent. Desirably, lane transitions should be designed on a tangent section. This can be accomplished by the following:

    a. Centered on Existing Roadway. Figure 45-3.A illustrates three designs for transitioning from four lanes to two lanes. The proposed pavements are centered about the centerline of the existing traveled way. The bottom drawing illustrates a transition to a raised-curb median, the middle drawing to an existing 40 ft (12.2 m) wide depressed median extended, and the top drawing to a proposed 50 ft (15 m) wide depressed median.

    b. Existing Roadway on Left. Figure 45-3.B provides three designs where the new roadway is added to the right of the existing roadway. The bottom drawing illustrates a transition to a raised-curb median, the middle drawing to an existing 40 ft (12.2 m) wide depressed median extended, and the top drawing to a proposed 50 ft (15 m) wide depressed median.

    c. Existing Roadway on Right. Figure 45-3.C provides three designs where the new roadway is added to the left of the existing roadway. The bottom drawing illustrates a transition to a raised-curb median, the middle drawing to an existing 40 ft (12.2 m) wide depressed median extended, and the top drawing to a proposed 50 ft (15 m) wide depressed median.

    d. Raised-Curb Median. In Figures 45-3.A, 45-3.B, and 45-3.C, the bottom drawings illustrate a transition to a 30 ft (9.5 m) raised-curb median. Only use this design where the design speed is 45 mph (70 km/h) or less.

    e. Transition Radii. At the design speed, a motorist can make a comfortable lane shift of 12 ft (3.6 m) in approximately three seconds of travel time. The transition design radii of 3820 ft (1165 m) shown in Figures 45-3.A, 45-3.B, and 45-3.C satisfies this criterion for all expressway design speeds; see Figure 45-3.D. With a 45 mph (70 km/h) design speed and restricted right-of-way, the reverse curves may be designed with a minimum radius of 2085 ft (620 m).

64	986.83	19.40	298.502
54	906.75	16.70	278.465
37	750.99	11.05	226.651
32	698.52	9.65	211.893
27	641.74	8.30	196.492

LANE TRANSITIONS

Figure 45-3.D

2. Transitions on Curve. Where the transition is on a curve, the crossover crown line is an important design consideration. In going from two lanes to the separation of the lanes with a median, the crossover algebraic difference should be no greater than 5% for design speeds greater than or equal to 60 mph (100 km/h) and 6% for design speeds less than or equal to 55 mph (90 km/h).

   Figure 45-3.E illustrates an example of a curved-lane transition where the new roadway is added to the outside of an existing curve. Figure 45-3.F illustrates an example of a curved-lane transition where the new roadway is added to the inside of the curve.

45-3.02 Median Width Transitions

Figures 45-3.E and 45-3.F illustrate the geometric criteria for median width transitions. When designing median width transitions, consider the following:

1. Outside a Horizontal Curve. Where the added roadway for the proposed expressway is located on the outside of an existing horizontal curve, provide the alignment transition to the uniform median width on one end of the proposed horizontal curve only (i.e., either up or downstream). The alignment of the transition should be gradual unless intersections, critical right-of-way, etc., require a shorter transition to the project design median width.

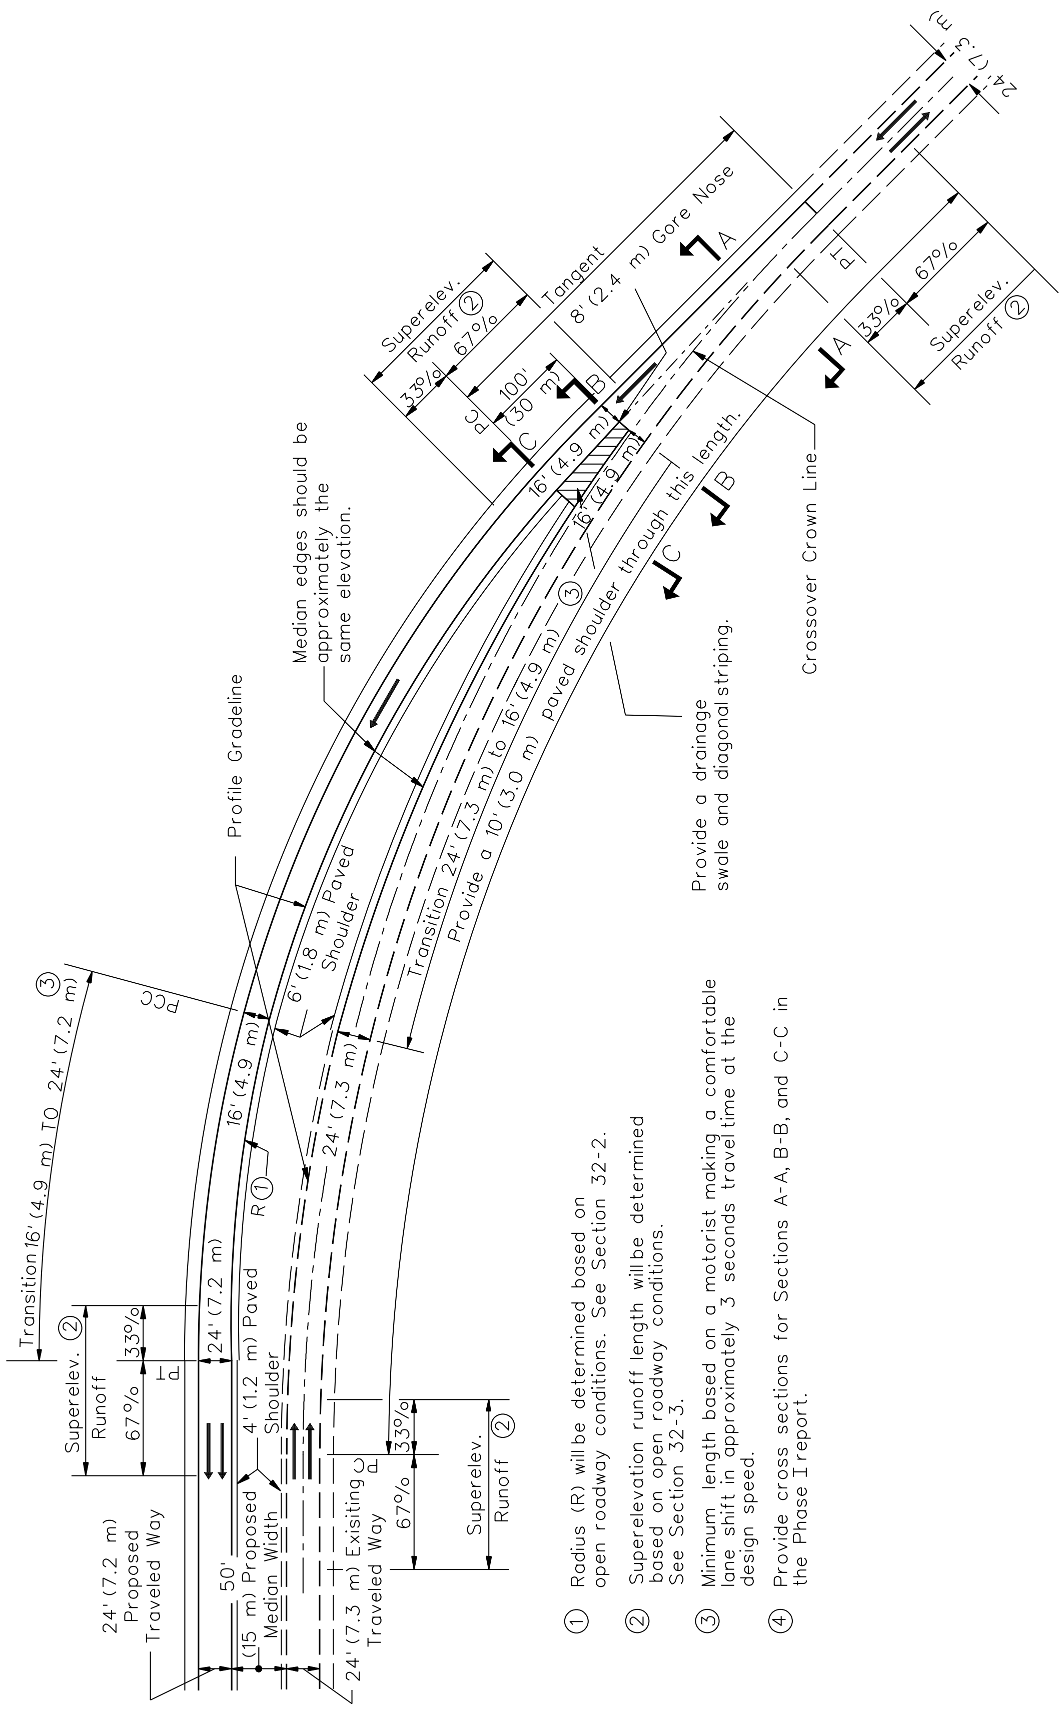
2. Inside a Horizontal Curve. Where the added roadway for the proposed expressway is located on the inside of an existing horizontal curve, design the proposed horizontal curve to fit into the back and forward tangents. This design may provide for a variable width median through the two adjacent horizontal curves.

45-3.03 Underdrains

Where there is a significant drainage problem, consider providing underdrains along an existing roadway or raising the elevation of the existing roadway to eliminate the drainage and stability problems.

45-3.04 Mailboxes

With typical 10 ft (3.0 m) wide right shoulders, separate mailbox turnouts will not be required along expressways. Place the mailbox post 2 ft (600 mm) minimum from the edge of the paved shoulder. Locating mailboxes such that they require the crossing of the expressway median by a pedestrian is discouraged; the issue may be addressed on a case-by-case basis.



① Radius (R) will be determined based on open roadway conditions. See Section 32-2.

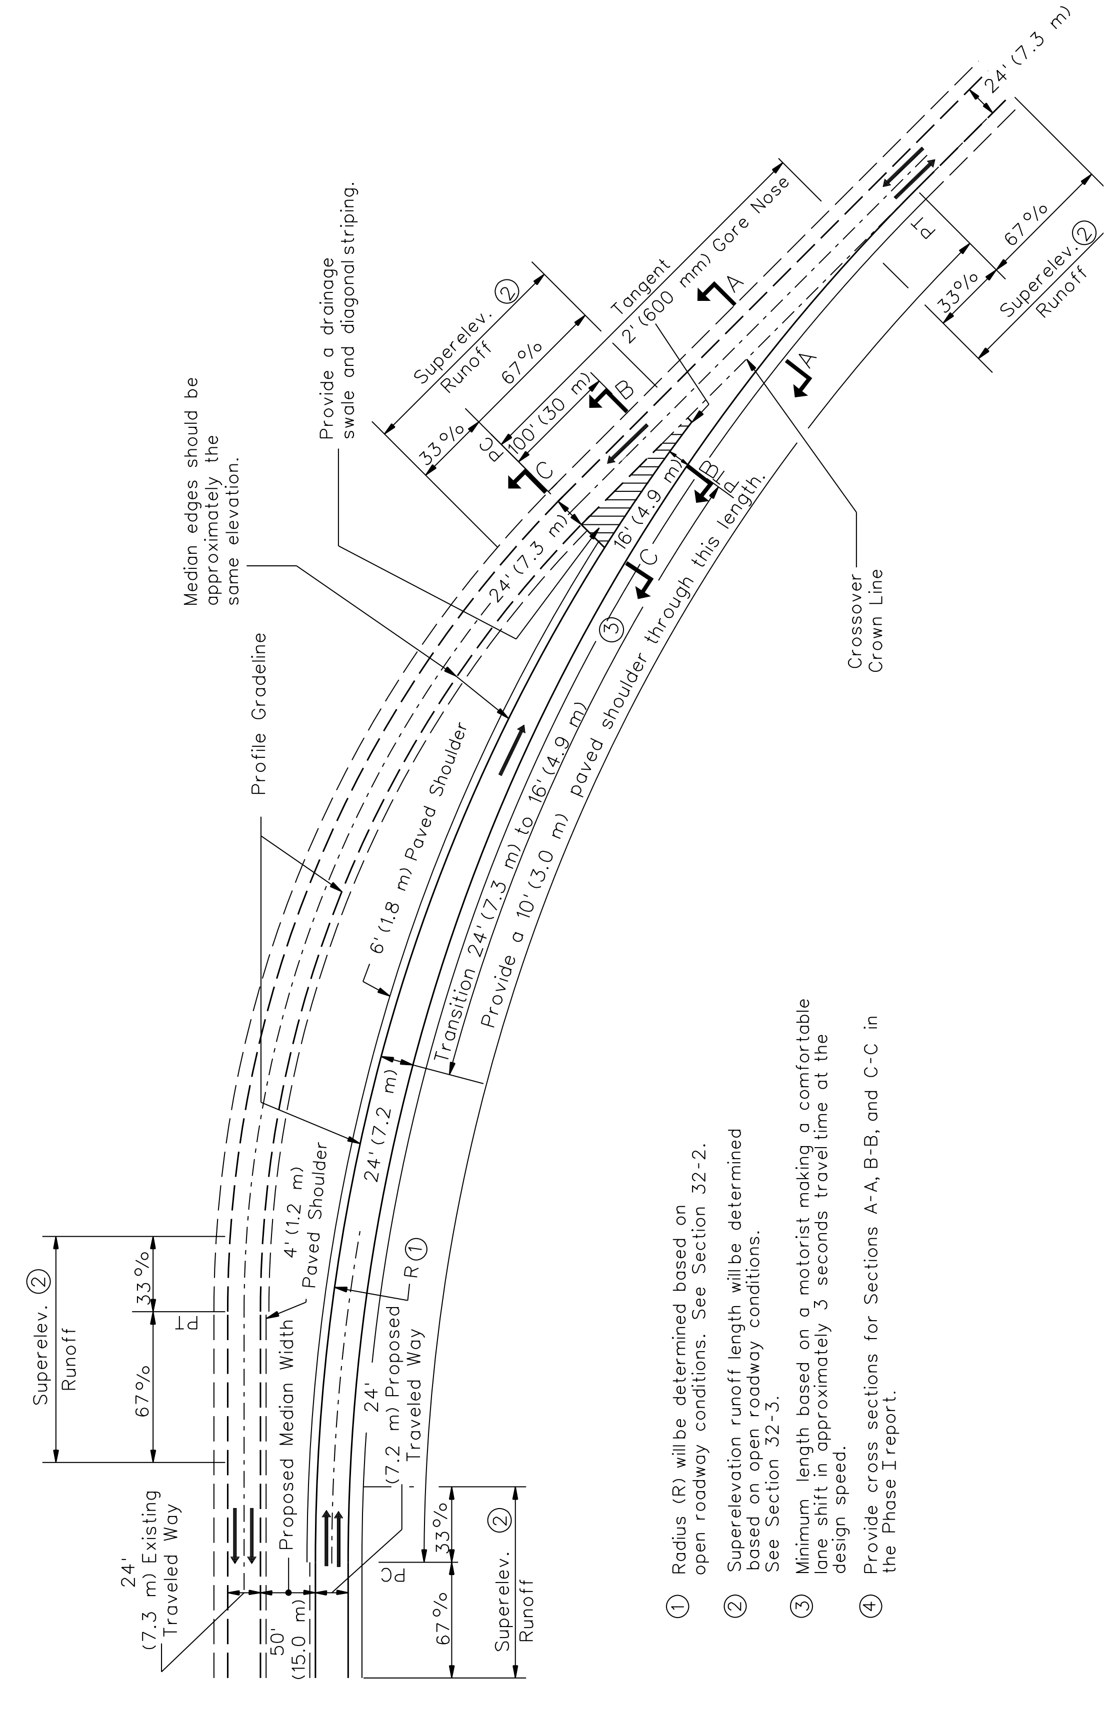
② Superelevation runoff length will be determined based on open roadway conditions. See Section 32-3.

③ Minimum length based on a motorist making a comfortable lane shift in approximately 3 seconds travel time at the design speed.

④ Provide cross sections for Sections A-A, B-B, and C-C in the Phase I report.

LANE TRANSITION DESIGN ON CURVE FROM FOUR TO TWO LANES
(New Roadway Outside)

Figure 45-3.E



① Radius (R) will be determined based on open roadway conditions. See Section 32-2.

② Superelevation runoff length will be determined based on open roadway conditions. See Section 32-3.

③ Minimum length based on a motorist making a comfortable lane shift in approximately 3 seconds travel time at the design speed.

④ Provide cross sections for Sections A-A, B-B, and C-C in the Phase I report.

(New Roadway Inside)

Figure 45-3.F

45-4 TABLES OF DESIGN CRITERIA

Figures 45-4.A, 45-4.B, and 45-4.C present the Department's design criteria for expressway projects. Note that these figures also provide criteria for an existing roadway elements allowed to remain in place. The designer should realize that some of the cross section elements included in the figures (e.g., raised-curb median) are not automatically warranted in the project design. The values in the figures only apply after the decision has been made to include the element in the highway cross section.

	Design Element		Manual Section	New Lanes (1a) One-Way DHV: Under 2400 (2)	Existing Lanes (1b) One-Way DHV: Under 2400 (2)

GEOMETRIC DESIGN CRITERIA FOR RURAL EXPRESSWAYS (New Construction/Reconstruction) (Metric)

Figure 45-4.A

(1) Design Criteria.

a. When upgrading an existing two-lane highway to a four-lane expressway, use the criteria in the new lanes column for the design of the new roadway and median.
b. The criteria in this column are the minimum cross-section elements allowed to remain in place for reconstruction of an existing roadway provided it is cost effective and safety record is satisfactory.

(2) Traffic Volumes. The design hourly volumes (DHV) are calculated assuming base conditions (except for 8% heavy vehicles) and a PHF = 1.0. Adjust these values using local factors. For volumes exceeding the listed DHV, use the *Highway Capacity Manual* to determine the applicable number of travel lanes.

(3) Design Speed.

a. In rolling terrain, a minimum design speed of 60 mph (100 km/h) may be considered with study and justification.
b. To determine the minimum design speed allowed to remain, see Section 45-2.02.

(4) Access Control. Bypasses around a community should be fully access controlled if the installation of traffic signals is likely at any intersection during the 20-year design period.

(5) Shoulder Width (Left). In most cases, left shoulders should be 6 ft (1.8 m) wide. This allows for the use of 1V:6H slopes in the median. However, if the 20-year level of service approaches Level C, then consider an 8 ft (2.4 m) wide left shoulder and decrease the median slopes to 1V:5H.

(6) Travel Lane Cross Slope. For each additional lane away from the crown lanes, increase the cross slope by 1/16″ /ft (0.5%) per additional lane up to a maximum of 5/16″ /ft (2.5%).

(7) Depressed Median Width. Median width based on 1V:5H median slopes and existing 2 ft (600 mm) ditch bottom width.

(8) Flush Median Width. In rural areas, only use flush medians with concrete barrier where right-of-way or topography restricts the use of a depressed median. Consider providing wider medians where required for snow storage.

(9) Clear Zone. The clear zone will vary according to design speed, traffic volumes, side slopes, and horizontal curvature. To achieve the proper clear zone for restricted right-of-way conditions, see Figure 34-4D.

(10) Ditch Bottom Width. Provide a wider outside ditch bottom where detention storage of storm water is a consideration.

(11) Back Slope. Where the height of cut exceeds 10 ft (3 m), consider using a 1V:2H back slope beyond the clear zone. Also, for heights greater than 30 ft (9 m), consider the use of benching.

(12) Fill Slope. For fill heights greater than 30 ft (9 m), use a 1V:2H uniform slope with a roadside barrier. Also, for heights greater than 30 ft (9 m), consider the use of benching.

(13) New and Reconstructed Bridge Widths. Clear roadway bridge widths are measured from face to face of parapets or rails. Bridge widths are normally defined as the sum of the approach traveled way width and the width of the paved shoulders.

GEOMETRIC DESIGN CRITERIA FOR RURAL EXPRESSWAYS
(New Construction/Reconstruction)

Footnotes Figure 45-4.A

(14) Existing Bridge Widths to Remain in Place.

a. Clear roadway bridge widths measured from face to face of parapets or rails. Implies elements allowed to remain in place without a design exception when cost effective and when safety record is satisfactory.
b. Bridges with total lengths greater than 250 ft (75 m) or any span longer than 120 ft (36 m) typically should have a clear roadway bridge width of 38 ft (11.4 m) or 40 ft (12.0 m).

(15) Vertical Clearance (Expressway Under).

a. The clearance must be available over the traveled way and any paved shoulder.
b. Table value includes allowance for future overlays.

* Controlling design criteria (see Section 31-8).

GEOMETRIC DESIGN CRITERIA FOR URBAN AND SUBURBAN EXPRESSWAYS (New Construction/Reconstruction) (Metric)

Figure 45-4.B

(1) Traffic Volumes. The design hourly volumes (DHV) are calculated assuming base conditions (except for 8% heavy vehicles) and a PHF = 1.0. Adjust these values using local factors. For volumes exceeding the listed DHV, use the *Highway Capacity Manual* to determine the number of travel lanes.

(2) Design Speed. With restricted urban conditions, a minimum design speed of 55 mph (90 km/h) may be considered with study and justification.

(3) Access Control.

a. Where an expressway design has been extended from a rural area and is planned to bypass an urbanized area on new alignment, the bypass route should be developed with full control of access.
b. Where an expressway design has been extended from a rural area through a developing urban area with restricted ROW, median crossovers according to Section 45-2.06. Signalized intersections also will exist and signal progression must be considered and investigated.

(4) Traveled Way Width. For existing pavements to remain, the following minimum widths will be allowed:

a. Expressway Six Lanes (EX-6) — 2 @ 33 ft (10.0 m)
b. Expressway Four Lanes (EX-4) — 2@ 22 ft (6.6 m)

(5) Travel Lane Cross Slope.

a. For each additional lane away from the crown lanes, increase the cross slope by 1/16″ /ft (0.5%) per additional lane up to a maximum of 5/16″ /ft (2.5%).
b. For raised-curb medians (proposed design speed ≤ 45 mph (70 km/h)) the cross slope of the two travel lanes adjacent to the median is 1/4″ /ft (2%) sloped away from the median. Where a third or outside lane is added to the traveled way in conjunction with a raised-curb median, the cross slope of the third lane will be 5/16″ /ft (2.5%).

(6) Depressed Median Width.

a. Median width based on 10 ft (3.0 m) left shoulders, 1V:5H median slopes, 3 ft (900 mm) ditch depth, and 2 ft (600 mm) ditch bottom width.
b. Right-of-way usually not available for a depressed median.
c. Desirably, the median width should be 50 ft (15.0 m). The median width of 44 ft (13.2 m) is based on a 1V:5H median slope and 2 ft (600 mm) ditch bottom width.

(7) Flush Median Width.

a. Provide a wider outside ditch where detention storage of storm water is a consideration.
b. Where dual left-turn lanes are required, use a 30 ft (9.5 m) to 36 ft (10.5 m) wide median and provide a crashworthy end treatment on the CMB. See Figure 36-3M.

GEOMETRIC DESIGN CRITERIA FOR URBAN AND SUBURBAN EXPRESSWAYS
(New Construction/Reconstruction)

Footnotes Figure 45-4.B

(9) Clear Zone. The clear zone will vary according to design speed, traffic volumes, side slopes, and horizontal curvature. To achieve the proper clear zone for restricted right-of-way conditions, see Figure 34-4D.

(10) Ditch Bottom Width. Provide a wider outside ditch bottom where detention storage of storm water is a consideration.

(11) Back Slope. Where the height of cut exceeds 10 ft (3 m), consider using a 1V:2H back slope beyond the clear zone. Also, for heights greater than 30 ft (9 m), consider the use of benching.

(12) Fill Slope. For existing slopes to remain in place, see Figures 34-4A or 34-4B. For fill heights greater than 30 ft (9 m), use a 1V:2H uniform slope with a roadside barrier. Also, for heights greater than 30 ft (9 m), consider the use of benching.

(13) New and Reconstructed Bridge Widths. Assumes roadway approach adjacent to bridge has median shoulders. Clear roadway bridge widths are measured from face to face of parapets or rails. Bridge widths are normally defined as the sum of the approach traveled way width and the width of the paved shoulders. See Figure 39-5K for more information on urban bridges.

(14) Existing Bridge Widths to Remain in Place. Clear roadway bridge widths are measured from face to face of parapets or rails. Implies elements allowed to remain in place without a design exception approval when cost effective and when safety record is satisfactory. See Figures 39-5.A and 39-5.B.

(15) Vertical Clearance (Expressway Under).

a. The clearance must be available over the traveled way and any paved shoulders.
b. Table value includes allowance for future overlays.
c. A 15 ft 0 in (4.5 m) clearance may be used where an alternative route is available with a 16 ft 0 in (4.9 m) clearance.

GEOMETRIC DESIGN CRITERIA FOR URBAN AND SUBURBAN EXPRESSWAYS
(New Construction/Reconstruction)

Footnotes Figure 45-4.B (Continued)

Design Element		Manual Section	Design Speed			
			50 mph	55 mph	60 mph	70 mph
*Stopping Sight Distance (1)		31-3.01	425′	495′	570′	730′

*Minimum Radii	e_{max} = 6% (3a)	32-2.03	835	1065	1335′	Desirable: ≥3000′ Minimum: 2045′ (3)
	e_{max} = 8% (3b)		—	—	—	1815′ (3b)
*Superelevation Rate (4)		32-3	New: e_{max} = 6% Reconstruction: e_{max} = 6% or 8%			
*Horizontal Sight Distance		32-4	(5)			
*Vertical Curvature (K-values)	Crest	33-4	84	114	151	247
	Sag		96	115	1367	181
*Maximum Grade	Level	33-2.02	New: 4% (6a)	New: 3% (6a)	New: 3% (6a)	New: 3% (6b)
	Rolling		New: 5% (6a)	New: 4% (6a)	New: 4% (6a)	New: 4% (6b)
Minimum Grade		33-2.03	Des: 0.5% Min: 0.3% (with Curb & Gutter) (7)	Des: 0.5% Min: 0.3% (with Curb & Gutter) (7)	Des: 0.5% Min: 0.3% (with Curb & Gutter) (7)	Des: 0.5% Min: 0.0% (with Special Ditching)

* Controlling design criteria (see Section 31-8)

(1) Stopping Sight Distance. Table values are for passenger cars on level grade.

(2) Decision Sight Distance. Table values are for the avoidance maneuver (speed/path/direction change).

(3) Minimum Radii.

a. An e_{max} of 6% may be used for both new and reconstruction projects.
b. In rural areas, existing horizontal curves with a maximum superelevation rate of 8% may remain if the radius is 1815 ft or more and there is no history of crashes.

(4) Superelevation Rate. See Section 32-3 for superelevation rates based on e_{max}, design speed, and radii of horizontal curves. For horizontal curves to remain in place, an e_{max} of 8% in rural areas and 6% in urban areas may be considered to remain in place. Where a crossroad intersection lies within the limits of an expressway horizontal curve, see Figure 36-1.E for the maximum superelevation rates allowed on the expressway.

(5) Horizontal Sight Distance. For a given design speed, the necessary middle ordinate will be determined by the radius of curve and the required sight distance.

(6) Maximum Grade.

a. Grades 1% steeper may be used for restricted conditions or to remain in place.
b. For existing roadways to remain, a maximum of a +4% on upgrades and -5% on downgrades may be retained.

(7) Minimum Grades. Where curb and gutter is required due to restricted right-of-way, use M-4.24 curb and gutter and locate it no closer than the outer edge of shoulder.

STRATEGIC REGIONAL ARTERIALS (New Construction/Reconstruction)

Strategic Regional Arterials (SRA's) are a network of highways designed to accommodate long-distance regional traffic, to complement a region's major transit and highway facilities, and to supplement the freeway system. The Department's SRA concept was originally developed for Northeastern Illinois and is presented in the IDOT publication *Strategic Regional Arterial Design Concept Report "Operation Green Light."* However, this concept could apply to other cities and regions throughout the State.

Many of the Department's existing arterials can be incorporated into a SRA system. SRA's may have widely varying characteristics. Existing rights-of-way, roadway features, land use, and access differ from route to route, and also may change from one segment of a route to another. Chapter 46 provides guidance in the planning and design of strategic regional arterials including specific design criteria and techniques encountered on SRA routes, which should be applied throughout the system. Information also applicable to SRA's is included in the following chapters:

- Chapters 31, 32, 33, 34, and 39 provide guidance on the geometric design elements that are applicable to SRA's.
- Chapter 36 provides information on the design of intersections including left- and right-turn lanes, channelization, and intersection sight distance.
- Chapter 37 discusses the type, location, and design of interchanges.
- Chapter 38 provides guidelines on roadside safety.

46-1 GENERAL

46-1.01 Objectives for a SRA System

The SRA System is designed to:

- improve regional mobility by providing a comprehensive network of arterial routes designed to carry significant volumes of long distance traffic across a region,
- complement a region's major transit and highway facilities by providing access for regional trips on these facilities, and
- supplement the regional freeway system.

46-1.02 SRA Route Definitions

Within the overall SRA network, there are significant differences in the roadway environment that determine how the different types of routes (urban, suburban, and rural) may function in the system. The information in Chapter 46 has been segregated accordingly. For SRA application, the following defines the characteristics for these designations:

1. Urban Routes. Urban areas are defined as those with densities over 5 households per acre (12 households per hectare) in the design year. SRA routes located in densely urbanized areas typically are existing facilities with minimal potential for roadway expansion. However, improvements can be made to intersections, local transit facilities, and low structural clearances.

2. Suburban Routes. Suburban areas are defined as those with densities between 0.5 to 5 households per acre (1 and 12 households per hectare) in the design year. For routes in developing suburban areas, the major concerns are preservation of right-of-way, additional lanes on roadways, new connections to improve route continuity, and operational improvements (e.g., signal coordination).

3. Rural Routes. Rural areas are defined as those with densities less than 0.5 households per acre (1 household per hectare) in the design year. In rural areas, the major issues are the preservation of right-of-way and controlled access on bypasses to emphasize the movement of through traffic and the accommodation of future needs.

46-1.03 Spacing of SRA's

Spacing of routes on the SRA system is based upon the projected levels of future travel demand within the different parts of a region. In northeastern Illinois, the spacing should range from about 3 miles (5 km) apart in the most densely areas to about 9 miles (15 km) apart in rural areas. Spacing for other parts of the State will be determined on a case-by-case basis.

46-1.04 Coordination with Local Land Use Plans

For the SRA system to successfully accomplish its objectives, coordinated planning with each local jurisdiction is necessary along the routes. Local planning and development policies, particularly the arrangement of land uses adjacent to the arterial street and type of access, will greatly affect the ability of the facility to fulfill its function of carrying long-distance traffic. Also right-of-way protection will need to be coordinated with local planning and development agencies. Dedication or preservation of right-of-way on the SRA routes through the local development process is an effective means of protecting needed right-of-way to provide for future roadway improvements. Land use planning techniques can also encourage use of alternative modes of transportation, with policies favorable to mixed-use development.

Because SRA routes create a regional network, the impact of planning and development decisions crosses local boundaries. The need for cooperation among local governments and regional transportation agencies in coordinating land development with planned SRA improvements is important whether or not a formal framework is established.

46-1.05 SRA Planning

46-1.05(a) Objectives

Development of comprehensive, long-range plans for a SRA network is necessary in order to implement a SRA system. These plans will identify both short-range and long-range improvements for each of the SRA routes. The following objectives may be used as a guide in the planning process:

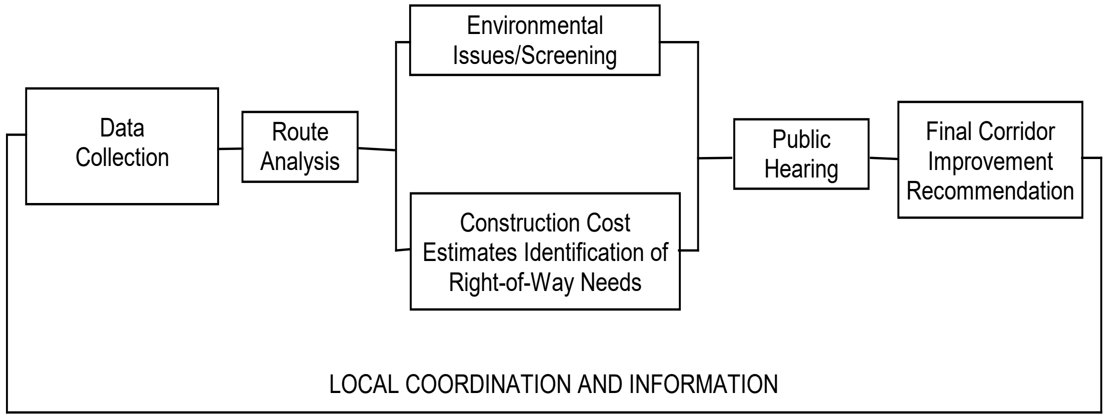
- Determine the types of roadway improvements needed for each route including additional lanes, signalization, and interchanges.
- Identify and protect needed rights-of-way.
- Manage access to SRA routes to improve through traffic movement and reduce conflicts.
- Coordinate land use and development projects with transportation improvements.
- Identify ways to accommodate the growth in commercial traffic.
- Accommodate necessary bicycle and pedestrian travel on or near the SRA route corridors.
- Identify potential environmental concerns.

The long-term plans are intended to be specific to each SRA route. However, this does not preclude consideration during the planning process of alternative segments on a route where warranted by circumstances. Also, the planning process should address the fact that not all transportation needs can be provided within the right-of-way of an SRA route, and that some types of travel may be better provided on parallel facilities.

46-1.05(b) Implementation Process

The SRA planning process has two parts:

- The first part consists of developing recommended design features and techniques for the SRA route. Chapter 46 provides the criteria that should be considered when developing route specific plans.
- The second part consists of preparing specific route studies for each SRA route. The studies will recommend both comprehensive short-range and long-range improvements for each route, through the work program; see Figure 46-1.A.



1. SRA Subcommittee
2. SRA Advisory Panel
3. Newsletter

THE SRA ROUTE STUIDES WORK PROGRAM

Figure 46-1.A

The principal activities in the route studies work program are:

1. Data Collection/Evaluation. The SRA planning process is designed to efficiently use available data. For each route, data is assembled from right-of-way information, roadway plans, traffic volume projections, transit information, bicycle usage, adjacent development characteristics, crash data, environmental studies, and other sources, and is analyzed to establish current conditions, constraints, and improvement needs.

2. Route Analysis. Possible improvements for the SRA route are determined by incorporating the recommended design features in specific configurations for each segment of the overall route. These configurations include alternative designs and techniques where necessary to accommodate local conditions or constraints. The timing of the recommended improvements, whether long-range or short-range, are also identified.

3. Environmental Issues/Screening. While the SRA planning process does not include detailed environmental assessments or analysis of specific mitigation measures, a screening process will identify significant environmental conditions along each route. Use the results of this process to evaluate improvement alternatives, and also to serve as an early indicator of environmental issues for future design studies.

4. Construction Cost Estimates/Identification of Right-of-Way Needs. Prepare construction cost estimates for each route segment, both for short-range and long-range improvements. Also identify right-of-way needs to accommodate the recommended long-range improvements.

5. Local Involvement and Coordination. Throughout the SRA route planning process, the involvement of local and regional agencies is an important consideration; see Section 46-1.04. Information and coordination efforts include forming Advisory Panels for each SRA route, which will work with IDOT during the planning process. A regular newsletter for each Panel will inform members about the SRA program and ongoing route studies. A public hearing in an open-house format will also be conducted for each route.

6. Final Route Improvement Plan/Report. As the final step in the planning process, prepare a report for each SRA route to document the recommended improvements and findings.

As planning for each route is completed, the design concepts will be used to help program the scope and timing for improvements along that route. For State routes, once an SRA improvement is included in the IDOT Five-Year Program, the process of implementation follows the process shown in Figure 46-1.B.

Pre-Phase I (SRA Route Studies)	**Phase I Reports**	**Phase II**	**Phase III**	**Phase IV**

THE SRA IMPLEMENTATION PROCESS FOR ROUTES UNDER IDOT JURISDICTION

Figure 46-1.B

46-2 URBAN SRA ROUTES

46-2.01 General Roadway Features

Urban SRA's are proposed with two or more lanes in each direction divided by a flush median. Measures to increase mobility will typically be associated with traffic signal systems, changes to access, and removal of parking rather than widening or other new construction. Figure 46-2.A illustrates the typical plan view design configuration for an urban SRA. Figure 46-2.B illustrates a desirable cross section for an urban SRA. For an illustration of a superelevated section, see Chapter 48. Where right-of-way or other restrictions do not allow the configuration in Figure 46-2.A, the designer may consider the following:

1. One-Way Arterial Pairs. One-way arterial pairs can dramatically increase the capacity of a roadway by reducing turning movements and conflicts. The one-way pairs should be within close proximity to each other. This concept is generally feasible in urban areas where right-of-way for increasing capacity is limited and where closely spaced parallel streets are available.
2. Reversible Lanes. In areas where there is substantial commuter traffic and a directional bias to the traffic corresponding to the time of day, reversible lanes may be considered. Lane control signals and other traffic control features will be required.

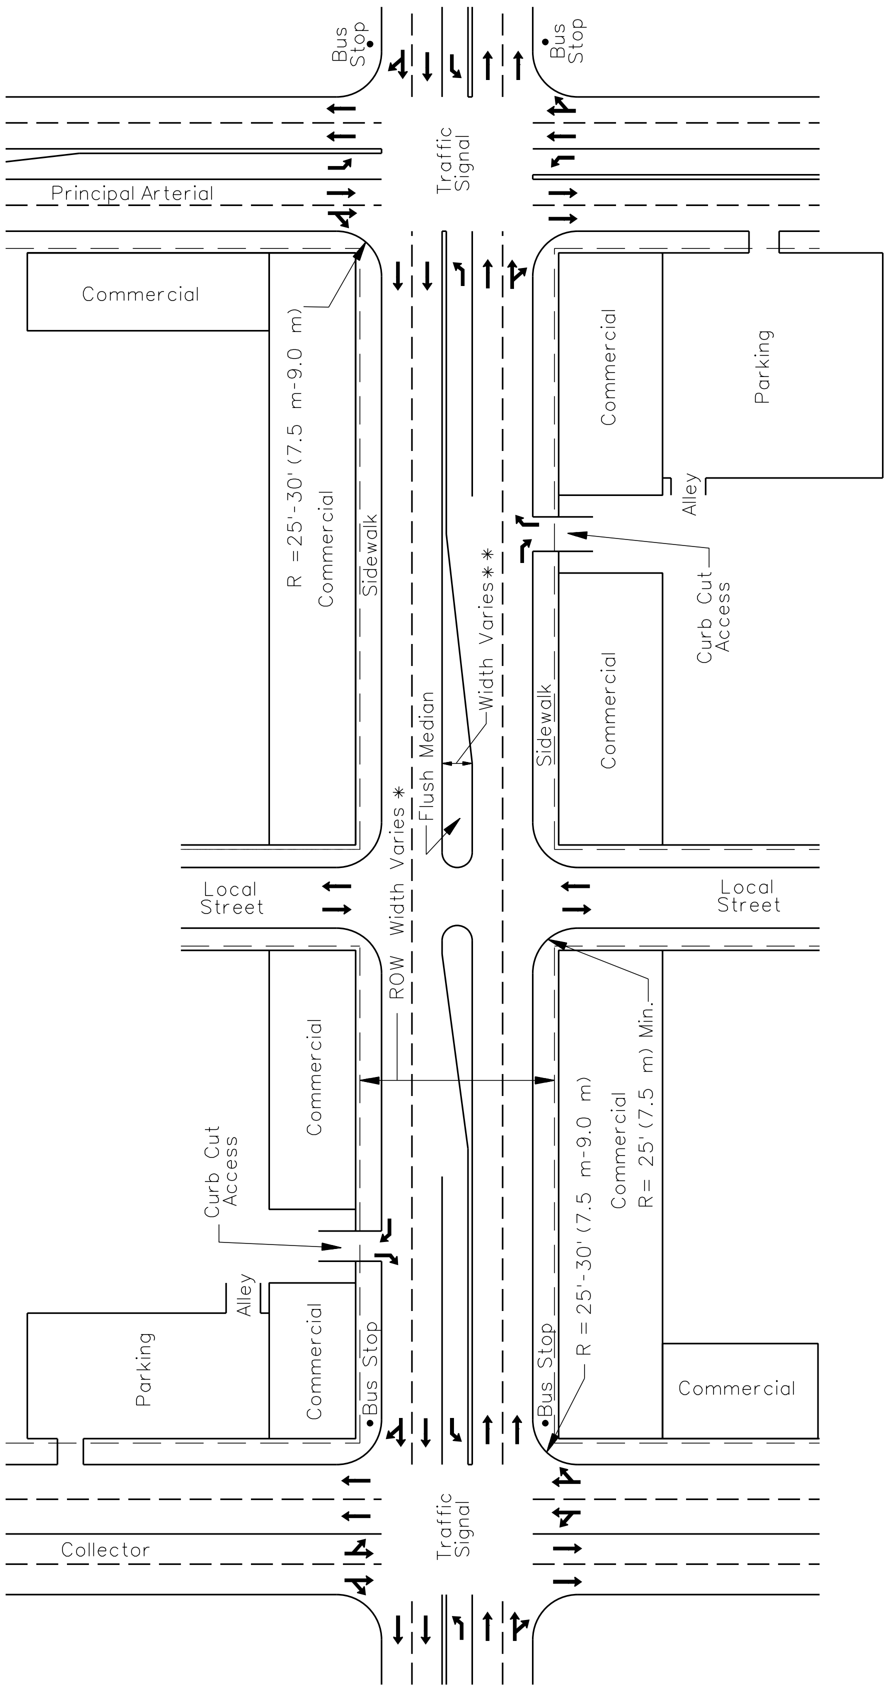
46-2.02 Geometric Design Elements

46-2.02(a) Median Type

The presence of a median on urban SRA routes will provide protection for left-turning vehicles at cross streets, direct turning movements to desired locations, and reduce opposing traffic conflicts. The typical design is a flush median with an 11 ft (3.3 m) width. A flush median delineated with thermoplastic or painted markings offers a measure of median control in urban areas where limited right-of-way is available and where numerous access points exist.

46-2.02(b) Additional Lanes

On urban SRA routes, there is often little right-of-way available for roadway widening. Additional lanes generally can only be added by using the existing pavement (e.g., converting a parking lane to a travel lane). Section 46-2.08 discusses the removal of on-street parking.

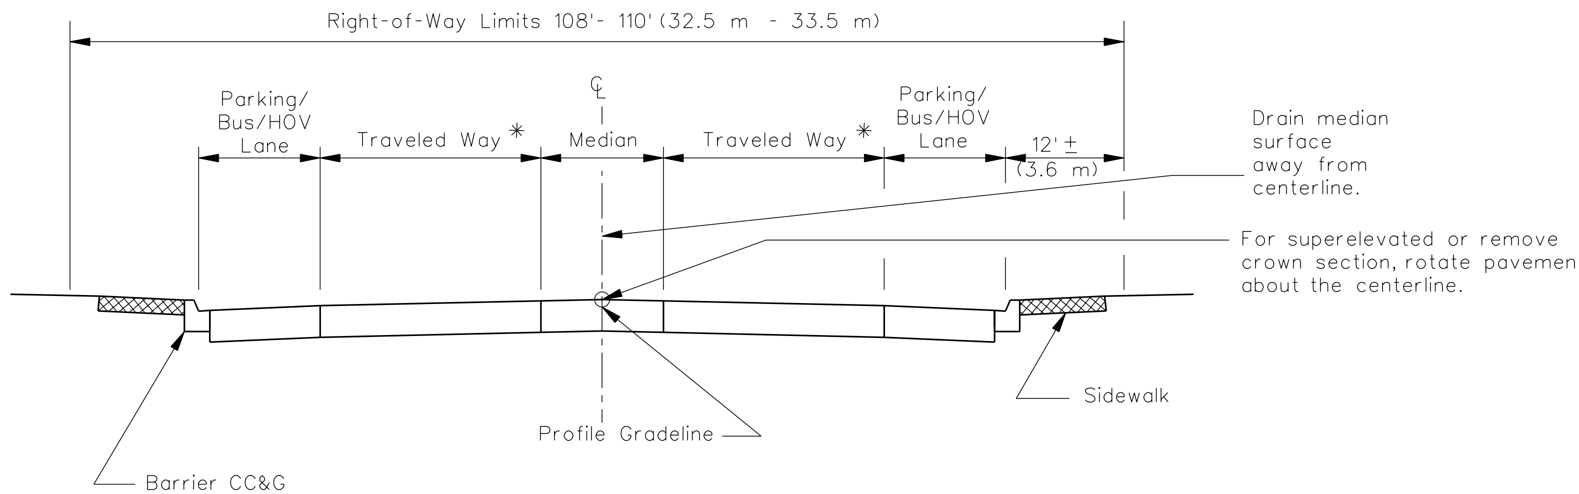


* If no bus/HOV only lanes are required, ROW is typically 82 ft to 87 ft (25 m to 26.5 m) assuming a flush left-turn lane.

** If an 11 ft (3.3 m) wide flush median cannot be obtained due to restricted ROW, then consider and investigate a one-way arterial pair.

TYPICAL URBAN SRA ROUTE
(Two-Block Segment)

Figure 46-2.A



* *Where it is desirable to accommodate bicycle demand and ROW is not restricted, an additional width may be added to each direction of the traveled way for bicycles.*

DESIRABLE URBAN SRA CROSS SECTION
(With HOV/Bus Lanes)

Figure 46-2.B

46-2.02(c) Horizontal and Vertical Clearances

The vertical clearances for urban SRA routes are presented in Figures 33-5.A and 46-2.E. Because most urban SRA's are existing routes, vertical clearances may need to be increased to provide for the unrestricted movement of large vehicles. Bridges that do not provide a minimum of 14 ft 09 in (4.50 m) clearance above the roadway are candidates for modification. Bridges which provide a vertical clearance of 14 ft 00 in (4.25 m) may remain in place, but should be considered for reconstruction or other means to achieve a minimum vertical clearance of 14 ft 09 in (4.50 m). Where the SRA route is an underpass, the recommended method to increase the vertical clearance is to lower the roadway through milling, raising the pier height, reconstructing the bridge, or other methods. Carefully evaluate potential drainage and utility problems where these methods are proposed.

Horizontal clearances along urban SRA routes should provide 1.5 ft (500 mm) from face of curb to an obstruction. Bridge railings and abutments are typically the two most important items to check concerning horizontal clearances. See Section 38-3 for additional guidance. Obstructions (e.g., utility poles) within this clearance should be modified or reconstructed, if feasible.

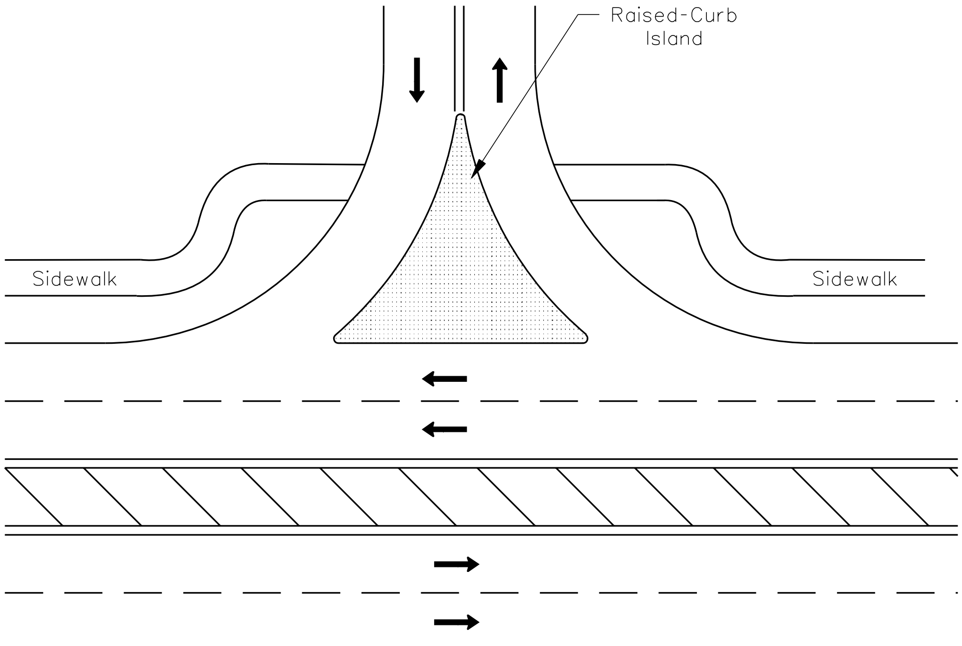
46-2.03 Access Management

The use of access management techniques is one of the most important concepts implemented on the SRA system. Length of travel time and driver safety are influenced by the number and configuration of access points to the SRA. Each driveway and cross street reduces mobility and safety. Where this may be a problem, consider the following techniques:

1. Eliminate Local Street Access. To improve operations, evaluate closing some local low-volume streets. This is generally not considered a problem where the typical urban street pattern is (8 to 12 streets per mile (5 to 8 streets per km)). Do not close streets that serve as collectors. Where streets are closed, maintain access for pedestrians and bicyclists, where practical.

2. Restricting Curb Cuts. Where curb-cut access is allowed along urban SRA routes, it is preferable that only right-in and right-out turns be permitted. This will prevent left-turn movements from and onto the SRA across through traffic lanes. An example of this design is shown in Figure 46-2.C. This is especially important where a left-turn lane cannot be provided. Another desirable feature is to minimize the number of access points by eliminating or consolidating curb cuts. However, because it is impractical to eliminate all curb cuts, the most beneficial way to increase the efficiency of through movements is to provide for a center-turn lane on the urban SRA. This design feature will remove turning traffic from through lanes.

   Chapter 35 provides further guidance on access management techniques that are also applicable to urban SRA routes.



Note: Where ROW is restricted, favor ingress maneuvers over egress maneuvers.

DRIVEWAY CHANNELIZATION
(Right-In and Right-Out Only)

Figure 46-2.C

46-2.04 Intersections

In addition to Chapter 36, the following is applicable to intersections on urban SRA routes:

1. Turn Lanes. Section 36-3 provides the warrants and design criteria for turn lanes. Where turn lanes are provided, maintain at least two through lanes in each direction. In addition, the following will apply:

   a. Left-Turn Lanes. Provide left-turn lanes at all signalized intersections. Where a left-turn lane cannot be provided on the SRA to local streets, discourage or prohibit the left turns.

   b. Right-Turn Lanes. Where pavement width is available, include right-turn lanes where warranted. It is recommended that parking on the approach and far side of the intersection be prohibited within 100 ft (30 m) of all major intersections to allow for a right-turn lane.

   c. Dual Left-Turn Lanes. Where there are high left-turn volumes and available right-of-way, dual left-turn lanes are recommended to alleviate congestion. If used, operate dual left-turn lanes using the "protected only" phasing. For access management, separate the dual left-turn lanes and the turn lane taper from opposing through lanes by a raised-curb median; see Chapters 35 and 36.

2. Turning Radii. Insufficient turning radii for trucks can significantly affect capacity at an intersection. Small radii may require large trucks to slow down to maneuver through the turn, encroach in opposing lanes, or encroach onto the curb. Design the curb radii to meet the expected design vehicle. Intersection design vehicles are discussed in Section 36-1.08. However, do not indiscriminately apply turning radii improvements to urban intersections. Frequently, in urban areas there are heavy pedestrian volumes and shallow setbacks for buildings. Only propose turning radii improvements after a determination that the existing sidewalk width and adequate pedestrian capacity can be maintained.

3. Approaches. Intersections on urban routes with more than four approaches can cause operational problems. To alleviate this problem, consider one of the following options:

   - close one of the approaches;
   - install a roundabout;
   - convert one of the approaches to one-way operation going away from the intersection;
   - provide an extremely short signal timing on one of the approaches to reduce the desirability of the approach; or
   - relocate the excess approaches away from the intersection. This is the most desirable option. However, right-of-way requirements usually make this option difficult to implement.

4. Medians. Where a median cannot be provided on the SRA route, movements between the local streets and the SRA may be restricted to the right-in/right-out.

5. Capacity. At intersections where capacity is limited and volumes are high, left-turn restrictions and the elimination of signalized turn phases may be necessary. This will increase the capacity on the SRA route and reduce intersection conflicts. Alternative routes or access will be required for the affected movements. In some instances, limiting left-turn movements during peak periods on the SRA route may be beneficial to through roadway operations. This alternative is appropriate at locations where turn lanes are not available.

6. Pavement Markings. Chapter 36 and the *Illinois MUTCD* provide information on pavement markings at channelized intersections.

7. Pedestrians. Where pedestrians are required to cross wide intersections, raised-curb center islands of sufficient size and width can provide a refuge area for pedestrians.

46-2.05 Railroad Grade Separations

Grade separations at railroads provide the greatest capacity and safety on an SRA route. However, limited right-of-way and economic considerations in urban areas may restrict the use of grade separations to isolated locations. Protection of sufficient right-of-way is critical where a grade separation is recommended. Design criteria for grade separations are discussed in Chapter 44.

46-2.06 Interchanges

In urban areas, right-of-way and economic feasibility tend to restrict the use of interchanges. However, where the intersection peak-hour level of service in the design year is expected to be E or F, consider providing an interchange. Where interchanges are provided, the single point urban diamond interchange or compressed diamond interchange are recommended to fit into existing right-of-way limitations. Chapter 37 provides further guidance on the selection of interchange types.

Under certain conditions, consider providing a U-turn movement at the cross street as discussed in Section 37-3.04. This design allows the exiting driver access to the opposing frontage road without passing through the signalized intersection on the cross street.

Where an interchange is proposed at the intersection of two SRA routes, give priority for the grade-separated structure to the route with the higher traffic volume.

Evaluate upgrading existing incomplete interchanges to provide for all movements (e.g., half diamonds, partial cloverleafs). Traffic conditions and directional flows that existed at the time of initial construction may have significantly changed. In addition to providing all movements, evaluate widening existing structures, lengthening storage bays for left-turning vehicles, adding right-turn lanes, and interconnecting traffic signals to improve traffic progression along the SRA route.

46-2.07 Drainage

Drainage problems are intensified in urban areas where high runoff coefficients are often combined with storm drainage systems of inadequate capacity. The *IDOT Drainage Manual* provides guidance for the design and construction of all drainage improvements. Chapter 48 illustrates a more efficient means to reduce the flow of water from the high side to the low side of a superelevated urban horizontal curve.

46-2.08 Removal of On-Street Parking

Although on-street parking is typically permitted on portions of urban SRA routes, it can significantly affect the capacity of the route and may constitute a safety hazard as drivers enter and exit parking spaces. Where practical, consider permanently removing the on-street parking or restricting it during peak hours. However, before pursuing these actions, there should be sufficient off-street parking available, and the route should meet one or more of the following conditions:

- there are less than two travel lanes in each direction and there is insufficient room to provide two through lanes within the existing cross section,
- the projected level of service is expected to be D or worse during peak hours,
- there are high number of crashes attributed to the on-street parking (e.g., 5 crashes per year per 10,000 ADT), and/or
- there is a need for a median where none currently exist.

If adequate off-street parking exists in public or private lots and garages, eliminate the on-street parking. If the existing parking inventory is not adequate to absorb those vehicles currently parked on the street, consider adjacent parcels (vacant or non-vacant) of land in the vicinity that could be developed for additional off-street parking.

46-2.09 Traffic Control Devices

46-2.09(a) Traffic Signals

Interconnect all traffic signals on urban SRA routes into signal networks or signal systems. Signal networks are beneficial in urban areas where grid patterns of signalized intersections, parallel one-way SRA routes, or intersecting SRA routes exist. The network should establish a priority of the through movement for the SRA route. Where an urban SRA route is not located in a grid pattern of signalized intersections, or where numerous other signals are too close to establish a network, then signals along the SRA should be interconnected into a system to provide for progression of traffic.

Time all signal networks and signal systems on urban SRA routes for optimal progression based on a traffic engineering study. When timing traffic signals on urban SRA routes, a peak-hour level-of-service D is the lowest level-of-service acceptable for the SRA through lanes. This may require turning movements and cross streets to operate at a lower level-of-service, or this could require the use of one-way arterial pairs.

The use of a lagging left-turn signal phase (i.e., the left-turn phase comes after the through phase) can improve signal synchronization. Progression bandwidths, which control the time available during which all vehicles can progress through a series of signals, can be increased with lagging left-turn phasing. However, use this type of phasing at T-intersections or intersections that only allow left turns during a protected phase. Do not use lagging left turns where left turns are permitted during the permissive green phase.

In many urban areas pretimed traffic signals are commonly used. If pretimed traffic signals that are not tied into the network are encountered along urban SRA routes, consider replacing them with fully actuated signals.

Chapter 57 and the Bureau of Operations *Policies and Procedures Manual* provide additional information on traffic signals.

46-2.09(b) Stop Sign Removal

Stop sign control for traffic movements on an SRA route is inconsistent with giving priority to the SRA through movement. Therefore, remove any stop signs on the urban SRA route. However, before removal, it will be necessary to conduct a traffic engineering study to determine the appropriate traffic control at the location for both the SRA route and the intersecting cross street.

46-2.09(c) Pavement Markings

Because of their durability and visibility, only use high-type pavement markings on SRA routes. High-type pavement markings include thermoplastic, epoxy, and pre-formed plastics. Also consider including raised pavement markers on SRA routes. Although street lighting is prevalent in the urban environment, raised pavement markers introduce an element of safety to the SRA route during inclement weather. Space raised pavement markers according to the criteria in the Bureau of Operations *Policies and Procedures Manual* and the *IDOT Highway Standards*.

46-2.09(d) Driver Information Systems

In addition to providing signs and pavement markings to guide motorists, furnishing motorists with information on congestion, construction, or other incidents that may affect their trip is important. Driver information systems may include variable or fixed message signing, radio and television traffic reports, newspaper articles, and brochures.

46-2.10 Trucks

Preferably, locate all loading and unloading areas off the SRA route. This may be accomplished by improving alley access, moving loading areas to nearby side streets, providing a central mid-block loading area, etc. Where off-street loading options are not available, one option is to remove or restrict on-street parking. Locate these unloading zones away from intersections so that right-turning traffic can use the curb lane at the intersection.

46-2.11 Transit

46-2.11(a) Improvements

There are numerous transit techniques that may be implemented to improve the operations of an urban SRA route. Some of these include:

1. Ridesharing. Carpools and vanpools are the most common form of ridesharing.

2. High Occupancy Vehicle (HOV) Lanes. This application is discussed in Section 46-2.11(c).

3. Transit Contra-Flow Lanes. This option allows transit vehicles to travel in the reverse direction from the general traffic in a reserved transit lane. This may be applicable if there is reserve capacity available in the non-peak direction. A physical barrier may be required to separate the bus lane from the opposing lanes.

4. Passenger Facilities. Consider providing passenger facilities that make it easier and safer to use transit facilities.

5. Signal and Intersection Improvements. Consider providing signal and intersection improvements that improve the transit operations (e.g., signal preemption, larger turning radii).

46-2.11(b) Local Bus Service

On urban SRA routes that accommodate bus routes, consider transit service enhancements to determine their potential for relieving traffic congestion. This may include the following:

1. Removing Parking. One option is to remove parking from the curb lane, with strict enforcement of parking restrictions, allowing the curb lane to be used as a HOV/bus lane (i.e., through or turning); see Section 46-2.08.

2. Bus Stops. Bus stop turnouts are generally not considered practical on urban SRA routes. However, review the location and spacing of bus stops, passenger amenities, and signal preemption to determine if improvements can be made. Major objectives would be to eliminate stops if there are more than one per block and to eliminate conflicts with right turns. Where the blocks are short, as in central business districts, stops could be located at every other block.

3. Exclusive Lanes. One strategy to improve travel times is to establish exclusive lanes for buses and high-occupancy vehicles during the morning and evening peak travel periods. The SRA route must have at least three traffic lanes in each direction. Section 46-2.11(c) provides further information on the suitability of HOV lanes in urban areas. A companion measure is to minimize access points next to an exclusive lane by eliminating curb cuts wherever practical.

46-2.11(c) HOV Lanes

High occupancy vehicle (HOV) lanes designated for buses, car pools, vanpools, and bicyclists may be appropriate in selected areas with high levels of transit ridership and ridesharing activity. There also should be adequate capacity to accommodate traffic in general use lanes. The following criteria and conditions are applicable outside the central business district for an HOV lane along the curb or median. The HOV lane should not involve major new construction or right-of-way acquisition (i.e., the existing pavement should be used). The facility should be designed primarily for buses, although car pools, van pools, and bicyclists should also be encouraged. One or more of the following conditions should apply and all of the following criteria should be met before an HOV lane is implemented:

1. Conditions. One or more of the following conditions should be met:

   a. High Level of Usage (Curb Lane). Route segments should have an existing or projected transit ridership of at least 1200 one-way passengers in the peak hour. A curb HOV lane should be used almost exclusively by buses. Existing or projected bus volumes should be 15 to 40 vehicles one-way in the peak hour. Figure 46-2.B illustrates a cross sectional view with a HOV/bus lane adjacent to a curb.

   b. High Level of Usage (Median Lane). Route segments should have an existing or projected usage of 2400 one-way passengers or rideshare occupants in the peak hour. A higher demand threshold has been established for a median HOV lane to reflect the potential for higher costs and operational problems associated with implementation. Figure 46-2.D illustrates bus lane treatments within the median. Where used, general vehicular traffic should only be allowed to make left turns at other SRA routes.

2. Criteria. All of the following criteria must be met:

   a. Reduce Total Person Delay. There should be a net reduction in the average travel time per person for all users of the route.

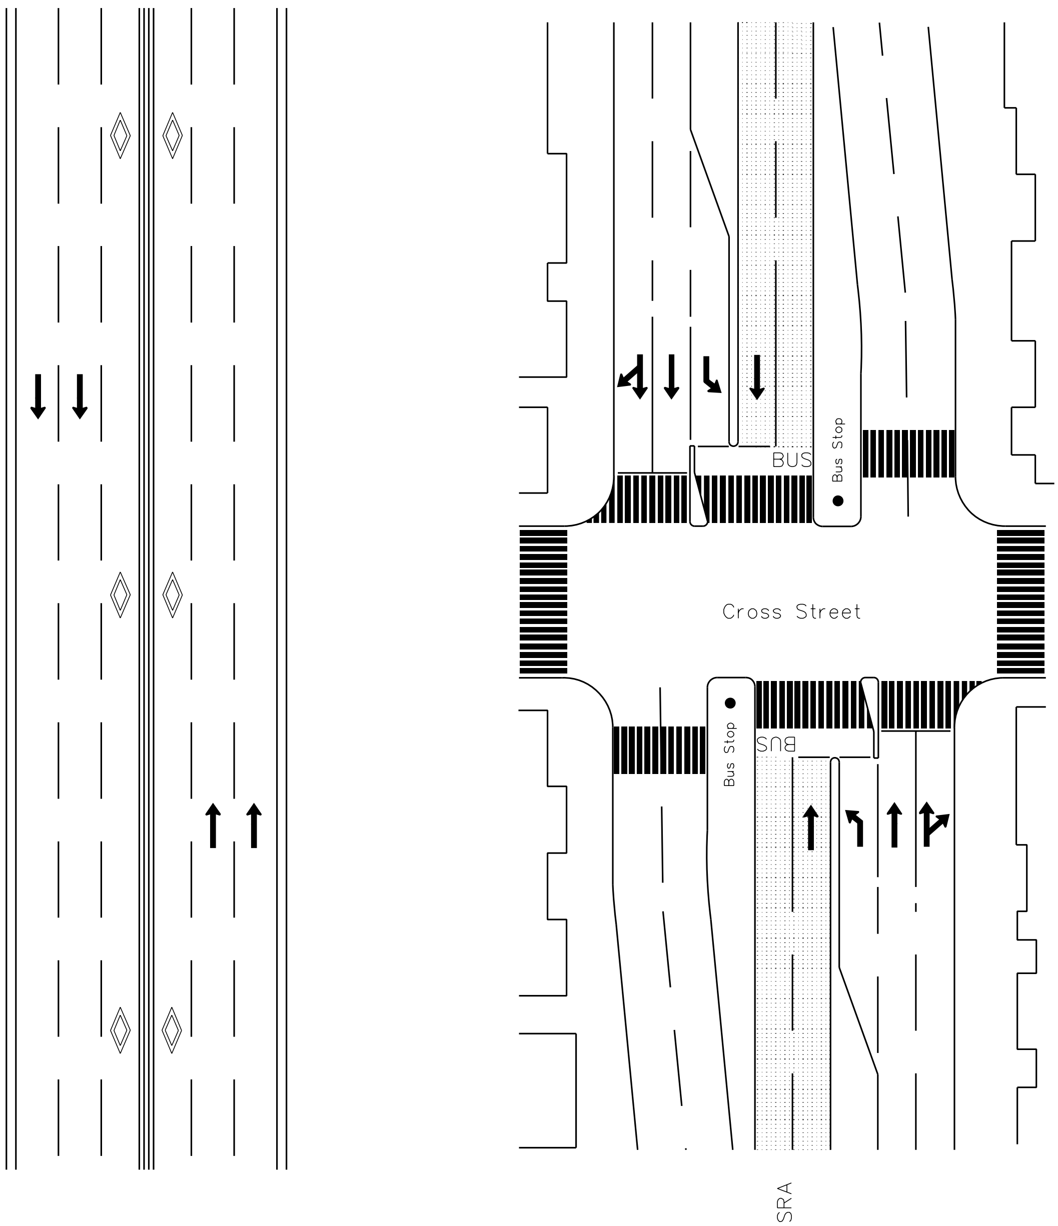
   b. Minimal Disruption to Traffic Operations. It must be feasible to institute left-turn restrictions and signalization adjustments necessary for HOV operations with only minimal disruption to traffic flow in the general use lanes.

   c. No Peak-Hour On-Street Parking or Loading. For implementation of a curb HOV lane, it must be feasible to prohibit parking and loading and unloading in the curb lane; see Section 46-2.08.

   d. More than the Minimum Number of Travel Lanes. In urban areas, three through lanes should exist in each direction where one lane can be assigned for HOV use. This provides for the minimum of two through lanes to be maintained unless the situation warrants changing the street into a one-way arterial pair.

46-2.12 Pedestrians and Bicyclists

Safe movement and accessibility are key issues for bicyclists and pedestrians. Urban SRA corridors are likely to experience bicyclists and a high volume of pedestrians, which may significantly impact the capacity and operations of the SRA route. One advantage of urban routes is that there typically are close parallel routes that may be considered for bicycle and pedestrian routes. Identify these parallel facilities as bicycle routes so that the SRA routes can



MEDIAN BUS LANE TREATMENTS

Figure 46-2.D

be reserved for vehicular traffic. At major obstacles (e.g., river crossings, canals, railroad bridges, limited access facilities), ensure that adequate provisions are available so that pedestrians and bicyclists have access across these barriers. Chapter 17 provides additional information for bicycle and pedestrian facilities. Chapter 58 provides information on accessibility requirements.

46-2.13 Environmental Considerations

The environmental analysis component of the SRA planning process is primarily an inventory of existing conditions. The inventory identifies those environmental resources in the corridor and probable impacts based on roadway improvements. Environmental assessments will be performed during the Phase I design work. These are discussed in Part III "Environmental Procedures" of this *Manual*.

46-2.14 Right-of-Way

Where there is restricted right-of-way, it is generally not feasible to provide the desirable urban SRA cross section as shown in Figure 46-2.B. In restrictive right-of-way locations, the designer should consider implementing one or more of the following options:

- providing a minimum of two through lanes in each direction,
- only allowing left turns from the SRA route at major intersections,
- consolidating and restricting intermediate access points,
- restricting on-street parking,
- restricting on-street loading and unloading zones,
- developing a one-way arterial pair, and/or
- considering alternative right-of-way acquisitions.

Where feasible, purchase additional right-of-way which allow improvements to the overall cross section of the SRA or to major intersections.

46-2.15 Tables of Design Criteria

Figure 46-2.E presents the Department's design criteria for new construction and reconstruction of urban strategic regional arterial projects. Figure 46-2.F provides the alignment criteria for urban SRA routes. The designer should realize that some of the cross section elements included in the figure (e.g., HOV/bus lanes) are not automatically warranted in the project design. The values in the figure only apply <u>after</u> the decision has been made to include the element in the highway cross section.

GEOMETRIC DESIGN CRITERIA FOR URBAN STRATEGIC REGIONAL ARTERIALS (SRA)
(New Construction/Reconstruction)
(Metric)

Figure 46-2.E
(1 of 2)

(1) Design Speed. The 30-mph (50-km/hr) design speed should only be used in central business districts.

(2) Traveled Way Width. If right-of-way is restricted, 11 ft (3.3 m) travel lanes may be used ((i.e., 2 @ 22 ft (6.6 m)).

(3) Flush Median Width. Use 14 ft (4.0 m) if there is a significant number of trucks making left turns. If a 11 ft (3.3 m) wide flush median cannot be provided due to restricted right-of-way, consider the use of a one-way arterial pair.

(4) Parking Lane Width. If the parking lane will be used as a travel lane or bus/HOV lane during peak hours or may be converted to a travel lane in the future, provide a 12 ft (3.6 m) width. The width of the parking lane includes the gutter width.

(5) Travel Lane Cross Slope. For parking/bus/HOV lanes, the cross slope is 5/16″ /ft (2.5%).

(6) Clear Zone. For curbed facilities, the minimum horizontal clearance to an obstruction is 1.5 ft (500 mm) measured from the face of curb.

(7) New and Reconstructed Bridge Widths. Clear roadway bridge widths are measured from face to face of outside curbs or parapets walls. Urban bridge widths are normally defined as the sum of the approach traveled way widths, the width of the median, and the width of gutters. A sidewalk or bikeway will result in additional bridge width. For sidewalks proposed on bridge, add 10 ft (3.0 m) to each side of bridge.

(8) Existing Bridge Widths to Remain in Place. Clear roadway bridge widths are measured from face to face of outside curbs or parapet walls. Implies elements allowed to remain in place without a design exception approval when cost effective and when safety record is satisfactory. Provide at least one sidewalk across the bridge.

(9) Vertical Clearance (SRA Under).

a. The clearance must be available over the traveled way and median where a flush median is used.
b. Table value includes allowance for future overlays.
c. The 14 ft 0 in (4.3 m) clearance may be allowed to remain in place with consideration for reconstructing to a clearance of 14 ft 9 in (4.5 m).

(5) Superelevation Rate. See Section 48-5 for superelevation rates based on e_{max}, design speed, and radii of horizontal curves.

(6) Horizontal Sight Distance. For a given design speed, the necessary horizontal sight line offset will be determined by the radius of curve and the required sight distance.

ALIGNMENT CRITERIA FOR URBAN STRATEGIC REGIONAL ARTERIALS (SRA)
(Metric)

Figure 46-2.F

46-3 SUBURBAN SRA ROUTES

46-3.01 General Roadway Features

46-3.01(a) General

The recommended design for suburban SRA's is three lanes in each direction divided by a raised-curb median. Initially, provide a minimum of two travel lanes in each direction. Reserve sufficient right-of-way to allow for the recommended design. Figure 46-3.A illustrates a plan view design configuration for a suburban SRA. Figure 46-3.B illustrates the initial and recommended cross sections for a suburban SRA. For an illustration of a superelevated section, see Figure 45-2.G.

46-3.01(b) Bypass Facilities

Certain suburban SRA routes are characterized by relatively lengthy segments of roadway that connect suburban central core areas. Frequently, these suburban central cores feature traffic capacity constraints (e.g., narrow right-of-way, minimal setbacks, numerous curb cuts, traffic signals). The recommended suburban SRA route (i.e., typical section of six through lanes and an 18 ft, 22 ft, or 30 ft (5.5 m, 7.0 m, or 9.5 m) median width) generally will not be attainable through such suburban cores. Therefore, it may be advantageous to designate a bypass route for the SRA around these central core areas. Bypass routes should be designated on parallel facilities reasonably close to the original SRA route and must be clearly signed as such. Bypass routes may be designed to work in tandem with the originally designated SRA or may become the solely designated SRA. In either case, the travel demands of the area and stipulated level-of-service requirements should be met where a bypass route is proposed.

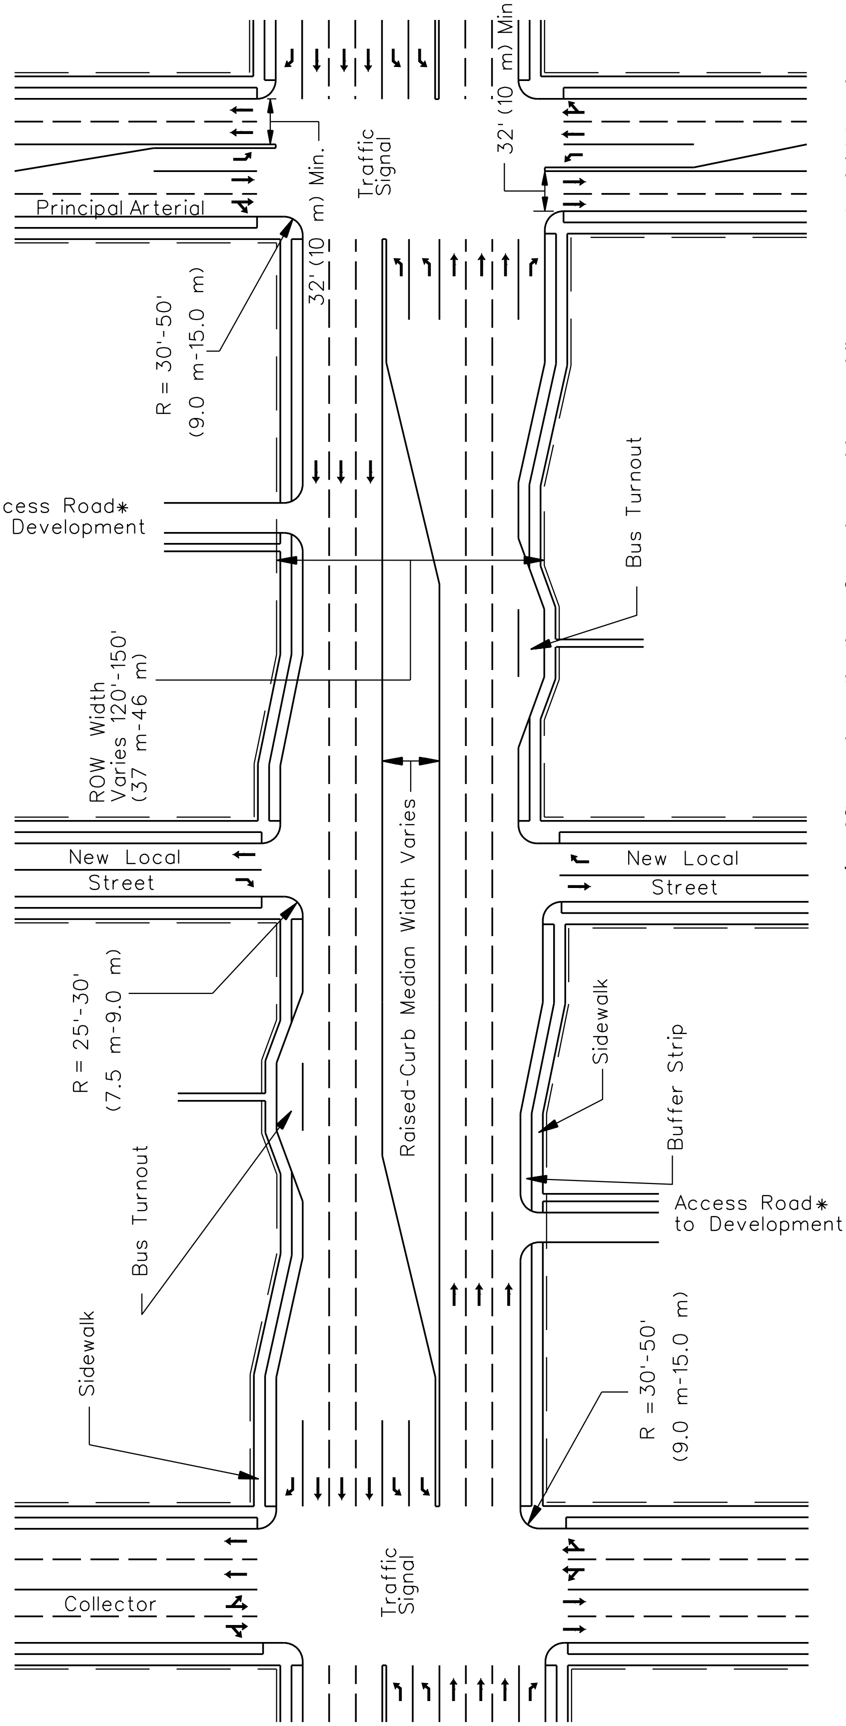
Due to the extent of suburban development, it is recommended that bypass routes usually be designated on existing roads. Only consider construction of a new roadway where large tracts of undeveloped land or unused rights-of-way exist. In this case, provide a facility with partial access control.

46-3.02 Geometric Design Elements

46-3.02(a) Median Types

When selecting and designing medians for suburban SRA routes, consider the following:

1. General. If a proposed suburban SRA route presently consists of only a four-lane cross section (two through lanes in each direction) in a restrictive right-of-way location, it is recommended that emphasis be placed upon the construction of an 18 ft (5.5 m) median to separate left-turning vehicles from the through stream of traffic. If no additional right-of-way is available for a median, only permit left turns at major intersections or consider the feasibility of creating one-way arterial pairs.

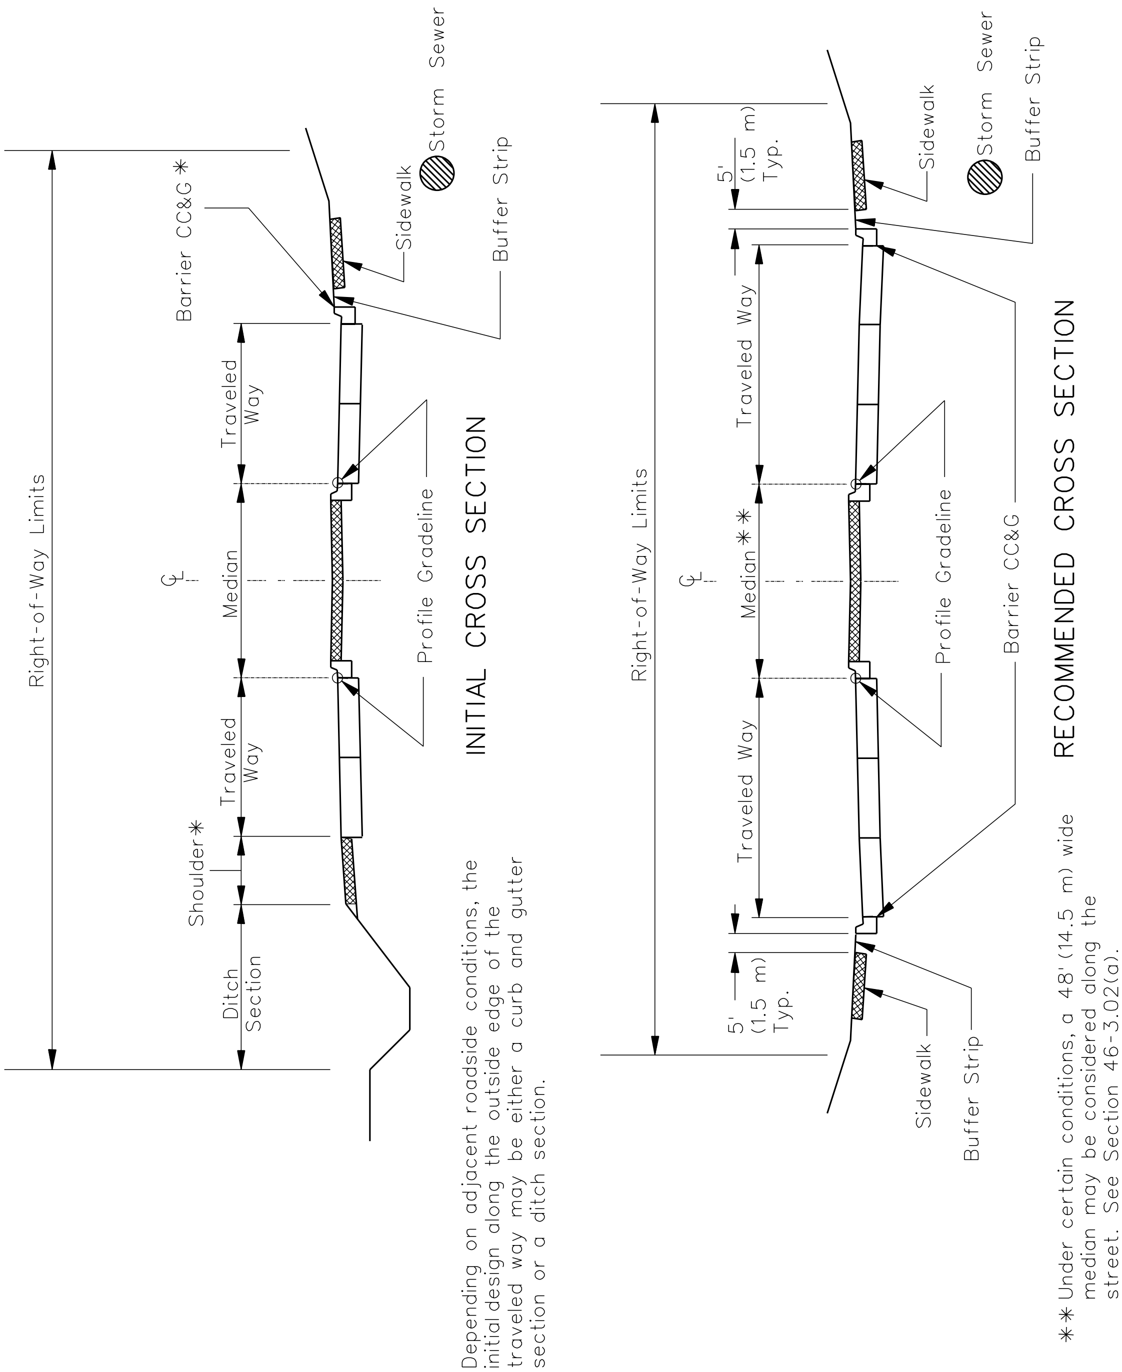


* After an investigation of need, consider providing a separate right-turn lane on the SRA into the development.

Note: See Section 36-1.08 for selection of design vehicles.

TYPICAL SUBURBAN SRA ROUTE (1/2 mile (800 m) Segment)

Figure 46-3.A



SUBURBAN SRA CROSS SECTION
(initial and Recommended)

Figure 46-3.B

2. <u>Raised-Curb Median</u>. It is recommended that all suburban SRA routes be constructed with barrier-curb medians, but barrier-curb is required adjacent to dual left-turn lanes. The raised-curb median will prohibit left-turning vehicles at minor cross streets and driveways, direct turning movements to desired locations, and reduce opposing traffic conflicts. Because raised-curb medians control the location of left turns from the street, there may be the need to allow occasional U-turn movements at certain signalized intersections along the SRA route. These movements can provide access to both sides of the roadway while limiting crossing maneuvers at mid-block locations. Signal timing must be adjusted to provide the additional left-turn signal time needed for the U-turns.

   The desirable median width on suburban SRA routes is 22 ft (7.0 m) where unsignalized intersections will exist. The 22 ft (7.0 m) width allows for the storage of most passenger vehicles in the median at unsignalized intersections for crossover movements or for left turns from the side street onto the SRA. If no unsignalized intersections will exist on a segment of the SRA or where right-of-way is restricted, the median width can be reduced to 18 ft (5.5 m) where single left-turn lanes are provided. However, if it is determined that dual left-turn lanes are needed, the minimum median width is 30 ft (9.5 m).

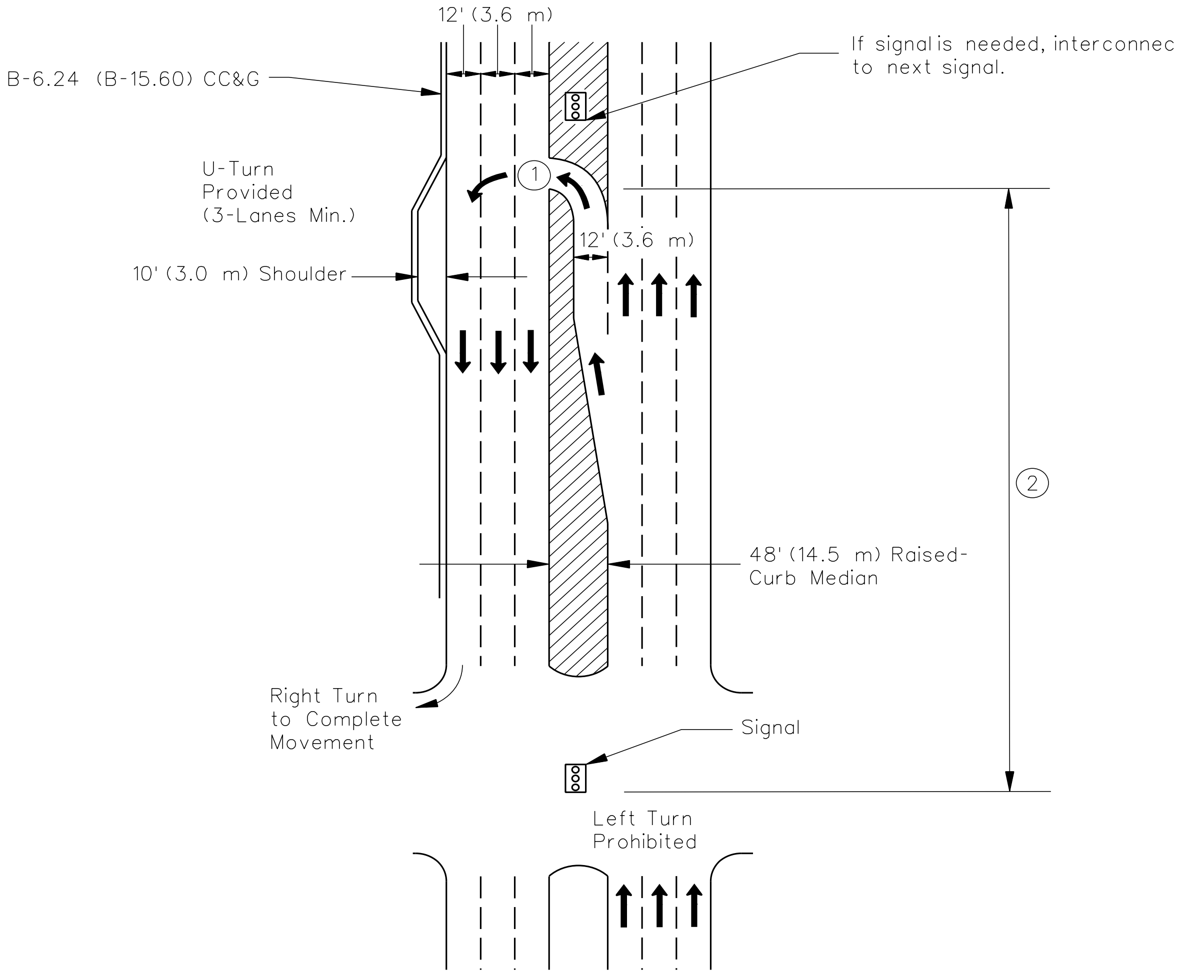
   Under some circumstances, it may not be practical to use a raised-curb median. In these cases, consider providing a flush or traversable TWLTL design.

3. <u>U-Turn Crossovers with Raised-Curb Medians</u>. On some high-volume suburban SRA routes, the volume of left turns at many intersections may cause reduced traffic flow for through movements. Also, there may be a considerable demand for U-turn movements by large trucks serving businesses and industry along the route. If sufficient right-of-way is available, an alternative strategy is to not allow left turns at major intersections, but instead provide for a U-turn movement beyond the intersection. The benefits are increased capacity on the SRA route and simplified intersection phasing. An example of this concept is shown in Figure 46-3.C.

   Only use this concept where it can be provided continuously for a distance of 3 miles to 5 miles (5 km to 8 km) and where the proposed median is at least 50 ft (14.5 m) wide. Provide a B-6.24 (B-15.60) curb and gutter along the median and mound the median with earth. The mounded earth median may be landscaped along the centerline.

   Use a WB-55 (WB-17) design vehicle for the design of the U-turn movement. Provide a 10 ft (3.0 m) wide outside stabilized shoulder with curb and gutter along the right edge of shoulder adjacent to the U-turn lane; see Figure 46-3.C.

4. <u>TWLTL Medians</u>. In areas where there are numerous access points along an existing roadway (e.g., commercial areas), continuous two-way left-turn lanes may increase mobility and reduce conflicts. This design may be considered in suburban areas where there are numerous existing access points and where other solutions to control access (e.g., frontage roads, access closures, raised-curb medians) cannot be implemented. Chapters 34 and 48 provide guidance on flush and traversable TWLTL.



Notes:

1. *Use the WB-55 (WB-17) design vehicle for the design of the U-turn movement.*

2. *The minimum distance is dependent on the design speed of the street, left-turning volumes, and space needed for advance guide signs.*

U-TURN CROSSOVERS WITH A RAISED-CURB MEDIAN

Figure 46-3.C

46-3.02(b) Additional Lanes

Some proposed suburban SRA routes may presently consist of a four- or five-lane pavement section through residential or commercial areas with minimal setbacks. It may not be feasible to obtain the additional right-of-way required for expansion into the recommended roadway cross section at these locations.

46-3.02(c) Vertical Clearances

The vertical clearances for suburban SRA routes are presented in Figure 46-3.E. Where practical on existing routes, vertical clearances may need to be increased to provide for the unrestricted movement of large vehicles. Bridges that do not provide a minimum of 14 ft 9 in (4.5 m) vertical clearance above the roadway are candidates for modification. Bridges which provide a vertical clearance of 14 ft 00 in (4.25 m) may remain in place, but should be considered for reconstruction or other means to achieve a minimum vertical clearance of 14 ft 9 in (4.5 m). Where the SRA route is an underpass, the recommended method to increase the vertical clearance is to lower the roadway through milling, raising the pier height, reconstructing the bridge or other methods. Carefully evaluate potential drainage and utility problems where these methods are proposed.

46-3.03 Access Management

The use of access management techniques is one of the most important concepts implemented on the SRA system. The number and configuration of access points to a suburban SRA route influence length of travel time and driver safety. Each driveway and cross street reduces mobility and safety. To improve access management, consider the following techniques:

1. Eliminate Local Street Access. To improve operations, consider closing some low-volume minor roads and local streets. The feasibility of terminating or rerouting the minor route will depend on local street traffic volumes, emergency vehicle response times, and the availability of alternative routes.

2. Restrict Curb Cuts. To improve mobility and safety on the suburban SRA route, consider the following restrictions:

   a. Sideroad Access. Where a parcel of property has access available from a side street, only allow access from the non-SRA route.

   b. Directional Movements. Where curb-cut access is allowed along a suburban SRA route, it is preferable that only right-in and right-out turns be permitted. This will prevent left-turn movements onto the SRA across through traffic lanes. An example of this design is shown in Figure 46-2.C.

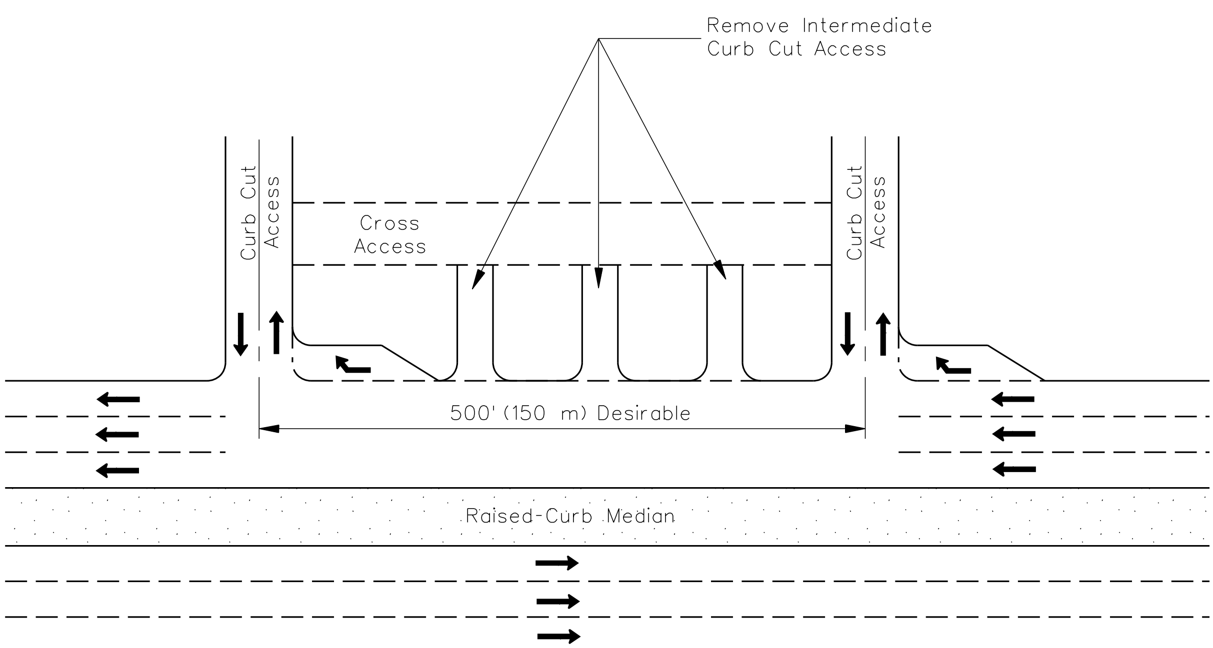
   c. Consolidating Access Points. In suburban areas where numerous curb-cut access points are present, it is recommended that the access be consolidated into single points at a desirable spacing of 500 ft (150 m) between access points.

This is illustrated in Figure 46-3.D. The properties should be interconnected through the use of cross-access easements.

d. Left-Turn Restrictions. Discourage left-turn movements from the SRA into curb-cut access points. However, where this prohibition may not be feasible, increase the length of the turn-lane storage to accommodate left-turn queues during peak hours.

3. Develop Internal Access. Where new development or redevelopment occurs adjacent to a suburban SRA, it is desirable to provide internal circulation roads within the development. Design the circulation roads to accommodate not only automobiles, but delivery trucks, transit, and bicycles. Also, provide sidewalks within the development. If a signal and median crossover are warranted at the new access point, the spacing should not be less than ¼ mile (400 m) to an adjacent signal.

Access management principles should be coordinated among communities along each suburban SRA route. Chapter 35 provides further guidance on access management techniques that are also applicable to suburban SRA routes.



CONSOLIDATED ACCESS
(Suburban SRA)

Figure 46-3.D

46-3.04 Intersections

In addition to Chapter 36, the following is applicable to intersections on suburban SRA routes:

1. Turn Lanes. Section 36-3 provides the warrants and design criteria for turn lanes. Where developing turn lanes, it is important to maintain at least two through lanes in each direction. In addition, the following will apply:

   a. Left-Turn Lanes. Provide left-turn lanes at all intersections. It is recommended that the turn lanes be offset to provide increased sight distance to opposing traffic. See Section 36-3.03 for the design of offset left-turn lanes.

   b. Right-Turn Lanes. Provide right-turn lanes where warranted.

   c. Dual Left-Turn Lanes. Where there are high left-turn volumes, consider providing dual left-turn lanes to alleviate congestion where the single left-turn lane storage length is inadequate (e.g., 350 ft (100 m)). Phasing for the dual left-turn lanes must operate under the “protected only” phasing. For access management, separate the dual left-turn lanes and the left turn taper from opposing through lanes by a raised-curb median; see Chapters 35 and 36. Within a suburban environment where development is eminent, provide a 30 ft (9.5 m) wide median to allow for future flexibility at major entrances with dual left-turn lanes.

2. Turning Radii. Insufficient turning radii for trucks can significantly affect capacity at an intersection. Small radii may require large trucks to slow down to maneuver through the turn, to encroach into opposing lanes, or encroach onto the curb. Design the curb radii to meet the expected design vehicle, typically a WB-50 (WB-15). Review turning radii improvements for their impacts on pedestrians and adjacent development. Design vehicles are discussed in Section 36-1.08.

3. Approaches. Intersections on suburban routes with more than four approaches can cause operational problems. To alleviate this problem, consider one of the following options:

   - close one of the approaches,
   - convert one of the approaches to one-way operation going away from the intersection,
   - provide an extremely short signal timing on one of the approaches to reduce the desirability of the approach, or
   - relocate the excess approaches away from the intersection; this is the most desirable option.

4. Channelization. In suburban locations, the recommended cross section consists of three through lanes in each direction, dual left-turn lanes, and exclusive right-turn lanes. To reduce the wide expanses of intersections, use center channelization and consider the

use of corner islands to direct the flow of vehicles through the intersection. Channelization also can be effective at intersections where approaches are not at or close to 90° angles. At these locations, channelization and corner islands can help guide motorists through the unusual turning movements that are often required. Chapter 36 provides guidance on the design of channelized intersections.

5. New Intersections. It is recommended that intersections with new local roads be restricted to right-in/right-out movements. A raised-curb median will restrict left-turn movements from the SRA to the local road, left-turn movements from the local road onto the SRA, and through movements on the local road across the SRA. However, alternative routes and emergency vehicular response times must be evaluated.

6. Intersection Lighting. All suburban SRA to SRA route intersections should have appropriate intersection lighting. See Chapter 56 for information on highway lighting.

7. Capacity. At intersections where capacity is limited and volumes are high, left-turn restrictions and the elimination of signalized turn phases may be necessary. This will increase the capacity on the SRA route and reduce intersection conflicts. Alternative routes or access will be required for the affected movements. In some instances, limiting left-turn movements to off-peak periods on the SRA route may be beneficial to through roadway operations.

46-3.05 Railroad Grade Separations

Providing a grade separation over an intersecting railroad can increase capacity and safety. However, the feasibility of this type improvement is dependent upon projected traffic volumes, roadway characteristics, posted speed, duration and volume of rail movements, and the amount of right-of-way available for overpass construction.

Evaluate all at-grade railroad intersections with suburban SRA routes for a potential grade separation. Preference for grade separation construction may be given to freight rail crossings where delays due to the length of freight trains are considerably longer than at crossings for passenger rail lines. However, the requirement for grade separations at commuter rail lines is important because peak rail and roadway traffic always coincide. Additional factors to assess include the proximity of the rail line to adjacent arterial intersections, access requirements, right-of-way availability, and projected traffic volumes on the suburban SRA.

At all locations where railroad grade separations are not feasible, investigate the use of constant warning time warning devices. Constant warning time (CWT) devices adjust the downtime of the gates based on the speed of the train. This helps reduce excessive delays to vehicular traffic caused by gates being down when trains are not present. This type of device can also recognize when a train is stopped. This can be beneficial where a train station is near an at-grade rail crossing. In some cases, it may be a more conservative design to have a simple DC circuit instead of the CWT circuitry. This proposal should be reviewed by someone who is knowledgeable in both crossing circuitry and train operations at the specific location.

46-3.06 Interchanges

Consider constructing an interchange if the projected level of service of an intersection in the design year is E or F using conventional improvements. Intersections that operate at level-of-service D or better generally are not candidates for interchange construction, unless unsafe geometric design features (e.g., excessive intersection skew) are present. Chapters 37 and 45 provide further guidance for interchange warrants and interchange design.

Suburban SRA routes are frequently characterized by a limited right-of-way availability. Interchange types that require the least amount of right-of-way (e.g., single point urban diamond, compressed diamond) are considered the most appropriate for suburban SRA routes. See Chapter 37 for further information.

For an intersection of two suburban SRA routes and where sufficient right-of-way is available, consider providing a cloverleaf interchange design. The advantage of this interchange type over the diamond interchange is that both intersecting facilities have uninterrupted through movements.

Under certain conditions, a U-turn movement could be added to a compressed diamond interchange between a suburban SRA route and a lower class/volume cross street. The underpass U-turn lane allows SRA vehicles to access an opposing frontage road without passing through signalized intersections on the cross streets. Figure 37-3.G illustrates this design.

All suburban SRA interchanges should have lighting. However, the lighting should not create "light pollution" problems from spillover into nearby residential areas.

46-3.07 Drainage

On suburban SRA routes, roadway drainage generally will consist of an enclosed system. During roadway reconstruction for lane additions or intersection widening, evaluate the existing drainage system for capacity or flooding problems. Any improvements to the existing drainage system must meet the criteria in the *IDOT Drainage Manual*.

46-3.08 Removal of On-Street Parking

On-street parking is currently permitted on some portions of SRA routes in suburban areas. On-street parking can significantly affect the capacity of the SRA route and may constitute a safety hazard as drivers enter and exit parking spaces. Where practical, consider permanently removing the on-street parking or restricting it during peak hours. Section 46-2.08 provides criteria for removal of on-street parking on urban SRA routes. This is also applicable to a suburban SRA route with one exception — if the level-of-service on the suburban SRA route is C or worse, consider removing the on-street parking.

46-3.09 Traffic Control Devices

46-3.09(a) Traffic Signals

Section 46-2.09 provides information on traffic signals for urban areas. In addition, the following applies to traffic signals in suburban areas:

1. Signal Type. Provide fully actuated traffic signals at all signalized intersections.

2. Signal Interconnection. Where feasible, interconnect all signalized intersections with a spacing of ½ mile (800 m) or less into signal systems. The interconnection is used to provide signal coordination and vehicular progression along the SRA route. Synchronize all signal systems along suburban SRA's for vehicular progression based on a traffic engineering study.

3. Spacing. If a signal is warranted at a local road or street, the spacing should not be less than ¼ mile (400 m) to an adjacent signal, but ½ mile (800 m) spacing is preferred.

4. Bus Preemption. All signalized intersections on suburban SRA routes should be capable of priority preemption for express bus service. This preemption capability should only be used to keep buses on schedule. Coordinate the preemption by buses with vehicular progression along the SRA route.

5. Level of Service. The goal of the traffic signal timing along suburban SRA routes is to achieve a level-of-service C or better for the arterial through lanes. To achieve this, it may be necessary to lower the level-of-service for the turning movements and cross streets to maximize the through movements on the SRA.

46-3.09(b) Warrants for Traffic Signals

Install traffic signals on SRA routes where the signal warrants in the *Illinois MUTCD* are met.

46-3.09(c) Overhead Signing

All suburban SRA-to-SRA route intersections should have advance overhead signing with route numbers and/or street names and, where appropriate, regional destinations. The lettering should be large enough to read at a distance of 350 ft to 400 ft (100 m to 125 m).

46-3.09(d) Stop Sign Removal

Stop sign control for traffic movements on an SRA route is inconsistent with giving priority to the SRA through movement. Therefore, remove stop signs from the through lanes of a suburban SRA route. However, it will be necessary to conduct a traffic engineering study to determine the appropriate traffic control at the location for both the SRA route and the intersecting cross street.

46-3.09(e) Pavement Markings

Because of their durability and visibility, only use high-type pavement markings on suburban SRA routes. High-type pavement markings include thermoplastic, epoxy, and pre-formed plastics. Also, include raised pavement markers on suburban SRA routes. Space raised pavement markers according to the criteria in the Bureau of Operations *Policies and Procedures Manual* and the *Highway Standards*. In addition, place reflectors on top of the raised-curb median.

46-3.09(f) Driver Information Systems

In addition to providing signs and pavement markings to guide motorists, it may be necessary to furnish information on congestion, construction, or other incidents which may affect their trip. Driver information systems may include variable or fixed message signing, radio and television traffic reports, newspaper articles, and brochures.

46-3.10 <u>Trucks</u>

Locate all loading and unloading areas off the suburban SRA street.

46-3.11 <u>Transit</u>

46-3.11(a) Improvements

Techniques associated with mass transit that may be applicable in certain suburban situations are described in Section 46-2.11. For suburban areas, it will also be necessary to improve transit station accessibility using one or more of the following techniques:

1. <u>Actuated Traffic Signals</u>. Transit station usage is extremely intensive during peak periods. Incorporating traffic signals on the SRA or connecting streets with phasing and timings that are responsive to the varying levels of traffic during the day will make transit stations more accessible and reduce delays. If new traffic signals are proposed at transit stations, they should meet the established traffic volume warrants and criteria for spacing of signals.

2. <u>Turn Lanes</u>. To maximize through traffic movements for vehicles not wishing to access transit stations, provide channelized right- and left-turn lanes for vehicles turning into transit stations. If demand is sufficient, provide dual left- and/or right-turn lanes. Appropriate storage bay lengths for turning vehicles must also be implemented.

3. <u>Park and Ride Lots</u>. Investigate providing parking for commuters. If a potential parking lot site is judged too far from the transit station, then parking in this area could be free or at a greatly reduced rate to encourage use. Another option is to provide satellite lots with free shuttle buses to the stations. Preferential parking stalls nearest to transit stations could be designated for High Occupancy Vehicles. Also, provide secure bicycle

parking at transit stations. Include left- and right-turn lanes at the entrance to the facility to enhance safety.

4. Transit Access. If substantial parking for a transit station is located on the opposite side of a SRA route, consider providing appropriate access for pedestrians.

46-3.11(b) Express Bus Service

Bus service on suburban SRA routes should be limited to express buses that are equipped with priority signal preemption capability that can be deployed when they are running behind schedule. However, coordinate the bus preemption with existing vehicular progression along the SRA route.

Design stops as bus turnouts; see Chapter 58. Walkways to stops of intersecting services will facilitate transfers and promote safety. Nearside and far-side bus stop configurations should be planned to minimize distances between connecting lines.

46-3.12 HOV Lanes

High occupancy vehicle (HOV) lanes designated for buses, carpools, and vans may be appropriate in selected areas with high levels of transit ridership and ridesharing activity. Note that there should also be adequate capacity to accommodate traffic in the general use lanes.

46-3.13 Pedestrians and Bicyclists

On suburban SRA routes, more options are available for accommodating pedestrian and bicycle access than in urban areas. For example, although right-of-way availability is still a critical issue, dense development immediately adjacent to the roadway is not as common an occurrence as in urban areas. Provisions for bicyclists and pedestrians may be accommodated within the SRA right-of-way itself. In suburban situations, alternative parallel routes may not always be available.

Access across major obstacles (e.g., river crossings, railroads, limited access facilities) or barriers will be accommodated by the SRA if alternative access is not feasible. The choice of how to provide access within the SRA corridor is determined on a case-by-case basis. Under all situations, the goal is to provide a continuous system of bicycle and pedestrian routes. Chapter 17 provides guidance on the design of bicycle and pedestrian facilities. Chapter 58 provides information on accessibility requirements.

46-3.14 Environmental Considerations

The environmental analysis component of the SRA planning process is primarily an inventory of existing conditions. The inventory identifies those environmental resources in the corridor and probable impacts based on roadway improvements. Environmental assessments will be performed during Phase I design work. These are discussed in Part III "Environmental Procedures" of this *Manual*.

46-3.15 Right-of-Way Acquisition and Corridor Protection

A major goal of the SRA planning process is to identify and protect future right-of-ways that are needed to construct the recommended roadway design configuration. Suburban right-of-ways may adjoin both developed and undeveloped properties. During Phase I studies, local governments should be contacted and encouraged to work with roadway jurisdictional agencies. This will ensure that adequate right-of-way is provided for suburban SRA routes in the approval process for new developments. Local governments should review their building setback requirements to ensure that all new building construction is outside the recommended SRA right-of-way widths. This will protect the right-of-way for future roadway expansion.

See the Bureau of Land Acquisition's *Manual of Policies and Procedures* for information on corridor protection procedures.

46-3.16 Tables of Design Criteria

Figure 46-3.E presents the Department's design criteria for new construction and reconstruction of suburban strategic regional arterial projects. Figure 46-3.F provides the alignment criteria for suburban SRA routes. The designer should realize that some of the cross section elements included in the figure (e.g., TWLTL widths) are not automatically warranted in the project design. The values in the figure only apply after the decision has been made to include the element in the highway cross section.

	Design Element			Manual Section	Desirable Design Values
Design Controls	Design Forecast Year			31-4.02	20 Years

GEOMETRIC DESIGN CRITERIA FOR SUBURBAN STRATEGIC REGIONAL ARTERIALS (SRA)
(New Construction/Reconstruction)
(Metric)

Figure 46-3.E
(1 of 2)

(1) Level of Service. For signal timing on suburban SRA routes, provide a LOS C for the arterial through lanes, which may allow a lower level of service for the cross streets or turning lanes.

(2) Median Width.

a. Raised-Curb. Where there is a U-turn demand for large trucks and undeveloped right-of-way is available, consider a median width of at least 50 ft (14.5 m) with curb and gutter.

b. TWLTL Width. Use 14 ft (4.0 m) if there is a significant number of trucks making left turns.

(3) Parking Lane Width. If the parking lane will be used as a travel lane or bus/HOV lane during peak hours or may be converted to a travel lane in the future, provide a 12 ft (3.6 m) width. The width of parking lane includes the gutter width.

(4) Travel Lane Cross Slope. For the third lane away from the median, increase the cross slope by 1/16″ /ft (0.5%).

(5) Clear Zone. For curbed facilities, the horizontal clearance to an obstruction is 1.5 ft (500 mm) measured from the face of curb.

(6) Cut Section (Uncurbed). In some cases, the initial construction of a suburban SRA may involve only providing two lanes in each direction with a shoulder and an outside ditch section. See Figure 46-3.B.

(7) New and Reconstructed Bridge Widths. Clear roadway bridge widths are measured from face to face of outside curbs or parapet walls. Suburban bridge widths are defined as the sum of the approach traveled way width, the width of the median, and the width of gutters.

(8) Existing Bridge Widths to Remain in Place. Clear roadway bridge widths are measured from face to face of outside curbs or parapet walls. Implies elements allowed to remain in place without a design exception approval when cost effective and when safety record is satisfactory. Sidewalks must be carried across both sides of the, bridge. Approach width shown assumes initial stage construction of only two lanes in each direction.

(9) Vertical Clearance (SRA Under).

a. The clearance must be available over the traveled way and flush median.
b. Table value includes allowance for future overlays.
c. A 14 ft 0 in (4.3 m) clearance may be allowed to remain in place with consideration for reconstruction to a clearance of 14 ft 9 in (4.5 m).

(5) Superelevation Rate. See Section 48-5 for superelevation rates based on e_{max}, design speed, and radii of horizontal curves.

(6) Horizontal Sight Distance. For a given design speed, the necessary horizontal sight line offset will be determined by the radius of curve and the required sight distance.

ALIGNMENT CRITERIA FOR SUBURBAN STRATEGIC REGIONAL ARTERIALS (SRA)
(Metric)

Figure 46-3.F

46-4 RURAL SRA ROUTES

46-4.01 General Roadway Features

46-4.01(a) General

The recommended design for rural SRA's is to construct two or three lanes in each direction separated by a wide depressed median. The wide median will allow the addition of future through lanes in the median with minimum disruption to highway users and surrounding development. The facility may include two-way frontage roads on both sides of the mainline highway. Sufficient right-of-way should be reserved initially to allow for the recommended design. Figure 46-4.A illustrates a plan view design configuration for a rural SRA with frontage roads. Figure 46-4.B illustrates the recommended cross section for a rural four-lane SRA. Initial stage construction and bypass routes around communities would not involve the use of frontage roads. For an illustration of a superelevated section, see Figure 45-2.E.

46-4.01(b) Bypass Facilities

Many rural SRA routes are characterized by relatively lengthy segments of roadway that connect existing communities. A rural SRA route that approaches a community may better serve the concept of regional mobility if it bypasses the town. There are two options to consider for rural SRA routes at a community. One is to designate an existing highway through the town as the planned SRA route, and the other is to construct a new bypass facility. Only consider the construction of a bypass facility where there are large tracts of undeveloped land or unused rights-of-way. Also, every effort should be made to use the rights-of-way of existing roadways for the bypass alignment. As a minimum, any bypass facility should be designed with partial access control; see Chapter 45. Where full access control can be obtained, the bypass should be designed accordingly; see Chapter 44.

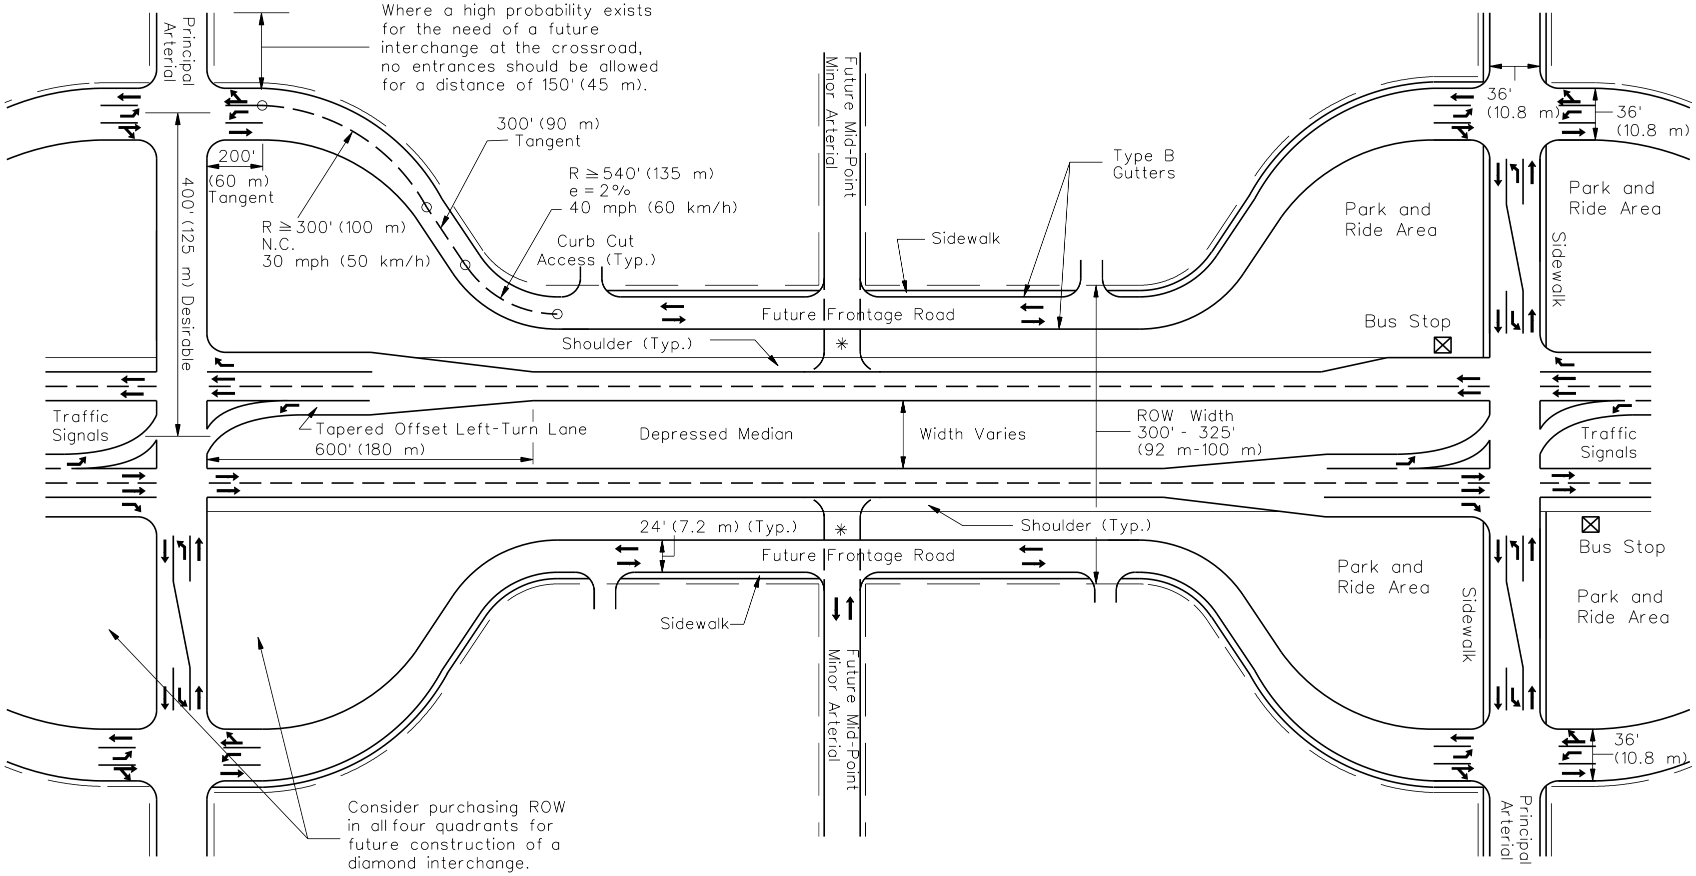
46-4.02 Geometric Design Elements

46-4.02(a) Median Types

When providing medians on rural SRA routes, consider the following:

1. Type. Typically, use a depressed median on rural SRA routes. This median type will provide space for left-turning vehicles at crossroads, direct turning movements to desired locations, reduce opposing traffic conflicts, and allow for high operating speeds.

2. Width. For rural SRA routes, the minimum width is 50 ft (15 m). Where there is a high probability of need for three lanes in each direction in the future, use a 74 ft (22.2 m) wide median initially. However, where right-of-way is restricted, a 50 ft (15 m) wide median may be used initially where six lanes will be required in the future. The median can be converted to a 26 ft (7.8 m) wide median with a concrete median barrier.

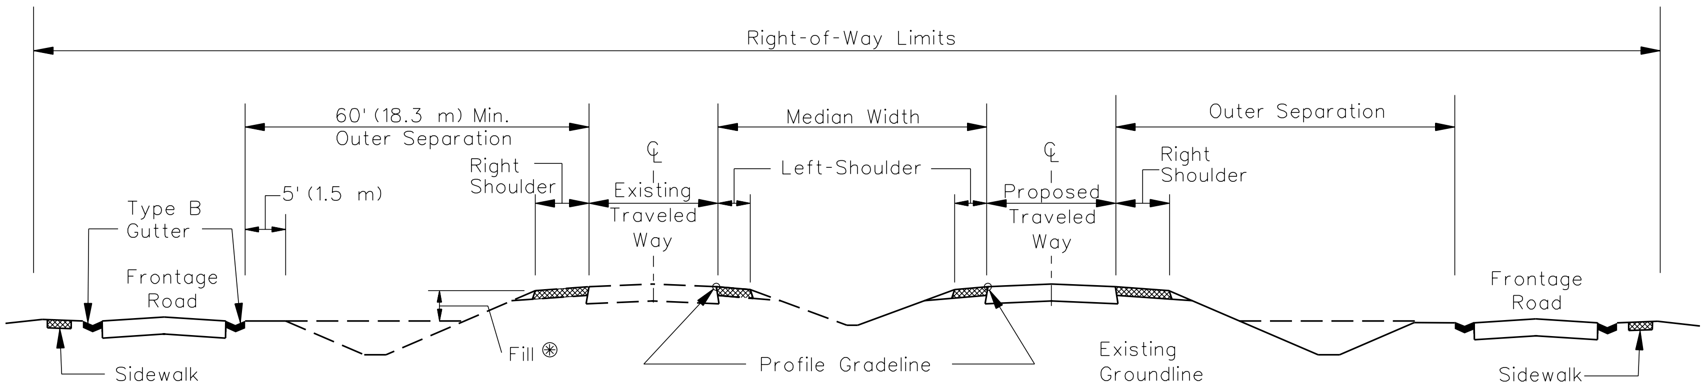


* *Before frontage roads are constructed, the mid-point minor arterial may be connected directly to the mainline and provided with right-in and right-out turns.*

Note: See Section 36-1.08 for selection of appropriate design vehicle.

TYPICAL RURAL SRA ROUTE WITH FRONTAGE ROADS
(1 mile (1.6 km) Segment)

Figure 46-4.A



⊛ Existing roadway should be approximately 3' (1.0 m) above the existing ground line. If not, raise the elevation of the existing roadway in the design of the project. See Section 33-6.04.

Note: Initial construction usually will not include frontage roads.

RURAL SRA CROSS SECTION
(Typical Design with Frontage Roads)

Figure 46-4.B

3. Median Crossovers. Only permit median crossovers at major intersections. Space these crossovers at intervals of 1 mile (1.5 km) or greater. Where local access to a crossroad is severely restricted or will cause significant delay for a large number of turning vehicles, crossovers may be reduced to ½ mile (800 m) intervals. However, do not use this spacing extensively along rural SRA routes. The intent of rural SRA routes is to give priority to through movements and provide for high operating speeds.

4. Flush Median with Concrete Median Barrier (CMB). This median type may be used where right-of-way is restricted; see Figure 36-3.M and Section 34-3.03.

46-4.02(b) Additional Lanes

On rural SRA routes, the desirable design is to provide sufficient right-of-way to allow two lanes in each direction with a depressed median and two-way frontage roads on each side. Where future capacity is required, a third lane can be constructed in the median.

The usual design to complete the multilane cross section is to provide a depressed median adjacent to an existing roadway and to construct a new roadway parallel to the existing lanes; see Figure 46-4.B. In some cases, it may be more appropriate to center all new construction about the centerline of the existing pavement. However, this would require all new pavements and a close examination of construction phasing for the maintenance of traffic flow.

46-4.02(c) Vertical Clearances

The vertical clearances for rural SRA routes are presented in Figure 46-4.C. Where practical on existing routes, vertical clearances may need to be increased to provide for the unrestricted movement of large vehicles. Existing bridges that do not provide a minimum of 16 ft 6 in (5.0 m) vertical clearance above the roadway are candidates for modification. Bridges which provide a vertical clearance of 16 ft 00 in (4.9 m) may remain in place, but should be considered for reconstruction or other means to achieve a minimum vertical clearance of 16 ft 6 in (5.0 m). Where the SRA route is an underpass, the recommended method to increase the vertical clearance is to lower the roadway through milling, raising the pier height, reconstructing the bridge, or other methods. Carefully evaluate potential drainage and utility problems.

46-4.03 Access Management

Sections 46-2.03 and 46-3.03 provide guidance on access management techniques that are also applicable to rural SRA routes. In addition, consider the following:

1. Frontage Roads. Because of the potential hazards introduced by intermittent access points, the most desirable form of access management is to provide two-way frontage roads along the SRA route. If the frontage roads are not constructed initially, consider providing sufficient right-of-way for incorporation of future frontage roads.

Where the frontage road is flared out at an intersection, do not allow development to occur within the interior area of the "jughandle." This area may be an appropriate location for park-and-ride lots; see Figure 46-4.A. Protection of this area will also allow the construction of a diamond interchange in the future.

2. Minor Road Access. The high speeds on rural SRA routes can make intersections with minor side roads potentially hazardous. Signalization is not recommended due to the delays that would be created on the rural SRA route. Desirably, terminate access to the minor road at the frontage road. If this is not practical, the next option is only to allow right-in and right-out maneuvers on the SRA route.

46-4.04 Intersections

In addition to Chapter 36, the following is applicable to intersections on rural SRA routes:

1. Turn Lanes. Section 36-3 provides the warrants and design criteria for turn lanes. In addition, the following will apply:

   a. Left-Turn Lanes. Provide tapered offset left-turn lanes at all signalized and major intersections. Use a parallel, left-turn lane design at minor road intersections where an intermediate median crossover is proposed.

   b. Right-Turn Lanes. In general, provide right-turn lanes at all intersections.

   c. U-Turn Crossovers. Where a crossover is required for U-turns, provide a parallel left-turn lane design into the crossover. The left-turn lane may be designed for 50 mph (80 km/hr) design speed.

2. Turning Radii. Insufficient turning radii for trucks can significantly affect the capacity of an intersection. Design the right- and left-turning radii to meet the expected design vehicle. Intersection design vehicles and truck routes are discussed in Section 36-1.08.

3. Channelization. To reduce the wide expanses of intersections, use corner islands to direct the flow of right-turning vehicles through the intersection. Channelization also can be effective at intersections where approaches are not at or close to 90° angles. At these locations, channelization and corner islands can help guide motorists through unusual turning movements. Section 36-3 illustrates typical design features that should be used at rural SRA intersections.

4. New Intersections. Where new local roads are proposed, restrict them to right-in/right-out movements. The depressed median will restrict left-turn movements from the SRA to the local road, left-turn movements from the local road to the SRA, and through movements on the local road across the SRA. However, alternative routes and emergency vehicular response times must also be evaluated and may result in the design of a median crossover. When frontage roads are provided, remove these minor roads from the SRA route and tee them into the frontage road; see Figure 46-4.A.

5. Intersection Lighting. All major intersections should have appropriate intersection lighting. See Chapter 56 for information on highway lighting.

46-4.05 Railroad Grade Separations

Where there is one or more trains per day crossing a rural SRA, consider providing for a future structure over the railroad. The feasibility of this type of improvement is dependent upon projected traffic volumes, roadway characteristics, posted speed, duration and volume of rail movements, and the amount of right-of-way available for overpass construction. Right-of-way should be protected at all rural SRA routes that will cross railroads at-grade.

In general, do not provide a grade-separation structure for frontage roads adjacent to the rural SRA route. Instead, flare the frontage roads out an appropriate distance from SRA grade-separation structure so that sight lines along the tracks are not blocked by the embankment and structure.

46-4.06 Interchanges

Right-of-way should be protected at all major intersections with rural SRA routes for eventual interchange construction. This will help to eliminate most signalized intersections and improve safety and mobility. Right-of-way is typically available at rural SRA crossroads to construct a diamond interchange; see Chapter 37. Where right-of-way is restricted, consider using a single point urban diamond or compressed diamond interchange. Figure 46-4.A shows the typical design of how frontage roads are flared out at major intersections initially, and how they might be incorporated into an interchange design.

If two intersecting rural SRA routes have unusually high projected traffic volumes and where sufficient right-of-way is available, consider providing a cloverleaf interchange design. The projected level of service on both routes should be level D or lower with conventional improvements before this option is considered. The route with the highest projected volumes should be considered to have the priority movement. The crossover of the lower priority route should have a design speed of 60 mph (100 km/hr) through the interchange.

All rural SRA interchanges should have lighting. However, lighting should not create “light pollution” problems from spillover into nearby residential areas.

46-4.07 Drainage

On rural SRA routes, open ditches will be used to accommodate roadway drainage. Design of ditches and drainage appurtenances must meet the criteria in the *IDOT Drainage Manual*. Outside ditches should be at least 6 ft (1.8 m) wide to provide for extra detention storage and adequate clear zone.

46-4.08 Frontage Roads

Frontage roads may be appropriate along rural SRA routes to separate slower local traffic from the higher speed through traffic on the SRA route and to reduce the number of conflict points. The most desirable option is to provide two-way frontage roads on both sides of the rural SRA route. Direct access to the SRA route should only occur at major crossroad intersections. Design criteria for frontage roads are presented in Chapter 44. Between major intersections, the total SRA right-of-way should be approximately 300 ft to 350 ft (90 m to 100 m). At intersections, flare the frontage road out approximately 400 ft (125 m) to create separate intersections on the crossroad between the frontage road and the rural SRA; see Figure 46-4.A. This spacing will also allow for signal coordination.

46-4.09 Traffic Control Devices

46-4.09(a) Traffic Signals

Provide fully actuated traffic signals at all signalized intersections on rural SRA routes. Chapter 57 and the Bureau of Operations *Policies and Procedures Manual* provide additional information on traffic signals.

46-4.09(b) Overhead Signing

All rural SRA-to-SRA route intersections should have advance overhead signing with route numbers and/or road names and, where appropriate, regional destinations. The lettering should be large enough to read at a distance of 400 ft to 500 ft (125 m to 150 m).

46-4.09(c) Stop Sign Removal

Stop sign control for traffic movements on an SRA route is inconsistent with giving priority to the SRA through movement. Therefore, remove all stop signs from the through lanes of a rural SRA route. However, it will be necessary to conduct a traffic engineering study to determine the appropriate traffic control at the location for both the SRA route and the intersecting crossroad.

46-4.09(d) Pavement Markings

Because of their durability and visibility, only use high-type pavement markings on rural SRA routes. High-type pavement markings include thermoplastic, epoxy, and pre-formed plastics. Include raised pavement markers and delineators on rural SRA routes. Raised pavement markers introduce an element of safety to the SRA route during inclement weather. Space raised pavement markers and delineators according to the Bureau of Operations *Policies and Procedures Manual* and the *IDOT Highway Standards*.

46-4.10 Transit

46-4.10(a) Improvements

Techniques associated with mass transit that may be applicable in certain rural situations are described in Section 46-2.11. For rural areas, it will also be necessary to improve transit station accessibility as discussed in Section 46-3.11. Ridesharing is a common approach to transit in rural areas. The “jughandle” design of the frontage road at major crossroad intersections typically provides adequate locations for park-and-ride facilities; see Figure 46-4.A.

46-4.10(b) Express Bus Service

Bus service on rural SRA routes should be limited to express buses that are equipped with priority signal preemption capability that can be deployed when they are running behind schedule. However, coordinate the bus preemption with existing vehicular progression along the SRA route. Bus stop locations generally should be located off the rural SRA route on side roads or park-and-ride lots. Space these stops at approximately 5 mile (8 km) intervals. Where it is impractical to locate bus stops off the SRA route, design bus turnouts and stops according to the criteria in Chapter 58.

46-4.11 Pedestrians and Bicyclists

The criterion for pedestrians and bicyclists presented in Section 46-3.13 is also applicable for rural SRA routes.

46-4.12 Environmental Considerations

The environmental analysis component of the SRA planning process is primarily an inventory of existing conditions. The inventory identifies those environmental resources in the corridor and probable impacts based on roadway improvements. Environmental assessments will be performed during the Phase I design work. These are discussed in Part III “Environmental Procedures” of this *Manual*.

46-4.13 Right-of-Way

Section 46-3.15 provides guidance for protecting future right-of-way needs which is also applicable to rural SRA routes. Also the *Illinois Highway Code,* 605 ILCS 5/4-510 provides guidance on the use of protective right-of-way buying as it applies to existing alignments.

46-4.14 Tables of Design Criteria

Figure 46-4.C presents the Department’s design criteria for new construction and reconstruction of rural strategic regional arterial projects. Figure 46-4.D presents the alignment of criteria for rural SRA routes. The designer should realize that some of the cross section elements included in the figure (e.g., flush median with concrete barrier) are not automatically warranted in the project design. The values in the figure only apply after the decision has been made to include the element in the highway cross section.

Design Element				Manual Section	Desirable Design Values

GEOMETRIC DESIGN CRITERIA FOR RURAL STRATEGIC REGIONAL ARTERIALS (SRA)
(New Construction/Reconstruction)
(Metric)

Figure 46-4.C
(1 of 2)

(1) Access Management. Direct access to the SRA route will be controlled by future two-way frontage roads. Where bypass routes are proposed around communities, the bypass desirably should be fully access controlled or, at a minimum, partially access controlled.

(2) Traveled Way Width. Existing 22 ft (6.6 m) width may remain in place.

(3) Left Shoulder Width. Consider providing a 8 ft (2.4 m) shoulder width and 1V:5H median slopes where level of service is approaching "C."

(4) Flush Median Width. Only use flush medians with CMB where right-of-way or topography restricts the use of a depressed median. Consider providing wider medians where required for snow storage.

(5) Travel Lane Cross Slope. For the additional lane away from the crown lanes, increase the cross slope by 1/16″/ft (0.5%).

(6) Clear Zone. The clear zone will vary according to design speed, traffic volumes, side slopes, and horizontal curvature. For restricted right-of-way conditions, see Figure 34-4.D.

(7) Ditch Bottom Width. Provide a wider outside ditch bottom where detention storage of storm water is a consideration.

(8) Back Slope. Where the height of cut exceeds 10 ft (3 m), consider using a 1V:2H back slope beyond the clear zone. Also, for heights greater than 30 ft (9 m), consider the use of benching.

(9) Fill Slope. For fill heights greater than 30 ft (9 m), use a 1V:2H uniform slope with a roadside barrier along the shoulder. Also, for fill heights greater than 30 ft (9 m), consider the use of benching.

(10) New and Reconstructed Bridge Widths. Clear roadway bridge widths are measured from face to face of parapets or rails. Bridge widths are normally defined as the sum of the approach traveled way width and the width of the paved shoulders.

(11) Existing Bridge Widths to Remain in Place. Clear roadway bridge widths are measured from face to face of parapets or rails. Implies elements allowed to remain in place without a design exception approval when cost effective and when safety record is satisfactory.

(12) Vertical Clearance (SRA Under).

a. The clearance must be available over the traveled way and any paved shoulders.
b. Table value includes allowance for future overlays.

GEOMETRIC DESIGN CRITERIA FOR RURAL STRATEGIC REGIONAL ARTERIALS (SRA)
(New Construction/Reconstruction)

(2 of 2)

Design Element		Manual Section	Desirable Speed 60 mph
* Stopping Sight Distance **(1)**		31-3.01	570′
Decision Sight Distance **(2)**		31-3.02	990′
Intersection Sight Distance **(3)**		36-6	665′
* Minimum Radii		32-2.03	1330′
* Superelevation Rate **(4)**		32-3	e_{max} = 6%
* Horizontal Sight Distance		32-4	**(5)**
* Vertical Curvature (K-values)	Crest	33-4	151
	Sag		136
* Maximum Grade **(6)**	Level	33-2.02	3% New Construction
	Rolling		4% New Construction
Minimum Grade		33-2.03	0.5% Minimum 0.0% (with Special Ditching)

* Controlling design criteria (see Section 31-8)

(1) Stopping Sight Distance. Table values are for passenger cars on level grades.

(2) Decision Sight Distance. Table values are for the avoidance maneuver on rural road (speed/path/direction change).

(3) Intersection Sight Distance. Table values are for passenger cars turning right or left from a stopped condition. A wide median is assumed on the rural SRA for left turns from the crossroad. See Section 36-6 for trucks.

(4) Superelevation Rate. See Section 32-3 for superelevation rates based on e_{max}, design speed, and radii of horizontal curves. For horizontal curves to remain in place, an e_{max} of 8% may be considered to remain in place for a design speed of 60 mph. Where a crossroad intersection lies within the limits of a horizontal curve, see Figure 36-1.D for the maximum superelevation rates allowed on the SRA curve.

(5) Horizontal Sight Distance. For a given design speed, the necessary horizontal sight line offset will be determined by the radius of curve and the required sight distance.

(6) Maximum Grades. For existing roadways to remain in place, a maximum of +4% on upgrades and -5% on downgrades may be retained.

ALIGNMENT CRITERIA FOR RURAL STRATEGIC REGIONAL ARTERIALS (SRA)
(US Customary)

Chapter Forty-seven

RURAL TWO-LANE/MULTILANE STATE HIGHWAYS (New Construction/Reconstruction)

Chapter 47 provides guidance in the design of rural two-lane principal arterials, multilane minor arterials, two-lane minor arterials, and collectors on the State highway system. Information that is also applicable to these facilities is included in the following chapters:

- Chapter 11 discusses the procedures for determining the facility location.
- Chapter 14 discusses intersection design studies.
- Chapters 31, 32, 33, 34, and 39 provide guidance on geometric design elements that are also applicable to these facilities.
- Chapter 35 provides guidelines for access control along interchange crossroads and intersections. It also discusses the procedures for preparing access control plans.
- Chapter 36 provides information on the design of intersections including left- and right-turn lanes, channelization, and intersection sight distance.
- Chapter 38 provides guidelines on roadside safety issues.
- Chapter 45 discusses the procedures for designing expressways.

47-1 GENERAL

Construction of new two-lane State highways, full reconstruction of long segments of existing two-lane State highways, or new construction of rural multilane State highways without access control are no longer common highway designs in Illinois. Instead, existing two-lane highways are more commonly improved using 3R guidelines (Chapter 49) or upgraded to a four-lane expressway design with partial access control (Chapter 45).

47-2 TWO-LANE HIGHWAYS

47-2.01 General

The minimum design for a State route is a two-lane, two-way highway. In some areas of the State, the two-lane highway system carries a large portion of the rural traffic. Many of these highways are located near major urbanized areas and are experiencing rapid growth in traffic.

The following describes some of the more common situations where new construction or reconstruction projects might be proposed for a two-lane highway improvement:

- realigning of an existing low-speed horizontal curve;
- raising the profile gradeline of a roadway to remedy flooding problems;
- providing a bypass around a small community;
- modifying the vertical profile or improving an intersection to enhance safety;
- upgrading a major route (i.e., arterial or collector) approaching an urbanized area where the current ADT is 5000 or greater, and where there is a small probability of traffic growth warranting four lanes in 20 years; and/or
- increasing passing opportunities to break up platoons and to reduce delay.

47-2.02 Typical Sections

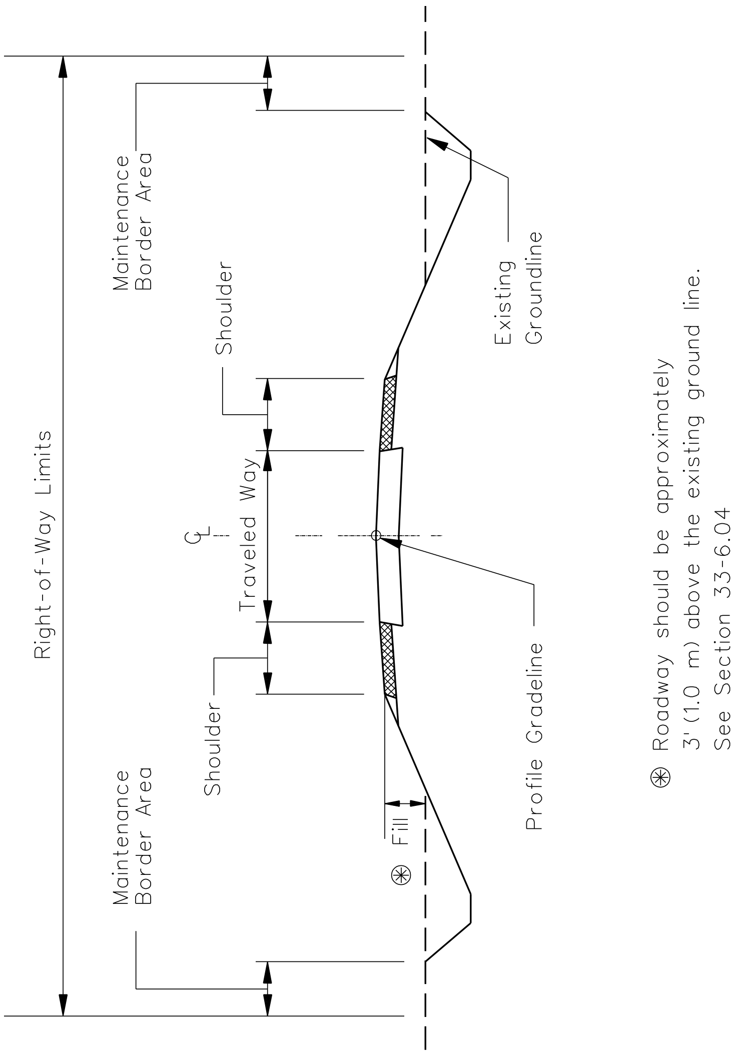
Figures 47-2.A and 47-2.B illustrate typical schematic cross sections for two-lane highways. The tables in Section 47-2.06 provide the minimum criteria for lane widths, shoulder widths, and other cross section elements that should be used on rural two-lane highways.

47-2.03 Passing Sight Distance

47-2.03(a) Design Derivation

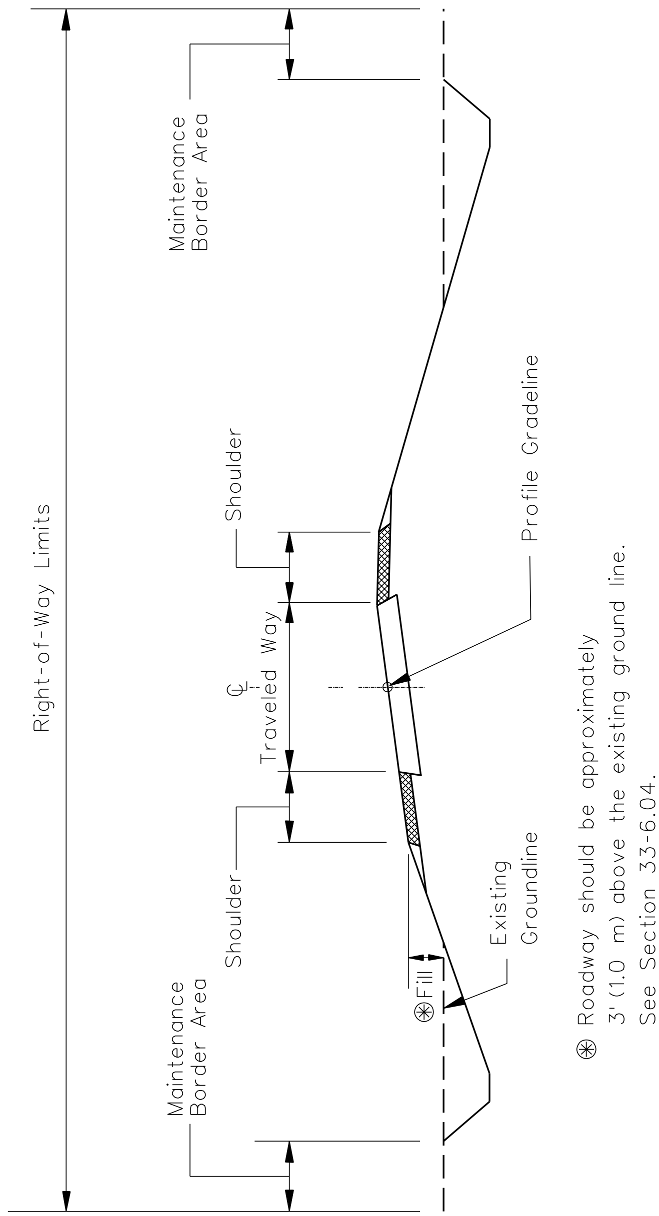
Passing sight distance considerations are limited to two-lane, two-way highways. On these facilities, vehicles may overtake slower moving vehicles, and the passing maneuver must be accomplished on a lane used by opposing traffic.

The minimum passing sight distance for two-lane highways is determined from the sum of four distances as illustrated in Figure 47-2.C. Figure 47-2.D and the following provides the basic assumptions used to develop passing sight distance values for design:



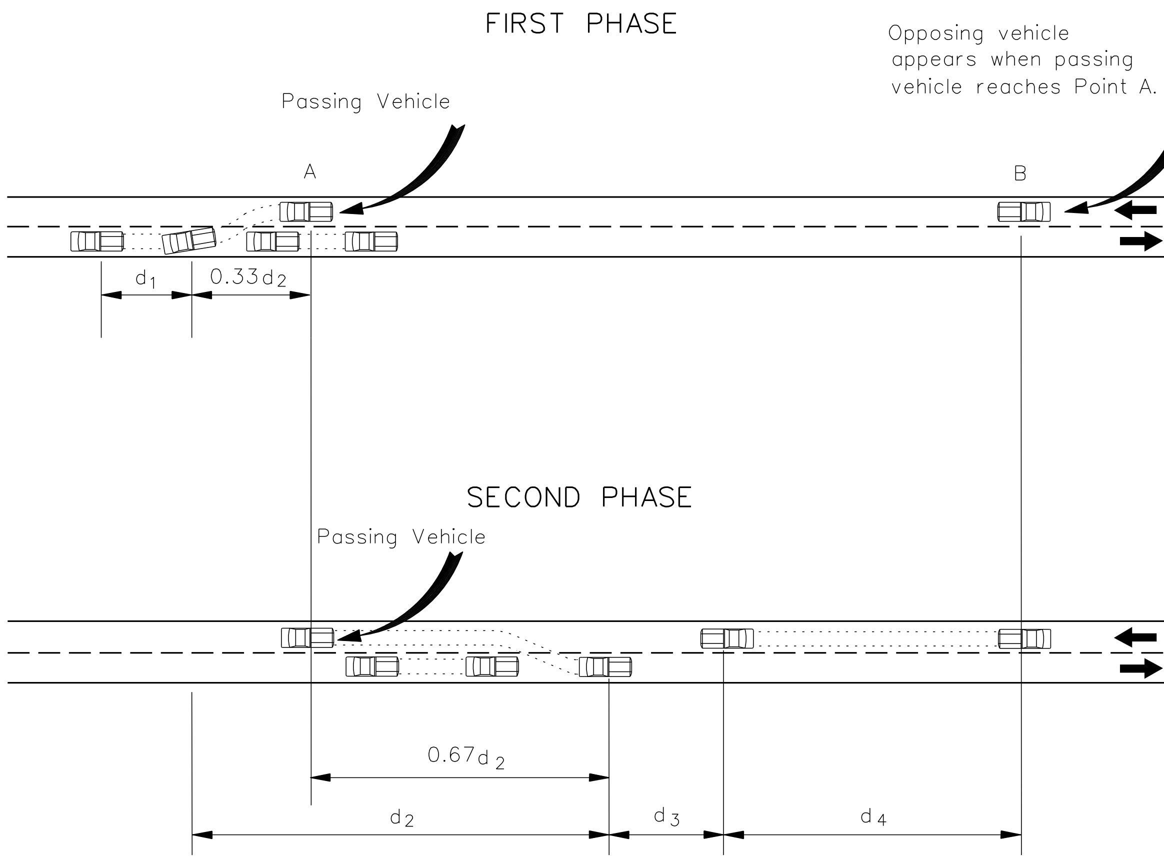
TYPICAL TANGENT SECTION FOR RURAL TWO-LANE HIGHWAYS

Figure 47-2.A



TYPICAL SECTION FOR SUPERELEVATED RURAL TWO-LANE HIGHWAYS

Figure 47-2.B



Note: The Illinois MUTCD definition for passing sight distance uses only the second phase of signing and pavement markings distances.

Note: See Figure 33-4.D for K-values for passing sight distances for passenger cars on crest vertical curves.

MINIMUM DESIGN PASSING SIGHT DISTANCE
(Assumes Entire Maneuver is Completed)

Figure 47-2.D

1. Initial Maneuver Distance (d_1). This is the distance traversed during the perception and reaction time and during the initial acceleration to the point of encroachment on the left lane. For the initial maneuver, the overtaken vehicle is assumed to be traveling at a uniform speed, and the passing vehicle is accelerating at a rate from 1.41 mph/sec to 1.47 mph/sec (2.25 km/h/sec to 2.37 km/h/sec). The average speed of the passing vehicle is assumed to be 10 mph (15 km/h) greater than the overtaken vehicle. Use Equation 47-2.1 to determine d_1:

$$d_1 = 1.47t_1\left(v - m + \frac{at_1}{2}\right)$$ (US Customary) Equation 47-2.1

$$d_1 = \frac{t_1}{3.6}\left(v - m + \frac{at_1}{2}\right)$$ (Metric) Equation 47-2.1

where:

t_1 = time of initial maneuver, sec
a = average acceleration, mph/sec (km/h/sec)
v = average speed of passing vehicle, mph (km/h)
m = difference in speed of passed vehicle and passing vehicle, mph (km/h)

2. Distance of Passing Vehicle in Left Lane (d_2). This is the distance traveled by the passing vehicle while it occupies the left lane. Use Equation 47-2.2 to determine d_2:

$$d_2 = 1.47\ vt_2$$ (US Customary) Equation 47-2.2

$$d_2 = \frac{vt_2}{3.6}$$ (Metric) Equation 47-2.2

where:

t_2 = time passing vehicle occupies the left lane, sec
v = average speed of passing vehicle, mph (km/h)

3. Clearance Distance (d_3). This is the distance between the passing vehicle at the end of its maneuver and the opposing vehicle. Based on various studies, this clearance distance at the end of the passing maneuver is assumed to be between 100 ft and 250 ft (30 m and 75 m).

4. Opposing Vehicle Distance (d_4). This is the distance traversed by an opposing vehicle during the time the passing vehicle occupies the left lane. As shown in Figure 47-2.C, the opposing vehicle appears after approximately one-third of the passing maneuver (d_2) has been accomplished. The opposing vehicle is assumed to be traveling at the same speed as the passing vehicle. Therefore, $d_4 = 0.67\ d_2$.

47-2.03(b) Applications

Figure 47-2.D shows the minimum passing sight distance for design on two-lane, two-way highways. These distances allow the passing vehicle to safely complete the entire passing maneuver. These values are not the same as those values presented in the *Illinois MUTCD* for the placement of no-passing zone stripes. The *Illinois MUTCD* values are based on different operational assumptions (i.e., distance for the passing vehicle to abort the passing maneuver). The designer should also realize that the highway capacity adjustment in the *Highway Capacity Manual* for two-lane, two-way highways is based on the *Illinois MUTCD* criteria for marking no-passing zones. It is not based on the percent of passing sight distance as calculated from the AASHTO *A Policy on Geometric Design of Highways and Streets* and shown in Figure 47-2.D.

On rural new construction/reconstruction projects, the designer should attempt to provide passing sight distance over the length of the project consistent with the percentages shown in Figure 47-2.E. In determining the percentages, each passing sight distance segment should be greater than 800 ft (240 m). It is generally not cost effective to make significant improvements to the horizontal and vertical alignment solely to increase the available passing sight distance.

Appreciable upgrades can increase the sight distances required for safe passing maneuvers. Where these upgrades are encountered in the design of the project, take this into account when selecting the appropriate passing sight distances.

Passing sight distance is measured from a 3.5 ft (1080 mm) height of eye to a 3.5 ft (1080 mm) height of object. Figure 33-4.D presents the K-values for crest vertical curves based on passing sight distances and these eye and object heights. This 3.5 ft (1080 mm) height of object allows 9 in (225 mm) of a typical passenger car to be seen by the opposing driver.

47-2.04 Passing Lanes

47-2.04(a) General

Passing lanes are defined as short added lanes which are provided in one or both directions of travel on a two-lane, two-way highway to improve passing opportunities. They present a relatively low-cost type of improvement for traffic operations by breaking up traffic platoons and reducing delay on facilities with inadequate passing opportunities.

Terrain	Minimum Percent Passing Sight Distance		
	Arterials	Collectors	Local
Level	60%	50%	40%
Rolling	40%	30%	20%

GUIDELINES FOR PERCENT PASSING DISTANCE
(Rural)
Figure 47-2.E

Truck-climbing lanes are one type of passing lane used on steep grades to provide passenger cars with an opportunity to pass slow-moving vehicles. The warrant and design criteria for truck-climbing lanes are discussed in Chapter 33. Procedures for developing the climbing lane capacity analysis are also shown in Chapter 33.

Passing lanes may serve to improve safety on a segment of two-lane highway. Three-lane roadways may be considered an intermediate solution to the ultimate expansion to a four-lane highway. The various methods of providing the third lane are shown in Figure 47-2.F.

47-2.04(b) Warrants

Passing lanes other than truck-climbing lanes may be warranted on two-lane facilities where passing opportunities are not adequate. Passing lanes also may be warranted, based on an engineering study that includes judgment, operational experience, and a capacity analysis. The use of a passing lane will be determined on a case-by-case basis. For more information on passing lane warrants, see the FHWA publication *Low Cost Methods for Improving Traffic Operations on Two-Lane Roads*, Report No. FHWA-IP-87-2.

47-2.04(c) Design

1. Capacity Analysis. *Low Cost Methods for Improving Traffic Operations on Two-Lane Roads* presents approximate adjustments that can be made to the capacity methodology in the *Highway Capacity Manual*. These adjustments can be used to estimate the level-of-service benefits from adding passing lanes to two-lane facilities.

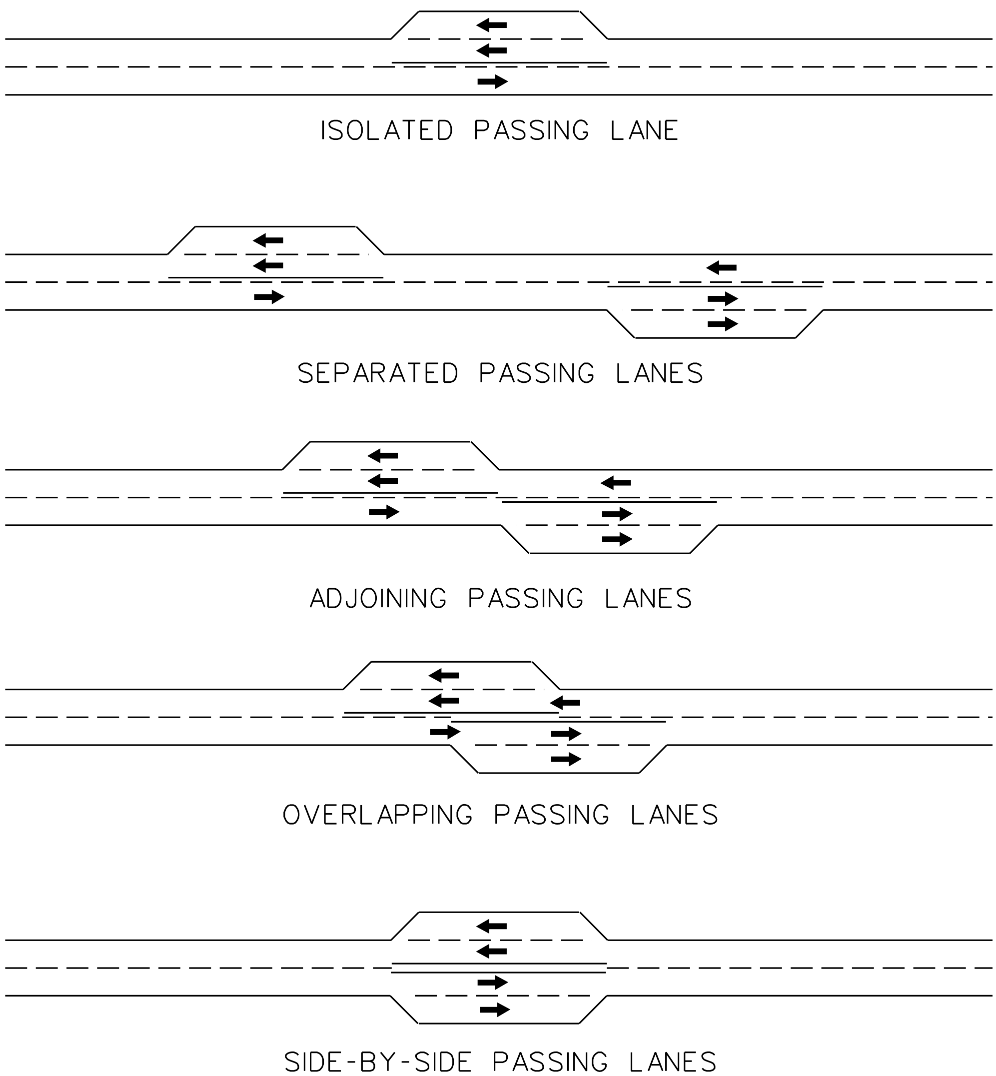
2. Spacing. When passing lanes are provided to improve the overall traffic operations over a length of roadway, they should be constructed systematically at regular intervals. Typical spacing for passing lanes may range from 3 miles to 10 miles (5 km to 15 km). Actual spacing of passing lanes will depend on the traffic volumes, right-of-way availability, and existing passing opportunities.

3. Location. When determining where to locate passing lanes, the designer should consider the following factors:

   a. Costs. Locate passing lanes to minimize costs. Rough terrain will generally increase the costs for construction of passing lanes.

   b. Appearance. The passing lane location should appear logical to the driver. The value of passing lanes is more obvious to the driver at locations where passing sight distances are restricted or where opposing volumes are significant.

   c. Horizontal Alignment. Avoid locating passing lanes on highway sections with low-speed horizontal curves.



TYPICAL CONFIGURATIONS FOR PASSING LANES

Figure 47-2.F

d. Vertical Alignment. Where practical, construct passing lanes on a sustained upgrade. The upgrade will generally cause a greater speed differential between slow moving vehicles and passing vehicles. However, passing lanes in level terrain still should be considered where the demand for passing opportunities exceeds supply.

e. Sight Distance. Locate the passing lane where there will be adequate sight distance to both the entrance and exit tapers of the additional lane. Because of sight distance concerns, do not locate exit tapers just beyond a crest vertical curve.

f. Intersections. Use special care when designing passing lanes through intersections and high-volume commercial entrances.

g. Structures. Avoid placing passing lanes where structures (e.g., large culverts, bridges) will restrict the overall width of the traveled way, passing lane, and shoulders.

h. Alternative Configurations. See Figure 47-2.F for various configurations of passing lanes.

4. Widths. Passing lane widths should be the same width as the adjacent travel lane width. Paved shoulder widths next to the passing lane should be a minimum of 4 ft (1.2 m).

5. Tapers. Design passing lanes by providing an additional lane to the right side of the traveled way; see Figure 47-2.G. Develop the additional lane with an entrance taper of 25:1. For the exit taper, the most commonly used taper rate is 50:1. However, where a location warrants an extended length of taper, the following equation may be used:

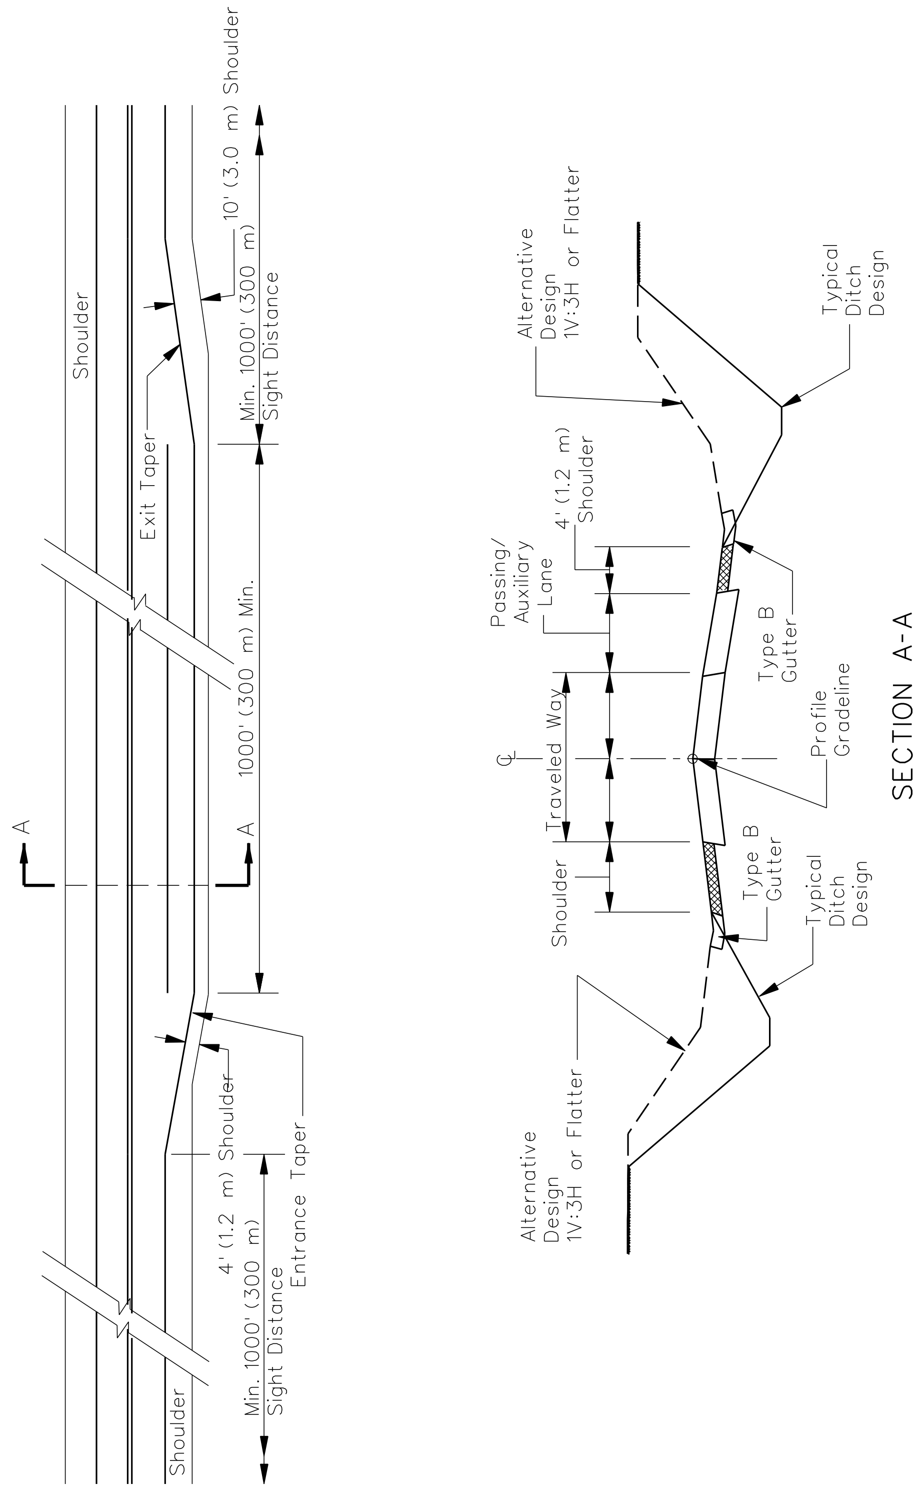
$$L = WS \qquad \text{(US Customary) Equation 47-2.3}$$

$$L = 0.6WS \qquad \text{(Metric) Equation 47-2.3}$$

where:

L = length of taper, ft (m)
W = width of passing lane, ft (m)
S = design speed, mph (km/h)

6. Length. The length of the passing lane will be determined by traffic volumes, length of the platoon, location of major intersections, geometrics, and distances between successive passing opportunities. The optimal length of passing lanes is usually between ½ mile and 1 mile (1 km and 1.5 km). At a minimum, passing lanes should not be less than 1000 ft (300 m) long. On the other hand, passing lane lengths greater than 1 mile (1.5 km) tend to have diminishing reductions in platooning per unit length.



Note: For final signing and pavement markings, contact the Bureau of Operations.

TYPICAL DESIGN LAYOUT FOR ONE DIRECTION PASSING LANE

Figure 47-2.G

7. Typical Design Layout. Figure 47-2.G illustrates a typical design for a passing lane in one direction. Advance signing is necessary to indicate to drivers that passing opportunities exist ahead (e.g., PASSING LANE 1/2 MILES AHEAD). Coordinate the final signing and pavement marking placement with the Bureau of Operations.

8. Typical Sections. Figure 47-2.G illustrates a cross section design for one directional passing lanes and Figure 47-2.H illustrates side-by-side passing lanes.

9. Four-Lane Sections. Short segments of a four-lane cross section, designated as side-by-side passing lanes in Figure 47-2.F, may be constructed along a two-lane highway to break up platoons, to provide the desired frequency of safe passing zones, and to eliminate interference from low-speed vehicles. These sections may be advantageous in rolling terrain, where the alignment is winding, or where the profile includes critical grades in both directions. The decision to use a short four-lane segment, as compared to using a three-lane option, should be based on long-range planning objectives for the facility, the availability of right-of-way, the existing cross section, topography, and the desire to reduce platooning and passing problems.

   Provide sufficient sight distance (e.g., 1000 ft (300 m)) in the transition area from the two-lane section to the four-lane section to allow a driver to anticipate the passing opportunity. Four-lane sections of 1 mile to 1.5 miles (1.5 km to 2.5 km) in length are usually sufficient to dissipate most queues formed by slow vehicles and terrain conditions.

47-2.05 Two-Way, Left-Turn Lanes (TWLTL)

TWLTL may be appropriate at isolated rural locations, where the highway is transitioning into a suburban or urban area having sizable left-turn volumes, or where there are several closely spaced driveways. Rural facilities will typically consist of a three-lane cross section illustrated in Figure 47-2.I. For posted speeds greater than 45 mph, exercise caution in designing the TWLTL. See Sections 48-4 and 34-3 for TWLTL design criteria.

47-2.06 Tables of Design Criteria

Figures 47-2.J through 47-2.L present the Department's design criteria for rural two-lane principal arterials, two-lane minor arterials, and two-lane collectors. Note that Figures 47-2.J, 47-2.K, and 47-2.L also provide criteria for existing design elements allowed to remain in place. The designer should realize that some of the cross section elements included in the figures (e.g., TWLTL) are not automatically warranted in the project design. The values in the figures only apply after the decision has been made to include the element in the highway cross section.

GEOMETRIC DESIGN CRITERIA FOR RURAL TWO-LANE PRINCIPAL ARTERIALS
(New Construction/Reconstruction)
(Metric)

Figure 47-2.J

(1) Design Criteria. The criteria in this column are the minimum cross-section elements allowed to remain in place provided it is cost effective and the safety record is satisfactory.

(2) Traffic Volumes. The design hourly volumes (DHV) assumes base conditions (except for 8% heavy vehicles) and a PHF = 1 for LOS shown. Adjust these values according to the actual factors.

(3) Design Speed.

a. In rolling terrain, a minimum design speed of 60 mph (100 km/h) may be considered with study and justification.
b. To determine the minimum design speed allowed to remain in place, see Section 45-2.02.

(4) Access Control. For bypass routes on new alignment, design the roadway with partial access control.

(5) Cross Slopes. Cross slopes for auxiliary lanes should be 1/16″/ft (0.5%) greater than the adjacent travel lane.

(6) Clear Zone. The clear zone will vary according to design speed, traffic volumes, side slopes, and horizontal curvature.

(7) Ditch Bottom Width. Provide a wider outside ditch bottom where detention storage of storm water is a consideration.

(8) Back Slope. Where the height of cut exceeds 10 ft (3 m), consider using a 1V:2H back slope beyond the clear zone. Also, for heights of cut greater than 30 ft (9 m), consider the use of benching.

(9) Fill Slope. For fill heights greater than 30 ft (9 m), use a 1V:2H uniform slope with a roadside barrier. Also, for heights greater than 30 ft (9 m), consider the use of benching.

(10) New and Reconstructed Bridge Widths. Clear roadway bridge widths are measured from face to face of parapets or rails. Bridge widths are normally defined as the sum of the approach traveled way width and the width of the paved shoulders. See Figure 39-6.A.

(11) Existing Bridge Widths to Remain in Place. Clear roadway bridge widths measured face to face of parapets or rails. Implies elements allowed to remain in place without a design exception when cost effective and when safety record is satisfactory. See Figure 39-6.A.

(12) Vertical Clearance (Arterial Under).

a. The clearance must be available over the traveled way and any paved shoulders.
b. Table value includes an additional allowance for future overlays.

GEOMETRIC DESIGN CRITERIA FOR RURAL TWO-LANE MINOR ARTERIALS
(New Construction/Reconstruction)
(Metric)

Figure 47-2.K

(1) Design Criteria. The criteria in this column are the minimum cross-section elements allowed to remain in place provided it is cost effective and the safety record is satisfactory.

(2) Traffic Volumes. The design hourly volumes (DHV) assumes base conditions (Except for 8% heavy vehicles) and a PHF =1 for LOS shown. Adjust these values according to the actual factors.

(3) Design Speed.

a. In rolling terrain, a minimum design speed of 55 mph (90 km/h) may be considered with study and justification.
b. To determine the minimum design speed allowed to remain in place, see Section 45-2.02.

(4) Access Control. For bypass routes on new alignment, design the roadway with partial access control.

(5) Cross Slopes.

a. Traveled Way. Cross slopes for auxiliary lanes should be 1/6″/ft (0.5%) greater than the adjacent travel lane.
b. Shoulder. Where an aggregate shoulder is part of the shoulder width, slope the aggregate portion of the shoulder at 3/4″/ft (6%).

(6) Clear Zone. The clear zone will vary according to design speed, traffic volumes, side slopes, and horizontal curvature.

(7) Ditch Bottom Width. Provide a wider outside ditch bottom where detention storage of storm water is a consideration.

(8) Back Slope. Where the height of cut exceeds 10 ft (3 m), consider using a 1V:2H back slope beyond the clear zone. Also, for heights of cut greater than 30 ft (9 m), consider the use of benching.

(9) Fill Slope. For fill heights greater than 30 ft (9 m), use a 1V:2H uniform slope with a roadside barrier. Also, for heights greater than 30 ft (9 m), consider the use of benching.

(10) New and Reconstructed Bridge Widths. Clear roadway bridge widths are measured from face to face of parapets or rails. Bridge widths are normally defined as the sum of the approach traveled way width and the width of the paved shoulders. See Figure 39-6.A.

(11) Existing Bridge Widths to Remain in Place. Clear roadway bridge widths measured face to face of parapets or rails. Implies elements allowed to remain in place without a design exception when cost effective and when safety record is satisfactory. See Figure 39-6.A.

(12) Vertical Clearance (Arterial Under).

a. The clearance must be available over the traveled way and any paved shoulders.
b. Table value includes an additional allowance for future overlays.

GEOMETRIC DESIGN CRITERIA FOR RURAL TWO-LANE COLLECTORS
(New Construction/Reconstruction)
(Metric)

Figure 47-2.L

(1) Design Criteria. The criteria in this column are the minimum cross-section elements allowed to remain in place provided it is cost effective and the safety record is satisfactory.

(2) Traffic Volumes. The design hourly volumes (DHV) assumes base conditions (except for 8% heavy vehicles) and a PHF = 1 for LOS shown. Adjust these values according to the actual factors.

(3) Design Speed.

a. In rolling terrain, a minimum design speed of 55 mph (90 km/h) may be considered with study and justification.
b. To determine the minimum design speed allowed to remain in place, see Section 45-2.02.

(4) Access Control. For bypass routes on new alignment, design the roadway with partial access control.

(5) Cross Slopes.

a. Traveled Way. Cross slopes for auxiliary lanes should be 1/16″/ft (0.5%) greater than the adjacent travel lane.
b. Shoulder. Where an aggregate shoulder is part of the shoulder width, slope the aggregate portion of the shoulder at 3/4″/ft (6%).

(6) Clear Zone. The clear zone will vary according to design speed, traffic volumes, side slopes, and horizontal curvature.

(7) Ditch Bottom Width. Provide a wider outside ditch bottom where detention storage of storm water is a consideration.

(8) Back Slope. Where the height of cut exceeds 10 ft (3 m), consider using a 1V:2H back slope beyond the clear zone. Also, for heights of cut greater than 30 ft (9 m), consider the use of benching.

(9) Fill Slope. For fill heights greater than 30 ft (9 m), use a 1V:2H uniform slope with a roadside barrier. Also, for heights greater than 30 ft (9 m), consider the use of benching.

(10) New and Reconstructed Bridge Widths. Clear roadway bridge widths are measured from face to face of parapets or rails. Bridge widths are normally defined as the sum of the approach traveled way width and the width of the paved shoulders. See Figure 39-6.A.

(11) Existing Bridge Widths to Remain in Place. Clear roadway bridge widths measured face to face of parapets or rails. Implies elements allowed to remain in place without a design exception when cost effective and when safety record is satisfactory. See Figure 39-6.A.

.

(12) Vertical Clearance (Collector Under).

a. The clearance must be available over the traveled way and any paved shoulders.
b. Table value includes an additional allowance for future overlays.

	Sag		136	181
* Maximum Grade **(6)**	Level	33-2.02	New: 3%	
	Rolling		New: 4%	
Minimum Grade		33-2.03	Desirable: 0.5% Minimum: 0.0% (with Special Ditching)	

* Controlling design criteria (see Section 31-8).

(1) Stopping Sight Distance. Table values are for passenger cars on level grade.

(2) Decision Sight Distance. Table values are for the avoidance maneuver (speed/path/direction change).

(3) Intersection Sight Distance. Table values are for passenger cars for assumed conditions described in Figure 36-6.E. See Section 36-6 for trucks.

(4) Superelevation Rate. See Section 32-3 for superelevation rates based on e_{max}, design speed, and radii of horizontal curves. For horizontal curves to remain in place, an e_{max} of 8% may be considered to remain in place. Where a crossroad intersection lies within the limits of a mainline horizontal curve, see Figure 36-1.E for the maximum superelevation rates allowed on the mainline curve.

(5) Horizontal Sight Distance. For a given design speed, the necessary horizontal sight line offset will be determined by the radius of curve and the required sight distance.

(6) Maximum Grade. Grades 1% steeper may be allowed to remain in place for existing roadways.

(6) Maximum Grade. Grades 1% steeper may be allowed to remain in place for existing roadways.

ALIGNMENT CRITERIA FOR RURAL TWO-LANE HIGHWAYS
(Metric)

Figure 47-2.M

47-3 MULTILANE HIGHWAYS

47-3.01 General

New rural four-lane highways with depressed medians and without access control are not a common highway design in Illinois. For construction or reconstruction projects, the following are descriptions of some of the more likely situations where a four-lane highway design might be proposed:

1. SRA Routes. Where rural routes are designated as Strategic Regional Arterials (SRA). See Chapter 46 for the details of SRA design.

2. Suburban Areas. Where highways are located in an open-suburban area, where reconstruction is required to satisfy capacity demands, and where a design speed of 50 mph (80 km/h) is desired. These highways will most likely be classified as either a minor arterial or as a collector route. Chapter 43 discusses open-suburban guidelines, and Chapter 34 provides general cross section information.

3. Passing Lanes. Where passing lanes are needed in both directions on a two-lane highway and right-of-way and topography favor using a four-lane section. Also, more desirable traffic operations can be accomplished by designing a four-lane section which consists of side-by-side passing lanes; see Figure 47-2.F.

47-3.02 Design Speed

The selected design speed depends on the type of proposed project and on the following:

1. Rural SRA. Where an arterial route is designated as a rural SRA, the desirable design speed for new and existing roadways is 60 mph (100 km/h). To determine the minimum elements allowed to remain in place in conjunction with the design speed, see Section 45-2.02.

2. Open Suburban Area. Where a route is proposed for reconstruction in an open-suburban area and a high-speed design is preferred, use a rural-type cross section with a 50 mph (80 km/h) design speed. See Section 34-3.04(c) for the median design details and Figure 47-3.C for other geometric elements.

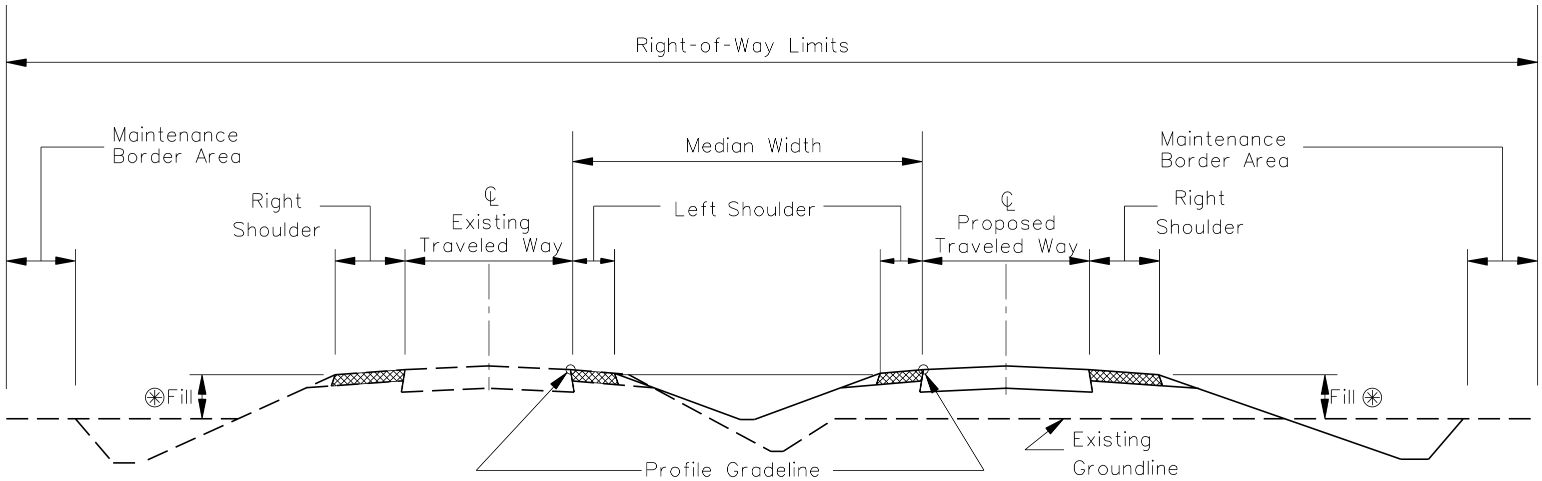
3. Passing Lanes. Where a two-lane highway requires additional passing opportunities and side-by-side passing lanes are proposed, provide a design speed of 60 mph (100 km/h) or greater. See Section 47-2.04 for design details.

47-3.03 Typical Sections

Figures 47-3.A and 47-3.B illustrate typical schematic cross sections for rural multilane highways. The tables in Section 47-3.04 provide the minimum criteria for lane widths, shoulder widths, median widths, and other cross section elements.

47-3.04 Tables of Design Criteria

Figures 47-3.C and 47-3.D present the Department's design criteria for rural multilane highways. Note that Figure 47-3.C also provides criteria for an existing roadway to remain in place. The designer should realize that some of the cross section elements included in the figures (e.g., flush concrete barrier) are not automatically warranted in the project design. The values in the figures only apply after the decision has been made to include the element in the highway cross section.

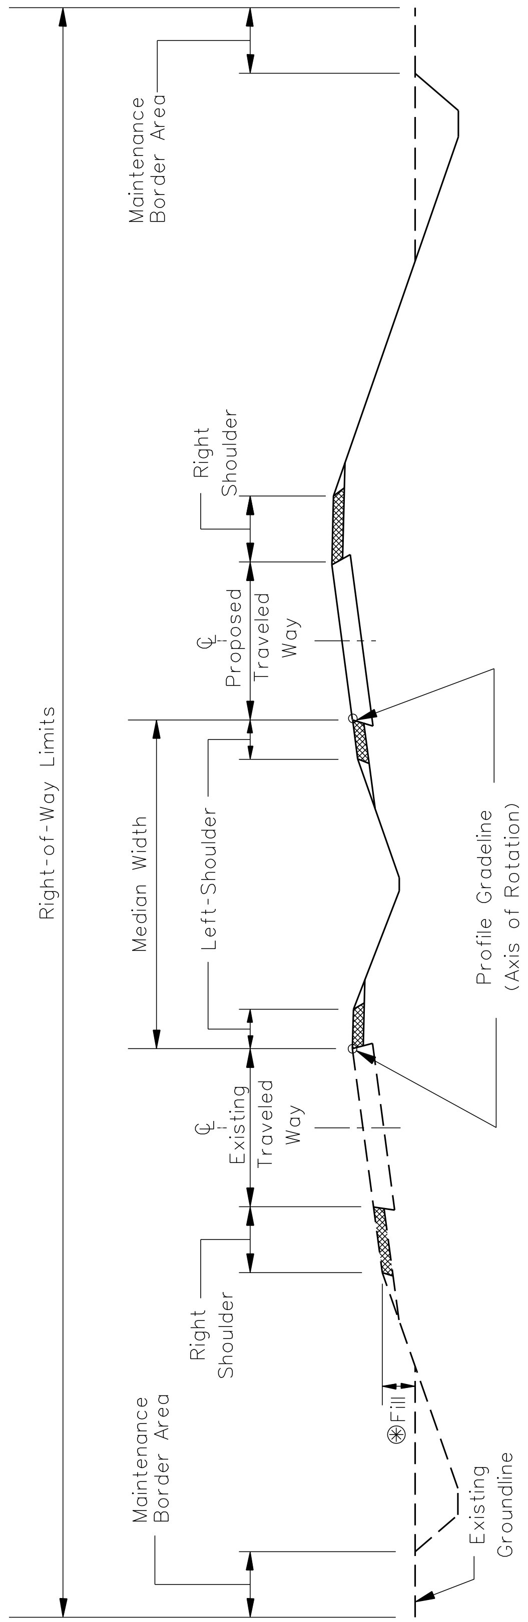


✻ Existing roadway should be approximately 3' (1.0 m) above the existing ground line. If not, raise the elevation of the existing roadway in the design of the project. See Section 33-6.04.

Note: See Figure 45-2.C for design of flush medians with concrete barrier.

TYPICAL TANGENT SECTION FOR RURAL MULTILANE HIGHWAYS
(Depressed Median)

Figure 47-3.A



⊛ Existing roadway should be approximately 3' (1.0 m) above the existing ground line. If not, raise the elevation of the existing roadway in the design of the project. See Section 33-6.04.

Note: See Figure 45-2.F for design of flush medians with concrete barrier.

GEOMETRIC DESIGN CRITERIA FOR RURAL FOUR-LANE MINOR ARTERIALS
(New Construction/Reconstruction)
(Metric)

Figure 47-3.C

(1) Design Criteria:

   a. When upgrading an existing two-lane highway to a four-lane facility, use the criteria in the new lanes column for the design of the new roadway and median.
   b. The criteria in this column are the minimum cross-section elements allowed to remain in place for reconstruction of an existing roadway provided it is cost effective and safety record is satisfactory.

(2) Traffic Volumes. The design hourly volumes (DHV) assumes base conditions (except for 8% heavy vehicles) and a PHF = 1.0. Adjust these values using local factors.

(3) Design Speed. To determine the minimum design speed allowed to remain, see Section 45-2.02.

(4) Access Control. Investigate and consider providing partial access control; see Sections 45-2.06 through 45-2.09. Bypasses around a community should be fully access controlled if the installation of traffic signals is likely at any intersection during the 20-year design period.

(5) Shoulder Width (Left). In most cases, left shoulders should be 6 ft (1.8 m) wide. This allows for the use of 1V:6H slopes in the median. However, if the 20-year level of service approaches Level C, then consider a 8 ft (2.4 m) wide left shoulder, and decrease the median slopes to 1V:5H.

(6) Travel Lane Cross Slope. For each additional lane away from the crown lanes, increase the cross slope by 1/16″/ft (0.5%) per additional lane up to a maximum of 5/16″/ft (2.5%).

(7) Depressed Median Width.

   a. Median width based on 1V:5H median slopes, 2 ft (600 mm) ditch width, 3 ft (900 mm) ditch depth, and 6 ft (1.8 m) left shoulders.
   b. Median width based on 1V:5H median slopes, existing 2 ft (600 mm) ditch width, 3 ft (900 mm) ditch depth, and 4 ft (1.2 m) left shoulders..

(8) Flush Median Width. Only use flush medians with CMB where right-of-way or topography restricts the use of a depressed median. Consider providing wider medians where required for snow storage.

(9) Clear Zone. The clear zone will vary according to design speed, traffic volumes, side slopes, and horizontal curvature.

(10) Ditch Bottom Width. Provide a wider outside ditch bottom where detention storage of storm water is a consideration.

(11) Back Slope. Where the height of cut exceeds 10 ft (3 m), consider using a 1V:2H back slope beyond the clear zone. Also, for heights greater than 30 ft (9 m), consider the use of benching.

(12) Fill Slope. For fill heights greater than 30 ft (9 m), use a 1V:2H uniform slope with a roadside barrier. Also, for heights greater than 30 ft (9 m), consider the use of benching.

GEOMETRIC DESIGN CRITERIA FOR RURAL FOUR-LANE MINOR ARTERIALS
(New Construction/Reconstruction)

Footnotes for Figure 47-3.C

(13) New and Reconstructed Bridge Widths. Clear roadway bridge widths are measured from face to face of parapets or rails. Bridge widths are normally defined as the sum of the approach traveled way width and the width of the paved shoulders. See Figure 39-6.A.

(14) Existing Bridge Widths to Remain in Place:

a. Clear roadway bridge widths measured from face to face of parapets or rails. Implies elements allowed to remain in place without a design exception when cost effective and when safety record is satisfactory. See Figure 39-6A.

b. Bridges with total lengths greater than 250 ft (75 m) or any span longer than 120 ft (36 m) typically should have a clear roadway bridge width of 38 ft (11.4 m) or 40 ft (12.0 m).

(15) Vertical Clearance (Arterial Under).

a. The clearance must be available over the traveled way and any paved shoulder.
b. Table value includes allowance for future overlays.

GEOMETRIC DESIGN CRITERIA FOR RURAL FOUR-LANE MINOR ARTERIALS
(New Construction/Reconstruction)

Footnotes for Figure 47-3.C
(Continued)

Design Element		Manual Section	Design Speed	
			50 mph	60 mph
*Stopping Sight Distance **(1)**		31-3.01	425′	570′
Decision Sight Distance **(2)**		31-3.02	750′	990′
Intersection Sight Distance **(3)**		36-6	555′	665′
*Minimum Radii	e_{max} = 6%	32-2.03	Desirable: ≥ 3000′ Minimum: 835′	Desirable: ≥ 3000′ Minimum: 1330′
*Superelevation Rate **(4)**		32-3	e_{max} = 6%	
*Horizontal Sight Distance **(5)**		32-4	**(5)**	
*Vertical Curvature (K-values)	Crest	33-4	84	151
	Sag		96	136
*Maximum Grade **(6)**	Level	33-2.02	New: 6%	New: 3%
	Rolling		New: 7%	New: 4%
Minimum Grade		33-2.03	Des: 0.5% Min: 0.0% (with Special Ditching)	

* Controlling design criteria (see Section 31-8)

(1) Stopping Sight Distance. Table values are for passenger cars on level grade.

(2) Decision Sight Distance. Table values are for the avoidance maneuver (speed/path/direction change).

(3) Intersection Sight Distance. Table values are for passenger cars turning right or left from a stopped condition. A wide median is assumed on the multilane facility for left turns from the crossroad.

(4) Superelevation Rate. See Section 32-3 for superelevation rates based on e_{max}, design speed, and radii of horizontal curves. For horizontal curves to remain in place, an e_{max} of 8% may be considered to remain in place. Where a crossroad intersection lies within the limits of a mainline horizontal curve, see Figure 36-1.E for the maximum superelevation rates allowed on the mainline curve.

(5) Horizontal Sight Distance. For a given design speed, the necessary horizontal sight line offset will be determined by the radius of curve and the required sight distance.

(6) Maximum Grade. Grades 1% steeper may be allowed to remain in place for existing roadways.

	Rolling		New: 7%	New: 4%
Minimum Grade		33-2.03	Des: 0.5% Min: 0.0% (with Special Ditching)	

* Controlling design criteria (see Section 31-8)

(1) Stopping Sight Distance. Table values are for passenger cars on level grade.

(2) Decision Sight Distance. Table values are for the avoidance maneuver (speed/path/direction change).

(3) Intersection Sight Distance. Table values are for passenger cars turning right or left from a stopped condition. A wide median is assumed on the multilane facility for left turns from the crossroad.

(4) Superelevation Rate. See Section 32-3 for superelevation rates based on e_{max}, design speed, and radii of horizontal curves. For horizontal curves to remain in place, an e_{max} of 8% may be considered to remain in place. Where a crossroad intersection lies within the limits of a mainline horizontal curve, see Figure 36-1.E for the maximum superelevation rates allowed on the mainline curve.

(5) Horizontal Sight Distance. For a given design speed, the necessary horizontal sight line offset will be determined by the radius of curve and the required sight distance.

(6) Maximum Grade. Grades 1% steeper may be allowed to remain in place for existing roadways.

Chapter Forty-eight

URBAN HIGHWAYS AND STREETS (New Construction/Reconstruction)

Chapter 48 provides guidance in the design of urban highways and streets. Information that is also applicable to these facilities is included in the following chapters:

- Chapter 14 discusses intersection design studies.
- Chapters 31, 32, 33, 34, and 39 provide guidance on the geometric design elements that are also applicable to these facilities.
- Chapter 36 provides information on the design of intersections, including left- and right-turn lanes, channelization, and intersection sight distances.
- Chapter 38 provides guidelines on roadside safety issues.
- Chapter 58 provides guidelines for off-street parking facilities.

48-1 GENERAL

48-1.01 Functional Classification

Urban highways and streets can be functionally classified as arterials, collectors, and local streets. Most of the State's urban facilities are arterials; however, there are some urban collectors on the State System. Practical improvements to urban collectors usually are more consistent with objectives pursued under the 3R program, which are presented in Chapter 49. For urban collector streets, planning and programming goals only occasionally include new construction and reconstruction of these highways for significant lengths such as between urban destinations. For criteria on new construction and reconstruction of urban collectors and local streets, the designer is referred to the *Bureau of Local Roads and Streets Manual* and AASHTO *A Policy on Geometric Design of Highways and Streets* for guidance.

Chapter 48 presents new construction and reconstruction criteria for urban and suburban arterials.

48-1.02 Closed and Open Suburban Designations

To better designate appropriate design criteria, the Department has divided its functional classifications into rural, suburban, and urban. Chapter 43 discusses the distinction among these area types. The suburban classification has been further subdivided as open or closed. These are defined in Chapter 43.

48-2 GENERAL DESIGN ELEMENTS

48-2.01 Design Speed

The most common design speed for urban streets is 30 mph (50 km/hr). In relatively undeveloped locations in urban or closed suburban areas and where economics, environmental conditions, and signal spacing permits, consider using a minimum design speed of 40 mph (60 km/hr). Design speeds of 45 mph to 50 mph (70 km/hr to 80 km/hr) are common in open suburban areas.

48-2.02 Median Types

Section 34-3 discusses the various medians that are used in urban and suburban areas and guidelines for selecting medians and widths. In addition, for medians in suburban and urban arterials, the designer should consider the following:

1. Flush/Traversable Medians. These median types may be used in both the urban and suburban areas in conjunction with curb and gutter along the outside edges of the traveled way. For most applications, the flush two-way left-turn lane (TWLTL) should be used. However, in larger metropolitan areas, a traversable TWLTL may be used. Section 48-4 further discusses the use of both types of TWLTL.

2. Depressed Medians. In open suburban areas, a depressed median may be used. This design is typically used with left shoulders and where the design speed is 50 mph (80 km/hr). Section 34-3.03 and Chapter 47 provide further guidance on depressed medians.

3. Raised-Curb Medians. Usually, a raised-curb median is proposed in suburban and urban areas where managed access to the street and control of left-turn movements are desired. Section 34-3.03 provides guidance on the selection and design of raised-curb medians. Figure 48-3.A discusses the advantages and disadvantages of raised-curb medians as compared to TWLTL medians. Chapter 36 illustrates typical treatments for left-turn lanes within raised-curb medians.

48-2.03 Typical Sections

Figures 48-2.A through 48-2.H present the typical cross sections for the various urban facilities. For a typical six-lane urban arterial with a raised-curb median; see Figure 34-3.B. Give consideration to safe accommodation of pedestrians and bicyclists during the development of the project. Chapter 17 provides detailed guidelines for these issues.

48-2.04 Sidewalks

Sidewalks are considered integral parts of the urban environment. In these areas, most travelers begin and end their trip as pedestrians; and many short trips are made without a vehicle, especially in the context of a dense urban core. When planning and designing sidewalks, the designer should consider the following:

1. Warrants. In general, if pedestrian activity is evident or anticipated, provide sidewalks along all curbed suburban and urban facilities. Extend all sidewalks to logical termini. If sidewalks are not provided in the initial design, grading should be completed so that sidewalks can be added in the future. The designer should confer with local officials.

2. Widths. A typical sidewalk is 5 ft (1.5 m) wide. If no buffer area is provided, the sidewalk should be 7 ft (2.0 m) wide to accommodate any appurtenances that may be included in the sidewalk; see Item #4 below. High pedestrian volumes may warrant greater widths in business areas and school zones. In these cases, a detailed capacity analysis may be required to determine the sidewalk width. Use the *Highway Capacity Manual* for this analysis.

3. Buffer Areas. If the available right-of-way is sufficient, provide a buffer area between the back of curb and sidewalk. These areas provide space for snow storage, utilities, and allow a greater separation between vehicles and pedestrians. The buffer area should be 2 ft to 3 ft (600 mm to 900 mm) wide to be effective and wider if practical. Buffer areas may also be used for the placement of roadside appurtenances.

4. Appurtenances. Where a buffer area cannot be provided, the designer must consider the impact of roadside appurtenances within the sidewalk (e.g., mailboxes, fire hydrants, parking meters, utility poles) as these elements typically reduce the usable width of the sidewalk and interfere with pedestrian activity. Typically, a 1 ft (300 mm) minimum width is provided between the sidewalk and right-of-way line. Utility poles usually can be located behind the sidewalk in this area providing a clear sidewalk width.

5. CBD Areas. In central business districts, the entire area between the back of curb and the front of buildings is fully paved as a sidewalk.

6. Accessibility. The design of the sidewalk (e.g., sidewalk width, cross slope, longitudinal grade, curb ramps) along public rights-of-way must meet the ADA criteria presented in Chapter 58.

7. Bridges. In general, if there is or expected to be pedestrian activity across a bridge, include sidewalks on both sides of the bridge. On long bridges, it may be more cost effective to provide a single sidewalk on one side. However, a safe crossing must be provided in advance of the bridge if there is evidence of pedestrian activity on both sides of the roadway. See Chapter 39 for typical sections.

48-2.05 Parking

For most urban projects, the designer must evaluate the demand for parking. Desirably, these parking needs will be accommodated by providing off-street parking facilities. Chapter 58 provides information on the design and layout of off-street parking facilities. When providing on-street parking along urban streets, the designer should evaluate the following:

1. Warrants. Do not introduce any new parking lanes along State highways. On-street parking reduces capacity, impedes traffic flow, and may produce undesirable traffic operations or may increase the crash potential. On State reconstruction projects, consider removing parking lanes. Removal of existing or revising existing on-street parking configurations will require coordination and concurrence with local officials and adjacent businesses. Chapter 58 discusses the procedures and guidelines for replacing on-street parking with off-street parking.

2. Local Agreements. Prior to implementation of parking on a project, the State will enter into a joint agreement with the municipality; see Chapter 5. The municipality will be required to maintain the parking lane and adopt and enforce an appropriate parking ordinance or provide copies of an existing ordinance in effect. Attach the ordinance to the joint improvement agreement as an exhibit and make a part thereof prior to execution of the agreement on behalf of the State. Enforcement of the ordinance is understood to include erection and maintenance of any necessary NO PARKING or PARALLEL PARKING ONLY signs.

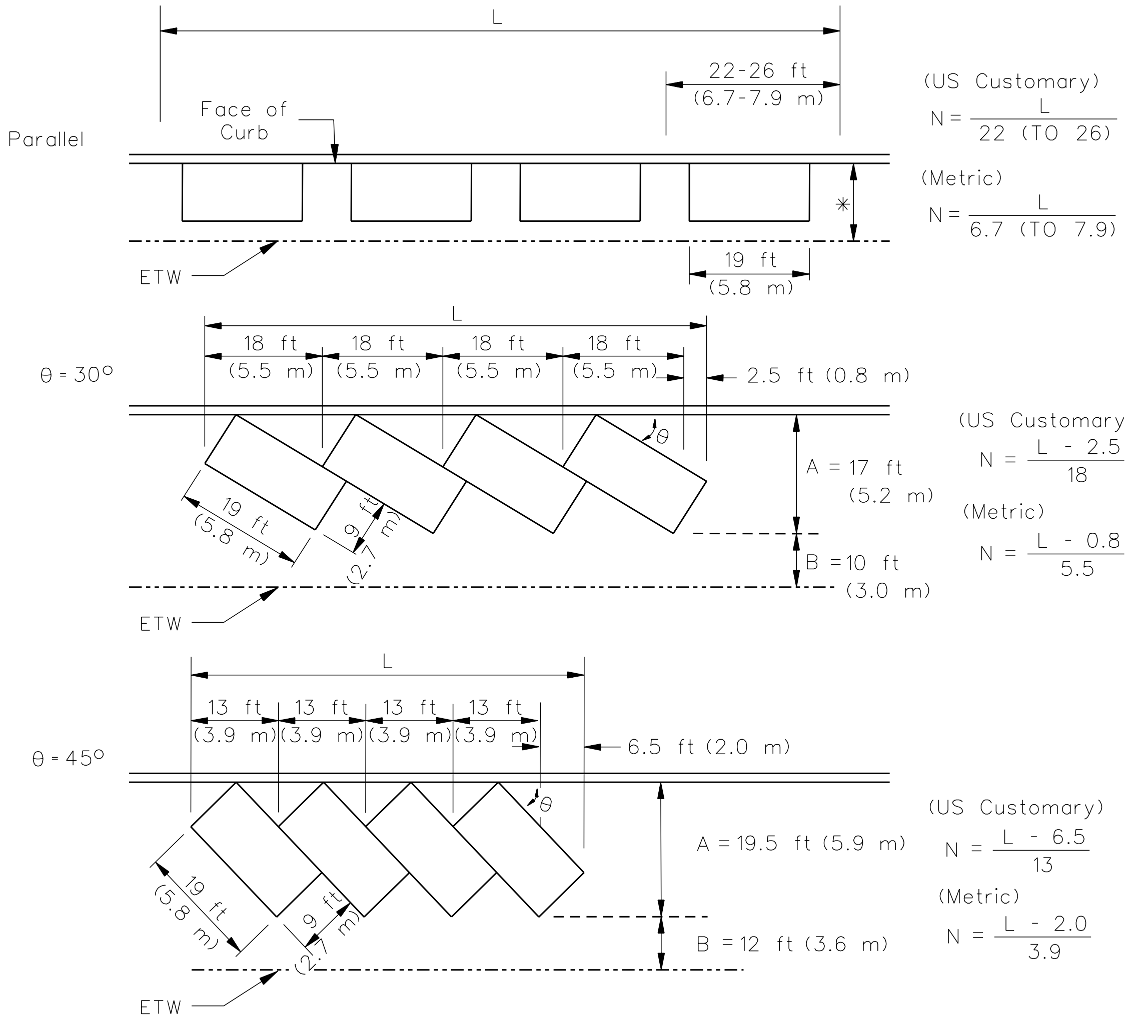
3. Configurations. There are two basic types of on-street parking — parallel and angle parking. These are illustrated in Figure 48-2.I.

4. Design Considerations.

   a. Department Authority. The *Illinois Vehicle Code* authorizes the Department to determine the propriety of diagonal parking upon routes under its jurisdiction. Section 11-1304(c) of the *Code* states:

      > *Local authorities may permit angle parking on any roadway, except that angle parking shall not be permitted on any federal-aid or state highway unless the Department has determined the roadway is of sufficient width to permit angle parking without interfering with the free movement of traffic.*

   b. Capacity. Parallel parking is the preferred arrangement where street space is limited and traffic capacity is a major factor. Where angle parking is provided, the overall level of service for the facility preferably should be not less than C.



** See Figures 48-6.A and 48-6.B for parallel parking lane widths.*
See Chapter 49 for 3R widths.

A + B = Parking Width for Angle Parking.

Key: L = given curb length with parking spaces

N = number of parking spaces over distance L

A = required distance between face of curb and back of stall, assuming that bumper of parked car does not extend beyond curb face.

B = clear distance needed for a parked vehicle to back out of stall while just clearing adjacent parked vehicles.

ETW = Edge of Traveled Way

CURB PARKING CONFIGURATIONS

Figure 48-2.I

c. Number of Spaces. Angle parking provides more spaces per linear foot (meter) than parallel parking, but requires a greater cross street width.

d. Angle. Angle parking should be 45° or less.

e. Backing Maneuver. Angle parking requires the driver to back into the traveled way when sight distance may be restricted by adjacent parked vehicles. This maneuver may surprise an approaching motorist. As indicated in Figure 48-2.I, the parked car will require a certain distance "B" to back out of its stall. Whether or not this is a reasonably safe maneuver will depend upon the number of lanes in each direction, lane widths, operating speeds, traffic volumes during peak hours, parking demand, and turnover rate of parked vehicles.

f. Crashes. After analyzing backing maneuver space, angle parking may be considered to remain if there is no history of crashes relating to the existing angle parking.

g. Trucks. If the truck traffic on the facility is 10% or more of the ADT, angle parking should be removed.

h. Agreement. The agreement with local officials must include provisions for monitoring and maintaining the angle parking after the project is completed to determine if safety or capacity problems develop as traffic volumes increase.

5. Stall Dimensions. Figure 48-2.I provides the width and length criteria for parking stalls of various configurations. The figure also indicates the number of stalls that can be provided for each parking configuration for a given curb length. The surface widths in Figures 48-6.A and 48-6.B assume parallel parking on one or both sides of the street.

6. ADA Requirements. Chapter 58 presents the accessibility requirements for on-street parking for persons with disabilities.

7. Location. When locating parking spaces, the designer should consider the following:

- Parking is prohibited within 20 ft (6.1 m) of any crosswalk.
- Prohibit parking within 10 ft to 16 ft (3 m to 5 m) of the beginning of the curb radius at mid-block driveway entrances.
- Parking is prohibited within 50 ft (15.2 m) of the nearest rail of a highway/railroad crossing.
- Parking is prohibited within 15 ft (4.6 m) of a fire hydrant.
- Parking is prohibited within 30 ft (9.1 m) on the approach leg to any intersection with a flashing beacon, stop sign, or traffic control signal.
- Parking is prohibited on bridges or within a highway tunnel.

- Prohibit parking from areas designated by local traffic and enforcement regulations (e.g., near school zones, loading zones, bus stops). See local ordinances for additional information on parking restrictions.
- Check intersection sight distance to side roads.
- Eliminate parking across from a T intersection.

48-3 RAISED-CURB MEDIANS

48-3.01 General

Figure 48-3.A presents advantages and disadvantages of raised-curb medians as compared to TWLTL medians. Section 34-3.03 provides guidance on the selection and design of raised-curb medians.

48-3.02 Four Lanes with Median

The most common typical section with raised-curb medians is two lanes in each direction separated by the curbed median; see Figures 48-2.A and 48-2.B.

48-3.03 Six Lanes with Median

Where traffic volumes indicate a need for three lanes in each direction, the recommended median design is a raised-curb. See Figure 34-3.B for a typical cross section design. Where there is a need for dual left turns, the minimum width of the median is 30 ft (9.5 m). Where major intersections are closely spaced and there is a need for dual lefts at most intersections, provide the 30 ft (9.5 m) median width along the entire street.

Where a five-lane facility exists and traffic volumes (ADT > 40,000) and/or capacity analysis warrants a six-lane design, consider providing a traversable type median with M-2 (M-5) curb. Prior to incorporating the M-2 (M-5) curb median into the design, evaluate the following:

1. Concentrated Left-Turn Movements. With raised-curb medians, left-turn movements are concentrated at the intersections, thereby reducing the overall conflict areas of the facility. However, drivers are forced to make all left turns at the intersections, which may overload the capacity of the intersections, increase driver travel time, and may create the need for U-turns at intersections.

2. Businesses. Business owners may perceive an adverse effect when a raised-curb median is proposed. See NCHRP 395 *Capacity and Operations Effects of Midblock Left-Turn Lanes* for guidance on the effects of curbed medians.

3. Opposing Gaps. Six-lane facilities contain high-traffic volumes that limit opportunities for left-turns across the opposing traffic. NCHRP 395 discusses the consequences of these movements on the facility.

4. Merging Gaps. Entering a six-lane facility with an M-2 (M-5) curbed median from a non-signalized side access point provides a considerable challenge for the driver. Upwards of nine different movements may need to be observed by the driver at any given time. Where M-2 (M-5) curbed facilities are justified, the TWLTL can be used as a waiting area before a gap occurs and a merge can take place. For additional concerns, see NCHRP 330 *Effective Utilization of Street Width on Urban Arterials*.

Advantages	Disadvantages
1. Provides an area for left-turn maneuvers.	1. Increases travel time and delay for many left-turning vehicles.
2. Discourages arbitrary crossings of the median.	2. Restricts direct access to adjoining properties.
3. Reduces the number of vehicular conflict points.	3. Installation and maintenance costs are higher.
4. Allows for better access management along the street increasing safety performance.	4. Can create an over concentration of turns at median openings.
5. Provides a positive and safer separation between opposing traffic flows.	5. Indirect routing may be required.
6. Provides a median refuge area for pedestrians.	6. May restrict access for emergency vehicles (e.g., fire, police, ambulance).
7. Provides a location for traffic control devices (e.g., signs, signals, lighting).	7. Lack of operational flexibility.
8. Provides an open space for aesthetic considerations and stormwater management.	8. When accidentally struck, curb may cause a driver to lose control of the vehicle.
9. Provides for enhanced traffic flow and reduces conflicts.	9. A minimum median width of 22 ft (7 m) is needed to accommodate U-turns or to shadow stopped passenger cars in the median when turning left or crossing through a median opening from a side street.

ADVANTAGES AND DISADVANTAGES OF RAISED-CURB MEDIANS

Figure 48-3.A

48-4 FLUSH OR TRAVERSABLE TYPE MEDIANS

48-4.01 Two Way Left Turn Lane Guidelines

The applicability of a two-way left-turn lane (TWLTL) is a function of the traffic conditions that result from the adjacent land use. Evaluate the area to determine the relative attractiveness of a flush median as compared to a raised-curb median. For example, a TWLTL may perpetuate more strip development. When this is not desirable, use a raised-curb median. For additional information on the use of a TWLTL design or flush alternating left-turn lanes along a street, see NCHRP 395 *Capacity and Operational Effects of Midblock Left-Turn Lanes* and Figures 34-3.C and 34-3.D. Also consider the following guidelines:

1. General. Only provide TWLTL in:

   - areas with a high number of existing driveways per mile (km) (e.g., 30-60 driveways total per mile (20-40 driveways total per km) on both sides of street);
   - areas of existing high-density commercial development;
   - areas with substantial mid-block left turns; and/or
   - areas where space is not available for raised-curb median widths and a need for left-turn lanes exists.

2. Highway Type. Two-lane and four-lane undivided urban or suburban arterials are the most common candidates for the implementation of a TWLTL design. Once these streets are reconstructed, they are commonly referred to as three-lane and five-lane facilities, respectively.

3. Traffic Volumes. Traffic volumes and the percent of left turns in each direction are a significant factor in the consideration of a TWLTL. Use a 20-year design for traffic volumes. As general guidance, consider the following:

   a. Two-Lane Facilities. On existing two-lane roadways, a TWLTL design will often be advantageous for traffic volumes between 5,000 and 14,000 ADT.

   b. Four-Lane Facilities. On existing four-lane undivided highways, a TWLTL will often be advantageous for traffic volumes between 10,000 and 40,000 ADT. The 40,000 ADT value assumes left-turn percentages less than or equal to 30%.

   c. Six-Lane Facilities. The decision on whether to provide a TWLTL or a raised-curb median will be determined on a case-by-case basis. See Section 48-3.03 for guidance.

   d. Pedestrians. Pedestrian crossing volumes are also a consideration because of the large paved area that must be traversed when a TWLTL is present (i.e., no pedestrian refuge exists). There may be significant delays for vehicles at signalized intersections to accommodate pedestrians having to cross the highway in one movement. A raised-curb median may provide a refuge area for pedestrians to cross the highway in two movements.

4. Speed. The design speed of an urban street is a major factor in TWLTL applications. Experience indicates that design speeds from 25 mph to 45 mph (40 km/hr to 70 km/hr) will properly accommodate TWLTL operations. For design speeds higher than 45 mph (70 km/hr), the use of TWLTL is not recommended.

5. Crash History. On urban or suburban arterials without medians, traffic conflicts often result because of a significant number of mid-block left turns combined with significant opposing traffic volumes. This may lead to a disproportionate number of mid-block, rear-end, and/or sideswipe crashes. The inclusion of a median for left turns is likely to reduce these types of crashes. Review and evaluate the available crash data to determine if disproportionately high numbers of these crashes are occurring.

6. Advantages and Disadvantages. Figure 48-4.A summarizes some of the advantages and disadvantages of a TWLTL median design.

48-4.02 Design Criteria

48-4.02(a) Median Width

Existing highways that warrant the installation of a TWLTL are often located in areas of restricted right-of-way, and conversion of the existing cross section may be difficult. To obtain the TWLTL width, the designer may have to consider the following:

- reducing the width of existing through lanes and analyzing side road radius returns,
- eliminating existing parking lanes and reconstructing curb and gutter and sidewalks,
- eliminating existing shoulders and ditches,
- eliminating existing buffer areas behind curbs and reconstructing curb and gutter and existing sidewalks,
- acquiring additional right-of-way to expand the pavement width by the amount needed for the TWLTL and sidewalks, and/or
- removing an existing raised-curb median.

See Sections 34-3.03 and 34-3.04 for further guidance on medians.

Advantages	Disadvantages
1. Provides an area for left-turn maneuvers. 2. Reduces circuitous travel distance and delay for left-turn vehicles. 3. Permits direct access to adjoining properties. 4. Provides separation between opposing traffic flows. 5. Eliminates the median island fixed object. 6. Provides temporary refuge for disabled vehicles. 7. Serves as temporary lane for emergency, maintenance, and construction activities. 8. Can be used as a reversible lane during peak hours. 9. Can be used to increase emergency vehicle efficiency. 10. Requires less right-of-way for left turns as compared to raised-curb medians.	1. Does not provide a pedestrian refuge area. 2. Does not guarantee unidirectional use at high-volume intersections unless left-turn bays are outlined with curb and gutter. 3. Allows numerous traffic conflict points to remain with no restrictions. 4. Allows for unrestricted development and turning movements along a street. 5. Cannot be used in areas where sight distance is restricted along the street. 6. Adds to drainage problems on the low side of superelevated horizontal curves. 7. May promote higher running speeds where proposed with paved outside shoulders and ditch sections. 8. May require reconstruction of inter-sections.

ADVANTAGES AND DISADVANTAGES OF FLUSH OR TRAVERSABLE TWLTL MEDIANS

Figure 48-4.A

48-4.02(b) Intersection Treatment

At intersections with public roads, consider the following:

1. Side Streets/Major Entrances. At intersections, convert the TWLTL to an exclusive left-turn lane and omit the pavement markings through the intersection. However, where turning volumes to minor streets are low, it will not be necessary to convert the TWLTL markings to an exclusive left-turn lane.

2. Turning Volumes. The left-turn demand into intersecting side streets is a factor in determining the appropriate length of the left-turn lane. As a general rule in urban areas, the minimum storage length will govern the length of left-turn lanes; see Section 36-3.02.

3. Minimum Length of TWLTL. The TWLTL should have sufficient length to operate properly, and the type of intersection treatments will determine the length of the TWLTL. Typically, the minimum length will be 650 ft to 1000 ft (200 m to 300 m) (one block long). The final decision on the length of the TWLTL will be based on site conditions.

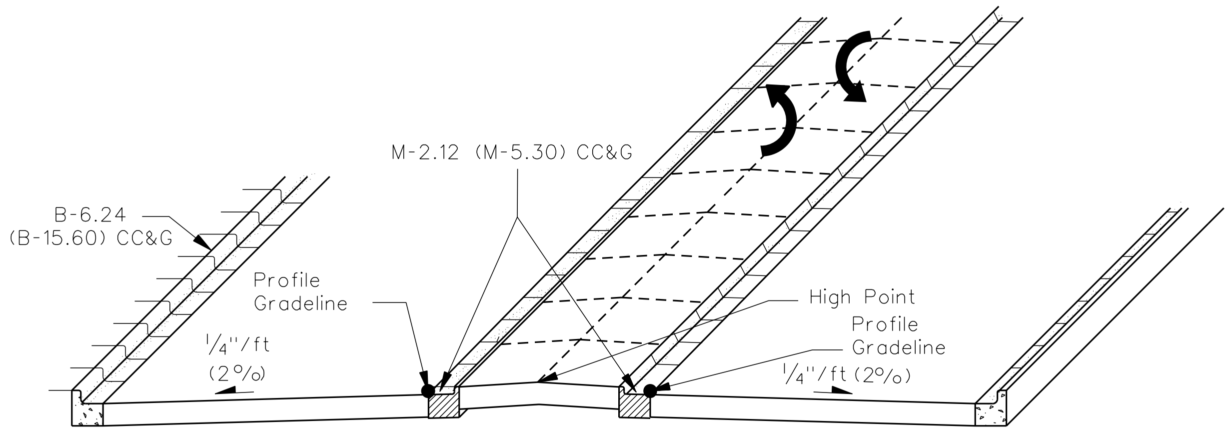
4. Operational/Safety Factors. Provide proper signing and stopping sight distance at the beginning and end of each TWLTL. Where a number of turning movements are expected into and out of entrances located close to a major intersection, it is desirable to design a raised-curb median (M-6 (M-15)) into the segment of the exclusive left-turn lane; see Figure 34-3.D.

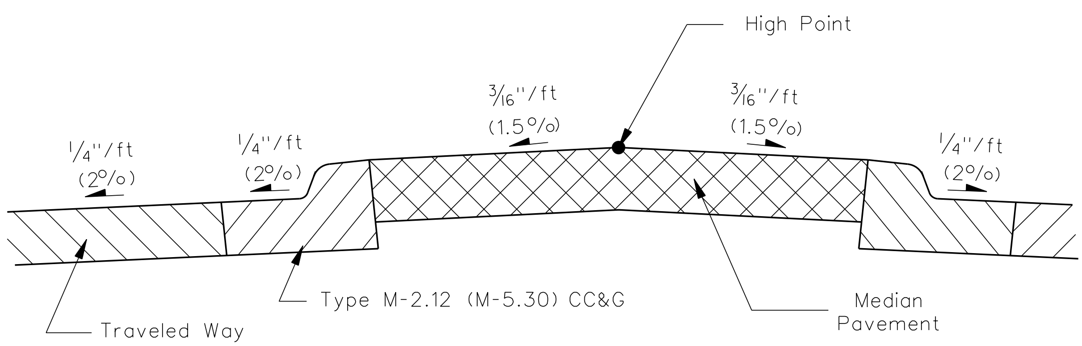
48-4.02(c) Curbing

In urban and suburban areas where a TWLTL is used, provide curb and gutter along the outside edges of the traveled way.

48-4.02(d) Traversable TWLTL

On most highways and streets, the TWLTL will be a flush design with the adjacent travel lanes. See Figures 34-3.D and 48-2.C. Where traffic volumes and mid-block left turns are unusually high, a traversable TWLTL median with a Type M-2.12 (M-5.30) Concrete Curb and Gutter may be a more appropriate design option. Figure 48-4.B illustrates the typical design for a traversable TWLTL. The M-2 (M-5) curb is used to delineate the edges of the TWLTL and traffic is allowed to turn left across the median. Also, where a horizontal curve with superelevation is proposed along a street with a flush TWLTL, use the Type M2.12 (M-5.30) Concrete Curb and Gutter along the median edges of the curve to improve drainage; see Figure 48-2.D.





Note: Drain the median surface away from the high point of the median.

TYPICAL TRAVERSABLE TWLTL CROSS SECTION

Figure 48-4.B

48-4.03 Railroad Crossings

TWLTLs are not extended across a highway/railroad grade crossing. Terminate the TWLTL 150 ft to 200 ft (45 m to 60 m) in advance of the crossing and provide a raised-curb median adjacent to the railroad; see Figure 7-3.E. In addition, the designer should coordinate the design with the Bureau of Operations.

48-5 HORIZONTAL ALIGNMENT

48-5.01 <u>General Application</u>

For urban and suburban streets and highways, the application of horizontal alignment criteria will depend on several factors. Figure 48-5.A summarizes the application of horizontal alignment criteria to urban facilities. The remainder of Section 48-5 specifically discusses the application to low-speed urban streets ($V \leq 45$ mph (70 km/hr)).

48-5.02 <u>General Superelevation Considerations</u>

For low-speed urban streets, the operational conditions and physical constraints are significantly different than those on rural highways and high-speed urban highways. The following lists some of the characteristics of low-speed urban streets that often complicate superelevation development:

1. <u>Roadside Development/Intersections/Driveways</u>. Built-up roadside development is common adjacent to low-speed urban streets. Matching superelevated curves with many driveways, intersections, sidewalks, etc., creates considerable complications. For example, this may require reconstructing the profile on side streets, and re-grading parking lots, lawns, etc., to compensate for the higher elevation on the high side of the superelevated curve.

2. <u>Non-Uniform Travel Speeds</u>. On low-speed urban streets, travel speeds are often non-uniform because of frequent signalization, stop signs, vehicular conflicts, etc. It is undesirable for traffic to stop on a superelevated curve, especially when snow or ice is present.

3. <u>Limited Right-of-Way</u>. Superelevated curves often result in more right-of-way impacts than would otherwise be necessary. Right-of-way is often restricted along low-speed urban streets.

4. <u>Wide Pavement Areas</u>. Many low-speed urban streets have wide pavement areas because of the number of traffic lanes, the use of a flush-type median, or the presence of parking lanes. In general, the wider the pavement area, the more complicated is the development of superelevation.

5. <u>Surface Drainage</u>. Proper cross slope drainage on low-speed urban streets can be difficult even on sections with a normal crown. The minimum longitudinal gradient on a street with curb and gutter is 0.30%. A curve with superelevation (or remove crown) and/or where a flush-type median is proposed introduces another complicating factor unless special features are designed into the median. See Figure 48-2.D, which illustrates the use of Type M-2.12 (M-5.30) Concrete Curb and Gutter to control drainage.

Land Use Category*	**Design Speed**	**Design Assumptions**	e_{max}	***BDE Manual* References**
Urban [1]	V ≤ 45 mph (V ≤ 70 km/hr)	Low-Speed Urban Streets	4.0%	Section 48-5
Closed Suburban	V = 40 or 45 mph (V = 60 or 70 km/hr)	Low-Speed Urban Streets	4.0%	Section 48-5

Suburban SRA	V = 45 mph (V = 70 km/hr)	Low-Speed Urban Streets	4.0%	Section 48-5

** See Sections 48-1.02 and 43-2 for definitions.*

Note: [1] If an exit ramp connects to a facility where low-speed urban street conditions apply and if the intersection is stop or signal controlled, than the last horizontal curve on the exit ramp should be designed assuming low-speed urban street conditions.

HORIZONTAL ALIGNMENT APPLICATIONS IN URBAN/SUBURBAN AREAS

Figure 48-5.A

48-5.03 Horizontal Curves

48-5.03(a) Design Procedures

Because of the unique operational conditions for low-speed urban streets, it is appropriate to use a modified theoretical basis for horizontal alignment criteria when compared to open-roadway conditions. Specifically, the use of AASHTO Method 2 to distribute superelevation and side friction. This Method assumes maximum design side friction is used before any superelevation is introduced. The practical benefit is that most horizontal curves can be designed with little or no superelevation on low-speed urban streets when compared to the criteria for open roadway conditions in Chapter 32. See the AASHTO publication *A Policy on Geometric Design of Highways and Streets* for a further discussion on Method 2.

48-5.03(b) Maximum Superelevation Rate

For new construction projects, use e_{max} = 4.0% for low-speed urban streets. For urban reconstruction projects, existing horizontal curves can remain in place with a superelevation rate up to 6%. However, the use of 6% on a low-speed urban street is a Level Two design exception as discussed in Section 31-7. See Section 36-1.05(b) for a discussion on superelevation for intersections on curves.

48-5.03(c) Minimum Radii

Figure 48-5.B presents the minimum radii for various design speeds for low-speed urban streets. These values should only be used where highly restricted right-of-way conditions exist.

48-5.03(d) Minimum Radii with Retain Normal Crown or Superelevate at Normal Crown

In urban areas, restricted right-of-way conditions usually exist. The radii for superelevation rates of -6% to +6% are shown in Figure 48-5.C. The -2% line provides the minimum curve radii for which a normal crown of ¼ in/ft (2%) should be retained. For radii and design speeds between the -2% line and +2% line, provide a superelevation of 2.0%. For radii and design speeds above the +2% line, superelevate at the indicated rate.

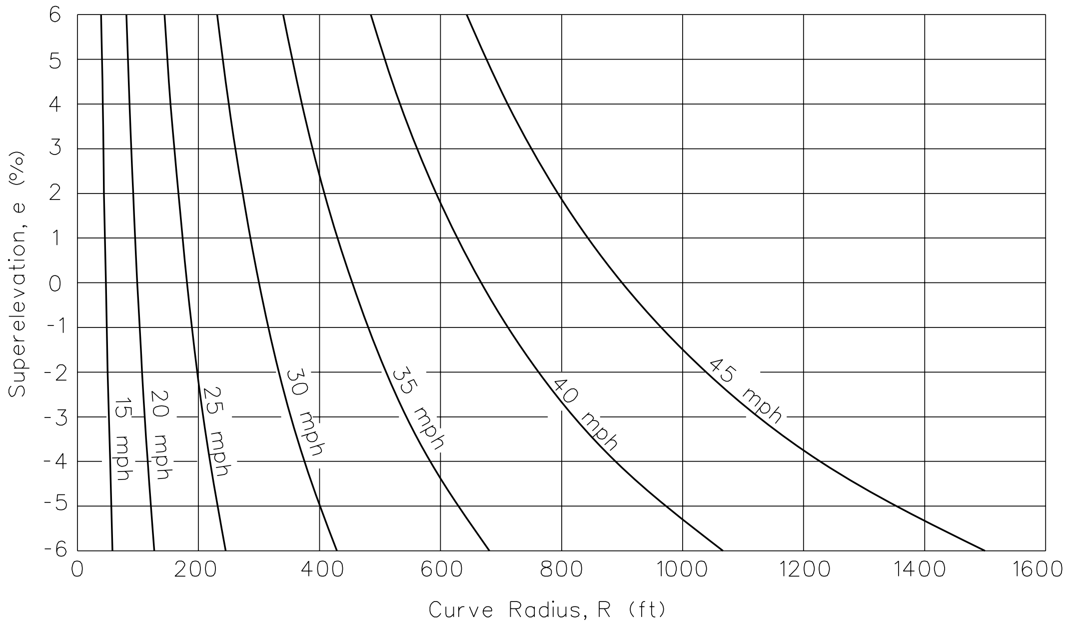
$$R_{min} = \frac{V^2}{15(e_{max} + f_{max})} \text{ (US Customary)} \qquad R_{min} = \frac{V^2}{127(e_{max} + f_{max})} \text{ (Metric)}$$

MINIMUM RADII ON LOW-SPEED URBAN STREETS

Figure 48-5.B

Also, Figure 48-5.C provides a visual means to select a curve and pavement cross-slope with a higher factor of safety than normally would be used for a certain design speed (i.e., providing a curve and/or superelevation rate with a higher theoretical design speed). This is a useful function provided by the format of the graph for designing horizontal curves at the fringes of urbanized areas. When motorists first enter the edge of an urbanized area, they normally take a few seconds to slow down to the posted urban speed limit, and as a result, it is desirable to provide a higher factor of safety for this speed transition area in conjunction with horizontal curves to the left. With the most common horizontal curve design being one with a normal crown section, the factor of safety can easily be increased by sloping the entire traveled way at the rate of the normal crown slope. Using this design feature thereby minimizes excessive lateral accelerations for inbound motorists.



Notes:

① *The Figure provides a range of design speeds and superelevation rates that apply to a selected curve* radius.

② *AASHTO Method 2 is used to distribute superelevation and side-friction for low-speed urban street conditions. Therefore, the basic point-mass equation applies:*

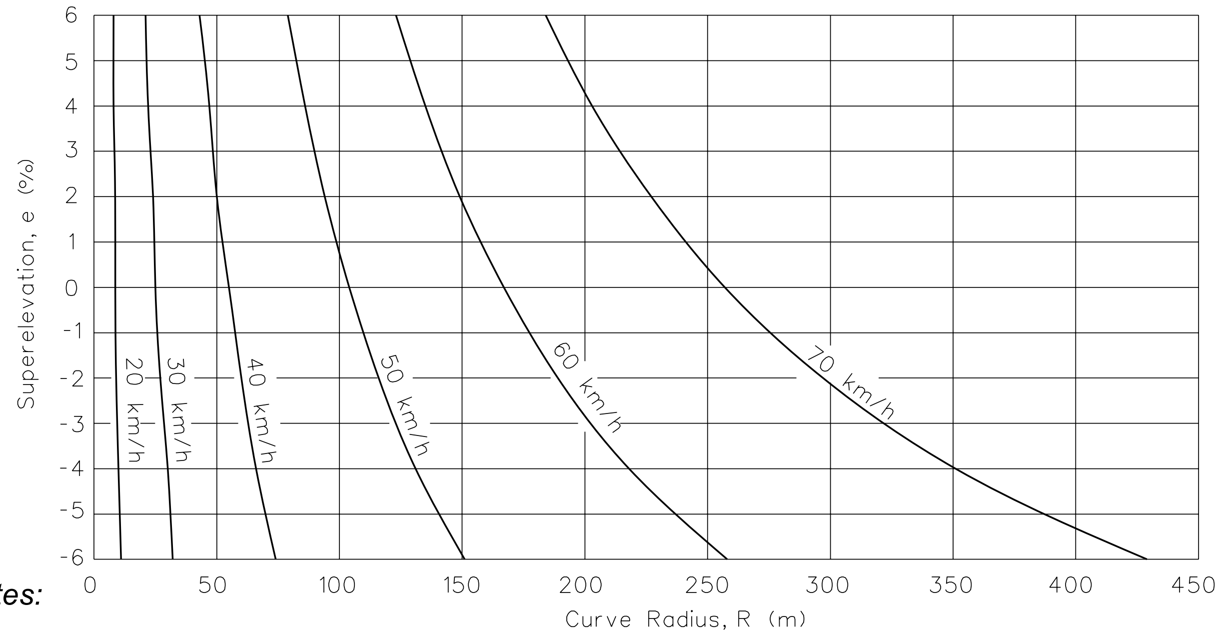
$$R = \frac{V^2}{15(e + f_{max})}$$

Where: *R* = *curve radius, ft*
V = *design speed, mph*
e = *assumed superelevation rate, decimal*
f_{max} = *assumed maximum side-friction factor for selected design speed (see Figure 48-5.B), decimal*

③ *For curves between the -2% and +2% lines, consider removing the crown slope through the curve. This will ensure that maximum comfortable side friction is not exceeded due to a negative slope in one direction of travel. It will also minimize potential rollover of trucks (on dry pavement) with low rollover thresholds and minimize possible skidding of trucks with smooth tires on polished, wet pavement surfaces. On a tangent section, a low-speed urban street normally should be sloped away from the curbed median or centerline of the roadway (5-lane flush) at a minimum cross-slope rate of 1/4″/ft.*

SUPERELEVATION RATES
(Low-Speed Urban Streets)
(US Customary)

Figure 48-5.C



Notes:

① *The Figure provides a range of design speeds and superelevation rates that apply to a selected curve* radius.

② *AASHTO Method 2 is used to distribute superelevation and side-friction for low-speed urban street conditions. Therefore, the basic point-mass equation applies:*

$$R = \frac{V^2}{127\,(e + f_{max})}$$

Where: *R* = *curve radius, m*
V = *design speed, km/hr*
e = *assumed superelevation rate, decimal*
f_{max} = *assumed maximum side-friction factor for selected design speed (see Figure 48-5.B), decimal*

③ *For curves between the -2% and +2% lines, consider removing the crown slope through the curve. This will ensure that maximum comfortable side friction is not exceeded due to a negative slope in one direction of travel. It will also minimize potential rollover of trucks (on dry pavement) with low rollover thresholds and minimize possible skidding of trucks with smooth tires on polished, wet pavement surfaces. On a tangent section, a low-speed urban street normally should be sloped away from the curbed median or centerline of the roadway (5-lane flush) at a minimum cross-slope rate of 2%.*

SUPERELEVATION RATES
(Low-Speed Urban Streets)
(Metric)

Figure 48-5.C

48-5.03(e) Superelevated Curves

Figure 48-5.C allows the designer to select a curve with superelevation where a radius to retain normal crown or remove crown slope cannot be achieved.

* * * * * * * *

Example 48-5.02(1)

Given: 22 ft raised-curb median with 24 ft traveled ways in each direction
Design speed = 40 mph
Radius = 800 ft
Cross slope of traveled way = 1/4″/ft (2.0%) in each direction

Problem: Determine if superelevation is needed.

Solution: Figure 48-5.C indicates the assumed design speed can be achieved with an adverse crown slope of up to approximately -2.5%. If the normal crown is maintained throughout the curve, the worst-case superelevation rate in one direction is -2.0%. Therefore, the normal crown can be maintained, and the horizontal curve will provide for the assumed design speed.

Example 48-5.02(2)

Given: Two-lane, two-way street at 30 ft f-f
Design speed = 40 mph
Radius = 650 ft
Cross slope of traveled way = 1/4″/ft (2.0%) in each direction

Problem: Determine if superelevation is needed.

Solution: Figure 48-5.C indicates the assumed design speed can be achieved with a 0% cross slope. The normal crown would provide a rate of -2.0% for the worst-case condition in one direction. The -2.0% will accommodate a vehicular speed of approximately 38 mph. Also the footnote in Figure 48-5.C states that any set of conditions between the -2% and +2% lines should be superelevated at the rate of the normal crown slope. Therefore, the curve should have a superelevation rate of +2.0% across the entire traveled way.

Example 48-5.02(3)

Given: Five-lane section with flush TWLTL
Design speed = 40 mph
Radius = 550 ft (restricted ROW conditions)
Cross slope of traveled way = 1/4″/ft (2.0%)

Problem: Determine if superelevation is needed.

Solution: Figure 48-5.C yields a rate of 4.0%, which is the maximum allowable rate for new construction. Therefore, the entire traveled way should be transitioned and superelevated at this rate. Because this is a five-lane section, use Type M-2.12 Concrete Curb and Gutter on both median edges of the horizontal curve for improved drainage.

* * * * * * * *

48-5.03(f) Maximum Deflection Without Curve

It may be appropriate to omit a horizontal curve where very small deflection angles are present. As a guide, the designer may retain deflection angles of about 1° or less on low-speed urban streets. For these angles, the absence of a horizontal curve should not affect aesthetics.

48-5.04 Superelevation Development

48-5.04(a) Transition Length

The superelevation transition length is the distance required to transition the traveled way from a normal crown section to the full design superelevated section. The superelevation transition length is the sum of the tangent runout distance and superelevation runoff length. See Section 32-3. The following applies to low-speed urban streets:

1. Calculation. Section 32-3 presents the methodology for calculating the superelevation runoff and tangent runout for open roadway conditions. This methodology also applies to superelevation transition lengths on low-speed urban streets. Figure 48-5.D presents superelevation runoff lengths (L_1) and tangent runout lengths (TR) for a two-lane urban street, assuming the axis of rotation is about the roadway centerline; i.e., the width of rotation is one travel lane (13 ft (4.0 m)). See Section 32-3 for guidelines on determining modifications to the superelevation transition distance where the width of rotation is more than one travel lane. Include the plot of the pavement edges in the construction plans to ensure a smooth profile design. See Section 63-4.07(b).

2. Portion of Superelevation Runoff Prior to Curve. Typically, 67% of the superelevation runoff length will be placed on tangent and 33% on curve. Exceptions to this practice may be necessary to meet field conditions. Generally, the accepted range is 60%-80% on tangent and 40%-20% on curve.

SUPERELEVATION TRANSITION LENGTHS FOR TWO-LANE STREETS
(Low-Speed Urban Streets with 13 ft (4.0 m) Lanes)

Figure 48-5.D

48-5.04(b) Axis of Rotation

On low-speed urban streets, the axis of rotation for horizontal curves is as follows:

1. Two-Lane Facilities. The axis of rotation is typically about the centerline of the roadway.

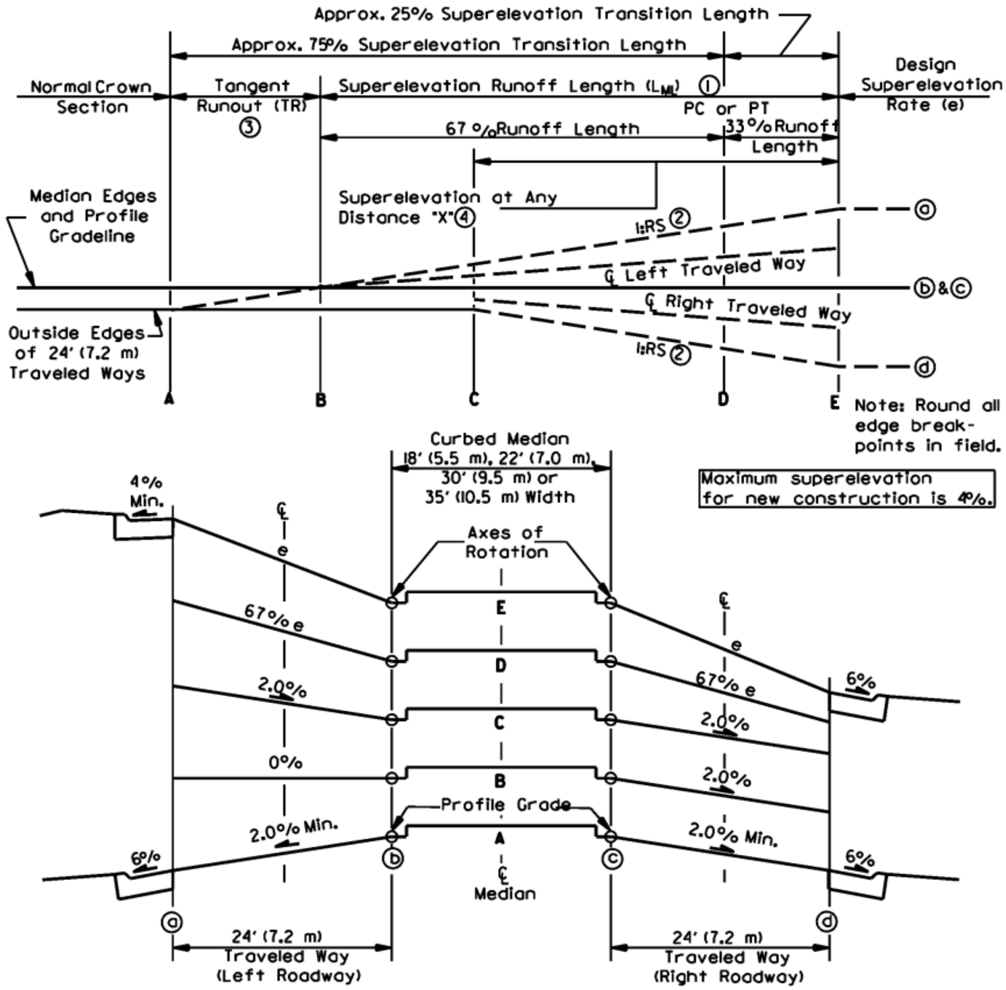
2. Multilane Facilities (Median Width ≤ 16 ft (5.0 m)). The axis of rotation is typically about the centerline of roadway or median.

3. Multilane Facilities (Median Width > 16 ft (5.0 m)). The axis of rotation is typically about the two median edges.

Low-speed urban streets may also present special problems because of the presence of two-way, left-turn lanes; turning lanes at intersections; intersections with major crossroads; drainage; etc. For these reasons, the axis of rotation may be determined on a case-by-case basis.

48-5.05 Typical Designs

See Figures 48-5.E and 48-5.F for typical multilane designs on low-speed urban streets that illustrate the superelevation transitions. See Figure 32-3.J for superelevation transitions on two-lane streets.



① $L_{ML} = L_1 \times C$. See Section 32-3.02(b) for multilane superelevation runoff calculations.

② The relative gradient of the superelevation runoff (G_{SR}, decimal) is:

$$G_{SR} = \frac{24e}{L_{ML}}$$ (US Customary)

$$G_{SR} = \frac{7.2e}{L_{ML}}$$ (Metric)

$$RS = \frac{1}{G_{SR}}$$

③ $$TR_{ML} = \frac{S_{normal}}{e}\left(L_{ML}\right)$$

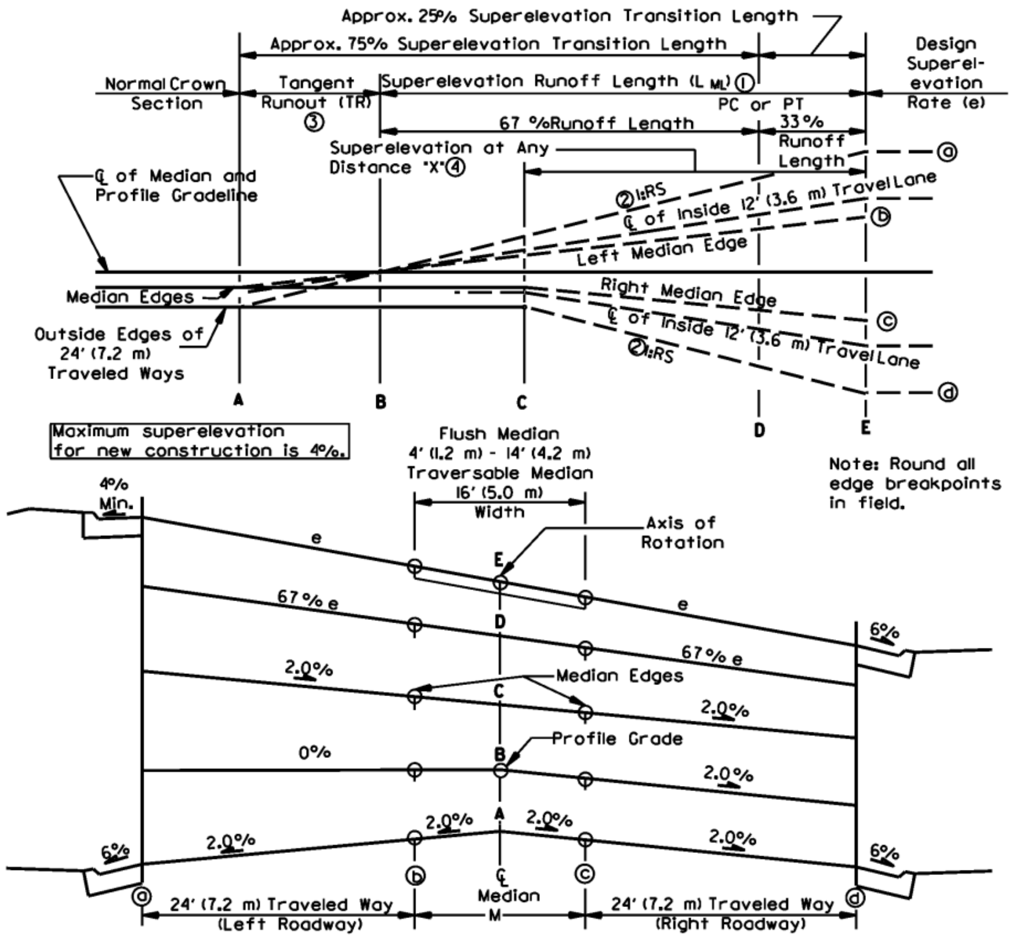
④ Superelevation rate (e) at any distance up to full superelevation attainment:

$$0.02 + \frac{G_{SR} \times \text{Distance "X"}}{24}$$ (US Customary)

$$0.02 + \frac{G_{SR} \times \text{Distance "X"}}{7.2}$$ (Metric)

AXIS OF ROTATION ABOUT EDGE OF CURBED MEDIAN
(Four-Lane Divided Highway With Curbed Median Widths of 18′, 22′, 30′ or 35′ (5.5, 7.0, 9.5 or 10.5 m))

Figure 48-5.E



① $L_{ML} = L_1 \times C$. See Section 32-3.02(b) for multilane superelevation runoff calculations.

The relative gradient of the superelevation runoff (G_{SR}, decimal) is:

$$G_{SR} = \frac{e(7.2 + M/2)}{L_{ML}}$$ (US Customary)

③ $$G_{SR} = \frac{e(24 + M/2)}{L_{ML}}$$

② $$TR_{ML} = \frac{S_{normal}}{e}\left(L_{ML}\right)$$ (Metric)

$$RS = \frac{1}{G_{SR}}$$

④ Superelevation rate (e) at any distance up to full superelevation attainment:

$$\frac{G_{SR} \times \text{Distance "X"}}{(24 + M/2)}$$ (US Customary)

$$\frac{G_{SR} \times \text{Distance "X"}}{7.2 + M/2}$$

48-6 TABLES OF DESIGN CRITERIA

Figures 48-6.A, 48-6.B, and 48-6.C provide the criteria for urban streets with raised-curb medians, two-way left-turn lane medians, and one-way streets. Where it has been decided that the cross section design should be a depressed median with outside shoulders (i.e., open suburban area), use the criteria presented in Chapter 47 for rural four-lane arterials.

The designer should realize that some of the cross section elements included in the figures (e.g., TWLTL) are not automatically warranted in the project design. The values in the figures only apply after the decision has been made to include the element in the highway cross section.

FIGURE 48-6.A
(2 of 4)

(1) Traffic Volumes. The design hourly volumes (DHV) are calculated using a PHF = 1.0; adjust these values using local peak-hour factors.

(2) Design Speed.

a. Consider using a minimum 40 mph (60 km/hr) design speed in relatively undeveloped areas where economics, environmental conditions, and signal spacing permit. The statutory speed limits in urbanized areas is 30 mph. Before the posted speed limit can be increased, complete an engineering study (Phase I report) and a speed study.

b. Only consider the 50 mph (80 km/hr) design speed in open-suburban areas. Do not place curb and gutter adjacent to the edges of the traveled way.

(3) Level of Service. In major urban areas, a level of service D may be considered with study and justification.

(4) Minimum Street Width. The minimum width of a two-way, two-lane street is set at 30 ft (9.2 m) f-f which allows two-way traffic to pass a stalled vehicle.

(5) Parking Lane Width. The desirable width of the parking lane is 10 ft (3.0 m) and includes the 2 ft (600 mm) gutter width. The minimum width is 8 ft (2.4 m) e-f.

(6) Gutter Width. Under restricted conditions, the gutter width adjacent to the edge of the turn lane may be narrowed or eliminated adjacent to a 12 ft (3.6 m) lane and narrowed adjacent to a 11 ft (3.3 m) lane.

(7) Shared Lane Width. Width of a shared lane for motor vehicle and bicyclist use shall be 14 ft (4.3 m) minimum to allow for vehicle passing of bicycles while staying within the lane.

(8) Cross Slope.

a. For the third lane away from the median, increase the cross slope by 1/16″ /ft (0.5%).
b. For reconstruction projects, an existing 3/16″ /ft (1.5%) cross slope may remain-in-place.

(9) TWLTL Median Width. Use a minimum 13 ft (4.0 m) wide median width if there are a significant number of trucks making left turns.

(10) Clear Zone. For curbed facilities, the minimum horizontal clearance to an obstruction is 1.5 ft (500 mm), measured from the face of curb.

GEOMETRIC DESIGN CRITERIA FOR SUBURBAN/URBAN TWO-WAY ARTERIALS
(New Construction/Reconstruction)

Footnotes for Figure 48-6.A
(3 of 4)

(11) New and Reconstructed Bridge Widths. Clear roadway bridge widths are measured from face to face of outside curbs or parapet walls. Urban bridge widths are defined as the sum of the approach traveled way widths, the width of the gutters, and the width of the median. A sidewalk or bikeway will result in additional bridge width. For proposed sidewalks on a bridge, add 5 ft (1.5 m) to each side of the bridge. Parking is prohibited on bridges.

(12) Existing Bridge Widths to Remain in Place. Clear roadway bridge widths are measured from face to face of outside curbs or parapet walls. At least one sidewalk must be carried across the bridge. Add a minimum 5 ft (1.5 m) for the sidewalk width.

(13) Vertical Clearance (Arterial Under).

a. The clearance must be available over the traveled way and flush or traversable median.
b. Table value includes allowance for future overlays.
c. A 14 ft 0 in (4.3 m) clearance may be allowed to remain in place with consideration for reconstruction to a clearance of 14 ft 9 in (4.5 m).

Chapter Forty-nine

3R GUIDELINES FOR RURAL AND URBAN HIGHWAYS (Non-Freeways)

49-1 INTRODUCTION

Section 31-6 identifies four project scopes of work:

- new construction;
- reconstruction;
- 3R (resurfacing, restoration, rehabilitation) (non-freeways); and
- 3R (resurfacing, restoration, rehabilitation) (freeways).

The applicable chapters in Parts IV and V present the Department's design criteria that apply to new construction and reconstruction projects. For these projects, the designer often has the liberty of designing the highway to meet the most desirable and stringent criteria possible. Therefore, exceptions to these criteria should be relatively rare.

Highways constructed to meet nationally recognized design criteria provide measurable advantages for the motoring public. The safety, comfort, and convenience of modern highways present strong incentives for funding programs based on ideal design considerations. However, available finances do not always permit the reconstruction of existing highways to an ideal level. A comparison of Statewide needs demonstrates that, with available revenues, the problem must be addressed not only at a project level but on a system-wide basis.

Therefore, the design of projects on existing highways must be viewed from a different perspective. These projects are often initiated for reasons other than geometric design deficiencies (e.g., pavement deterioration), and they often must be designed within restrictive right-of-way, financial limitations, and environmental constraints. As a result, the design criteria for new construction and reconstruction are often not attainable without major and, frequently, unacceptable adverse impacts. At the same time, however, the Department must exercise the opportunity to make cost-effective, practical improvements to the geometric design of existing highways and streets.

For these reasons, the Department has adopted revised limits for geometric design values for projects on existing highways that are, in many cases, lower than the values for new construction/reconstruction. These criteria are based on a sound, engineering assessment of the underlying principles behind geometric design and on how the criteria for new construction/reconstruction can be legitimately modified to apply to existing highways without sacrificing highway safety.

Chapter 49 presents the Department's criteria for 3R projects on rural and urban highways (non-freeways), and Chapter 50 presents the criteria for 3R freeway projects. These criteria are intended to find the balance among many competing and conflicting objectives. These include the objective of improving Illinois' existing highways; the objective of minimizing the adverse impacts of highway construction on existing highways; and the objective of improving the greatest number of miles (kilometers) within the available funds.

As a summary, Chapter 49 presents 3R criteria for:

- two-lane rural arterial highways (other than freeways) (Section 49-3);
- urban arterial highways and streets (other than freeways) (Section 49-4);
- high-speed, multilane highways (other than freeways) (Section 49-5); and
- rural unmarked collector or local routes on the State highway system (Section 49-6).

This chapter is not applicable to projects that are generally considered to be resurfacing-only type projects (e.g., maintenance overlays,) or fall under the Pavement Preservation Policy (3P).

49-2 GENERAL

49-2.01 Background

49-2.01(a) Federal 3R Regulations

The *Federal-aid Highway Act* of 1976 amended the term “construction” to permit Federal-aid funding of resurfacing and widening and resurfacing of existing rural and urban pavements with or without revision to the horizontal or vertical alignment or other geometric features. The 1982 *Surface Transportation Assistance Act* stipulated that resurfacing, rehabilitation, and restoration (3R) projects be constructed to standards to preserve and extend the service life of highways and enhance safety.

On June 10, 1982, the FHWA issued its Final Rule entitled *Design Standards for Highways; Resurfacing, Restoration and Rehabilitation of Streets and Highways Other Than Freeways,* which adopted a flexible approach to the geometric design of 3R projects. In the Final Rule, FHWA determined that it was not practical to adopt 3R design criteria for nationwide application. Instead, each State can develop its own criteria and/or procedures for the design of 3R projects, subject to FHWA approval, to tailor its design criteria according to the conditions that prevail within that State. This approach is in contrast to the application of geometric design criteria for new construction and reconstruction, for which the AASHTO *A Policy on Geometric Design of Highways and Streets* provides nationwide criteria for application.

49-2.01(b) Special Report 214

In 1987, the Transportation Research Board published Special Report 214 *Designing Safer Roads; Practices for Resurfacing, Restoration and Rehabilitation*. The *Surface Transportation Assistance Act* of 1982 mandated this study. The objective of the TRB study was to examine the safety cost-effectiveness of highway geometric design criteria and to recommend minimum design criteria for 3R projects on non-freeways. The final TRB report (SR 214) presented specific numerical criteria for the geometric design of 3R projects for the following elements:

- lane and shoulder widths,
- horizontal curvature and superelevation,
- crest vertical curvature,
- bridge width,
- side slopes, and
- pavement cross slopes.

The SR 214 information has been considered, where appropriate, for the Department’s criteria and procedures for 3R projects.

49-2.01(c) FHWA Technical Advisory T5040.28

Pursuant to its adoption of SR 214, FHWA issued on October 17, 1988, Technical Advisory T5040.28 “Developing Geometric Design Criteria and Processes for Non-Freeway RRR Projects.” The purpose of the Advisory is to provide guidance on developing or modifying criteria for the design of Federal-aid, non-freeway 3R projects. The information from the Technical Advisory has been considered, where appropriate, for the Department's criteria and procedures for 3R projects.

49-2.02 Objectives

From an overall perspective, the 3R program is intended to improve the greatest number of highway miles (kilometers) within the available funds for highway projects. Improve is meant to apply to all aspects that determine a facility's serviceability, including:

- the structural integrity of the pavement, bridges, and culverts;
- the drainage design of the facility to, among other objectives, minimize ponding on the highway, to protect the pavement structure from failure, and to prevent roadway flooding during the design-year storm;
- from a highway capacity perspective, the level of service provided for the traffic flow;
- the adequacy of access to abutting properties;
- the geometric design of the highway to safely accommodate expected vehicular speeds and traffic volumes;
- the roadside safety design to reduce, within some reasonable boundary, the adverse impacts of run-off-the-road vehicles; and
- the traffic control devices to provide the driver with critical information and to meet driver expectancies.

These objectives are competing for the limited funds available for 3R projects on existing highways. The Department's goal is to realize the greatest overall benefit from the available funds. Therefore, on individual projects, some compromises may be necessary to achieve the goals of the overall highway program. Specifically for geometric design and roadside safety, the balance is between what is desirable (new construction/reconstruction) and what is practical for the specific conditions of each highway project.

Therefore, based on these objectives, the Department has adopted and FHWA has approved its policy for the geometric design of 3R projects. These objectives are summarized as follows:

1. 3R projects are intended to extend the service life of the existing facility and to return its features to a condition of structural or functional adequacy. This includes providing smoother riding surfaces and structurally improving bridges.

2. 3R projects are intended to enhance highway safety. Safety improvements should be selected to support the State's Strategic Highway Safety Plan (SHSP) and "Zero Fatalities" goal. To accomplish this, identified "Five Percent" locations, and other locations and conditions that present cost-effective opportunities to reduce fatal and

severe injury crashes must be identified and examined in order to apply 3R funds effectively. 3R projects are intended to incorporate cost-effective, practical improvements to the geometric design of the existing facility. This includes increasing roadway and bridge widths.

49-2.03 Application

The design policies and criteria in Chapter 49 apply to 3R projects on existing facilities within the general constraints of the existing alignment and right-of-way. If the purpose and scope of the project is intended to replace or expand the facility, then Chapter 49 is not appropriate, and reconstruction policies will apply. For definitions and application to new construction and reconstruction projects, see Section 31-6.

49-2.04 3R Project Evaluation

Sections 49-3 through 49-6 present the specific geometric design and roadside safety criteria that will be used to define the scope of 3R projects. In addition, the designer should consider several other factors and conduct applicable technical evaluations using appropriate Department units as may be necessary. The potential evaluations are discussed below:

1. Conduct Field Review. The district will normally conduct a thorough field review of the proposed 3R project to ascertain the appropriateness of 3R criteria and on-site conditions and their effects on project development decisions. Other personnel should accompany the designer as appropriate, including district scoping, safety, environmental, Operations, Project Implementation, Bureau of Safety Programs and Engineering, Bureau of Design and Environment, and FHWA (on applicable Interstate projects or project included in a FHWA specific project PoDI plan (see Section 4-2), etc. Objectives of the field review should be to collect relevant field data, to identify potential safety problems, and to determine the need for safety improvements to the facility.

2. Document Existing Geometrics. The designer will normally review the most recent as-built highway plans and combine this with the field review to determine the existing geometrics within the project limits. The review includes lane and shoulder widths, horizontal and vertical alignment, intersection geometrics, and the roadside safety design. A field survey may also be needed to verify certain geometric features.

3. Safety Analysis. Conduct a project safety analysis as described in Chapter 11-2.02(f) for each 3R project.

4. Crash Data. Crash data and analysis of the data are critical to the identification of problem areas. The Phase I engineering report shall include the identified Five Percent Report (FPR) Location evaluations and schematic collision diagrams.

   The designer shall evaluate the last three years of crash data available, identify over-represented crash trends, and propose appropriate countermeasures. The Phase I engineering report shall include schematic collision diagrams and recommendations based on an analysis for all crash patterns throughout a proposed project. The diagrams should show the location and type of crashes for the previous three years.

5. Early Coordination for Right-of-Way (ROW) Acquisition. ROW acquisitions are sometimes required for 3R projects. Therefore, determine the improvements that will be incorporated into the project design as early as feasible and initiate the ROW process.

6. Pavement Condition. 3R projects are often programmed because of a significant deterioration of the pavement structure. The extent of deterioration will influence the decision on whether a project can be designed using the 3R design criteria or whether it should be designed using new construction/reconstruction criteria. In addition, all 3R projects shall include a pavement surface that meets the Department's skid resistance criteria. See Chapter 53 for the Department's policies, procedures, and criteria for the rehabilitation of existing pavements.

   Whenever the proposed pavement improvement is major, it may be practical to include significant geometric improvements (e.g., lane and shoulder widening) in the project design. However, the proper level of geometric improvement is often determined by many additional factors other than the extent of pavement improvement. These include available right-of-way, environmental studies, traffic volumes, crash experience, and available funds for the project. Therefore, it may be appropriate for the 3R project to include, for example, full-depth pavement reconstruction and minimal geometric improvement, if supported by safety studies and the operational objectives of the 3R program.

7. Geometric Design of Adjacent Highway Sections. The designer should examine the geometric features and operating speeds of highway sections adjacent to the 3R project. This will include investigating whether or not any highway improvements are in the planning stages. The 3R project should provide design continuity with the adjacent sections. This involves a consideration of factors such as driver expectancy, geometric design consistency, and proper transitions between sections of different geometric designs.

8. Continuity of Design. Consistency is an important factor to be considered in the development of 3R projects. 3R projects are based on current traffic; however, consider the probable future traffic to ensure the appropriate use of 3R policies. Avoid the use of design changes that violate driver expectancy regarding width, curvature, or other roadway features, as practical. Continuity of design may justify constructing certain highway elements to higher or lower design criteria than normally prescribed.

9. Physical Constraints. The physical constraints within the limits of the 3R project may determine what geometric improvements are practical and cost-effective. These include topography, adjacent development, right-of-way, utilities, and environmental constraints. Identified safety countermeasures relative to impacts and costs should be considered and an appropriate balance achieved.

10. Traffic Control Devices. All signing and pavement markings on 3R projects shall meet the criteria of the *Illinois Manual on Uniform Traffic Control Devices*. The Bureau of Operations is responsible for selecting and locating the traffic control devices on the project. The designer should work with the Bureau to identify possible geometric and safety deficiencies that will remain in place (i.e., no improvement will be made).

11. Bridges Within Project Limits. One or more bridges may be within the limits of a 3R project. If bridge improvement is needed, it may be performed prior to, simultaneous with, or deferred from highway projects in accordance with the priorities established in the applicable sections of Chapter 49 (e.g., Section 49-3.09 for rural arterials).

    Highway bridge improvement includes all work necessary for the improvement of existing rural or urban bridges to be consistent with 3R objectives for increased safety, improved operating conditions, and structural adequacy. Bridge improvement could include complete replacement of a bridge when no other cost-effective means of meeting these criteria are feasible. For definition and clarification, a bridge constructed at a different location or an existing bridge requiring replacement of all elements as a part of a 3R project is designated as a replacement rather than a new bridge. New bridge designations are reserved for new construction/reconstruction projects because they generally are subject to different width requirements than replacement bridges.

12. Design Exceptions. The use of lower design criteria than described in Chapter 49 will require approval from BDE and, where applicable, FHWA. Where exceptions to these criteria are necessary, they should be processed according to the procedures described in Section 31-8.

13. Spot Improvements. Recently completed spot improvements (e.g., safety or bridge projects) may be considered for omission from 3R projects. The proposed limits of an omission should be identified, and all applicable features within the limits of the spot improvement should be discussed at district coordination meetings and included in the Phase I engineering report. These reports should also discuss the omissions to ensure that they are treated in accordance with 3R policies. Any exceptions to the 3R criteria within omissions shall be identified and addressed in accordance with the 3R procedures.

49-3 TWO-LANE RURAL ARTERIAL HIGHWAYS

49-3.01 Application

Section 49-3 is applicable to resurfacing, rehabilitation, and restoration (3R) projects on the State highway system that are:

- marked two-lane rural arterials,
- marked two-lane rural highways functionally classified as collectors,
- unmarked two-lane rural arterials, or
- expressways (project-by-project basis).

49-3.02 Design Speed

The typical design speed for rural arterial 3R projects is 55 mph (90 km/h), or the regulatory speed, whichever is less.

49-3.03 Roadway Cross Section Elements

Figure 49-3.A presents design criteria for roadway cross section elements for 3R projects on rural two-lane arterial highways. The proposed improvements are primarily related to existing roadway widths and traffic volumes.

49-3.04 Horizontal Alignment

49-3.04(a) General

Engineering judgment and/or a cost-effectiveness evaluation will reveal the need for improvements to the horizontal alignment within a 3R project. In general, improvements to existing horizontal alignment and/or superelevation should be considered if a specific problem is identified. Examples include:

- a disproportionate number of run-off-the-road crashes,
- a disproportionate number of multi-vehicle crashes at curve sites, and/or
- the presence of a major intersection within a horizontal curve.

The evaluation of potential improvements will include the consideration of existing curvature, speed, traffic volumes, truck volumes, right-of-way and utility impacts, environmental impacts, driver expectancy, construction costs, etc.

Current ADT	EXISTING Traveled Way WIDTHS		
	18 ft – 20 ft (5.48 m - 6.10 m)	22 ft (6.71 m)	24 ft (7.32 m)

WRS = Widening and Resurfacing
RS = Resurfacing Only

Note: See next page for footnotes.

ROADWAY CROSS SECTION ELEMENTS
(3R Projects — Two-Lane Rural Arterials)

Figure 49-3.A

Notes to Figure 49-3.A.

(1) *Roadway widths less than 34 ft (10.3 m) generally will be widened to meet one of the following widths depending on the width of the existing traveled way:*

Existing Traveled Way Width	*Pavement/Striped Width*	*Proposed Shoulder Width*	*Total Roadway Width After Construction*
22 ft (6.71 m)	*22 ft (6.7 m/6.6 m)*	*8 ft (2.4 m)*	*38 ft (11.5 m)*
18 ft – 20 ft (5.48 m - 6.10 m)	*24 ft (7.2 m/7.2 m)*	*8 ft (2.4 m)*	*40 ft (12.0 m)*
24 ft (7.32 m)	*24 ft (7.3 m/7.2 m)*	*8 ft (2.4 m)*	*40 ft (12.0 m)*

The paved shoulder will be 3 ft (900 mm) wide, and the remainder will be an aggregate wedge as noted in Figure 49-3.A except as modified by Note (2).

In some cases, widening an existing roadway to only 34 ft or 36 ft (10.3 m or 10.9 m) may be permitted, depending on the existing traveled way width and right-of-way conditions. Where the existing traveled way is 22 ft or 24 ft (6.7 m or 7.3 m) wide, the construction of 6 ft (1.8 m) shoulders may be considered if such a proposed roadway width can reasonably be accommodated within the existing right-of-way, and a 38 ft to 40 ft (11.5 m to 12.1 m) roadway will require additional right-of-way.

(2) *Use an aggregate wedge for part of the shoulder on roadways with a current ADT up to 5000. For roadways where the current ADT is more than 5000, the aggregate wedge will be replaced by a minimum aggregate thickness of 6 in. (150 mm) (minimum design considered as stabilized aggregate). Where the stabilized width of shoulder construction from Figure 49-3A is less than the proposed shoulder width in Footnote (1), the proposed width of the aggregate wedge or stabilization should be increased to include the remaining shoulder width. See the Highway Standards for details.*

(3) *Where resurfacing is proposed on a Class II Designated Truck Route or where the ADT of multiple-unit trucks exceeds 250, the paved shoulder should be increased to 2 ft (600 mm) wide, and the width of aggregate wedge should be decreased by 1 ft (300 mm).*

(4) *The 1 ft (300 mm) paved shoulder width is constructed as an integral part of the pavement widening. See the* Highway Standards *for details.*

(5) *Where an unusually high number of multiple-unit trucks are present or anticipated (e.g., coal hauling routes) on a highway, the designer may consider providing 11 ft (3.3 m) travel lanes with resurfacing or 11 ft (3.3 m) travel lanes with widening and resurfacing and striping for 1 ft (300 mm) paved shoulders in both cases. For an existing 20 ft (6.1 m) traveled way, the designer may consider the option of only resurfacing the traveled way and constructing 2 ft (600-mm) paved shoulders.*

(6) *All 1 ft (300 mm) wide paved shoulders under "Proposed Improvement Widths" which are not an integral part of the widening should be 6 in. (150 mm) thick. See the Highway Standards for details.*

49-3.04(b) Radius of Curvature/Superelevation

It is often impractical and unnecessary to correct horizontal curves on 3R projects to meet new construction/reconstruction criteria for the minimum radius of curvature. Consequently, existing horizontal curves should be evaluated to determine if an existing horizontal curve should remain in place; if there is a need for providing more superelevation on a curve; or if the curve must be reconstructed. Reconstruction should be considered only if at least one of the following conditions is met:

1. Safety analysis indicates a problem at the curve site.

2. The comfortable operating speed of an existing horizontal curve is more than 15 mph (25 km/h) below the 3R design speed (or posted or regulatory speed if less than 55 mph (90 km/h)). This assumes an increased superelevation rate cannot reduce this difference. Figure 49-3.B should be used to determine the comfortable operating speed of an existing curve. This figure is based on AASHTO's Method 2 for the distribution of superelevation and side friction.

   Comfortable operating speed is defined as the speed at which a motorist can drive an existing horizontal curve and still feel comfortable traversing the curve. In all cases, maximum comfortable side friction (f) is assumed. See Section 32-2.

If it is determined to reconstruct a curve to meet the minimum radius criteria, the curve typically should be reconstructed to meet all horizontal alignment details for new construction/reconstruction (e.g., superelevation rate, superelevation transition lengths, distribution of superelevation runoff between tangent and curve) as discussed in Chapter 32.

If it is determined to retain an existing curve based on the above criteria, the designer still may be able to cost effectively improve other details of the horizontal curve. The following are potential improvements:

1. Improve the frictional characteristics of the roadway with a new pavement surface.

2. Increase the superelevation rate by specifying a tapered overlay.

3. Improve the superelevation transition length.

4. Specify wider lanes throughout the curve and use paved shoulders. Also, add reflectorized pavement markers to the centerline.

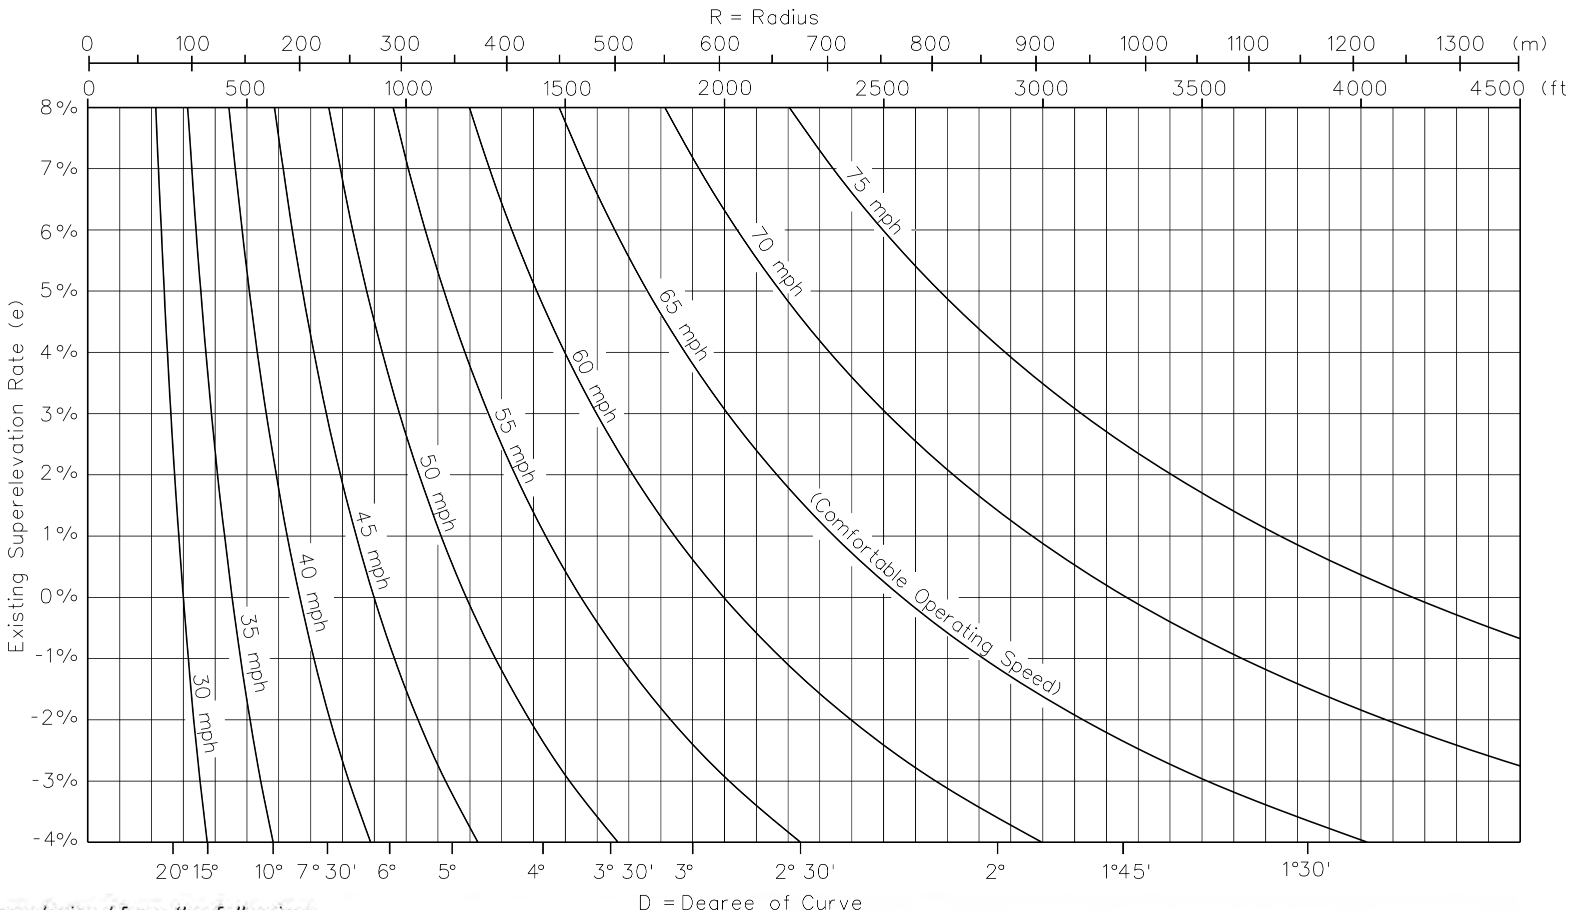

Figure derived from the following:

1. *Use AASHTO Method 2 for the distribution of superelevation and side friction.*

2. *Assume design speed and use f_{max} for selected design speed in all cases.*

3. *Assume different values of "e" and calculate values for "R" on graph for each speed.*

$$R=\frac{V^2}{15\,(e + f_{max})}$$, *where V = mph and R = ft. (US Customary)*

$$R=\frac{V^2}{127\,(e + f_{max})}$$, *where V = km/h and R = m. (Metric)*

HORIZONTAL CURVATURE ALLOWED TO REMAIN IN PLACE FOR 3R NON-FREEWAY PROJECTS

Figure 49-3.B

Notes on How To Use Figure 49-3.B

1. *Figure 49-3.B. applies to all rural highways (open-roadway conditions) and to all urban highways and streets.*

2. *Obtain existing curve radius and the surveyed superelevation rate. Plot point on graph and determine comfortable operating speed for existing conditions. TRB Special Report 214 and FHWA Technical Advisory T5040.28 (October 17, 1988) both are used as references for 3R work. They may be referenced for further information.*

3. *If existing conditions do not provide a sufficiently high speed, then increase the superelevation rate up to a maximum of 8% to increase the comfortable operating speed on the curve.*

4. *If increasing the superelevation rate up to 8% does not provide a sufficiently high comfortable operating speed to allow a curve to remain in place, then the designer shall consider realigning the curve. The following applies:*

    a. *The preferred alternative is to upgrade the curve (using new construction criteria) to the appropriate design speed for the given functional classification. This is accomplished by using AASHTO Method 5 for superelevation rates and for the calculation of curve radii. See Section 32-2.*

    b. *In certain cases, a second alternative for reconstruction may be considered for curve realignment. This might occur where environmental issues become critical, where right-of-way is determined to be highly restricted, or where a major at-grade intersection falls within the limits of the curve and the curve radius cannot be increased due to alignment restrictions. The maximum superelevation rate typically used on curves at a major crossroad intersection is 4%. In this case, the designer may determine the appropriate radius by using AASHTO Method 2 for superelevation and side-friction distribution. Figure 49-3.B values would apply.*

49-3.04(c) Treatment of Existing Horizontal curves

The basic objectives for improving operating speeds on horizontal alignment of rural type highways with ADTs of 1000 or more are:

- to determine if a horizontal curve can remain in place by increasing superelevation up to a maximum of 8% which, in turn, will provide a comfortable operating speed of 40 mph (65 km/h) or greater;
- to retain existing horizontal curves adequate for comfortable operating speeds of 40 mph – 50 mph (65 km/h – 80 km/h) by increasing the superelevation rate;
- to determine appropriate superelevation rates on horizontal curves adequate for speeds greater than 50 mph (80 km/h); and
- to realign horizontal curves not adequate for a 40 mph (65 km/h) comfortable operating speed when the design speed is 55 mph (90 km/h).

<u>Regulatory Speed on Adjacent Tangents is 50 mph (80 km/h) or Greater and Current ADT >1000</u>

1. <u>Radius Less Than 460 ft (140 m)</u>. The following applies:

    a. Realign horizontal curve according to functional classification of highway and use appropriate design speed criteria (see applicable chapter in Part V) or, in some cases, use Figure 49-3.B to determine curvature. See the footnotes for Figure 49-3.B for determination of cases.

    b. If the proposed realignment lies along a highway with a lower current traffic volume, a 60 mph (100 km/h) design speed may be considered for the realignment if this is compatible with the remainder of the route.

    c. The following design features will apply to any realignments:

        - The traveled way should be 24 ft (7.2 m) wide, and the lanes should be striped 12 ft (3.6 m) wide through the curve.
        - The shoulders should be 8 ft (2.4 m) wide. The minimum paved shoulder will be 1 ft (300 mm) wide, and an aggregate wedge will be provided adjacent to the paved shoulder. Stabilization could be wider to be compatible with the remainder of the project.
        - Front slopes generally should be 1V:4H, but they may vary in relationship to prevailing slopes throughout the project and/or adjacent roadway sections. Back slopes generally should not be steeper than 1V:3H.

2. <u>Radius 460 ft to 750 ft (140 m to 230 m)</u>. The following applies:

   a. Retain existing horizontal curvature and use an 8% superelevation rate.

   b. Find comfortable operating speed from Figure 49-3.B and post with an advisory speed as follows:

      - For 40-42 mph (64–68 km/h) operating speeds, post curve at 40 mph.
      - For 43-47 mph (69–76 km/h) operating speeds, post curve at 45 mph.
      - For 48-50 mph (77–80 km/h) operating speeds, post curve at 50 mph.
      - For operating speeds greater than 50 mph (80 km/h), no posting is required.

   c. The following design features will apply to horizontal curves in this category:

      - Lanes should be a minimum of 12 ft (3.6 m) wide through the curve.

      - The minimum paved shoulder widths are 1 ft (300 mm) on the outside and 3 ft (900 mm) on the inside of the curve. Stabilization could be wider to be compatible with the remainder of the project.

      - A minimum stopping sight distance for 50 mph (80 km/h) should be considered across the inside of the curve. See Section 32-4.

      - Where the district determines that the truck volumes are high, consider using 13 ft (4.0 m) lanes through the curve. Curve widening on the inside generally is preferable.

      - Reflectorized pavement markers should be placed along the centerline of the curve.

3. <u>Radius Greater than 750 ft (230 m)</u>. The following applies:

   a. Superelevate curve in accordance with Figure 49-3.B to accommodate the tangent regulatory speed.

   b. The following design features will apply to horizontal curves in this category:

      - Use a minimum of 12 ft (3.6 m) lanes.

      - The minimum paved shoulder widths are 1 ft (300 mm) on the outside and 3 ft (900 mm) on the inside of the curve. Stabilization could be wider to be compatible with the remainder of the project.

      - A minimum stopping sight distance for 55 mph (90 km/h) should be considered across the inside of the curve. See Section 32-4.

      - Reflectorized pavement markers should be placed along the centerline of the curve.

Regulatory Speed on Adjacent Tangents is 45 mph (75 km/h) or Less in Rural Areas or Where Rural Cross Sections Exist

1. If the comfortable operating speed using an 8% superelevation rate equals at least 30 mph (50 km/h) (R = 250 ft (75 m)), then the horizontal curve may be retained. Appropriate advisory speeds shall be posted.

2. For curves with radii of 250 ft to 600 ft (75 m to 180 m), use an 8% superelevation rate to accommodate the tangent regulatory speed. Refer to Figure 49-3.B and post the appropriate advisory speed.

3. For curves with radii greater than 600 ft (180 m), superelevate the curve to accommodate the tangent regulatory speed by using an e_{max} up to 6%. Refer to Figure 49-3.B.

Regulatory Speed on Adjacent Tangents is 50 mph (80 km/h) or Greater and Current ADT < 1000

1. If the comfortable operating speed using an 8% superelevation rate equals at least 35 mph (60 km/h) (R = 350 ft (106 m)), then the horizontal curve may be retained. Appropriate advisory speeds shall be posted.

2. For curves with radii of 350 ft to 750 ft (106 m to 230 m), use an 8% superelevation rate to accommodate the tangent regulatory speed. Refer to Figure 49-3.B and post the appropriate advisory speed.

3. For curves with radii greater than 750 ft (230 m), superelevate the curve by using Figure 49-3.B to accommodate the tangent regulatory speed.

49-3.04(d) Superelevation Transition Lengths

The length of superelevation transition consists of two parts — the length of superelevation runoff and the length of tangent runout. For a discussion of superelevation development, see Section 32-3.

When the regulatory speed on an adjacent tangent is 50 mph (80 km/h) or greater and the radius of the curve is greater than 750 ft (230 m), a desirable superelevation transition length of 230 ft (70 m) should be used. The minimum superelevation transition length should be approximately 200 ft (60 m).

For all other speed and curve combinations in a rural area, a desirable superelevation transition length of approximately 200 ft (60 m) should be used. The minimum superelevation transition length should be approximately 150 ft (45 m).

For new construction and reconstruction projects, the Department's practice is to provide 67% of the superelevation runoff on tangent and 33% on curve. However, due to the nature of 3R projects, the location of superelevation runoff lengths with respect to the PC and PT may vary, and strict compliance with this runoff ratio is not mandatory. Where reverse curves may restrict the distribution of the runoff, a ratio of 50% on tangent and 50% on curve may be used for the superelevation runoff.

49-3.04(e) Traveled Way/Shoulder "Rollover"

Through horizontal curves where the proposed or remaining shoulder width is 6 ft (1.8 m) or wider, the maximum rollover (algebraic difference between slopes) at the intersection of the traveled way and shoulder should not be greater than 10%. Where the shoulder width is 4 ft (1.2 m) or less, the maximum rollover may be 12%. Where 1 ft (300 mm) wide paved shoulder strips are used, the rollover should occur at the edge of the paved shoulder rather than at the traveled way edge for ease of construction.

49-3.04(f) Summary

Figure 49-3.C summarizes the horizontal curve criteria for 3R projects on rural arterial facilities.

SUMMARY OF HORIZONTAL CURVE POLICY

Figure 49-3.C

49-3.05 Vertical Alignment

49-3.05(a) Crest Vertical Curves

The following will apply:

Current ADT	Treatment
1000 or more	All existing crest curves which are not within 15 mph (25 km/h) of the posted or regulatory speed, as determined from the available stopping sight distance (SSD), will be upgraded by one of the following options: • flatten the crest curve within the existing right-of-way to satisfy 55 mph (90 km/h) (desirable) or 45 mph (70 km/h) (minimum) SSD; or • flatten the crest curve by using additional right-of-way to satisfy a 50 mph to 55 mph (80 km/h to 90 km/h) SSD; or • flatten the crest curve with sufficient additional right-of-way to satisfy the SSD design speed for reconstruction criteria. A 60 mph (100 km/h) design speed may be considered on low-volume highways. • Where a structure lies on a crest curve, flatten the approaches to a SSD design speed using reconstruction criteria. In addition through the limits of the reconstructed embankment, the improved shoulder width should be a minimum of 8 ft (2.4 m). The designer should consider sight distances, intersection influences, overall safety, the need for road closures, detours, stage construction, and especially the prevailing vertical alignment in evaluating the above alternatives. Such an analysis will allow designers to determine the most practical alternative for flattening crest vertical curves.
Less than 1000	Crest curves may be retained where the stopping sight distance on the vertical curve is no more than 20 mph (30 km/h) less than the posted or regulatory speed but not less than a 30 mph (50 km/h) available stopping sight distance.

49-3.05(b) Sag Vertical Curves

For all traffic volumes, sag vertical curves generally may be retained except for sags that include a structure requiring a complete replacement. In this case, the designer shall consider and investigate upgrading the sag vertical curve to meet a SSD design speed using reconstruction criteria versus allowing the profile to remain in place.

49-3.05(c) Maximum Grades

Existing mainline grades are acceptable; i.e., flattening grades usually is not within the scope of a 3R project.

49-3.06 Intersections

49-3.06(a) Superelevation Rate Changes Through Intersections

Superelevation rates less than that specified for the preceding horizontal alignment may be used through certain intersections because of significant intersection conflicts and when supported in the Phase I engineering report. Refer to Figure 36-1D for guidance. Agreement should be reached with the District Operations Engineer on the appropriate advisory speed to be posted for the curve and noted in the Phase I engineering report.

49-3.06(b) Stop-Controlled Approaches on Horizontal Curves

For curved, stop-controlled approaches on State-marked routes or collector route intersections, with arterial highways, it is desirable to provide as flat an alignment as practical (with lower superelevation rates), even though traffic is operating at lower speeds than on comparable non-stop approaches. On a project-by-project basis, the benefits of higher superelevation rates for high operating speeds (during clear weather or wet pavement conditions) versus the benefits of lower superelevation for low operating speeds (during icy pavement conditions) should be carefully considered when selecting an appropriate superelevation rate. Where curve flattening is not practical, an existing curve may be retained when it will accommodate a comfortable operating speed of at least 30 mph (50 km/h) with 8% superelevation. The minimum radius in this case is 250 ft (75 m).

49-3.06(c) Sideroad Approach Grades

All connecting sideroad approaches should be examined for drainage away from the arterial route. The gradeline on the sideroad should normally drain away from the intersected arterial highway for 50 ft to 100 ft (15 m to 30 m) or, at a minimum, to the ditch line of the arterial highway. The minimum sideroad gradeline should be approximately -1.0% from the intersected State highway, and the maximum gradeline is -4.0%. Where the arterial highway is on a horizontal curve, use a maximum of -2.0% on the sideroad connection to minimize rollover at the edge of traveled way. When marked or unmarked crosswalks exist or are proposed across the intersection, roadway approach grade values more restrictive than those shown in this Section may be necessary to achieve accessibility standards. See Sections 58-1.10 and 36-1.06 for more information.

49-3.06(d) Sideroad Turning Radii

For rural arterial 3R projects, the design vehicle used for sideroad turning radii may be site specific with justification. See Section 36-1 for guidance in the selection of a design vehicle considering functional classification.

49-3.06(e) Intersection Sight Distance (ISD)

At rural, public road intersections with a stop condition on the sideroad, provide 600 ft (180 m) of sight distance for the stopped approach in both the left and right directions along the arterial highway. Use a 12 ft (3.5 m) distance from the edge of traveled way to the driver's eye. Approval of a Level Two design exception will be required for the retention of less sight distance. In addition, the posting of a warning sign may be appropriate on the arterial highway.

49-3.07 Roadside Treatment and Highway Appurtenances

49-3.07(a) General

The intent of these guides is to perform cost-effective work that may reduce the number and severity of run-off-the-road crashes. Remove or shield obstacles within the clear zone, including protrusions that extend more than 4 in. (100 mm) above the ground line, where cost effective.

49-3.07(b) Earth Slopes

Other than specifically described in Section 49-3, existing parallel slopes should generally remain. Where existing right-of-way permits significant slope flattening or where grading within existing right-of-way is necessary, the designer should consider flattening earth slopes, particularly at horizontal curves.

Where considerable new right-of-way is required, front slopes should be 1V:4H or flatter and back slopes 1V:3H or flatter, but slopes may vary in relationship to prevailing conditions throughout the project and/or adjacent highway sections. Reconstructed ditch bottoms should be at least 2 ft (600 mm) wide and 3 ft (900 mm) deep.

Transverse slopes within the right-of-way shall be regraded to be not steeper than 1V:4H.

49-3.07(c) Clear Zones

For rural arterials other than at horizontal curves, clear zone widths (measured from the edge of traveled way) should be in accordance with Figure 49-3.D.

It may be warranted to expand the roadway clear zone on the outside of relatively sharp horizontal curves. This addresses the increased potential of motorists running off the roadway at curves. Figure 49-3.E presents the clear zones at horizontal curves.

Regulatory Approach Speed and ADT	Proposed Ditch Cross Section [1]	Clear Zone
50 mph (80 km/h) or greater and ADT > 1000	Traversable	18 ft (5.5 m) or ROW line [2]
	Non-Traversable	18 ft (5.5 m) or Toe of Back Slope [2]
All Others		12 ft (3.6 m) or Non-Traversable Ditch [2]

Notes:

(1) *A traversable ditch cross section is one where the following configuration applies: 1V:4H front slopes, 2 ft (600 mm) wide ditch bottom, and 1V:3H back slopes. If any of these minimum criteria are not satisfied, the ditch cross section is considered non-traversable.*

(2) *Use whichever is less.*

CLEAR ZONES ON TANGENT SECTIONS
(3R Rural Arterial Projects)

Figure 49-3.D

Regulatory Approach Speed mph (km/h)	Comfortable Operating Speed on Curve, Range in mph (km/h)	Proposed Ditch Cross Section[1]	Clear Zone [2]
50 (80)	35-50 (55 – 80)	Traversable	25 ft (7.5 m)[3]
50 (80)	35-50 (55 – 80)	Non-traversable	25 ft (7.5 m) or Toe of Back Slope[4]
55 (90)	35-55 (55 – 90)	Traversable	25 ft (7.5 m)[3]
55 (90)	35-55 (55 – 90)	Non-traversable	25 ft (7.5 m) or Toe of Back Slope[4]

Notes:

(1) *A traversable ditch cross section is one where the following configuration applies: 1V:4H front slopes, 2 ft (600 mm) wide ditch bottom, and 1V:3H back slopes. If any of these minimum criteria are not satisfied, the ditch cross section is considered non-traversable.*

(2) *Clear zone values apply only to the outside of horizontal curves. For regulatory approach speeds less than 50 mph (80 km/h) or for comfortable operating curve speeds greater than those shown in the figure, use the roadway clear zones in Figure 49-3.D.*

(3) *Use ROW line if it is less than 25 ft (7.5 m) from edge of traveled way.*

(4) *Use whichever is less.*

CLEAR ZONES ON OUTSIDE OF HORIZONTAL CURVES
(3R Rural Arterial Projects)

Figure 49-3.E

49-3.07(d) Guardrail

The designer should carefully analyze all existing guardrail installations to determine if the guardrail should be removed or upgraded in accordance with Section 38-6 and the following:

1. Guardrail Removal. Remove guardrail that is not warranted. An existing guardrail installation should be removed when a life-cycle benefit to cost analysis shows this is preferable to updating, and maintaining the guardrail. Benefit to cost analysis may be done using the Roadside Safety Analysis Program (RSAP), provided by AASHTO, or by using the benefit-cost tool developed to support the Highway Safety Improvement Program (HSIP) referenced in Safety Policy 1-06.

2. Guardrail Upgrading. Existing guardrail that is warranted may remain in place if it meets the all of the following:

   a. Guardrail installed using Highway Standard 630001-06 or earlier may remain in place if all of the following are met:

      - Safety analysis does not show a pattern of severe crashes related to the existing guardrail.
      - There is no loss of steel section from rusting of the steel rail, posts, or other structural components.
      - The system does not have structural damage (e.g., buckled/kinked elements, torn elements, holes). These criteria may be evaluated in light of guidelines adopted by the Department for acceptable elements.
      - Weathering steel guardrail may not remain.
      - The system must have 6 in. (150 mm) wood or approved plastic blockouts.
      - Slope from the edge of pavement to the face of rail must be 1:10 or flatter, or may be obtained by regrading if this can be done without violating any other of these requirements.
      - Height to the top of rail must be between 27 ¾ in. (705 mm) and 30 in. (760 mm) measured at the face of rail.
      - May not have any washers (e.g., “Plate Washer F” on some old Highway Standards) under bolt heads holding the rail at posts.
      - All other structural details are as shown on *Highway Standard* 630001-06. Post lengths may be confirmed from the Highway Standard in effect at the time of installation of the existing guardrail.

b. For guardrail installed under *Highway Standard* 630001-07 or later:

- There is no loss of steel section from rusting of the steel rail, posts, or other structural components.
- The system does not have structural damage (e.g., buckled/kinked elements, torn elements, holes). This criterion may be evaluated in light of guidelines adopted by the Department for acceptable elements.
- Weathering steel guardrail may not remain.
- The system must have 12 in. (300 mm) wood or approved plastic blockouts.
- Slope from the edge of pavement to the face of the rail must be 1:10 or flatter.
- Height to the top of the rail must be 28 in. (710 mm) to 32 in. (810 mm) measured at the face of the rail.
- All other functional details as shown on the current *Highway Standard* 630001 are provided. Items such as adjusting holes are not considered functional.

3. <u>End Sections</u>. Ensure all guardrail end sections for existing guardrail meets the approved lists of devices in force in December 2006, or subsequent versions appropriate for later *Highway Standards* for guardrail. Ensure all transitions from guardrail to bridge rails or to structures meet the *Highway Standards* in effect in December 2006, or subsequent versions appropriate for later *Highway Standards* for guardrail.

4. <u>Length of Need</u>. Use the length-of-need criteria in Section 38-6.01 to determine the sufficiency of the existing length of guardrail based on the posted speed. Upgrade existing guardrail that is deficient in length by more than 10 percent to provide a proper length of need. Guardrail less than 10 percent deficient may remain in place unless crash data shows that the additional length will reduce crash severity. Also, provide the proper length of need if placement of a new crashworthy terminal is required. Where practical, the designer should shorten the required length of need by tapering the barrier away from the traveled way. In addition, where an intersecting sideroad, driveway, or field entrance interferes with the placement of the length of need of continuous guardrail at a bridge approach, the relocation of the sideroad, driveway, or field entrance should receive preference over reducing guardrail length.

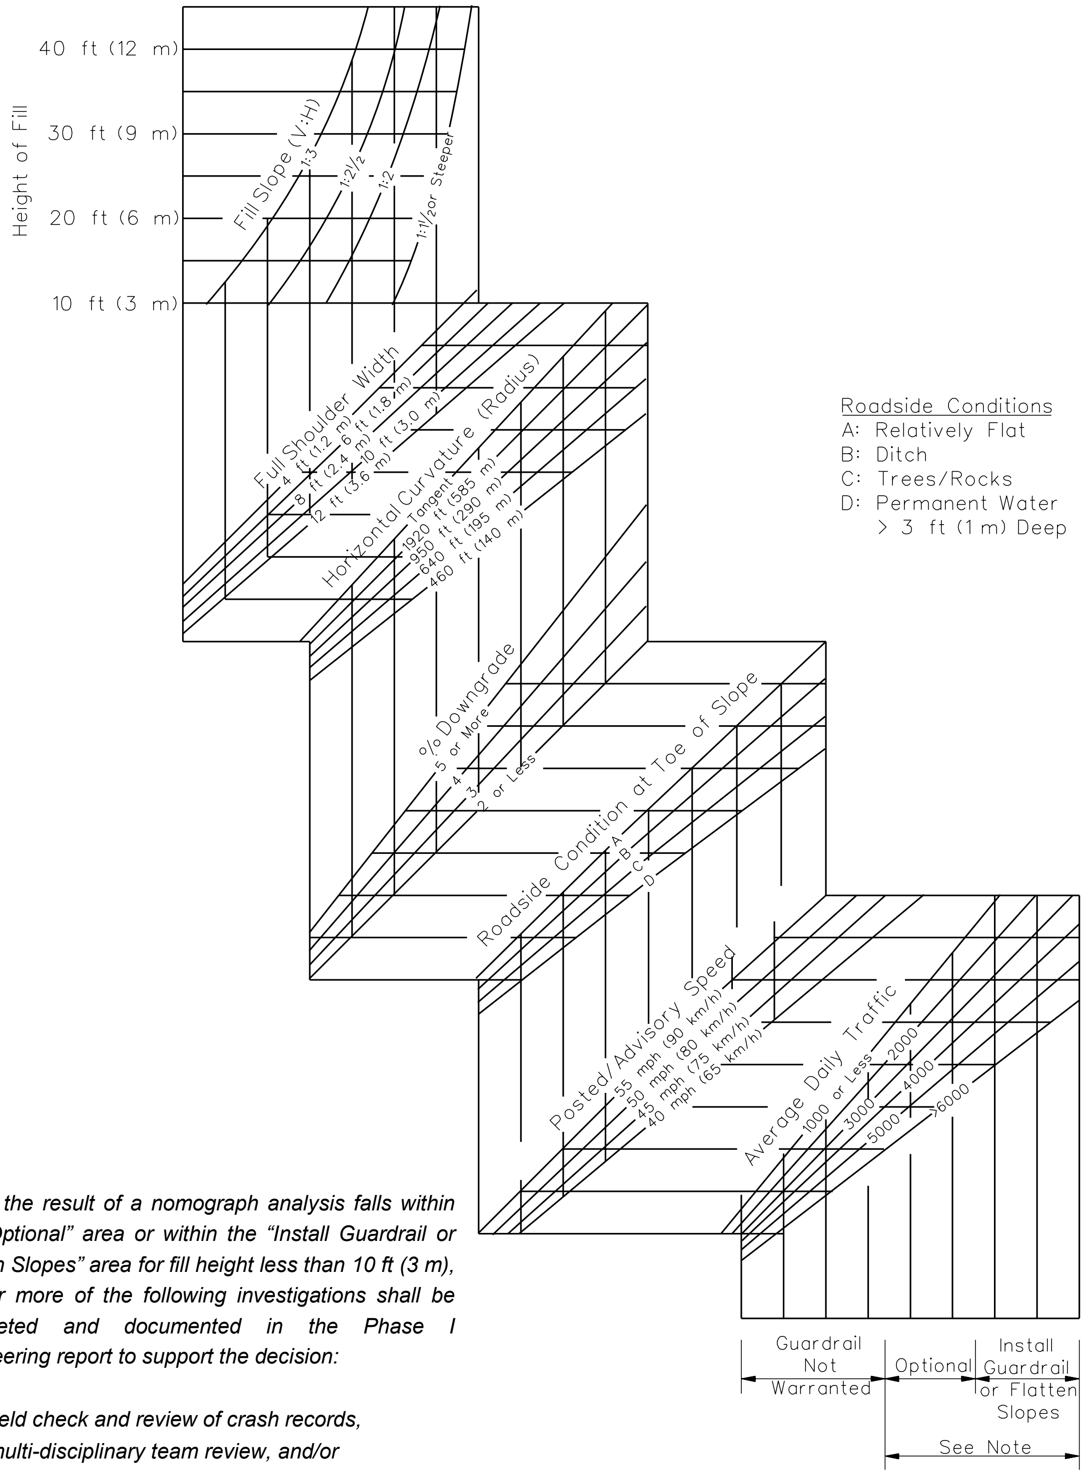
5. New Guardrail Installation. New guardrail should be installed in accordance with Section 38-6 and:

   - at bridge approaches where none exists,
   - at departure ends of two-way bridges,
   - in accordance with the culvert criteria (Section 49-3.07(e)),
   - at locations where the warrants are satisfied in accordance with Figure 49-3.F and the use of the hierarchy of preferences results in a guardrail application.

6. Short-Radius Guardrail. Where practical, roadside safety should be upgraded at locations where short-radius guardrail is present or considered. See Section 38-6.09 for guidance on short-radius guardrail. Short-radius guardrail occurs when the radius is 150 ft (45 m) or less and is usually associated with a side road or entrance.

7. Departure Ends of Two-way Bridges. Due to the extreme hazard posed by the end of a bridge parapet, shielding of the departure end must be provided, even when the bridge parapet end is outside the clear zone for the opposing direction traffic. To determine the required length of need for the departure end, refer to Section 38-6.01.

8. Cable Barrier. Determine the installation of new or disposition of existing cable-guard or cable barrier from special studies. If it appears desirable to use cable barrier for roadside hazards, see Section 38-6.02. Also, contact the Bureau of Safety Programs and Engineering regarding other possible uses on a case-by-case basis.



Note: When the result of a nomograph analysis falls within the "Optional" area or within the "Install Guardrail or Flatten Slopes" area for fill height less than 10 ft (3 m), one or more of the following investigations shall be completed and documented in the Phase I engineering report to support the decision:

- *field check and review of crash records,*
- *multi-disciplinary team review, and/or*
- *cost-effective economic analysis.*

GUARDRAIL WARRANTS FOR 3R PROJECTS
(Arterial Routes)

Figure 49-3.F

49-3.07(e) Culverts

For the Department's practices for the roadside safety treatment of both cross-drainage and parallel drainage structures, see Section 38-4.06(b). For the determination of guardrail warrants for non-traversable culverts on 3R projects, Figure 49-3.G may be used in lieu of analytical calculations found in Chapter 38.

An example of how to transition the re-graded front slope at the culvert to the steeper existing front slopes on both the approach and departure ends of the culvert is shown in Figure 49-3.H.

The designer should reference Section 3-500, "Construction/Reconstruction and Maintenance of Sideroad and Street Intersections with State Highways," of the Bureau of Operations' *Maintenance Policy Manual* for additional guidance.

49-3.07(f) Sign and Light Supports

Posts or poles used to support signs or lights to remain within the clear zone should be breakaway. Wood sign supports may be modified to properly reduce the cross sectional area or replaced with breakaway supports.

49-3.07(g) Trees

Trees maturing to a diameter greater than 4 in. (100 mm), unless shielded by a protective device required for other purposes, shall be removed within the clear zone. Trees on back slopes that are not likely to be impacted by vehicles may generally remain in place. In cases where unusual specimens are in jeopardy, guardrail or attenuator protection may be considered as an alternative to removal; see Chapter 59.

49-3.07(h) Concrete Signal Bases

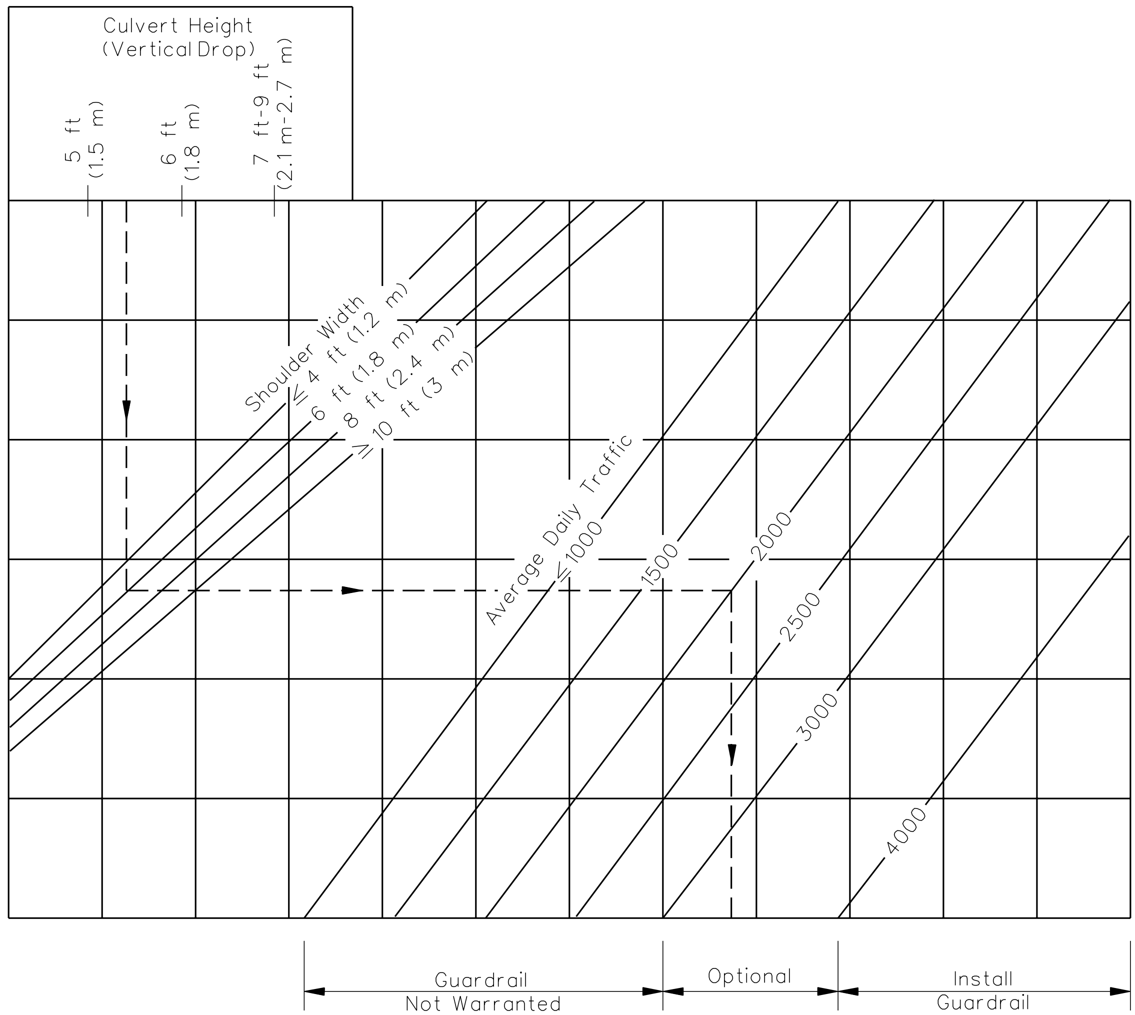
Concrete signal bases (Type B) within the clear zone and extending higher than 4 in. (100 mm) above the ground line shall be removed, and standard supports with frangible bases installed where appropriate. Note: Mast arm signal supports cannot have frangible bases.

49-3.07(i) Curbs

Curbs higher than 4 in. (100 mm) within the shoulder area should be removed where posted speeds are greater than 45 mph. The proper placement of traffic control devices shall be reviewed before considering the removal of corner island curbs where such devices are located. Curb removal is not intended to include intermittent center channelizing islands separating two-lane, two-way traffic and supplemented by illumination. Reflectorizing devices should be placed on curbs in accordance with the Bureau of Operations practices to improve delineation.

49-3.07(j) Traffic Control Devices

All traffic control devices shall conform to the *Illinois Manual on Uniform Traffic Control Devices*.



Notes:

1. *This nomograph supplements, but does not supersede Figure 49-3.F.*

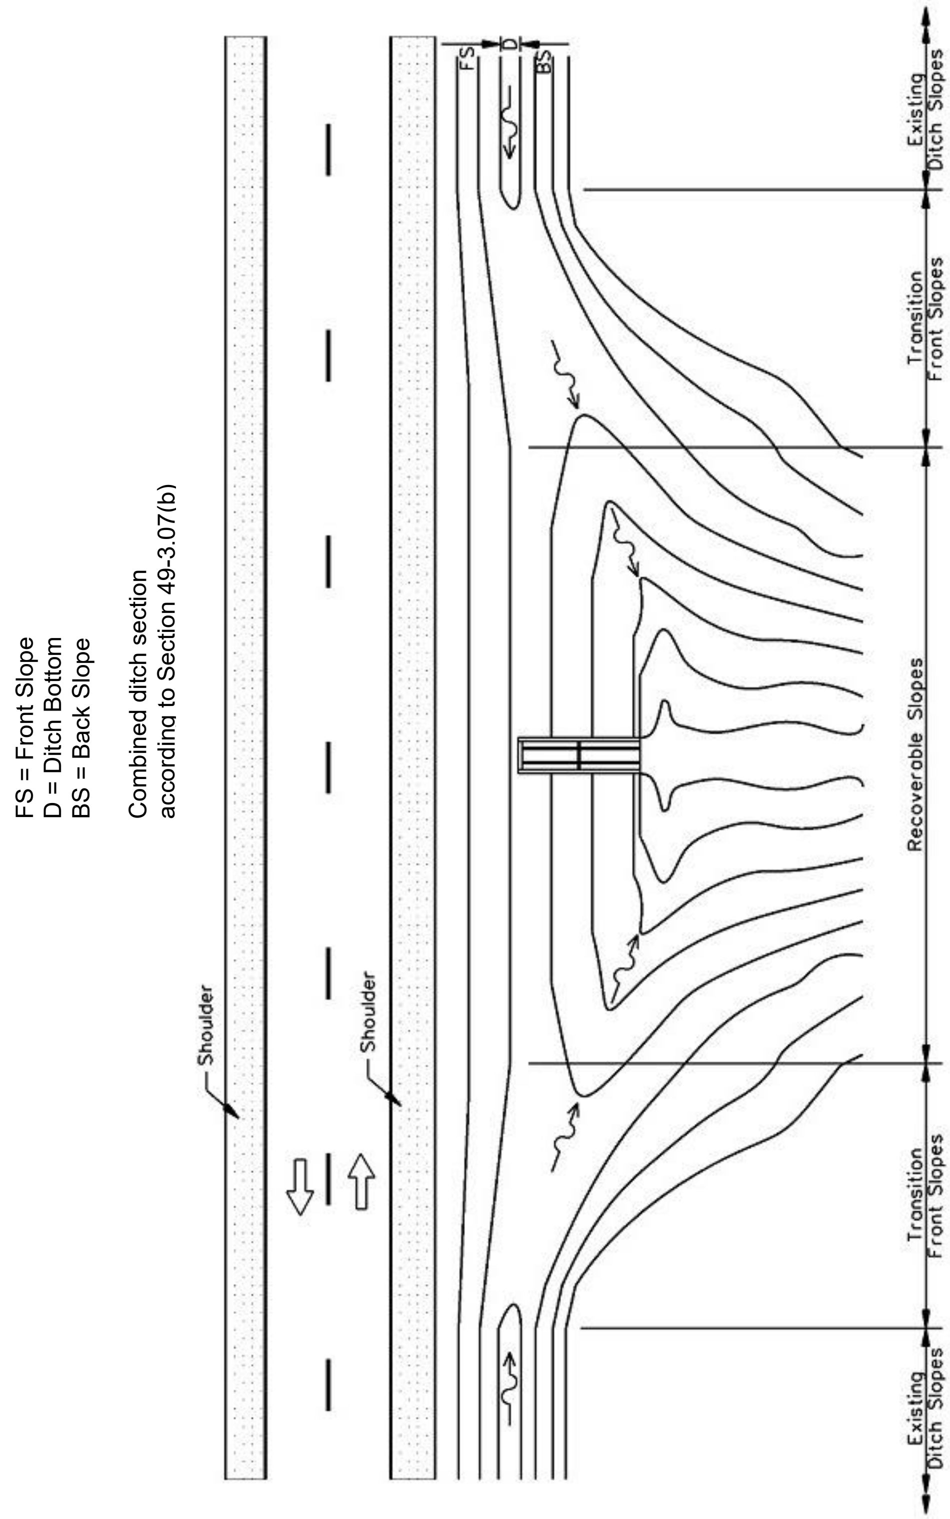
2. *Culvert height includes the earth cover immediately above the culvert if it increases the "drop-off." Where the culvert height is 10 ft (3.0 m) or greater, guardrail is warranted. Follow the hierarchy of preferences in Section 38-4.06(b) for cross road culverts.*

3. *When the result of a nomograph analysis falls within the "optional" area, one or more of the following investigations shall be completed and documented in the Phase I engineering report to support the decision:*

   - *field check and review of alignment and crash records*,
   - *multi-disciplinary team review, and/or*
   - *cost-effective economic analysis.*

3R GUARDRAIL WARRANTS FOR NON-TRAVERSABLE CULVERTS

Figure 49-3.G



REGRADING PLAN FOR EXTENDED CULVERTS
(3R Rural Arterial Projects)
Figure 49-3.H

49-3.07(k) Mailbox Turnouts

The design and construction of mailbox turnouts should be in accordance with the criteria in Chapter 58 and the *Highway Standards*. Where appropriate, the designer should discuss the mailbox supports considered hazardous and within the clear zones with the property owners:

- to inform the owner of the potential severity of the support, such as the results of pertinent research and tests as reported in the TRB Paper "The Rural Mailbox – A Little Known Hazard";
- to inform the owner of the possibility of personal liability; and
- to request the owner to change the support to reduce the potential seriousness of the hazard. Changed supports will be consistent with the designs contained in *AASHTO Roadside Design Guide.*

49-3.07(l) Lighting and Landscaping

Installation of lighting to improve operations and/or safety should be considered in accordance with the guides in Chapter 56. Generally, landscaping should be directed toward replacing appropriate existing plants and turf removed or damaged by construction and, where practical, planting for safety or erosion control purposes. See Chapter 59.

49-3.07(m) Above-Ground Utilities

Where practical, above ground utility facilities should not be allowed to remain inside the clear zone, except where protected by devices required for other purposes. Existing utility facilities may generally remain:

- where located beyond non-traversable ditch cross sections, or
- where right-of-way is so narrow that the maximum adjustment possible within the existing right-of-way is minimal and considered impractical.

Where regrading of the back slopes is necessary for a significant length within the area of utility facilities, the utilities should be relocated according to the Bureau of Operations' publication *Accommodation of Utilities on Right-of-Way of the Illinois State Highway System*. See Section 6-1.02 for other publications.

49-3.07(n) Airports

Near airports, the erection of any signs, trusses, light supports, structures, etc., 15 ft (4.5 m) or higher than the roadway, shall be coordinated with Aeronautics. Such obstructions and under what conditions they may apply to clear zone heights are described in Chapter 11.

49-3.07(o) Other

There may be other non-Department-owned objects within the desired clear zone that may be roadside obstacles. Accordingly, they should also be evaluated.

49-3.08 Railroad Crossings and Signals

Railroad crossings and signals should be upgraded prior to or concurrent with 3R projects. When work on existing railroad crossings, new crossings, protection devices, structures, etc., requires coordination of planning with railroad companies and/or the Illinois Commerce Commission, the results of these activities should be included in the Phase I engineering report. Also, coordinate, as necessary, with the IDOT Bureau of Rail in the Office of Intermodal Project Implementation to ascertain the status of affecting railroad improvements or abandonments; see Chapter 7.

Where the existing railroad crossing surface is in good condition and will remain, the roadway overlay shall be tapered to match the existing crossing profile. If required by current practices, the crossing surface outside the traveled way should consist of bituminous or other approved material.

Locate the crossing warning signal devices in accordance with current safety requirements and upgrade if not in conformance with State guidelines as discussed in Chapter 7 and in the IDOT publication *Requirements for Railroad/Highway Grade Crossing Protection*. Any other associated work performed must also meet State guidelines.

If, as an exceptional case, there will be a significant lapse of time in the relocation of railroad warning signal devices, the widened pavement should be constructed up to the crossing. Offsets to the existing warning signal devices should temporarily consist of tapered edge lines and diagonal pavement markings. If the location of the existing warning signal devices precludes this treatment, taper the widened pavement to the existing pavement width at or near the signal location.

Plans showing required changes in railroad facilities should be prepared in time to enable agreement negotiations to be concluded so that railroad work may proceed concurrently with that of the highway contract. The appropriate offices, on a project-by-project basis, shall approve variances to this procedure. See Chapter 7.

49-3.09 Bridges

49-3.09(a) Bridge Condition Reports/Structure Sketches

A Bridge Condition Report (BCR) and a Proposed Structure Sketch are required for every structure within a roadway section covered by a Phase I engineering report or when a bridge itself is the reason for preparing a Phase I engineering report. In advance of submitting the BCR and Proposed Structure Sketch to the Bureau of Bridges and Structures (BB&S) for review and concurrence, a typical section that shows the proposed clear roadway bridge width is approved by BDE. Before design approval can be granted, all BCRs shall be approved by the BB&S and concurrence also must be received on all Proposed Structure Sketches.

A Bridge Condition Report also is required for a bridge proposed to remain in place. This will ensure that the bridge meets the minimum requirements for width, safety, and structural capacity. However, the Illinois Structure Information System-Master Report (R107) may be substituted for a Bridge Condition Report.

See Section 39-3.02 for more information on Bridge Condition Reports.

49-3.09(b) Scope of Work

Bridges on existing two-lane rural arterials will be rehabilitated to correct operational, structural, and/or significant safety deficiencies.

Bridges meeting the criteria in Section 49-3.09(c) will remain in place. Improvement of deficient bridge rails and curb sections and deck repair and resurfacing, when appropriate, should be performed concurrently with a 3R highway project.

Bridges not meeting the criteria for bridges to remain in place will be improved. They shall meet the criteria for improved bridges as discussed in Section 49-3.09(d). Bridges with clear roadway bridge widths less than the improved pavement widths for the appropriate volumes (see Section 49-3.03) should be improved concurrently with a 3R highway project or deferred for a period of no more than one year from the completion of the highway project.

The improvement of bridges with clear roadway bridge widths equal to or greater than the specified traveled way width, but less than those required to remain in place, and bridges with insufficient structural capacity may be deferred; however, they should be included in the Multi-Year Improvement Program (MYP). Bridges included in the MYP and classified as narrow (i.e., those having clear widths less than 2 ft (600 mm) wider than the required lane width) should be protected and delineated in accordance with Figure 49-3.I and the Bureau of Operations “Policy on Delineation of Narrow Bridges.”

Improvement of deficient rails and/or curb sections, as described in Section 49-3.09(c) for an interim period, should be completed concurrently with a 3R highway project.

49-3.09(c) Criteria for Bridges to Remain in Place

Bridges on existing two-lane rural arterials will remain in place according to the following guidelines:

The clear roadway bridge width is equal to or greater than the values in Column I of Figure 49-3.J. The clear roadway bridge width will be measured between the faces of rails or curbs when curb removal is not practical.

The main supporting elements of the bridge including the bridge deck are structurally sound and capable of carrying an HS-20 (MS-18) structural design loading without exceeding 65% of the strength of any member.

Structurally sound bridge decks with poor riding quality that could jeopardize the safety of the motorist or cause undue discomfort should be repaired and resurfaced; however, resurfacing may not be extended across decks without appropriate repair and waterproofing or when the bridge cannot safely carry the additional dead load resulting from the resurfacing.

49-3.09(d) Criteria for Improved Bridges

Minimum clear roadway bridge widths for improved bridges are provided in Figure 49-3.J. These widths will be applicable on all bridge rehabilitation projects:

- that utilize structurally sound elements of the existing bridge,
- that involve total replacement of all elements of the existing bridge, and/or
- that involve replacement bridges on short relocations.

When the Bridge Condition Report indicates deck replacement is necessary, the structure shall be widened to the extent possible without requiring substructure additions. Necessary repairs to or replacement of superstructure elements will be permitted. However, the minimum widths shown in Column I of Figure 49-3.J shall not be violated.

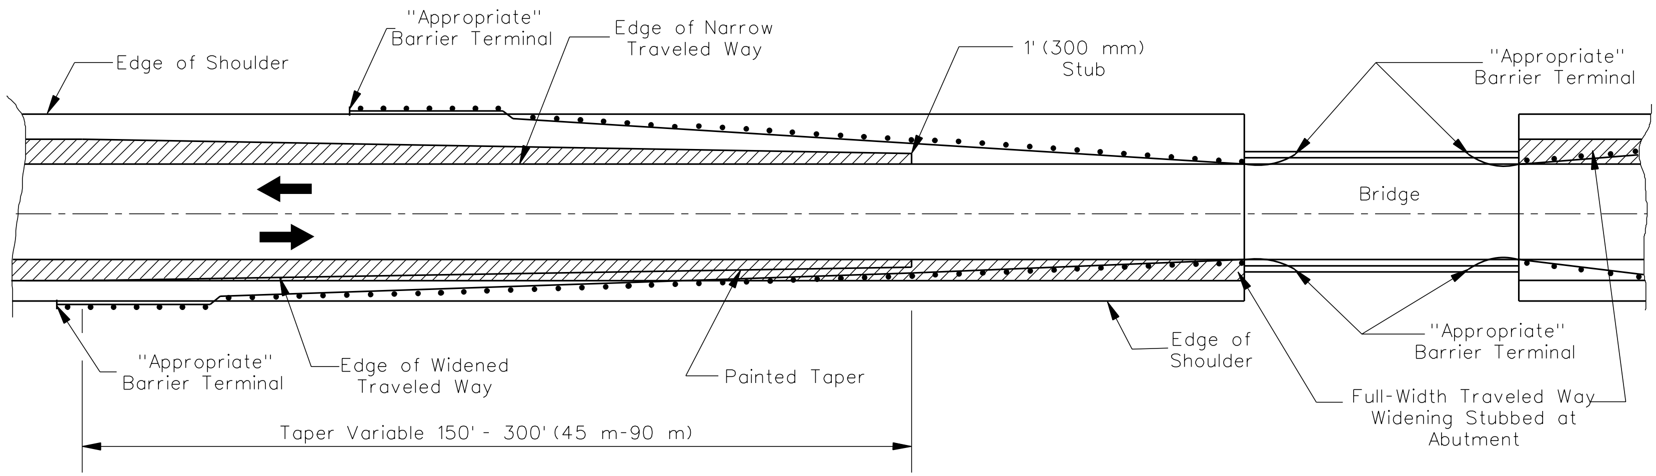
Bridge roadway widths resulting from the optimum use of prefabricated modular deck units may exceed those widths designated in Column II. The minimum clear roadway bridge width on marked routes will be 32 ft (9.6 m). Structural design loading for improved bridges shall be HS-20 (MS-18).

The hydraulics of proposed bridge improvements shall be analyzed to determine the capacity to accommodate floods for the frequencies shown in Column III of Figure 49-3.J. Bridges also shall be evaluated for a base 100-year flood.

Where the existing vertical alignment is maintained and there is no history of serious hydraulic deficiencies, the existing bridge waterway opening for the improved bridge may be retained. However, the designer must evaluate backwater effects of vertical realignments or minor reductions in openings.

49-3.09(e) Vertical Clearance

The minimum vertical clearance for bridges to remain in place is 14 ft (4.3 m). Economics may dictate exceptions.



Notes:

1. *Guardrail requirement will be as determined from the length of need criteria in Section 38-6.*

2. *The "Appropriate" Barrier Terminal should be selected using the guidelines set forth in Section 38-6.*

3. *If the use of the "Appropriate" Barrier Terminal results in a roadway clear width less than that given in Section 49-3.03, a Traffic Barrier Terminal, Type 10 and 25 ft (7.6 m) of Type B guardrail may be substituted for the above terminal.*

4. *Guardrail will be installed on a 1:25 taper from the bridge end rail to the shoulder edge, then parallel to the shoulder until the length of need is fulfilled.*

5. *Signing, object markers, and delineation will be as specified by the Bureau of Operations.*

6. *See Chapter 38 and the Highway Standards for more information.*

WIDENING AT NARROW BRIDGES

Figure 49-3.I

Current ADT	Column I Minimum Width of Bridges to Remain in Place	Column II Width of Improved Bridges (2)	Column III Design Flood Frequency
Greater than 5000	Improved Traveled Way Width (1) Plus 6 ft (1.8 m)	40 ft (12.0 m)(3)	50 yr.
5000 to 3000	Improved Traveled Way Width (1) Plus 6 ft (1.8 m)	36 ft (10.8 m)(4)	50 yr.
2999 to 1000	Improved Traveled Way Width (1) Plus 4 ft (1.2 m)	32 ft (9.6 m)	50 yr.
Less than 1000	Improved Traveled Way Width (1) Plus 2 ft (600 mm)	32 ft (9.6 m)	50 yr.

Notes:

(1) *The improved traveled way widths refer to the striped widths in Figure 49-3.A.*

(2) *These clear roadway widths will be considered the minimum widths for safety and the maximum widths for cost effectiveness. For minor arterials, an existing 32 ft (9.6 m) may remain.*

(3) *When the striped widths plus stabilized shoulders are less than 38 ft (11.5 m), a clear roadway bridge width of 36 ft (10.8 m) may be provided. A stabilized shoulder is defined as a paved shoulder and/or an aggregate shoulder at least 6 in. (150 mm) thick.*

(4) *Clear roadway bridge widths less than 36 ft (10.8 m) may be approved, on an exception basis, when all of the following conditions exist*:

- *The width of the existing or improved striped width plus stabilized shoulders, located between logical termini, will not be equal to or greater than 36 ft (10.8 m)*.
- *Projected traffic growth is minimal*.
- *The proposed clear roadway bridge width will be consistent with the width of other bridges to remain in place along the roadway section. In addition, no upgrading of the roadway is contemplated within the foreseeable future.*
- *Existing and projected truck traffic is moderate (10% or less of ADT).*

(5) *If an exception to a bridge width is warranted, the Phase I engineering report shall document the basis (minutes from a coordination meeting) for proposing and selecting the lesser width. However, for bridges located on the arterial system, the minimum clear roadway bridge width for improved bridges shall be no less than 32 ft (9.6 m).*

3R RURAL PRINCIPAL ARTERIAL BRIDGE CROSS SECTION ELEMENTS(5)

Figure 49-3.J

49-4 URBAN ARTERIAL HIGHWAYS AND STREETS

49-4.01 Application

Section 49-4 is applicable to resurfacing, rehabilitation, and restoration (3R) projects on the State highway system that are:

- urban arterials,
- marked urban highways or streets functionally classified as collectors, or
- expressways (project-by-project basis).

49-4.02 Scope of Work

A 3R project on an urban arterial highway or street may include work such as lane widening, the addition of auxiliary lanes, channelization, median installation, revision of median type, median widening, resurfacing in conjunction with appropriate widening, new or replaced curb and/or gutter, curb ramps to meet the accessibility criteria, pavement markings, landscaping, lighting, and any associated utility adjustments. Except for relatively short sections, 3R work does not include the addition of continuous through lanes that change the basic number of lanes throughout the project.

Other than widening the traveled way, much of this work may also be included in resurfacing only projects. Widening and resurfacing or resurfacing only, in general, should also include any associated improvements necessary to ensure adequate structural support for the new pavement. Widening and resurfacing and resurfacing of parking lanes, replacement of curbs and gutters, sidewalk construction/ replacement, curb ramps to meet accessibility criteria, and other work performed on municipally maintained facilities will be subject to State policy on joint participation improvements as discussed in Chapter 5.

Where considerable amounts of right-of-way will be acquired along a significant length of the project to accommodate widening and resurfacing, most geometric design criteria should be in accordance with the reconstruction requirements of the applicable chapters in this *Manual* (e.g., Chapter 48). Some highway elements may be designed to criteria consistent with restricted site conditions and 3R objectives.

49-4.03 Design Speed

Design speeds for 3R projects on urban and suburban arterials may be the regulatory speed limit when appropriate. A regulatory speed of 45 mph is the maximum design speed where (1) a two-way left-turn (TWLT) lane is allowed in the street/highway design, and (2) continuous curbing is used along either edge of the traveled way.

49-4.04 Roadway Cross Section Elements

For uncurbed urban and suburban arterial facilities, the criteria in Section 49-3.03 for rural facilities will apply. Typical practice is to resurface existing curbed pavements with through lanes of 10 ft (3.0 m) or wider (e-e) or turning lanes (e-f), TWLT lanes (e-e), and 8 ft (2.4 m) (e-f) or wider parking lanes without widening except on Designated Truck Routes (DTR). On DTR routes, prepare special studies to support retaining through lanes less than 11 ft (3.3 m) (e-e) wide.

Where widening will be accommodated within the existing right-of-way or where right-of-way acquisition is minimal, the cross section elements may be consistent with site conditions. Under these conditions, through and TWLT lanes may be striped as 11 ft (3.3 m) and other auxiliary lanes may be 10 ft (3.0 m) wide. Parking lanes may be 8 ft (2.4 m) wide.

49-4.05 Capacity

Design capacities, at a minimum, should be adequate for current traffic at a level of service D.

49-4.06 Diagonal Parking

Parking (existing or proposed) should generally be parallel and adjacent to the curb. Diagonal parking may be permitted to remain if a brief engineering analysis of the existing angle parking is included in the Phase I engineering report and the analysis clearly demonstrates that there will be no adverse effect on street capacity and safety. The analysis must describe parking characteristics, crash history, and an observation of street operations and potential problems. See Chapter 48 for more information.

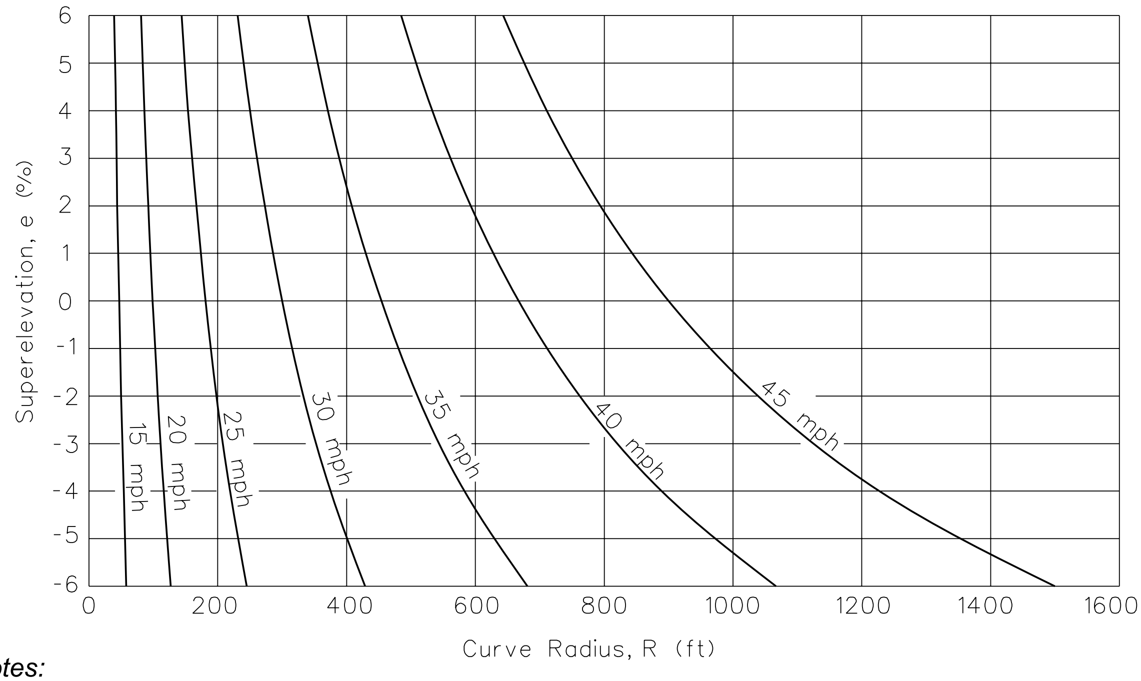
49-4.07 Horizontal Alignment

49-4.07(a) V = 50 mph (80 km/h)

Where the design speed equals 50 mph (80 km/h), the horizontal alignment criteria in Section 49-3.04 for rural arterials will apply to urban arterial 3R projects.

49-4.07(b) V ≤ 45 mph (70 km/h)

For low-speed (V ≤ 45 mph (70 km/h)) urban streets, the designer will use Figure 49-4.A to determine the acceptability of existing horizontal curves. Where a horizontal curve will be improved (i.e., flatten the radius and/or increase the superelevation), the designer will also use Figure 49-4.A for the reconstructed horizontal curve.



Notes:

1. *The figure provides a range of operating speeds and superelevation rates that are used to determine an acceptable curve radii.*

2. *AASHTO Method 2 is used to distribute superelevation and side friction for low-speed urban streets. Therefore, the basic point-mass equation applies:*

$$R = \frac{V^2}{15\,(e/100 + f_{max})}$$

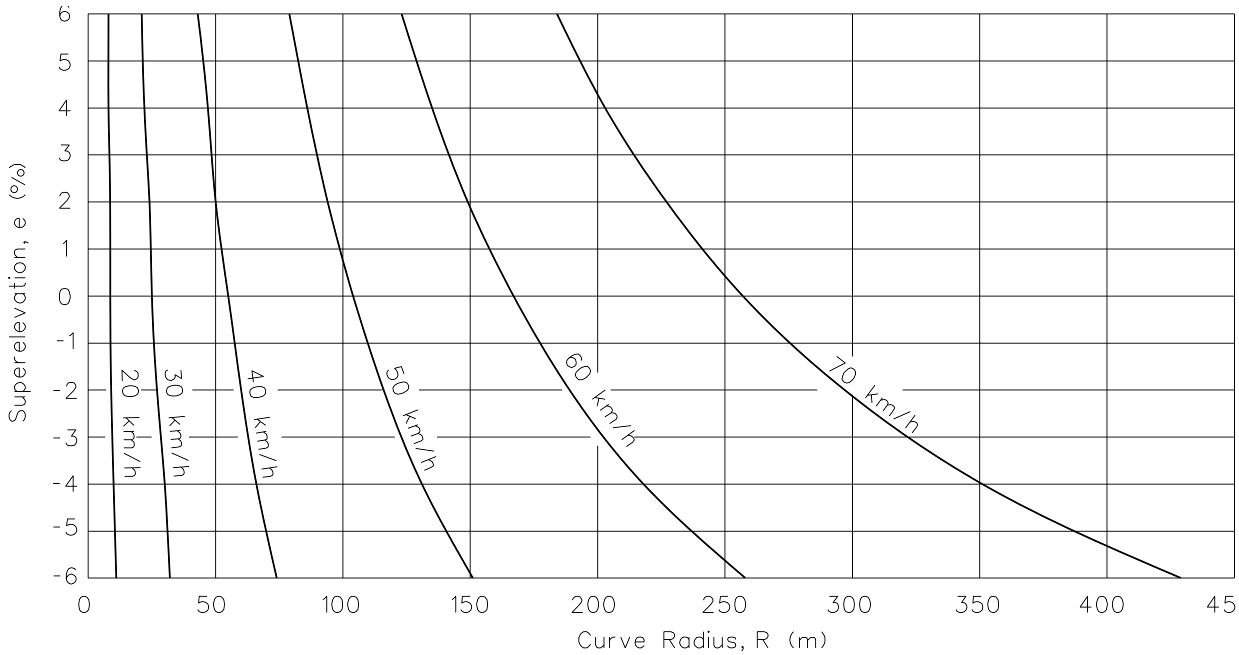
Where: R = *curve radius, ft*
V = *speed, mph*
e = *actual superelevation rate, percent*
f_{max} = *assumed maximum side-friction factor (see Figure 48 5.B) for selected speed, decimal*

3. *For curves that fall between the -2% and +2% lines, remove the adverse crown slope through the curve. This will ensure that the maximum comfortable side-friction factor is not exceeded due to a negative slope in one direction of travel. It will also minimize potential rollover of trucks (on dry pavement) with low rollover thresholds and minimize possible skidding of trucks with smooth tires on polished, wet pavement surfaces.*

4. *The maximum superelevation rate for new construction is 4%. For reconstruction and 3R, a maximum rate of 6% may be considered to remain in place.*

HORIZONTAL CURVES TO REMAIN IN PLACE
(Low-Speed Urban Streets)
(US Customary)

Figure 49-4.A



Notes:

1. *The figure provides a range of curves in feet (meters) operating speeds and superelevation rates that are used to determine a comfortable operating speed acceptable curve radii.*

2. *AASHTO Method 2 is used to distribute superelevation and side friction for low-speed urban streets. Therefore, the basic point-mass equation applies:*

$$R = \frac{V^2}{127\ (e / 100\ + f_{max}\ )}$$

Where: R = *curve radius, ft*
V = *speed, mph*
e = *actual superelevation rate, percent*
f_{max} = *assumed maximum side-friction factor (see Figure 48 5.B) for selected speed, decimal*

3. *For curves that fall between the -2% and +2% lines, remove the adverse crown slope through the curve. This will ensure that the maximum comfortable side-friction factor is not exceeded due to a negative slope in one direction of travel. It will also minimize potential rollover of trucks (on dry pavement) with low rollover thresholds and minimize possible skidding of trucks with smooth tires on polished, wet pavement surfaces.*

4. *The maximum superelevation rate for new construction is 4%. For reconstruction and 3R, a maximum rate of 6% may be considered to remain in place.*

HORIZONTAL CURVES TO REMAIN IN PLACE
(Low-Speed Urban Streets)
(Metric)

Figure 49-4.A

The basic objective for improving conditions on the existing horizontal alignment of low-speed urban streets (V $\leq$ 45 mph (70 km/h)) is to retain the existing alignment and to check for comfortable operating speeds by using Figure 49-4.A. This figure assumes the use of AASHTO Method 2 for the distribution of side-friction and superelevation to determine the appropriate superelevation rates in conjunction with existing radii and posted speeds. See Section 48-5 for more information.

49-4.08 Vertical Alignment

The vertical alignment criteria in Section 49-3.05 for rural arterials will apply to urban arterial 3R projects.

49-4.09 Intersections

The intersection criteria in Section 49-3.06 for rural arterials generally will apply to urban arterial 3R projects. In addition, the following will apply.

49-4.09(a) Turning Radii

In urbanized areas, right-turn maneuvers at intersections are critical for two reasons. One is the speed at which the design vehicle can make a right turn from the main road onto a side street; the second is how much encroachment, assuming the selected design vehicle, will occur into opposing lanes when the design vehicle makes a right turn onto the main road. For right turns at urban intersections, the following guidelines should be considered for 3R projects:

1. Simple radii of 15 ft to 25 ft (4.5 m to 7.5 m) are adequate for a passenger car design vehicle. These radii may be retained on existing side streets where:
   - very few trucks are expected to turn into the side street,
   - encroachment by a single unit or tractor/semitrailer unit into opposing lanes of the main road is acceptable, or
   - a parking lane is present and parking is restricted a sufficient distance from the intersection thereby providing a larger area for a right-turn maneuver.
2. Where practical, use a simple radius of 30 ft (9 m) or a two-centered curve at all major intersections and at all minor intersections with some frequency of truck turning volumes. This design will provide for the single-unit vehicle and the occasional tractor/semitrailer unit.
3. At intersections where tractor/semitrailer combinations and buses turn frequently, provide a simple radius of 40 ft (12 m) or more or a two-centered curve.

49-4.09(b) Curb Cuts/Ramps

Curb cuts/ramps shall meet the accessibility criteria in Chapter 58.

49-4.09(c) Intersection Sight Distance (ISD)

At urban, public road intersections with a two-way stop condition or at signalized intersections where right-turn-on-red is allowed, provide ISD along the arterial for the regulatory or posted speed. Use a distance of 14.4 ft (4.4 m) from the edge of the traveled way to the eye of the stopped motorist. See Chapter 36 for details on ISD.

49-4.10 Roadside Treatment and Highway Appurtenances

Clear zones along urban arterials are as follows:

1. Where the arterial is curbed, no obstacles should be located closer than 1.5 ft (500 mm) from the face of curb. This distance is not considered a clear zone, but an operational offset. Make every effort to provide the clear zones of a rural cross section. Where parallel parking lanes are included, a 1 ft (300 mm) clearance to the face of curb may be considered.

2. Where the arterial has a rural cross section, minimum clear zone widths should be:

   - 18 ft (5.5 m) or the non-traversable ditch if less, where the regulatory speed is equal to 50 mph (80 km/h);

   - 10 ft (3 m) where the regulatory speed is 45 mph (75 km/h); or

   - the shoulder width where the regulatory speed is 40 mph (65 km/h) or less.

3. For the treatment of roadsides and highway appurtenances other than described above, as appropriate for the cross section, refer to Section 49-3.07.

   - Where pedestrian traffic is significant, breakaway sign and light supports should not be used.

   - Where the removal of trees may adversely affect the roadside environment, these trees should be removed only when necessary for reasons of safety.

49-4.11 Railroad Crossings and Signals

The criteria in Section 49-3.08 for rural arterials will apply to urban arterial 3R projects.

49-4.12 Bridges

49-4.12(a) Bridge Condition Reports/Structure Sketches

The information in Section 49-3.09(a) for rural arterials will apply to urban arterial 3R projects.

49-4.12(b) Criteria for Bridges to Remain in Place

Urban bridges may remain in place:

- where they meet the structural requirements for rural bridges (see Section 49-3.09(c)) including those requirements for decks and bridge rails;
- where the clear roadway bridge width is sufficient to accommodate the number of approach lanes; and
- where the clear roadway bridge width includes traffic lanes 10 ft (3 m) or wider.

For urban bridges, bridge deck repairs similar to those cited for rural bridges may be undertaken. However, bituminous resurfacing carried across bridge decks is restricted as with rural bridges.

49-4.12(c) Criteria for Improved Bridges

Urban bridges that do not meet the criteria to remain in place should be improved. Such improvements shall include the following:

- The bridge shall meet the structural requirements of improved rural bridges (refer to Section 49-3.09(d)).
- The bridge shall accommodate the number of lanes and the median on the approach roadways.
- The bridge shall provide lane widths equal to those on the roadway approaches but not less than 11 ft (3.3 m).

Parking lanes on the approach roadways usually are not carried across urban bridges.

49-4.12(d) Vertical Clearance

The minimum vertical clearance for bridges to remain in place is 14 ft (4.3 m). Economics may dictate exceptions.

49-5 HIGH-SPEED, MULTILANE HIGHWAYS (WITHOUT ACCESS CONTROL)

49-5.01 General

High-speed, multilane highways are those facilities where the regulatory speed is 50 mph (80 km/h) or higher. In general, for 3R projects, the design will be determined on a project-by-project basis. Section 49-5 provides some guidance on the design of these projects.

49-5.02 Shoulders

If bituminous shoulders do not exist, the designer should include a minimum 1 ft (300 mm) bituminous strip adjacent to each edge of the traveled way. For ADT's over 10,000, the designer should consider the use of 3 ft (900 mm) bituminous right shoulders for each roadway.

49-5.03 Medians/Posted Speed

During the preparation of the Phase I engineering report for 3R work on high-speed, multilane highways, the designer should evaluate the design of the existing median relative to the existing and proposed posted speeds. Although it is necessary to provide an unencumbered median of appropriate width on new and reconstructed high-speed, multilane highways, this is not unconditionally required for 3R projects. On these projects, the need for a median, a median barrier, and/or appropriate median width is primarily based on cost and safety-effectiveness.

To determine whether adjustments should be made to the median design and/or posted speed, the following factors should be examined:

1. ADT. Lower ADT's provide lower exposure to and probability of crashes and operational problems. ADT's less than 10,000 are considered low because this is near the threshold of a four-lane warrant.

2. Safety Analysis. Conduct a project safety analysis as described in Section 11-2.02(f) for each 3R project.

3. Speed. Because these high-speed facilities are posted either at 50 mph or 55 mph, it generally is not effective to simply reduce the posted speed by 5 mph or 10 mph, respectively. However, if other factors strongly suggest a posted speed of 45 mph or less, the facility would then be rehabilitated using 3R criteria for rural arterials (Section 49-3) or 3R criteria for urban arterials (Section 49-4).

4. Intersections. Frequent and closely spaced intersections suggest a potential for crashes involving left-turning vehicles. This may be especially true where no median exists or where a narrow median exists that does not allow the development of separate left-turning lanes. At intersections that exhibit a significant number of crashes due to the absence of left-turn lanes, consider designing channelization at those intersections. Also, investigate the need to add right-turn lanes.

5. <u>Other Factors</u>. Multilane highways should be closely examined for design and operational continuity. Evaluate the influences of speed and cross section due to adjacent sections, length of project, alignment, and current and future potential for abutting land development.

49-6 UNMARKED ROUTES ON THE STATE HIGHWAY SYSTEM

49-6.01 General

The following general information applies to unmarked rural collector and local highways on the State highway system:

1. Application. Section 49-6 is applicable to resurfacing, rehabilitation, and restoration (3R) projects that meet all of the following:

    - the facility is eligible for Federal funding,
    - the facility is an unmarked route, and
    - the facility is on the State highway system.

    In addition, proposed improvements to unmarked routes are usually initiated only after an agreement is reached with a local agency for a jurisdictional transfer of the route. See Section 43-4.

    If the purpose and scope of the project is intended to replace or expand the facility, then Section 49-6 is not appropriate, and reconstruction criteria will apply.

2. Exceptions. Where these criteria will result in improvements that are inconsistent with adjacent sections or are not cost and safety-effective, the actual treatment implemented will be on the basis of a special study and evaluation.

3. Local System. Where the route is also on the local system and it is unclear which policies should be used, the district should coordinate the proposed improvements with the Central Office and, subsequently, with either the county or municipality.

4. Jurisdictional Transfers. On unmarked routes, the districts should negotiate jurisdictional transfers preferably before improvement projects are included in the program. However, when improvements are proposed, any additional work that exceeds the 3R criteria, primarily undertaken to minimize future maintenance costs and ease the jurisdictional transfer, should be carefully evaluated for long-range cost effectiveness.

5. Ditches. Drainage improvements or restoration by ditch cleaning should be performed as necessary to extend the service life of the pavement and to minimize inundation of the pavement and adjacent properties. Suitable portions of the excavated material may be used for embankment and shoulders.

6. Safety Analysis. Conduct a project safety analysis as described in Section 11-2.02(f) for each 3R project. This analysis will guide selection of cost-effective countermeasures for medians and other project locations.

49-6.02 Design Speed

The typical design speed for rural projects on unmarked routes on the State highway system is 55 mph (90 km/h) or the regulatory speed whichever is less. Design speeds for urban and suburban areas may be the regulatory or posted speed limit. A posted speed of 45 mph is the maximum speed where: 1) a TWLT lane is used in the street/highway design, and 2) continuous curbing is used to delineate the edges of the traveled way.

49-6.03 Roadway Cross Section Elements

Figure 49-6.A presents criteria for roadway cross sections for 3R projects on rural unmarked routes on the State highway system.

49-6.04 Horizontal Alignment

49-6.04(a) Radius of Curvature/Superelevation

An existing horizontal curve may remain in place if its comfortable operating speed is not more than 15 mph (25 km/h) less than the regulatory speed for the highway but not less than 30 mph (50 km/h). Appropriate advisory speed signs will be used on horizontal curves where the comfortable operating speed is more than 5 mph (10 km/h) less than the regulatory speed.

Superelevation rates for horizontal curves on rural facilities to remain in place shall be commensurate with the comfortable operating speed of the curve using a maximum rate of 8%. See Figure 49-3.B for guidance on curves to remain in place.

49-6.04(b) Traveled Way/Shoulder "Rollover"

Through horizontal curves, the maximum rollover (algebraic difference between slopes) at the traveled way/shoulder intersection should not be greater than 10% where the proposed (or remaining) shoulder width is 6 ft (1.8 m) or wider. Where the shoulder width is 4 ft (1.2 m) or less, the maximum rollover may be 12%. Where 1 ft (300 mm) paved shoulders are used, the rollover should occur at the edge of the paved shoulder rather than at the traveled way edge for ease of construction.

	Current ADT			
	Under 400	**400-999**	**1000-3000**	**Over 3000**
Width of Traveled Way[(1)]	18 ft (5.4 m)	22 ft (6.6 m)	22 ft (6.6 m)	24 ft (7.2 m)
Width of Shoulder[(2)]	2 ft (600 mm)	4 ft (1.2 m)	4 ft (1.2 m)	6 ft (1.8 m)
Shoulder Type	Turf [(4)] or Aggregate Wedge [(5)]		Aggregate Wedge [(3)(5)]	

Notes:

(1) *Resurfacing only: Traveled way widths may be reduced by 2 ft (600 mm), but the traveled way width shall not be less than 18 ft (5.4 m).*

(2) *For rural cross sections, shoulder width includes a 1 ft (300 mm) wide paved strip for either a resurfacing or resurfacing and widening project.*

(3) *Use full-width, 6 in. (150 mm) thick aggregate shoulders for ADTs over 5000 in addition to the 1 ft (300 mm) wide shoulder strip. For definition purposes, a stabilized shoulder will be aggregate of 6 in (150 mm) minimum thickness.*

(4) *Turf will consist of compacted, stable, roadway embankment or granular material capable of supporting growth and will not contain a high percentage of organic or unstable material.*

(5) *The width of the aggregate wedge will be 3 ft (900 mm) or equal to the width of the usable shoulder if less than 3 ft (900 mm). The minimum wedge thickness will equal the depth of resurfacing at the edge of traveled way and tapering to zero.*

ROADWAY CROSS SECTION ELEMENTS
(3R Projects on Unmarked Routes on the State Highway System)

Figure 49-6.A

49-6.05 Vertical Alignment

49-6.05(a) Crest Vertical Curves

The following will apply:

Current ADT	Treatment
1000 or more	All existing crest curves which are not within 15 mph (25 km/h) of the posted or regulatory speed, as determined from the available stopping sight distance (SSD), will be upgraded by one of the following options: • flatten the crest curve within the existing right-of-way to satisfy 55 mph (90 km/h) (desirable) or 45 mph (70 km/h) (minimum) SSD; or • flatten the crest curve by using additional right-of-way to satisfy a 50 mph to 55 mph (80 km/h to 90 km/h) SSD. The designer should consider sight distances, intersection influences, overall safety, the need for road closures, detours, stage construction, and especially the prevailing vertical alignment in evaluating the above alternatives. Such an analysis will allow designers to determine the most practical alternative for flattening crest vertical curves.
Less than 1000	Crest curves may be retained if adequate for 20 mph (30 km/h) less than the posted or regulatory speed but not less than a 30 mph (50 km/h) available SSD.

49-6.05(b) Sag Vertical Curves

Sag curves generally may be retained.

49-6.05(c) Maximum Grades

On 3R non-freeway projects, the existing roadway grades are acceptable; i.e., flattening grades is not within the scope of a 3R project on unmarked highways.

49-6.06 Intersections

49-6.06(a) Superelevation Rate Changes Through Intersections

Superelevation rates less than that specified for the preceding horizontal alignment may be used through certain intersections because of significant intersection conflicts and when supported in the Phase I engineering report. Refer to Figure 36-1E for guidance. Agreement should be reached with the District Operations Engineer on the appropriate advisory speed to be posted for the curve and noted in the Phase I engineering report.

49-6.06(b) Stop-Controlled Approaches on Horizontal Curves

On curved, stop-controlled approaches to the unmarked route, the existing superelevated cross section generally is left in place.

49-6.06(c) Sideroad Approach Grades

Where considerable amounts of additional right-of-way are required, geometric design criteria should be in accordance with applicable new construction/reconstruction policies where practical. Some elements may be consistent with site conditions when based on special study and analysis results.

All connecting sideroad approaches should be examined for drainage away from the unmarked route. The gradeline on the sideroad should normally drain away from the intersecting unmarked highway for 50 ft to 100 ft (15 m to 30 m) or, at a minimum, to the ditch line of the unmarked highway. If the sideroad profile is reconstructed, the minimum sideroad gradeline should be approximately -1.0% from the intersecting unmarked highway, and the maximum gradeline is -4.0%. Where the unmarked highway is on a horizontal curve, use a maximum of -2.0% on the sideroad connection to minimize rollover at the traveled way edge.

49-6.06(d) Sideroad Turning Radii

The design vehicle used for sideroad turning radii may be site specific with justification. Refer to Section 36-1 for guidance in the selection of design vehicles based on functional classification.

49-6.06(e) Intersection Sight Distance

At rural, public road intersections with a stop condition on the sideroad, provide 465 ft (140 m) of sight distance for the stopped approach in both the left and right directions along the free-flowing highway. Use a 12 ft (3.5 m) distance from the edge of the traveled way to the driver's eye.

49-6.07 Roadside Treatment and Highway Appurtenances

49-6.07(a) General

The intent of these guides is to perform cost-effective work that may reduce the number and severity of run-off-the-road crashes. Remove or shield obstacles within the clear zone, including protrusions that extend greater than 4 in. (100 mm) above the groundline, where cost effective.

49-6.07(b) Earth Slopes

Other than specifically described in Section 49-6, existing earth slopes should generally remain. Where existing right-of-way permits significant slope flattening or where grading within existing right-of-way is necessary, the designer should consider flattening earth slopes, particularly at horizontal curves.

49-6.07(c) Clear Zones

On unmarked routes on the State highway system, clear zone widths (measured from the traveled way edge) should be in accordance with Figure 49-6.B.

<table>
<tr><th colspan="2">Roadway Criteria</th><th>Ditch Cross Sections (1)</th><th>Clear Zone</th></tr>
<tr><td rowspan="3">On Tangent</td><td rowspan="2">Regulatory Speed 50 mph (80 km/h) or greater and ADT Greater than 1000</td><td>Traversable</td><td>13 ft (4.0 m) or ROW Line (2)</td></tr>
<tr><td>Non-Traversable</td><td>13 ft (4.0 m) or
Toe of Back Slope (2)</td></tr>
<tr><td>All Others</td><td>-</td><td>10 ft (3.0 m)</td></tr>
<tr><td rowspan="3">On Curve (3)</td><td rowspan="2">Comfortable Operating Speed less than 50 mph (80 km/h)</td><td>Traversable</td><td>20 ft (6.0 m) or ROW Line (2)</td></tr>
<tr><td>Non-Traversable</td><td>20 ft (6.0 m) or Ditch Line (2)</td></tr>
<tr><td>Comfortable Operating Speed 50 mph (80 km/h) or greater</td><td colspan="2">Same as tangent Clear Zone above</td></tr>
</table>

Notes:

(1) Traversable ditch cross sections are those with at least 1V:4H front slopes, 1V:3H back slopes, and 2 ft (600 mm) wide ditch bottom. If any of these criteria are not satisfied, the ditch cross section is considered non-traversable.

(2) Use whichever is less.

(3) Clear zone values apply only to the outside of curve. Tangent clear zone values apply to inside of curve. Use Figure 49-3.B to determine comfortable operating speed.

CLEAR ZONES
(3R Projects on Unmarked Routes on the State Highway System)

Figure 49-6.B

49-6.07(d) Guardrail

The criteria provided in Section 49-3.07(d) for the treatment of guardrail and locations warranting guardrail will also apply to unmarked routes on the State Highway System. However, any reference to Figure 49-3.F in Section 49-3.07(d) should be read as Figure 49-6.C.

49-6.07(e) Culverts

The criteria present in Section 49-3.07(e) for the treatment of culverts will also apply for unmarked routes on the State Highway System. For jurisdictional transfer projects, end treatments of cross road culverts will be in accordance with the *Bureau of Local Roads and Streets Manual* or the end treatments described in 49-3.07(e).

49-6.07(f) Mailbox Turnouts

The design and construction of mailbox turnouts should be in accordance with the *Highway Standards,* BLR-24.

49-6.07(g) Lighting and Landscaping

Installation of lighting to improve operations and/or safety should be considered in accordance with the guidelines in the *Bureau of Local Roads and Streets Manual*. Generally, landscaping should be directed toward replacing appropriate existing plants and turf removed or damaged by construction and, where practical, planting for safety or erosion control purposes. See Chapter 59.

49-6.07(h) Other

Section 49-3.07 presents criteria for rural arterials for the following roadside elements:

- sign and light supports,
- trees,
- concrete signal bases,
- curbs,
- traffic control devices,
- mailbox supports, and
- above-ground utilities.

These criteria apply to 3R projects on unmarked routes on the State Highway System.

49-6.08 Railroad Crossings and Signals

The criterion in Section 49-3.08 for rural arterials also applies to unmarked routes on the State Highway System.

49-6.09 Bridges

49-6.09(a) Bridge Condition Reports/Structure Sketches

The information in Section 49-3.09(a) for rural arterials also applies to unmarked routes on the State Highway System.

49-6.09(b) Scope of Work

Bridges on unmarked routes on the State Highway System will be rehabilitated to correct operational, structural, and significant safety deficiencies and will be subject to the following conditions:

1. The roadway template is not anticipated to be widened beyond the proposed bridge cross section within the next 20 years.

2. Where an existing bridge is not of sufficient width to remain in place, it may be gapped within the project limits if its future rehabilitation or replacement is committed as staged construction to be completed within the next five years. No bridge will be gapped for more than one year if the clear roadway bridge width is less than the approach traveled way width.

3. Hazard panels and appropriate pavement markings will be required for all bridges which remain in place and which are narrower than the improved traveled way width; see Figure 49-3.I.

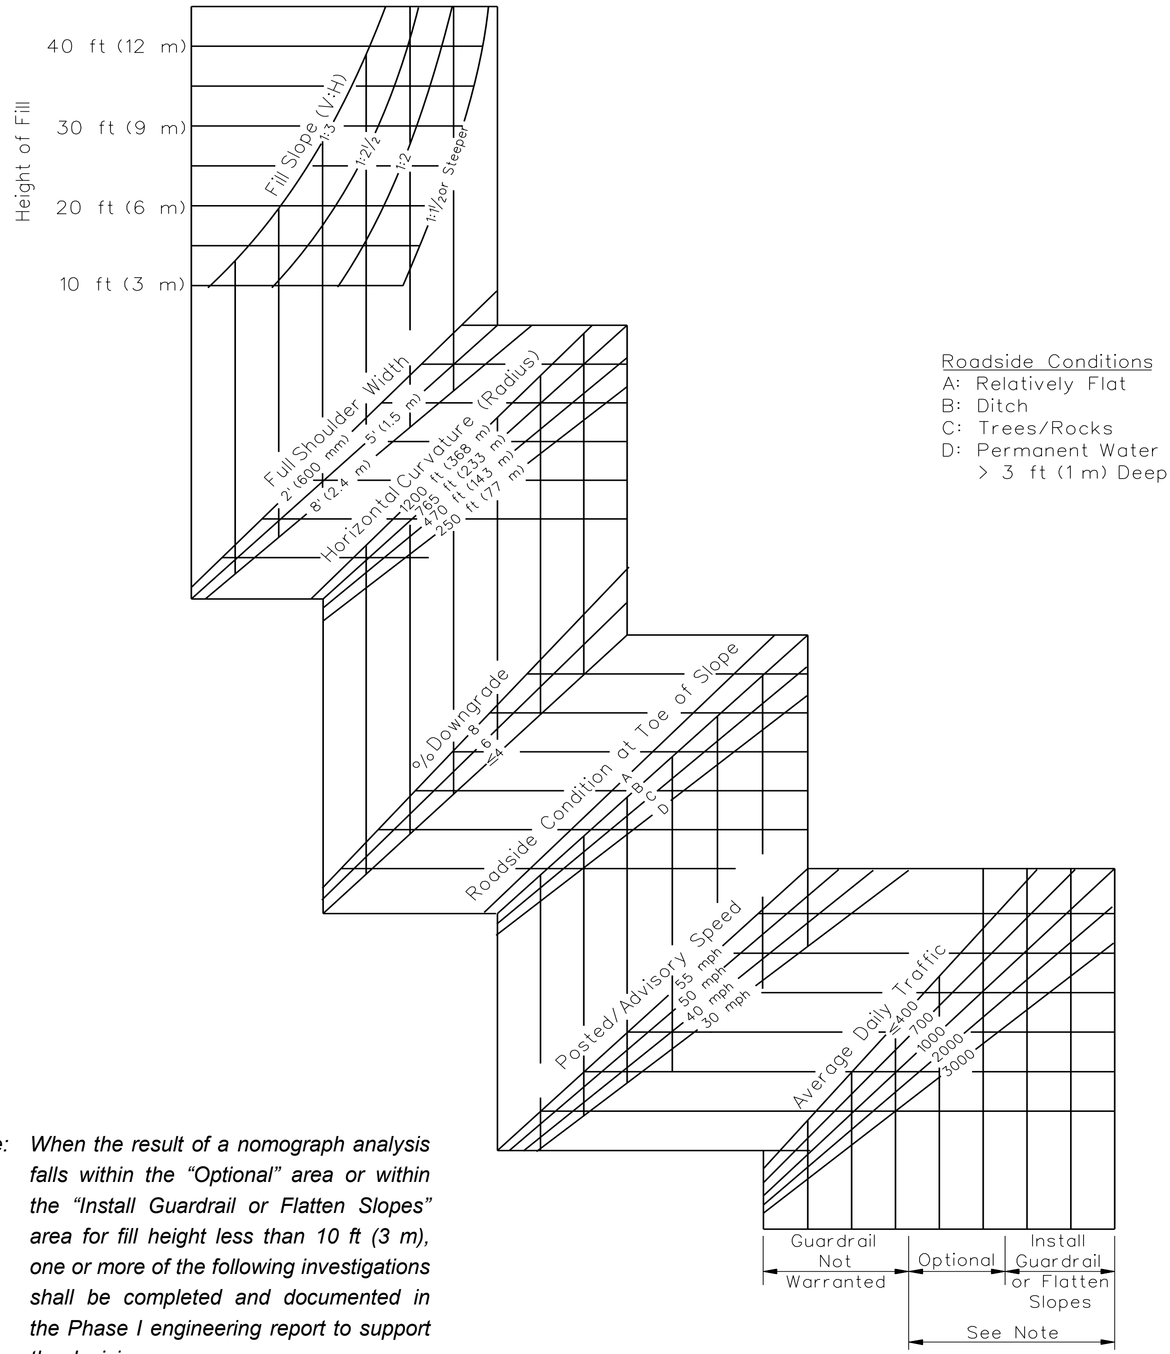
49-6.09(c) Criteria for Bridges to Remain in Place

Bridges on rural unmarked routes on the State Highway System will remain in place provided that the clear roadway bridge width is equal to or greater than the values given in Figure 49-6.D and that the structural capacity is met.

The designer should repair, retrofit, or replace any rails on bridges to remain in place that could be easily penetrated by a passenger vehicle, that show evidence of crash damage, that are in questionable condition, or that contain irregularities that could cause intolerable vehicular decelerations. If replaced, rails and their connections to the deck shall be designed to meet current AASHTO strength and safety performance standards.

Curb sections that project horizontally more than 9 in. (225 mm) but less than 3 ft (900 mm) from the face of rail will be removed or new rail elements installed in accordance with the standards for bridge rail retrofit.

Structurally sound bridge decks with poor riding quality that could jeopardize the safety of the motorist or cause undue discomfort should be repaired and resurfaced; however, resurfacing



Note: When the result of a nomograph analysis falls within the "Optional" area or within the "Install Guardrail or Flatten Slopes" area for fill height less than 10 ft (3 m), one or more of the following investigations shall be completed and documented in the Phase I engineering report to support the decision:

- *field check and review of crash records,*
- *multi-disciplinary team review, and/or*
- *cost-effective economic analysis.*

GUARDRAIL WARRANTS FOR 3R PROJECTS
(On Unmarked Routes on the State Highway System)

Figure 49-6.C

may not be extended across decks without appropriate repair and waterproofing or when the bridge cannot safely carry the additional dead load resulting from the resurfacing.

49-6.09(d) Criteria for Improved Bridges

All rehabilitated or replaced bridges will be constructed to a clear roadway width equal to the values in Figure 49-6.E. The widths assume a rural type cross section approaching the bridge.

49-6.09(e) Vertical Clearance

The minimum vertical clearance for bridges to remain in place over an unmarked route is 14 ft (4.3 m). Economics may dictate exceptions.

Current ADT [2]	Current ADT	Current ADT	Current ADT
Under 400	**400 - 999**	**1000 - 3000**	**Over 3000**
Clear Roadway Bridge Width [3]			
20 ft (6.0 m)	22 ft (6.6 m)	24 ft (7.2 m)	28 ft (8.4 m)

Notes:

(1) In all cases, except as noted in (2) below, the bridge to remain in place shall have a structural capacity of H-15 (MS-13.5) loading.

(2) When the current ADT is less than 75, a bridge with a structural capacity of H-10 (MS-9) loading will be acceptable if it meets the width criteria.

(3) Between rails or between curbs if the curb projects more than 9 in. (225 mm) beyond the face of the rail.

(4) In no case will the bridge be narrower than the approach traveled way.

3R WIDTHS OF BRIDGES TO REMAIN IN PLACE [1][4]

Chapter Fifty
3R GUIDELINES FOR FREEWAYS

Chapter 50 presents the Department's geometric and roadside safety design guidelines for 3R projects on existing freeways. However, these 3R freeway guidelines should not be substituted for sound engineering judgment. See Chapter 44 for the application of design criteria to new construction/ reconstruction freeway projects.

50-1 GENERAL

50-1.01 Background

The Department began construction of its freeway system in the 1950's. The system has introduced a level of mobility and safety for the traveling public that was unattainable without its special features, including full control of access, wide roadway widths, and high design speeds.

The freeway system requires repair and upgrading which exceeds the limits of normal maintenance. In general, these capital improvements are referred to as 3R freeway projects (resurfacing, restoration, rehabilitation). As with non-freeway 3R projects (Chapter 49), it is often impractical to fully apply new construction/reconstruction criteria to 3R freeway projects without some qualifications. Freeway 3R projects reflect economics and safety relative to their design until full design criteria can be applied; i.e., reconstruction.

50-1.02 Objectives

The objective of a 3R freeway project is, within practical limits, to restore the freeway to its original service or to improve it to meet current demands. This objective applies to all aspects of the freeway's serviceability, including:

- structural adequacy,
- drainage,
- slope and embankment stability,
- level of service for the traffic flow,
- geometric design,
- roadside safety, and
- traffic control.

These objectives are competing for the limited funds available for 3R projects on existing freeways. The Department's responsibility is to realize the greatest overall benefit from the available funds. This is accomplished by:

- recognizing that most 3R freeway projects are typically initiated to make a specific improvement (e.g., pavement rehabilitation) to the existing freeway (i.e., 3R freeway projects are not intended to fully upgrade or reconstruct the facility);

- defining the project scope of work to ensure that the project accomplishes the specific objective as identified at project initiation but does not expand into a full reconstruction project; and

- selectively evaluating and implementing geometric and roadside safety design improvements to the freeway which are a cost-effective expenditure of the Department's highway construction funds.

50-1.03 Approach

The Department's approach to the design of 3R freeway projects is to evaluate and selectively improve the existing geometrics. This is summarized as follows:

1. Nature of Improvement. Identify the specific improvement intended for the 3R project. For example, design improvements might include:

   - pavement rehabilitation/resurfacing/restoration,
   - upgrade roadside safety,
   - increase the length of one or more acceleration lanes at an interchange,
   - eliminate a weaving area at an interchange,
   - widen an existing bridge as part of a bridge rehabilitation project, and/or
   - improve bridge structural adequacy.

2. Selecting Design Criteria. This Chapter addresses 3R freeway projects. If reconstruction is needed to address an identified operational or safety element, the designer will use the new construction/reconstruction criteria in Chapter 44.

3. Design Considerations. Identify and evaluate any design deficiencies that may be precipitated by the freeway improvement. For example:

   - The installation of a concrete barrier may restrict horizontal sight distance.

   - A pavement overlay may require the adjustment of roadside barrier heights or reduce the vertical clearance to below the Department's allowable criteria.

4. Safety Analysis. Identify other geometric and roadside safety design deficiencies within the project limits. Conduct a crash analysis when determining any other improvements that can be practically included without exceeding the intended project scope of work. For example, if a concrete barrier is constructed, it is reasonable to correct any superelevation deficiencies to full standards at the same time, because superelevation corrections in the future may require major modifications to the wall.

5. Project Evaluation. Section 49-2.04 discusses project evaluation for 3R non-freeway projects. This includes, for example, crash data, pavement condition, geometric design consistency, and traffic control devices. As applicable, these evaluation objectives also apply to 3R freeway projects.

6. Design Exceptions. The discussion in Section 31-7 on design exceptions applies equally to the geometric design of 3R freeway projects.

50-1.04 Documentation

50-1.04(a) Phase I Report

A Phase I engineering report shall be prepared and, when required due to funding type or design exceptions, transmitted to FHWA through BDE. See Chapters 11 and 12 for a detailed discussion. The report should be brief and should contain at least the following:

1. Reasons for Project Initiation.

2. Description of Existing Conditions. Before determining the scope of the proposed 3R freeway project, an analysis of the existing conditions is necessary. Provide a fact sheet indicating project length, design and posted speed, current ADT and percentage of trucks, CRS values, etc. From as-built plans and as verified by a field survey, the following should be determined:

    - existing roadway, structure, and interchange geometrics;
    - general pavement distress or failure mode;
    - specific areas of failure;
    - presence of underdrains and pipe drain headwalls;
    - location and performance level of existing roadside safety appurtenances; and
    - locations of existing shallow roadside ditches.

3. Proposed Scope of Work. Provide a brief description of the proposed scope of work. This description must include at least the following items:

    - a Sketch Map showing the location of the proposed improvement, the limits of the proposed work, and any omissions;
    - a typical cross section showing the proposed resurfacing thickness, shoulder widths, pavement and shoulder cross slopes, side slopes, bridge widths; and
    - exceptions from policy resurfacing thicknesses. This will also include justification for the exceptions as discussed in Chapter 53.

4. Estimated Cost for the Proposed Improvement.

5. Categorical Exclusion. The applicable Group for Categorical Exclusions should be identified in the Phase I engineering report (see Chapter 23) plus any required special reports (see Chapter 26). The certification statement is not needed for Group I projects.

6. Other. The Phase I engineering report should document any other special reports such as;

   - justification for requests for exceptions from design policies,
   - discussion of Five Percent Report Locations or other over-represented crash locations and proposed countermeasures,
   - proposed geometric revisions and superelevation corrections,
   - vertical clearances,
   - condition of existing structures, and
   - environmental concerns.

50-1.04(b) Contract Provisions

In addition to providing the various contract documents needed for the 3R freeway project (see Part VII "Plan and Contracts"), the contract should contain provisions for the following items:

1. Markers. The contract should provide for the removal, storage, and replacement of all edge-of-shoulder-mounted delineators and milepost markers that will interfere with construction. When the field survey indicates missing or damaged delineators or markers, the contract should provide for a pay item for replacement. See the *Highway Standards* for placement requirements for delineators. For milepost markers, consult the Bureau of Operations.

2. Bridge Approach Shoulders. The bridge approach shoulders should be surveyed to determine the need for any corrective work if settlement has occurred. See Chapter 53.

3. Erosion. For existing foreslopes that have a history of erosion problems, consider the selective use of Shoulder Inlet and Curb. See the *Highway Standards*. However, barrier (vertical) curbs shall not be used and the placement of any curbs in front of guardrails should be avoided. See Section 50-3 and Chapter 38.

50-2 GEOMETRIC DESIGN

In general, the Department's geometric design criteria for new construction/reconstruction also apply to 3R freeway projects. See Parts IV "Roadway Design Elements" and V "Design of Highway Types." However, the designer must still make certain decisions, and there is some flexibility that can be applied. This is discussed in the following sections.

50-2.01 Design for Original Construction

A specific geometric design element on an existing freeway may not meet the Department's current criteria but did meet the criteria at the time of original construction. In these cases, the design criteria used for horizontal and vertical alignment and traveled way; shoulder and median width can remain in place if they met the AASHTO freeway design criteria in effect at the time of original construction or inclusion into the Interstate system.

50-2.02 Design Speed

The existing posted speed limit will be acceptable as the minimum design speed for the 3R freeway project. However, check with the Bureau of Operations to determine if the existing posted speed limit is likely to change after project completion. For metric projects, consider that the design speed of the project may be in metric and that the posted speed limit will be in English. Figure 50-2.A provides the conversion that will apply to 3R freeway projects.

50-2.03 Design Traffic Volumes

Some design elements on 3R freeway projects will require the selection of the DHV (e.g., level of service) or ADT (e.g., roadside clear zones). The current ADT shall be used unless geometric or structural improvements are made. Use the traffic for 20 years beyond the date of completion for these items.

Posted Speed Limit (mph)	Minimum Design Speed (km/hr)	
	(mph)	(km/hr)
50	50	80
55	55	90
60	60	100
65	65	110
70	70	110

DESIGN SPEED
(3R Freeway Projects)

Figure 50-2.A

50-2.04 Horizontal Curves

Mainline horizontal curves should have minimum superelevation rates equal to those allowed to remain in place as shown in Figure 50-2.B. If the required minimum superelevation rates are not met, provide additional resurfacing thickness or milling to correct the superelevation to the rate for the required comfortable operating speed. See Section 49-3 for more information on the use of Figure 50-2.B.

Where the curve occurs beneath an existing overhead structure, the additional thickness may cause the vertical clearance to become less than that required, and appropriate adjustments will be required. See Section 50-2.05.

All ramp superelevation rates should be corrected to the full superelevation rates for new construction. See Chapter 37.

50-2.05 Vertical Alignment

50-2.05(a) Vertical Curves

Analyze vertical curves to determine if they meet the criteria found in Section 33-4. If not, determine if operational or safety problems exist at the location. Where no operational or safety hazard is present, the curve may remain in place.

50-2.05(b) Vertical Clearances

The minimum vertical clearance for 3R rural interstate projects is 16 ft 00 in. The allowable vertical clearance for 3R urban interstate projects is 16 ft 00 in for single routing around urban areas. For urban interstates within the single routing 15 ft 00 in is permitted. If these vertical clearances cannot be met, a design exception must be sought.

Refer to Section 31-7.04(c) for directions to process a design exception for vertical clearances over interstates. The urban areas in Illinois where single routing occurs are:

- Peoria,
- Quad Cities,
- Metro-east St. Louis area, and
- the Chicago metropolitan area.

Maps of the single interstate route for these urban areas are shown in the figures in Section 44-6.

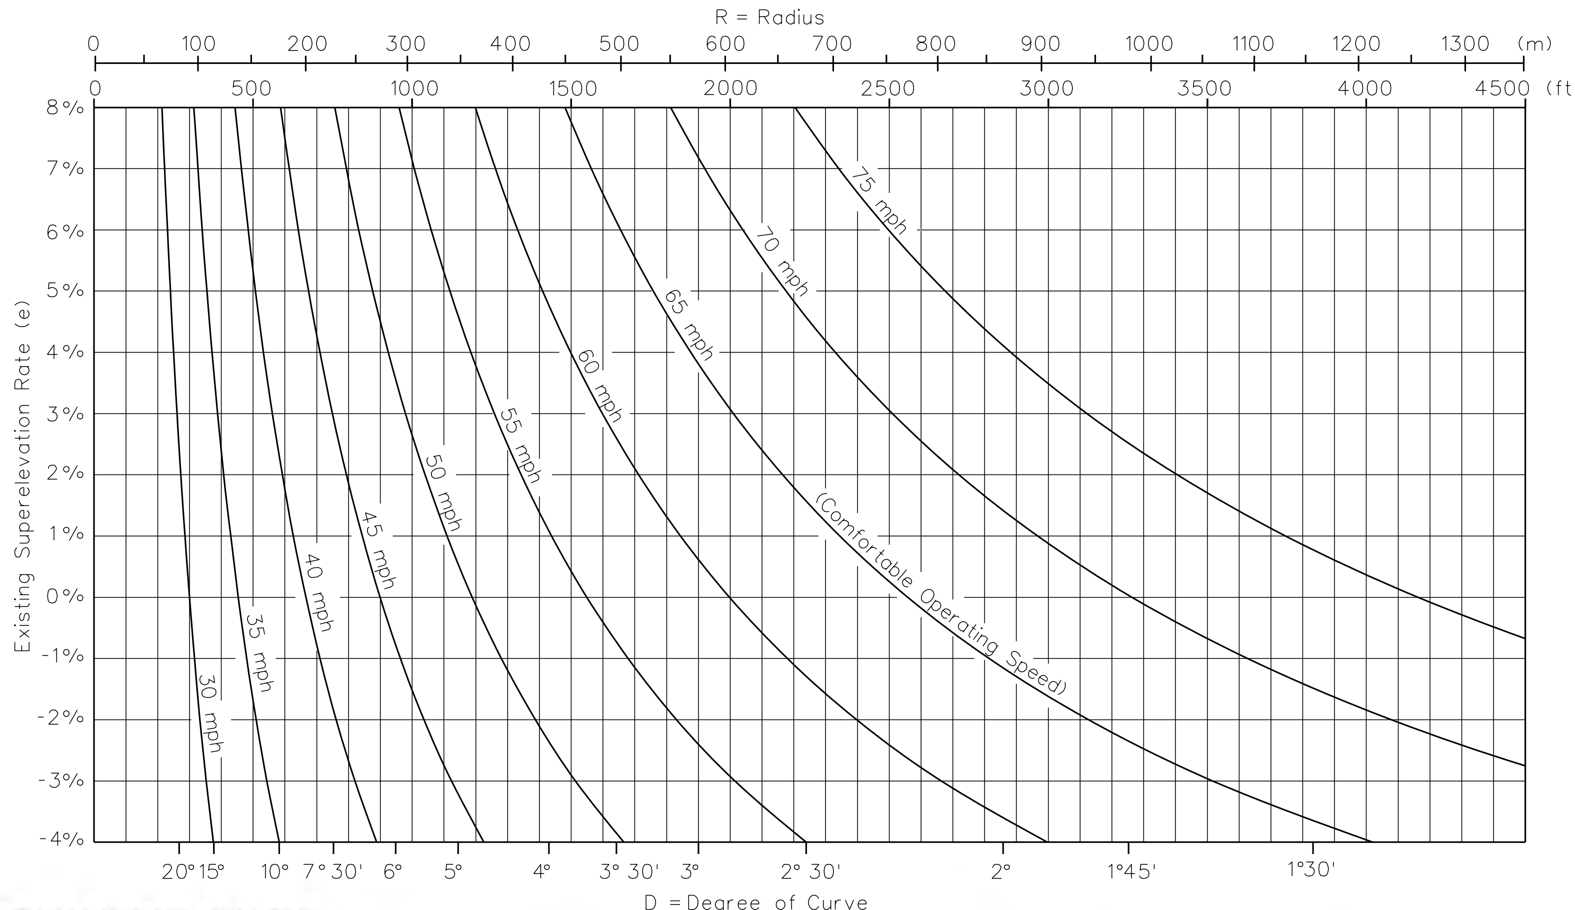

Figure derived from the following:

1. *Use AASHTO Method 2 for the distribution of superelevation and side friction.*
2. *Assume design speed and use f_{max} for selected design speed in all cases.*
3. *Assume different values of "e" and calculate values for "R" on graph for each speed.*

$$R = \frac{V^2}{15\,(e + f_{max})}$$, *where V = mph and R = ft. (US Customary)*

$$R = \frac{V^2}{127\,(e + f_{max})}$$, *where V = km/h and R = m. (Metric)*

HORIZONTAL CURVATURE ALLOWED TO REMAIN IN PLACE FOR 3R FREEWAY PROJECTS

Figure 50-2.B

50-2.06 Bridges

Because of the high traffic volumes usually involved, bridges on six-lane or greater facilities must be examined on a case-by-case basis whenever 3R type work is performed. For structures on four-lane facilities, the following will apply to the geometric design criteria for bridges within the limits of 3R freeway projects.

50-2.06(a) Bridge Condition Reports/Structure Sketches

A Bridge Condition Report (BCR) and a Proposed Structure Sketch are required for every structure within a roadway section covered by a Phase I engineering report or when a bridge itself is the reason for preparing a Phase I engineering report. Before design approval can be granted, the BCR's must be approved by the Bureau of Bridges and Structures. In addition, the Bureau of Design and Environment must approve the typical section.

A Bridge Condition Report also is required for a bridge proposed to remain in place. This will ensure that the bridge meets the minimum requirements for width, safety, and structural capacity. However, the Illinois Structure Information System-Master Report (R107) may be substituted for a Bridge Condition Report.

50-2.06(b) Safety Analysis for Bridges

Narrow mainline, interchange, and ramp bridges within the project limits must first be analyzed to determine if widening is necessary to address a high-crash experience or other operational problems. This analysis will include a review of crash data for the previous four years and, if necessary, a field check by the district, FHWA, BDE, Bureau of Safety Engineering, and Bureau of Bridges and Structures. If it is determined that the overall safety of the roadway will be enhanced, include the widening of the bridge within the 3R project or schedule the work no later than one year following the letting of the highway project, unless an extension of time is approved by FHWA.

50-2.06(c) Bridges to Remain in Place

A 3R freeway project may be primarily intended, for example, to improve the pavement condition over several miles (kilometers). A bridge or several bridges may be within the limits of the 3R project. Desirably, the bridge widths will equal the full approach roadway width, including paved shoulders. However, this may not be the case. If the existing bridge is structurally sound and if it meets the Department's design loading structural capacity, an analysis should be performed to determine the cost effectiveness of improving the geometrics of the bridge. However, geometric deficiencies and/or adverse crash experience at the bridge may warrant widening the bridge as part of the 3R project. Design exceptions are required for bridge widths that do not meet Department criteria; see Chapter 31.

50-2.06(d) Bridge Replacement/Rehabilitation

3R freeway projects may include bridge replacements or bridge rehabilitation work and, in some cases, this may be the entire project scope of work. The following will apply to the geometric design of these projects:

1. Horizontal and Vertical Alignment. An existing bridge may have an alignment that does not meet the Department's current criteria. For bridge replacement projects, the designer should evaluate the practicality of realigning the bridge to meet the applicable alignment criteria for new construction/reconstruction (Chapters 32 and 33). For bridge rehabilitation projects, it is unlikely to be cost effective to realign the bridge to correct any alignment deficiencies.

2. Width. When the Bridge Condition Report indicates deck replacement is necessary, widen the structure to the extent possible without requiring substructure additions. Necessary repairs to or replacement of superstructure elements will be permitted. In no case shall the structure be made narrower than the existing width. The bridge width should equal the full approach roadway width, including paved shoulders, as determined by the criteria in Chapter 44. Capacity analyses could determine the need for auxiliary lanes and/or the need for wider shoulders. For example, if the predicted volume of trucks exceeds 250 DHV, the future shoulder width on the approach should be 12 ft (3.6 m). Because freeway bridges represent major economic investments with lengthy design lives, it may be warranted to provide the wider widths as part of a bridge replacement or rehabilitation project.

   As another example, a capacity analysis may indicate the need for an additional through lane to meet the level-of-service criteria for the design year. The decision may be made to widen the bridge as part of the replacement/rehabilitation project. Until the roadway approach is widened, it may be necessary to indicate with pavement markings or temporary barriers that the additional width on the bridge cannot be used by through traffic.

3. Length. The length of the freeway bridge determines the cross section of the crossroad passing beneath the freeway. Therefore, if practical, the freeway bridge should be designed to accommodate any future widening of the underpassing roadway. This may involve an assessment of the potential for further development in the general vicinity of the underpass.

4. Roadside Safety. See Section 50-3.01.

50-2.07 Interchanges

A 3R freeway project may include proposed geometric design improvements at an existing interchange. The work may be to rehabilitate the entire interchange or to make only selective improvements to the interchange geometrics. Chapter 37 will be used to design the interchange element.

50-2.08 Median Crossovers

50-2.08(a) Permanent

Close or correct all existing median crossovers that do not meet the requirements of Section 3-400 *Median Crossovers on the Fully Access Controlled Highways*, of the Bureau of Operations *Maintenance Policy Manual* or for which a variance has not been granted by the Bureau of Operations and FHWA. When the field survey indicates locations of unauthorized median crossovers, the contract should provide for the installation of 4 in. x 4 in. (100 mm x 100 mm) wood posts to discourage intrusions.

Use the following for bituminous surfaces for these crossovers:

1. New Crossovers. Provide an 8 in (200 mm) of BAM meeting the requirements of the *Standard Specifications for Road and Bridge Construction*.

2. Existing Crossovers. If the existing crossover has a minimum thickness of 6 in (150 mm) of aggregate surface, grade the aggregate to a uniform cross section and cover with 3 in. (75 mm) of Bituminous Concrete, Superpave, or 3 in. (75 mm) of BAM meeting the requirements of the *Standard Specifications for Road and Bridge Construction*. If the minimum thickness of aggregate is less than 6 in. (150 mm), reconstruct the crossover to meet the requirements for new crossovers.

See also Section 50-3.08 for guidance on slopes for permanent median crossovers.

50-2.08(b) Temporary (for Construction)

A cost savings may be realized if some construction crossovers remain in place after the project is completed. Because these crossovers are designed to carry freeway traffic, they are often constructed with a high-type pavement that adds to the cost. If the pavement is removed, it may eventually have to be rebuilt to accommodate another project. If the crossover had remained in place, it could have been reused.

The following are examples where it may be advisable to leave temporary crossovers in place:

1. At Major River Crossings. At these locations, there is usually only one location where a crossover can be placed, and any future work will require the rebuilding of the same configuration.

2. Locations Where Physical Constraints Exist. In some instances, factors such as sight distance limitations, closely spaced structures, nearby interchanges, or elevation differences between lanes limit where a crossover can be built. At times, even though the projects may be at different locations, the location of a crossover is set by these limitations.

3. When Future Work is Planned in the Same Area. If structure work is scheduled for one year and roadway work anticipated within the next five years, the same crossover may be

used for both projects. Another example is a series of structures that are rehabilitated during a multi-year program.

Where these and similar situations are encountered, the designer should consider leaving the temporary crossovers in place after the project is completed. Provisions must be included in the contract to close the crossover during the time it is not in use. Discuss these provisions at a regular district coordination meeting and obtain FHWA and Central Office concurrence.

50-3 ROADSIDE SAFETY

50-3.01 General

50-3.01(a) Objective

Although ideally the roadside should be totally forgiving to those motorists who run off the roadway, geometrics, terrain, right-of-way, and economic considerations often render this impractical on existing freeways. Therefore, the objective should be to use the available highway funds to provide the most cost-effective design. This objective will require the designer to identify hazardous features and to determine:

- which hazards should be redesigned to be made traversable,
- which hazards should be removed or relocated,
- which hazards should be shielded with an appropriate barrier, and
- which hazards are not cost effective to redesign and therefore should remain untreated.

Section 50-3 provides the designer with guidelines for recognizing these hazards and provides suggested countermeasures for 3R freeway projects. Other approved countermeasures may be substituted where maintenance, operational, or other considerations are involved. Also, although some hazards may not require treatment according to these guidelines, specific circumstances may be such that treatment is necessary.

Recurring crash locations or over-represented crashes shall be identified early in the preliminary stages of plan preparation and appropriate action included in the plans to ameliorate the cause of these crashes. A recurring crash location is defined as any location that appears on the Five Percent Report Location for any two out of three-year period in the five years prior to plan preparation.

Any item identified as requiring treatment by these guidelines may remain untreated if that item is shielded by a roadside barrier required for some other hazard. In addition, some hazards may be allowed to remain just inside the clear zone when there are other similar hazards just outside the clear zone that do not require treatment and if the crash experience for the facility does not indicate a problem with the type of hazard involved.

50-3.01(b) Safety Reviews

It is not possible to include all hazards in any one set of guidelines. Therefore, a safety or plan-in-hand field review with representatives from the district, FHWA, and BDE may be required at the request of FHWA. Contact BDE for guidance on hazards not covered in Section 50-3.

50-3.01(c) Applicability

Chapter 38 presents Department criteria on roadside safety design for new construction/reconstruction. These apply to 3R freeway projects except as modified in Section 50-3.

50-3.02 <u>Structures</u>

50-3.02(a) Bridge Rehabilitation

If deck replacement is not necessary, treat any substandard bridge rails (which are defined as rails which were designed prior to the 1989 AASHTO *Standard Specifications for Highway Bridges*) on mainline, interchange, and ramp structures as discussed below. Rails built to the 1965 and later specifications essentially meet the 1989 specifications and may remain in place with prior approval:

1. <u>Metal Handrails Mounted on Safety Curbs</u>. Corrective action for handrails in this category is:

   - to remove the curb and rail and retrofit with an F-shaped parapet providing the greatest shoulder width practical without the addition of superstructure beams, or

   - to retrofit using a metal rail as shown in the *Highway Standards*.

   The decision on which type of retrofit will be employed will be based on an economic analysis combined with maintenance and performance considerations.

2. <u>Metal Handrail Mounted on a Vertical Face Concrete Parapet (Constructed on a Concrete Safety Curb)</u>. No corrective action is recommended for handrails in this category where the concrete safety curb is less than 9 in. (230 mm) wide. Where the safety curb is more than 9 in. (230 mm) wide, remove the curb and rail and retrofit with an F-shaped parapet or provide a metal retrofit rail as in Item #1.

3. <u>Concrete Parapets with General Motors Barrier Configuration</u>. Although this configuration may not have the same optimum redirective capability as the New Jersey configuration, it is considered acceptable. Therefore, no corrective action is recommended.

4. <u>Wide Safety Curbs</u>. For mainline, ramp, and interchange structures with rails not considered substandard but with safety curbs greater than 9 in. (230 mm) wide, remove the curb and existing rail and retrofit with an F-shaped parapet or a metal retrofit rail as in Item #1.

Bridges that have handrails that do not fit into these categories should be referred to BDE and Bureau of Bridges and Structures for analysis and remedial treatment.

If deck replacement is not necessary and the structure has previously been treated with a metal retrofit rail, no further action is required.

50-3.02(b) Piers/Abutments

Correct or shield any piers or abutment walls located within the clear zone, which are unshielded or improperly shielded, in accordance with the following criteria:

1. <u>Piers and Abutment Walls Located 0 ft to 2 ft (0 mm to 600 mm) from the Shoulder Edge</u>. If the pier is not shielded by any device, provide the proper length of need of guardrail and attachment with a Traffic Barrier Terminal, Type 6 or Type 6B. If a concrete barrier wall is present or planned along the median, modify the existing crash wall by filling in the gaps between the columns with concrete to a height of the Standard concrete barrier and attach to the pier with a Traffic Barrier Terminal, Type 6 or Type 6B. If a concrete barrier wall is not present or planned along the median, modify the existing crash wall by filling in the gaps between the columns with concrete to a height of 36 in. (915 mm) and attach to the pier with a Traffic Barrier Terminal, Type 6 or Type 6B.

   If the pier is shielded by existing guardrail that provides proper anchorage to the pier, see Section 50-3.09, provide the proper length of need guardrail for a minimum 25 ft (7.6 m) clear zone to prevent errant vehicles from becoming trapped between the beams and the slopewall.

   See Section 38-6.06 for more information on terminal treatments.

2. <u>Piers and Abutment Walls Located 2 ft to 4 ft (600 mm to 1.2 m) from the Edge of Shoulder</u>. If the pier or wall is unshielded, provide a proper guardrail treatment. This treatment will include Type B rail 25 ft (7.6 m) in advance of and along the front of the hazard.

   If the hazard is shielded by existing guardrail, add posts, where necessary, to provide Type B rail as above and a runout length sufficient for a 25 ft (7.6 m) clear zone as in Item #1.

3. <u>Piers and Abutment Walls Located 4 ft (1.2 m) or More from the Shoulder Edge</u>. Treat unshielded piers as follows:

   - If the foreslope is steeper than 1V:6H, the guardrail should be located at the shoulder line.
   - If the foreslope is between 1V:6H and 1V:10H, place the guardrail 4 ft (1.2 m) from the pier or abutment wall provided there will be at least 12 ft (3.6 m) between the shoulder hinge point and the rail. Otherwise, place the guardrail at the shoulder line.
   - If the foreslope is or can be graded to 1V:10H or flatter, place the guardrail 4 ft (1.2 m) from the structure.
   - Consider other options (e.g., sand barrels or other appropriate NCHRP 350 or MASH crash TL-3 tested devices) if space permits and the placement requirements of Section 38-8.05(d) can be obtained.

   If there is existing guardrail at least 4 ft (1.2 m) from the structure, provide the proper runout length. If it is less than 4 ft (1.2 m) from the structure, install additional posts to provide 25 ft (7.6 m) of Type B rail in advance of the structure and along the front of the structure.

For overhead grade separation structures with vertical face abutments 30 ft (9 m) from the edge of traveled way, no remedial treatment is warranted. However, concrete headwalls or ditch drainage pipe projecting through the bridge cone, parallel to the mainline, should be cost evaluated for remedial treatment where necessary.

50-3.02(c) Overhead Bridge Structures

Guidelines for upgrading overhead bridge structures and roadways that cross the freeway at locations other than interchanges are as follows:

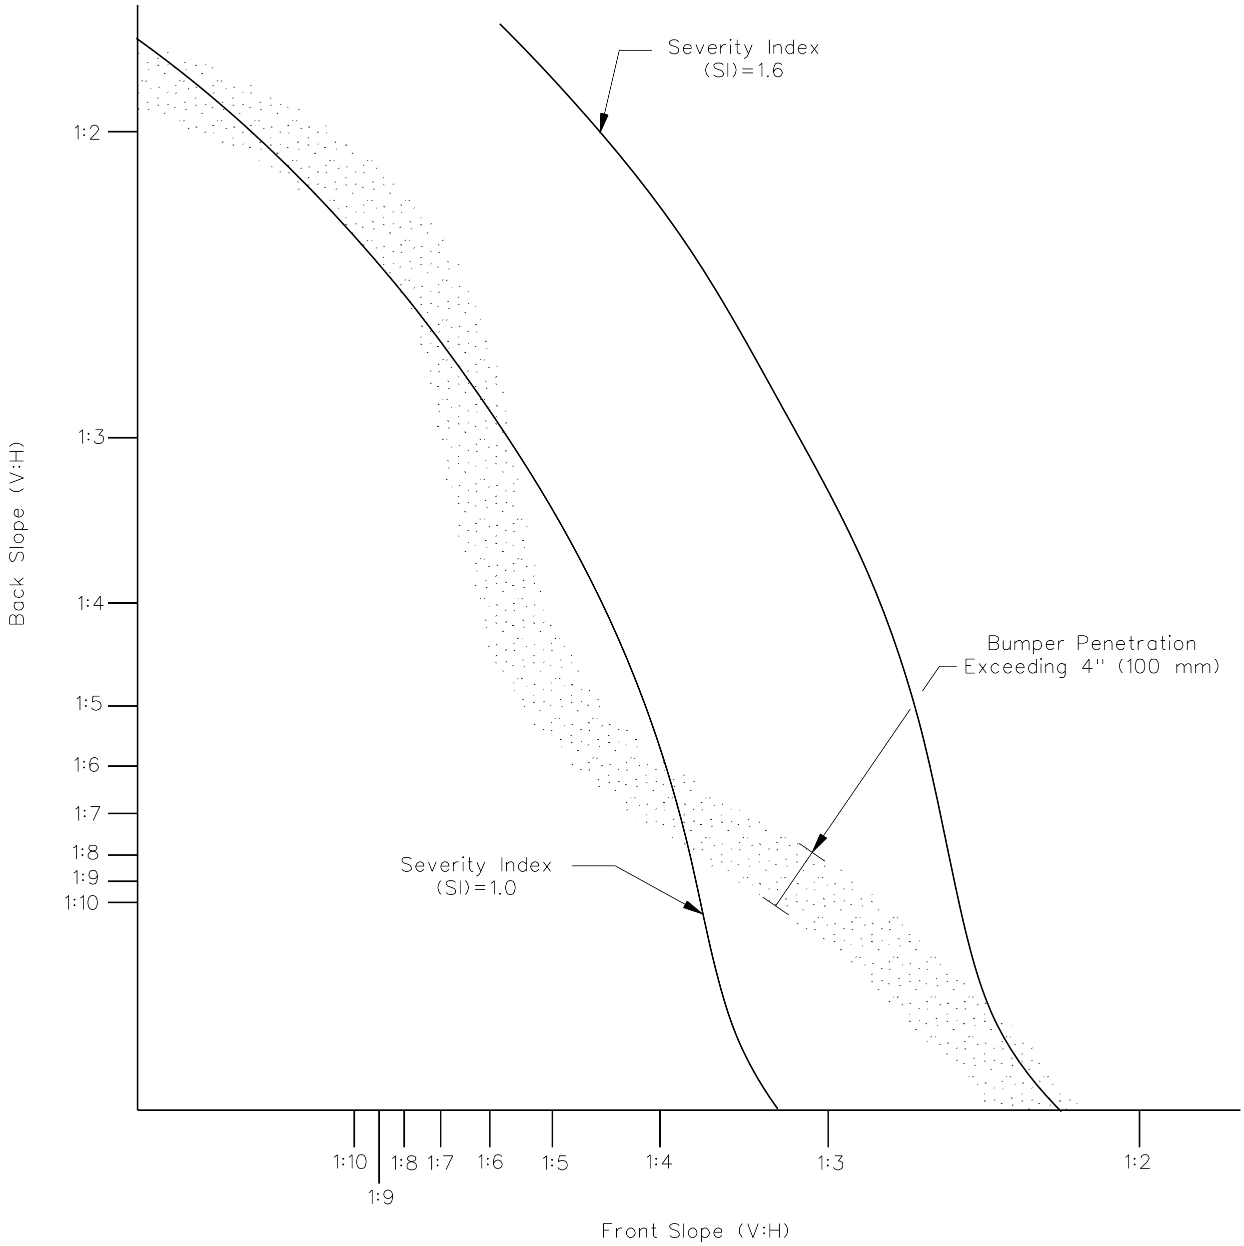
1. In general, all upgrading should be in accordance with existing 3R guidelines for the roadway classification of the overhead facility. See Chapter 49 or *Bureau of Local Roads and Streets Manual*.
2. Guardrail to remain in place shall be upgraded with the addition of posts and/or blockouts to provide minimum 6 ft 3 in. (1905 mm) post spacing. Also provide a proper connection to the bridge.
3. Repair, retrofit, or replace any rails on bridges that:
   - can be easily penetrated by an “average” vehicle (usually assumed to be a full-size domestic passenger car),
   - show evidence of crash damage,
   - are in questionable condition, or
   - contain irregularities that could cause intolerable vehicular decelerations.

   If replaced, rails and their connections to the deck shall meet current AASHTO strength and functional requirements. Because of the high potential for severe crashes if a vehicle penetrates a rail and lands on the freeway, retrofit or replace all substandard rails where the current ADT is greater than 750 or 50 MUs per day.
4. Remove any curb sections that project more than 9 in (230 mm) but less than 3 ft (915 mm) from the face of the rail or install new retrofit rail elements to shield the curb where the ADT is greater than 400 or 40 MUs per day.

50-3.02(d) Overhead Bridge Cones

The following presents guidelines for upgrading safety features on existing overhead bridge cones with 1V:2H side slopes located within the clear zone of the freeway.

Examine the cones and, if needed, modify the toe of the slope to prevent bumper penetration by errant vehicles. Using the roadway foreslopes and the bridge cone slope in the severity index curve in Figure 50-3.A, a severity index greater than 1.0 indicates that remedial filling and grading at the toe of the bridge cone may be warranted.



Note: Severity Index and bumper penetration contours based on 12 in. (300 mm) ditch, 60 mph (95 km/hr), and 25 degree encroachment angle.

SEVERITY INDICES FOR ROADSIDE DITCHES

Figure 50-3.A

50-3.03 Drainage Structures

50-3.03(a) Cross Drainage Structures

When evaluating existing cross drainage pipe structures, see Section 49-3.07(e) and the criteria presented in Section 38-4.06(b).

50-3.03(b) Cost-Effective Analyses

For all culverts greater than 36 in. (915 mm) in diameter more than 30 ft (9 m) from the edge of traveled way, prepare a cost-effective analysis to determine if a safety treatment is warranted. See Section 38-4.03 for Department policies on cost-effective analyses.

50-3.03(c) Raised Median Inlets

Replace raised median inlets with flush inlets as follows:

1. If the median is less than 65 ft (19.5 m) wide, replace all raised inlets.

2. For medians 65 ft (19.5 m) wide and greater, replace raised inlets only where the ADT is greater than 20,000.

50-3.04 Sign Supports

50-3.04(a) Wood Posts

Treat all wood posts as follows:

1. Drill or notch 6 in. x 6 in. (150 mm x 150 mm) wood posts at a point 4 in. (100 mm) above the ground to reduce the cross sectional area to that for an S4S 4 in. x 6 in. (100 mm x 150 mm) post. The direction of drilling must be perpendicular to the roadway and the notches must be on the backside of the post.

2. No more than two posts may be used in a 7 ft (2.1 m) wide path. If more than two posts are within a 7 ft (2.1 m) path, remove the posts or relocate the signs.

50-3.04(b) Steel Posts

Steel posts that are not breakaway shall be made breakaway unless shielded by guardrail required for other hazards. Also, all supplemental signs below the fuse plate shall be mounted such that they will not affect the breakaway action of the post.

50-3.04(c) Concrete Foundations

Concrete foundations for steel posts located within the clear zone must have no portion of the foundation or stub projection extending 4 in. (100 mm) or more above the grade. Regrading, or removal and replacement, is required for all foundations where the projection exceeds 4 in. (100 mm).

50-3.04(d) Sign Foundations

Treat all cantilever and sign truss foundations as follows:

1. Shield foundations located within the clear zone as in Section 50-3.02(b). Upgrade any existing guardrail used to shield foundations to current standards. An impact attenuator system may be used in lieu of a barrier.
2. Foundations located 30 ft (9 m) or more from the edge of traveled way do not require remedial treatment.

50-3.05 Light Standards

The following applies:

1. Concrete foundations for other than tower lighting must not project more than 4 in. (100 mm) above the grade; otherwise, regrade or remove and replace the foundation.
2. Install breakaway bases for unshielded light poles other than tower lights. Use non-breakaway poles:
   - on urban freeways where there is a possibility that the pole may fall on an area with high pedestrian traffic, and
   - in rest areas and weigh stations.
3. Treat tower lights as in Section 50-3.04(d). Impact attenuator systems may be used in lieu of barrier.

50-3.06 Trees

Remove all trees within the clear zone that, at maturity, will be 4 in. (100 mm) or greater in diameter. Also, remove trees that restrict proper sight distance or trees located immediately behind breakaway devices (e.g., sign supports, light poles).

50-3.07 Gutter and Combination Curb and Gutter

Treat non-traversable gutter sections and raised barrier curbs as discussed below. Non-traversable gutters are those gutters that could snag a wheel or cause other violent vehicular reactions if traversed by an errant vehicle. Raised barrier curb for this purpose is defined as any curb which will be greater than 3 in. (75 mm) in height after any resurfacing on the project is placed. Corrective work on gutters or curbs may also require revisions to existing drainage structures. If these revisions will result in excessive costs, the designer may consider rebuilding the curb or gutter as traversable.

The following applies to gutters and combination curb and gutter:

1. Remove any non-traversable gutter sections at the edge of traveled way or shoulder, or modify to make them traversable.

2. Remove any raised curb in exit gore area, and level the gore.

3. The removal of raised curb at the edge of shoulder, 1 ft (300 mm) in front of guardrail, and in entrance gore areas is not cost effective when modifications are also required to drainage structures. If no extensive regrading or modification to drainage structures is required, the designer should consider its removal.

4. Remove all curbs greater than 2 in. (50 mm) high in advance of impact attenuator systems or guardrail terminals. If curb is required for drainage or delineation in advance of the impact attenuator or terminal, use a Type M-2 (M-5) curb.

50-3.08 Slopes for Earth Ditch Checks and Permanent Median Crossovers

The following applies:

1. Slopes (No Inlet Boxes). Regrade all existing earth ditch checks and median crossovers without inlet boxes to provide a 1V:10H slope. Note that regrading existing ditch checks may create a condition where motorists may use the ditch check as an illegal crossover. Place 4 in. x 4 in. (100 mm x 100 mm) wood posts in these areas to discourage illegal crossings. See Section 50-3.04(a) for wood post spacing.

2. Slopes (With Inlet Boxes). Treat all existing ditch checks and median crossovers with inlet boxes as follows:

   - If the median width is less than or equal to 42 ft (12.8 m) and the slope of the inlet box is 1V:4H, regrade the ditch check to 1V:10H and install a new inlet box for all ADT's over 50,000. 1V:4H ditch checks may remain if the ADT is less than 50,000.

   - If the median width is 44 ft (13.4 m) or greater, 1V:4H ditch checks may remain in place for all ADT's.

- If the existing inlet box is 1V:6H or flatter, no treatment is necessary regardless of median width or ADT.

Remove any existing ditch checks that are not essential.

50-3.09 Guardrail

Identify and correct all guardrail deficiencies for all ADT. The designer should carefully analyze all existing guardrail installations to determine if the guardrail should be removed or upgraded in accordance with Section 38-6 and the following:

1. Guardrail Removal. An existing guardrail installation should be removed when a life-cycle benefit to cost analysis shows this is preferable to updating, and maintaining the guardrail. Roadside Safety Analysis Program (RSAP), provided by AASHTO, is one tool available for this analysis.

2. Guardrail Upgrading. Follow the analysis in Section 49-3.07(d) to determine whether existing guardrail may remain.

3. End Sections. Ensure all guardrail end sections for existing guardrail meets the approved lists of devices in force in December 2006, or subsequent versions appropriate for later *Highway Standards* for guardrail. Ensure all transitions from guardrail to bridge rails or to structures meet the *Highway Standards* in effect in December 2006, or subsequent versions appropriate for later *Highway Standards* for guardrail.

4. Insufficient Length. Use the length-of-need criteria in Section 38-6.01 to determine the sufficiency of the existing length of guardrail based on the posted speed. Upgrade existing guardrail that is deficient in length by more than 10% to provide a proper length of need. Guardrail less than 10% deficient in length may remain in place unless crash data shows that the additional length will reduce crash severity. Also, provide the proper length of need if placement of a new crashworthy terminal is required. Where practical, the designer should shorten the required length of need by tapering the barrier away from the traveled way.

5. Roadside Cable Barrier. Conduct special studies to determine the installation of new or disposition of existing cable-guard or cable barrier. If it appears desirable to use cable barrier for roadside hazards, see Section 38-6.02. Contact the Bureau of Safety Engineering regarding other possible uses on a case-by-case basis.

6. Cable Median Barrier. See Section 38-07 for guidance. For adjustment of existing cable median barrier, contact the Bureau of Safety Engineering.

7. Median Guardrail at Dual Structures. If the guardrail in the median does not meet MASH or NCHRP 350 , the following corrective treatment is appropriate:

   - Use an appropriate MASH or NCHRP 350 device.

- Remove the non-compliant guardrail and treat the opening between the bridges as a non-traversable roadside obstacle with sufficient length of shoulder-mounted Steel Plate Beam Guardrail, Type A preferably, flared as shown in Figure 38-6.X. For the approach end of the guardrail, provide an appropriate crashworthy end treatment, and provide the appropriate connection to the bridge.

8. Gaps. Unless unusual circumstances dictate otherwise, remove any gaps that are less than 200 ft (60 m) in length between warranted guardrail by installing new guardrail.

9. Re-Grading. Where the remedial treatment recommendation is to add a roadside barrier or impact attenuator system, re-grade the slope of the approach to the barrier or system to be 1V:10H or flatter. This grading shall be sufficient to also provide for a 1V:10H or flatter slope in advance of the barrier or system for a vehicle leaving the roadway at a 5-degree to 10-degree angle.

50-3.10 Impact Attenuator Devices

The following applies:

1. Evaluate any existing impact attenuator devices for conformity with the criteria in Section 38-8. If the array or configuration is inappropriate for the obstacle being shielded, implement any needed modification.

2. Shield any obstacle that warrants an impact attenuator device, which presently has none, with an appropriate system; see Section 38-8.

50-3.11 Concrete Barrier Walls

Correct the approach ends of concrete barrier walls which terminate in the clear zone with an appropriate MASH Test Level 3 end treatment.

50-3.12 Chain Link Fence

Where the ADT is greater than 30,000, modify all lengths of chain link fence located near the edge of the clear zone with a top rail which is susceptible to impact by errant vehicles (either on the mainline or adjacent roadways) by replacing the top rail with tension wire. Replace the top rail for all chain link fence located immediately adjacent to the traveled way for all ADTs.

50-3.13 Crossroads

Upgrade all crossroads, both at interchange and non-interchange locations, for safety within the limits of the original Interstate funding. The safety work will meet the 3R guidelines for the classification of roadway involved. See Chapter 49 and the Bureau of Local Roads and Streets policies. Provide special attention to ramp terminals, and consider improving the turning radii where there is evidence of the design vehicle encroaching on opposing traffic lanes or curbs. See Chapter 37.

Chapter Fifty-three

PAVEMENT PRESERVATION AND REHABILITATION STRATEGIES

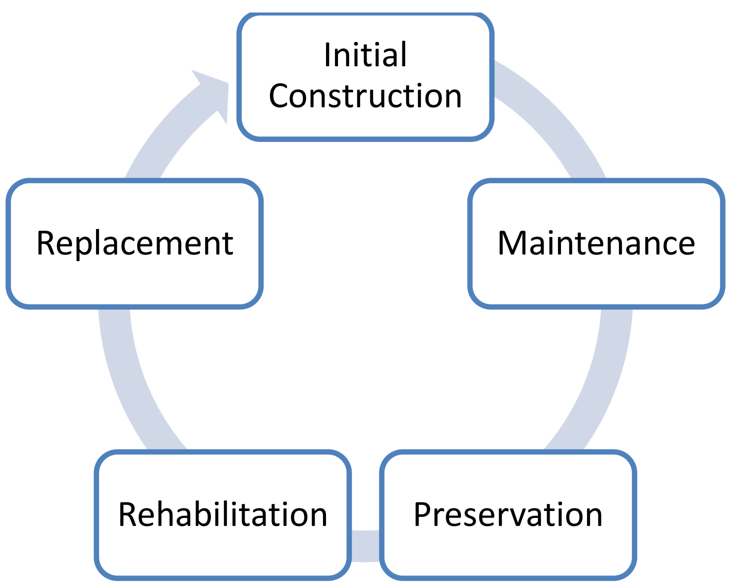
53-1 GENERAL

53-1.01 Scope of Chapter

The Illinois Transportation Asset Management Plan (TAMP) was developed and implemented consistent with the requirements established by 23 U.S.C. 119 and 23 CFR 515. The pavement management aspects of the TAMP are documented in this chapter as well as in the Pavement Management and Evaluation Manual.

This chapter focuses on the preservation and rehabilitation aspects of the pavement life cycle shown in Figure 53-1.A and should be used in conjunction with the Pavement Management and Evaluation Manual. Guidance is given to allow the user to:

- select the proper pavement management methodology,
- gather pavement information,
- identify feasible treatment alternatives,
- select the appropriate treatment, and
- develop the design of the selected treatment.



Pavement Life Cycle

Figure 53-1.A

Pavement design/replacement information is found in Chapter 54. Information previously contained in Chapter 52 has been integrated into this chapter. Contract maintenance program requirements are available in Chapter 12 of the Bureau of Operations Maintenance Policy Manual.

The pavement treatments outlined in this chapter are for pavements on the state system and local pavements on the National Highway System (NHS). Preservation and rehabilitation treatments for local agency pavements off the NHS should be developed using Chapters 45 and 46 of the Bureau of Local Roads and Streets Manual.

53-1.02 Definitions

1. Binder Course. One or more layers of a hot-mix asphalt (HMA) overlay or full-depth pavement structure. A surface course or wearing course must be placed over this course to protect it from environmental effects and provide appropriate friction characteristics.

2. Composite Pavement. A pavement structure consisting of a portland cement concrete (PCC) slab overlaid with HMA. The PCC slab may be either a newly constructed base course or an existing jointed PCC or continuously reinforced concrete pavement.

3. Condition Rating Survey (CRS). The primary pavement performance metric used by the Illinois Department of Transportation (IDOT) to quantify the condition of its pavement assets. CRS values range from 9.0 to 1.0, with 9.0 representing a newly constructed, rehabilitated, or preserved pavement and a 1.0 representing a pavement at the end of its service life.

4. Continuously Reinforced Concrete Pavement (CRCP). A rigid pavement structure having continuous longitudinal reinforcement. The continuous reinforcement is achieved by overlapping the longitudinal steel reinforcing bars.

5. Designed HMA Overlay. A hot-mix asphalt overlay consisting of two or more lifts intended to mitigate the effects of underlying structural distresses and provide a stable wearing surface over an existing pavement.

6. Flexible Pavement. A pavement structure whose surface and principle load distributing component is a combination of HMA binder and surface layers, and potentially coarse aggregate layer(s). These pavements may include both conventional flexible and full-depth HMA pavements.

7. Full-Depth Hot-Mix Asphalt Pavement. A flexible pavement structure that uses HMA throughout the entire thickness (binder course and surface course layers).

8. Jointed Plain Concrete Pavement (JPCP). A rigid pavement structure without reinforcing steel that uses doweled joints for effective load transfer at the transverse joints which are typically spaced at 15 ft (4.6 m). This pavement type is the Department’s default rigid pavement and is shown on Highway Standard 420101.

9. Jointed Reinforced Concrete Pavement (JRCP). A rigid pavement that uses distributed steel reinforcement and transverse contraction joints. This pavement type was discontinued in the late 1980s.

10. Major Rehabilitation. A strategy of placing an overlay with substantial thickness on a pavement in poor condition. These treatments restore serviceability and slow the propagation of underlying structural distresses with an anticipated service life of 10 to 15 years.

11. Minor Rehabilitation. A strategy of either placing an overlay with nominal thickness or recycling the existing HMA on a pavement in fair condition. These treatments reduce or eliminate functional distresses and restore serviceability with an anticipated service life of 10 to 15 years.

12. National Highway System (NHS). The NHS consists of the highway routes and connections to transportation facilities that serve major population centers, international border crossings, ports, airports, public transportation facilities, and other intermodal transportation facilities and other major travel destinations; meets national defense requirements; and serves interstate and interregional travel and commerce.

13. Pavement Field Investigation (PFI). A method of analyzing the existing pavement to determine the appropriate pavement management methodology and/or treatment selection.

14. Pavement Performance. The trend of pavement condition indices over time with respect to traffic and environmental effects.

15. Pavement Preservation. A cost-effective strategy of placing either a non-structural surface or proactive maintenance treatment on a pavement to extend service life at fair or good condition.

16. Pavement Structure. The combination of granular or stabilized subbase and pavement layers (flexible or rigid) which support the traffic load and distribute it to the subgrade.

17. Predicted CRS. The projected CRS value corresponding to the program year in which the treatment will be placed. This value is calculated annually by the Bureau of Programming.

18. Pre-Treatment Activity. An activity (e.g., milling, patching, etc.) that is used to correct a specific distress to improve the pavement condition, enabling the use of a treatment from another category (e.g., improve from standard overlay to pavement preservation).

19. Proactive (Preventive) Maintenance. A strategy of placing a minimal treatment at an early stage of service life in order to prevent deterioration or associated distresses and maintain the condition of the pavement. Preventive maintenance is a cost-effective means of extending the useful life of a pavement.

20. Ramp. A roadway that connects two or more legs at an interchange and includes at least one ramp terminal section. Roadways that connect two legs of freeway and are

continuations of mainline lanes or arise from tapers designed for high-speed operation are not considered ramps but are considered part of the mainline for structural design.

21. Reactive (Routine) Maintenance. Work that is performed in reaction to an event, season, or overall deterioration to restore serviceability of a pavement until a rehabilitation treatment can be constructed. This work includes that which is performed by State Operations forces and as part of the Contract Maintenance program.

22. Rehabilitation. A strategy of either recycling the HMA or placing a layer of HMA or PCC over a pavement in poor to fair condition.

23. Rigid Pavement. A pavement structure whose surface and principle load distributing component is a PCC slab (e.g., JPCP, CRCP, JRCP).

24. Rubblized PCC Pavement. Rubblization is a replacement alternative in which the existing PCC pavement is broken (in-place) into small pieces and compacted to create a uniform base for the new pavement.

25. Standard HMA Overlay. A hot-mix asphalt overlay consisting of two lifts to mitigate the effects of functional distresses and provide a stable wearing surface over an existing pavement.

26. Surface Course (Wearing Course). The top layer of an HMA pavement or overlay which resists skidding, traffic abrasion, and the disintegrating effects of the environment.

27. Surface Treatment. A non-structural, full-width wearing course. Examples include: cape seal, chip seal, micro-surfacing, and slurry seal.

28. Traffic Factor (TF). The total number of 18-kip equivalent single-axle load applications (ESALs) to the design lane anticipated during the design period, expressed in millions. It is used as an equivalency factor for mixed traffic loads.

53-2 PAVEMENT MANAGEMENT METHODOLOGIES

53-2.01 Selection of Pavement Management Methodology

The life cycle of pavements as defined in the TAMP includes initial construction, maintenance, preservation, rehabilitation, and replacement. Initial construction is not covered in this chapter. Figures 53-2.A and 53-2.B illustrate the relationship between the four major categories of treatments discussed here (maintenance, preservation, rehabilitation, and replacement), typical treatments representative of actions taken in those categories, and the CRS range in which those typical treatments are most applicable. These categories are only the initial step and further evaluation may warrant a change in either the category or specific treatment.

Pavement maintenance and preservation are the first levels of treatment. Pavement maintenance is briefly discussed in Section 53-2.02. The pavement preservation methodology is described in detail in Section 53-3. Once the pavement has deteriorated beyond the point where preservation is cost-effective, pavement rehabilitation should be utilized. The complete description of pavement rehabilitation methodology is provided in Section 53-4. As presented above, pavement replacement becomes necessary when pavement rehabilitation is no longer cost-effective. This methodology is discussed in detail in Chapter 54. However, Interstates with ADT < 15,000 and non-Interstates with ADT < 3,000 may receive a major rehabilitation treatment in lieu of Replacement.

Once the appropriate treatment category is determined, the process of matching pavements and treatments includes the following general steps:

- Gather pavement information,
- Identify feasible preservation treatments, and
- Select the most appropriate preservation treatment.

Additional information on activities necessary for final selection of a treatment strategy is contained in the Pavement Management and Evaluation Manual.

53-2.02 Maintenance Methodologies

Maintenance can take the form of preventive (proactive) or routine (reactive). Proactive maintenance activities are included in the pavement preservation category. Reactive maintenance activities are included in the Contract Maintenance program which is administered by the Central Bureau of Operations.

Proactive maintenance is a subcategory of pavement preservation and includes those activities used to prevent water and incompressible material infiltration, surface oxidation, and other environmental factors. These treatments are applied soon after initial construction or rehabilitation and can be reapplied as needed throughout the pavement's life cycle.

When a pavement segment is in need of treatment but cannot be brought into the annual or multi-year program, reactive maintenance can be used as a stop-gap measure to maintain the roadway in a serviceable condition until the program can accommodate the proper treatment for the project. Reactive maintenance is addressed through the contract maintenance program which may be used to supplement the maintenance work effort of state forces and is limited to repair and restoration of immediate needs. The contract maintenance program operates under guidelines issued by the Central Bureau of Operations.

53-2.03 Pavement Preservation Methodologies

Pavement preservation treatments are lower cost, non-structural treatments used to extend the surface life of a pavement before the roadway reaches a condition that requires rehabilitation. These treatments are a cost-effective means of increasing the overall service life of a pavement by addressing functional surface distresses before they progress to a structural issue. Matching the right preservation treatment with the right pavement calls for an awareness of the current condition of the pavement in terms of the types of distresses present as well as their severities. It also helps to understand the typical performance of the pavement in its location and considering how it’s used.

In some cases, the best strategy will consist of a combination of pre-treatment activities and preservation strategies in order to address a pavement’s current and expected performance.

Details on pavement preservation strategies are provided in Section 53-3.

53-2.04 Rehabilitation Methodologies

Rehabilitation consists of improvements made to an existing pavement section that has progressed beyond the limitations of pavement preservation treatments. These strategies remove surface distresses that develop in flexible pavements due to aging and exposure to environmental effects, such as block cracking, raveling, and weathering, as well as reduces the impacts of structural distresses caused by repeated loadings or loss of support. In concrete pavements, pavement rehabilitation consists of the addition of one or more layers of either hot-mix asphalt (HMA) or portland cement concrete (PCC) to address functional or structural distresses and restore ride quality and/or safety. Details on rehabilitation strategies are provided in Section 53-4.

53-2.05 Pavement Replacement Methodology

Once a pavement has insufficient load carrying capacity and can no longer be cost-effectively rehabilitated, the entire pavement structure should be replaced. When selecting this treatment methodology, a complete design and life-cycle cost analysis (LCCA) shall be performed according to Chapter 54 to determine the most cost-effective pavement type.

Category	Subcategory	Treatments	Service Life	Predicted CRS
Do Nothing			N/A	7.6-9.0
Preservation (Section 53-3)	Proactive Maintenance	Crack and Joint Filling, Crack and Joint Sealing, Diamond Grinding, Diamond Grooving, Longitudinal Joint Sealing (Concrete)	2 - 5	> 6.0
	Low	Micro-Surfacing	3 - 7	6.6-7.5
	High	Longitudinal Joint Partial-Depth Repair, SMART Overlay, Ultra-Thin Bonded Wearing Course, Load Transfer Restoration (Transverse Cracking - Concrete) (1)	7 - 12	5.5 - 6.5
Rehabilitation (Section 53-4)	Minor	Bonded Concrete Overlay on Asphalt (2), Standard HMA Overlay	10 - 15	4.6-5.4
	Major	Designed HMA Overlay, Structural Concrete Overlay (Requires an exception) (1)	10 - 15	4.0-4.5
Replacement (3) (Chapter 54)		Replacement of complete pavement structure, New Pavement (HMA or PCC) over Rubblized PCC, Unbonded Concrete Overlay	30-40	< 4.0
Contract Maintenance	Reactive Measures	See Contract Maintenance Program Guidelines (4)	Varies	< 5.5 (5)

Notes:
(1) Treatment will require an experimental feature according to Construction Memo 02-2.

(2) Bonded Concrete Overlay on Asphalt is limited to pavements with a rigid traffic factor less than or equal to 7.5.

(3) Interstates with ADT < 15,000 may receive a major rehabilitation treatment in lieu of replacement.

(4) Low Preservation treatments may be used as a stop-gap measure. High Preservation activities of Full-depth Repairs and Longitudinal Joint Partial-Depth Repair are allowed as Reactive Measures. HMA Surface Mill and Replacement will be approved on a case-by-case basis.

(5) For localized failures, any CRS value may be considered (patching, centerline failures, intermittent locations of surface repairs).

Interstate TAMP Category Selection Criteria - Pavements

Figure 53-2.A

Category	Subcategory	Treatments	Service Life	Predicted CRS
Do Nothing			N/A	7.6-9.0
Preservation (Section 53-3)	Proactive Maintenance	Crack and Joint Filling, Crack and Joint Sealing, Diamond Grinding, Diamond Grooving, Longitudinal Joint Sealing (Concrete)	2 - 5	> 6.0
	Low	Cape Seal, Chip Seal (A-1, A-2, A-3), Half-SMART, Micro-Surfacing	3 - 7	6.6 - 7.5
	High	Longitudinal Joint Partial-Depth Repair, Hot In-Place Recycling (1), SMART Overlay, Ultra-Thin Bonded Wearing Course, Load Transfer Restoration (Transverse Cracking - Concrete) (1)	7 - 12	5.0 - 6.5
Rehabilitation (Section 53-4)	Minor	Bonded Concrete Overlay on Asphalt (2), Cold In-Place Recycling (Requires a Design Exception) (1), Standard HMA Overlay	10 - 15	4.1 - 4.9
	Major	Designed HMA Overlay, Structural Concrete Overlay (Requires an exception) (1)	10 – 15	3.5 - 4.0
Replacement (3) (Chapter 54)		Replacement of complete pavement structure, New Pavement (HMA or PCC) over Rubblized PCC, Unbonded Concrete Overlay	30-40	< 3.5
Contract Maintenance	Reactive Measures	See Contract Maintenance Program Guidelines (4)	Varies	< 5.0 (5)

Notes:

(1) Treatment will require an experimental feature according to Construction Memo 02-2.

(2) Bonded Concrete Overlay on Asphalt is limited to pavements with a rigid traffic factor less than or equal to 7.5.

(3) Projects with ADT < 3,000 may receive a Major Rehabilitation treatment in lieu of Replacement.

(4) Low Preservation treatments may be used as a stop-gap measure. High Preservation activities of Full-depth Repairs and Longitudinal Joint Partial-Depth Repair are allowed as Reactive Measures. HMA Surface Mill and Replacement will be approved on a case-by-case basis.

(5) For localized failures, any CRS value may be considered (patching, centerline failures, intermittent locations of surface repairs).

Non-Interstate TAMP Category Selection Criteria - Pavements

Figure 53-2.B

53-2.06 Pavement Information Needed for Treatment Selection

Good treatment selection is guided by understanding as much as possible about the overall pavement structure, such as pavement type, overall pavement age and age of surface, traffic volumes, and pavement typical sections and materials. Much of this information is currently found in several databases within IDOT. The databases are identified in detail in the Pavement Management and Evaluation Manual. Once IDOT's Enterprise Asset Management System (EAMS) is implemented, it will allow data from multiple databases to be viewed in one central location and evaluated comprehensively.

Knowing the existing pavement structure and materials properties can be very useful to determine which treatment(s) will work best with the current structure and how the pavement section might perform in the future. Depending on the methodology being considered, a pavement field investigation (PFI) may be required. Details on the requirements for PFIs can be found in the Pavement Management and Evaluation Manual.

53-2.07 Pre-Treatment Activities and Other Factors

When determining final treatment selection, all aspects of the project must be considered to ensure a comprehensive approach, which will maximize performance. These include pre-treatment activities, secondary considerations, and additional design features.

53-2.07(a) Pre-Treatment Activities

When pavement preservation and rehabilitation treatments are being determined, pre-treatment activities can be used to eliminate or reduce distresses that are prohibiting the use of specific treatments and/or to improve the performance of the chosen treatment. The following pre-treatment activities, summarized in Section 53-5.05, may be considered based on the existing pavement type and results of the PFI.

- Cold Milling / Fine Milling
- Full-Depth CRCP Patches (Class A)
- Full-Depth Dowelled Patches (Class B)
- Full-Depth Undowelled Patches (Class C and Class D)
- Partial-Depth Patches
- Longitudinal Crack Repair

53-2.07(b) Secondary Considerations

Other factors that should be considered when making the final selection include ADA ramps, ADT, traffic control operations, constraints (e.g., bridge clearances, ramps, side slopes), condition of adjacent pavements, and costs. Job limits shall be extended to include intersections within 500 feet of paving and other improvement project termini for the inclusion of bicycle and pedestrian features. Job limits shall be extended to include intersections within 500 feet of paving and other improvement project termini for the inclusion of bicycle and pedestrian features. Improvements within the scope of Chapter 17 Part 1.02 should be considered. Normal project termini should remain in place.

53-2.07(c) Additional Design Features

While developing the scope of a project, the pavement section needs to be reviewed to determine if any additional design features will require attention, while the preservation or rehabilitation treatment is being constructed. The following additional design features, summarized in Section 53-5.05, should be evaluated to determine if they are still functioning properly.

1. Pipe Underdrains. Pavement distress can be accompanied by pumping of the subbase and subgrade material. For this reason, it is important to evaluate the need for underdrain installation. As part of a rehabilitation or replacement project, pipe underdrains should be installed on the Interstate System and other freeway facilities that are designed to Interstate criteria, if they have not been previously installed. Although pipe underdrains are not mandatory on non-Interstate primary facilities, they can be very useful where existing drainage problems exist. Pipe underdrains should be installed prior to patching unless there are valid reasons to do otherwise.

   See the *Highway Standards* for underdrain installation details for Interstate highways. Depending on the type of underdrain material specified, it may be necessary to adjust the depth of the underdrain to accommodate outfall drainage into existing shallow roadside ditches. Ensure the depth is sufficient to prevent overstressing the underdrain material. Generally, pipe will not be overstressed if the trench depth is 24 in. or greater. Consult the Engineer of Pavement Technology in the Bureau of Research for guidance if it is necessary to place pipe in shallower trenches. If deep roadside ditches or high fills are encountered, consider shifting the locations of pipe drain laterals to avoid outfall onto the long steep slopes. Replace any aggregate outlets of existing outfall pipe drains with concrete headwall outlets. If pipe underdrains have been installed on a previous contract, investigate to determine the need for cleaning or repairing the underdrain system.

2. Expansion and Terminal Joints. Expansion joints on PCC pavements and overlays of PCC pavements should be visually inspected to determine if they are in working order. If patching is an integral part of the rehabilitation strategy, closed expansion joints should be re-established regardless of the type of patching that is specified.

   Existing lug systems and/or wide flange beam terminal joints on CRCPs and overlays of CRCPs and should be closely inspected to determine if the joint is working properly both at the beam and at the expansion joint between the beam and the bridge approach or jointed pavement. In addition, the flange of the beam should be inspected for signs of fatigue cracking. When a terminal joint is determined to be non-functioning, contact the Pavement Design Engineer in the Bureau of Research for assistance in selecting a treatment strategy.

53-2.08 Exception Requests

If the district would like to deviate from the TAMP category selection criteria or the overlay policies contained in Chapter 53, an exception request will be required.

53-2.08(a) TAMP Category Selection Exception Requests

If the pavement investigation report indicates that a deviation from the category recommended by Figures 53-2.A or 53-2.B or a rehabilitation treatment recommended by Figure 53-4.A is the best alternative, a TAMP category selection exception request will be required when the project is entering the first three years of the multi-year program. Examples of TAMP category selection exception requests include:

- When Figure 53-2.A or Figure 53-2.B recommends replacement, however, the pavement evaluation indicates that rehabilitation is a better alternative.
- When Figure 53-4.A recommends minor rehabilitation, however the pavement evaluation indicates major rehabilitation is a better alternative.

53-2.08(b) Overlay Policy Exception Requests

An overlay policy exception request is required when either a lift thickness(es) would deviate from Figure 53-4.J in either the standard or designed overlays, or when there is preference to use a single lift instead of two lifts for an HMA overlay. This exception request must be submitted prior to the project entering the annual program.

53-2.08(c) Exception Request Submittals

All exception requests shall be submitted to the Asset Management Engineer in the Bureau of Programming, and the documentation shall include the following information:

1. Length and Limits of Project/Limits of Request. If the condition of the section is variable, clearly define the limits of the distressed areas that require additional thickness by station or log mile rather than requesting additional thickness over the entire project. Include the key route inventory number and the key route mileposts.
2. Traffic. Document traffic volumes including breakdown of passenger vehicles, single-unit trucks, and multiple-unit trucks.
3. Pavement History. Include the date of construction, pavement cross-section data, date and description of previous rehabilitations, current and historical CRS ratings, and distress history.
4. Pavement Investigation Report.

a. Existing Condition. Include the type, severity, and frequency of distress (including photos); directional differences, faulting measurements; rutting measurements; and estimated patching quantities.

b. Core Data. When core data is required, photos and descriptions of the cores and information on the quantity and location should be included. When available, additional information on the material characteristics of those cores should also be provided, such as: densities (%), conditioned split tensile strength (psi), and strip rating (numeric rating).

5. Calculations and Estimates. Include all relevant supporting calculations and cost estimates.

6. Other. Include any other supporting evidence and test data and photographs.

Based on the type of exception request, content of the submittal, and the total length of the project, a joint review with the district, the Asset Management Engineer in the Bureau of Programming, and the Engineer of Pavement Technology in the Bureau of Research may be warranted.

53-3 PAVEMENT PRESERVATION TREATMENT SELECTION GUIDELINES

53-3.01 Identify Feasible Preservation Treatments

When identifying the appropriate pavement preservation treatment for candidate projects, analyze the type and severity of pavement distresses present on the pavement, as well as other relevant collected information, to match pavement and project characteristics with treatment capabilities. Figures 53-3.A, 53-3.B, and 53-3.C can then be used to help identify feasible preservation treatments for flexible, composite, and rigid pavements. These figures provide guidance for treatment selection based upon attributes such as distresses and their level of severity, ride, friction, traffic levels, and relative costs. They relate a single distress or other characteristic to a single treatment; where there are multiple distresses, examine the appropriate treatment(s) to address each distress type. Then, use the recommended treatment(s) in combination with engineering judgment to make a final treatment selection.

Note that this process is not expected to result in the identification of a single treatment that is appropriate for a given set of site conditions; rather it is much more likely that there will be a number of feasible treatments that address those conditions. Therefore, there is at least one more step in the treatment selection process.

53-3.02 Select Appropriate Preservation Treatment

The selection of the most appropriate preservation treatment includes considering the various constraints on a project that affect treatment selection. The following list identifies some of the project constraints that should be considered when selecting the most appropriate preservation treatment.

- Availability of qualified contractors,
- Availability of quality materials,
- Time (of year) of construction,
- Initial costs,
- Ride quality (i.e., International Roughness Index),
- Pavement noise,
- Facility downtime, and
- Surface friction.

The effects of these constraints vary from project to project and should be reviewed for each project when finalizing treatment selection. Contact the Bureau of Research if assistance is needed in evaluating various treatment options to address constraints.

		Proactive Maintenance		Low Preservation Treatments [1]					High Preservation Treatments [1]			
Pavement Conditions	Severity Levels	Crack & Joint Filling/ Sealing	Diamond Grinding	Long. Jt. Micro-surfacing	Cape Seal [2]	Chip Seal [2]	Half-SMART [2]	Micro-surfacing [3]	Long. Jt. PD Repair	HIR [2]	SMART Overlay	UTBWC
Alligator/ Fatigue Cracking	L1	R	R	N/A	R**	R**	R**	R**	N/A	R	R	R
	L2, L3, L4	NR	NR	N/A	NR	NR	NR	NR	N/A	NR	NR	NR
Block Cracking	M1, M2	R	R	N/A	R	R	R	R	N/A	R	R	R
	M3	R	R	N/A	NR	NR	NR	NR	N/A	R	R	R
	M4	NR	NR	N/A	NR	NR	NR	NR	N/A	NR	NR	NR

R - Recommended treatment. Care must be taken to ensure all critical distress types are addressed by selected treatment.

R* - Recommended treatment when used with milling prior to treatment.

R** - If milling is not included as a mitigating activity, crack sealing is recommended one year prior to treatment.

F - Feasible treatment but depends upon other project constraints including other existing distresses.

F* - This is a localized distress and should be treated locally while other distress types present should dictate choice of global treatment.

NR - Treatment is not recommended to correct the specified pavement condition.

N/A - Distress does not impact treatment selection.

1 - Full-Depth and Partial-Depth patching only allowed as a mitigating activity. A maximum of 0.50 percent will be allowed with any preservation treatment.

2 - Treatment not allowed on Interstate pavements.

3 - ADT ≤ 25,000 use 1-pass; ADT > 25,000 use 2-pass

4 - If only distress present, use indicated treatments. If other distreses are present, use the treatment that addresses the distresses across the full lane.

R - Recommended treatment. Care must be taken to ensure all critical distress types are addressed by selected treatment.

R* - Recommended when used in conjunction with LTR.

F - Feasible treatment but depends upon other project constraints including other existing distresses.

F* - Feasible treatment if poor ride is a result of undoweled joints or faulted transverse (mid-slab) cracking.

F** - Other distress types should dictate choice of treatment.

NR - Treatment is not recommended to correct the specified pavement condition.

N/A - Distress does not impact treatment selection.

1- Full-Depth and Partial-Depth patching will only be allowed as a mitigating activity. A maximum of 0.50 percent will be allowed.

2 - If intermittent bump grinding, no additional activity necessary. Large areas of > 100 ft in length require diamond grooving.

3 - LTR (Load Transfer Restoration) is normally used in combination with diamond grinding.

TREATMENT SELECTION GUIDELINES FOR RIGID PAVEMENTS

Figure 53-3.C

53-3.03 Pavement Preservation Treatments

Available and commonly used pavement preservation treatments are summarized in this section by TAMP subcategory (proactive maintenance, low preservation, high preservation). Further details regarding the treatments are available in the *IDOT Standard Specifications*, supplemental specifications, and special provisions. One-page treatment summaries may be found in Section 53-5 and include additional detail on each treatment. Utilize the guidance contained there to select the final treatment.

53-3.04 Other Factors

There are several other factors that must be addressed during the selection and/or design of various pavement preservation techniques.

53-3.04(a) Shoulders Versus Mainline

Pavement preservation treatments may be different between mainline and shoulders. Some spray applications that are not allowed for high-speed mainline sections may be used on shoulders since that is not the travel lane.

53-3.04(b) Pavement Markings and Raised Reflective Pavement Markers

All pavement markings, except latex paint, shall be removed prior to placement of a preservation treatment. Review all pavement sections for the presence of raised reflective pavement markers (RRPMs) prior to treatment placement for edge-to-edge treatments. RRPMs cannot be masked to protect and leave in place. All treatments will require removal and replacement of RRPMs.

53-3.04(c) Rumble Strips

Care shall be taken to avoid reducing the effectiveness of existing rumble strips when applying pavement preservation treatments.

53-3.04(d) Surface Preparation

Pavement preservation treatments are thin compared to a traditional two-lift HMA overlay and certain existing conditions will negatively impact their performance if not addressed. These conditions include, but are not limited, to the following.

1. Existing Pavement Markings. Some pavement preservation treatments require complete removal of all pavement markings before placement (e.g., thermoplastic, paint). When designing a project, review construction requirements of the selected treatment to determine if this work is required.

2. Roughness. Most thin preservation treatments will not improve a rough ride, unless multiple applications are used. Even then, there are limitations to how much roughness can be corrected. Bumps greater than 0.5 in. (12.5 mm) (measured using a 16-ft [4.9 m] straightedge) should be ground off prior to construction, unless the project includes surface milling or recycling. If excessive bump grinding would be required, consider treating the entire surface with fine milling.

3. Insufficient Cross Slope. Preservation treatments are not thick enough to adjust pavement cross slope when it is needed. If a pavement needs cross slope improvements, this should be accomplished by milling.

4. Cracking. Medium and high severity cracks will reflect through a preservation treatment. Proactive crack sealing should be completed at least 3 months prior to the placement of the treatment to minimize difficulties in constructing the treatment. If considering as a pre-treatment activity before pavement preservation, investigate the possibility of performing a sealing contract in the previous construction season. The sealant should be flush with or slightly below the surface of the pavement to minimize bleed-through.

53-3.04(e) Pavement Markings

A period of several days of good drying weather is necessary prior to the placement of permanent markings on various flexible pavement preservation treatments. Review each treatment specification to determine how much time is needed. Temporary markings of water-based paint or foil-backed tape will be necessary until permanent markings can be applied.

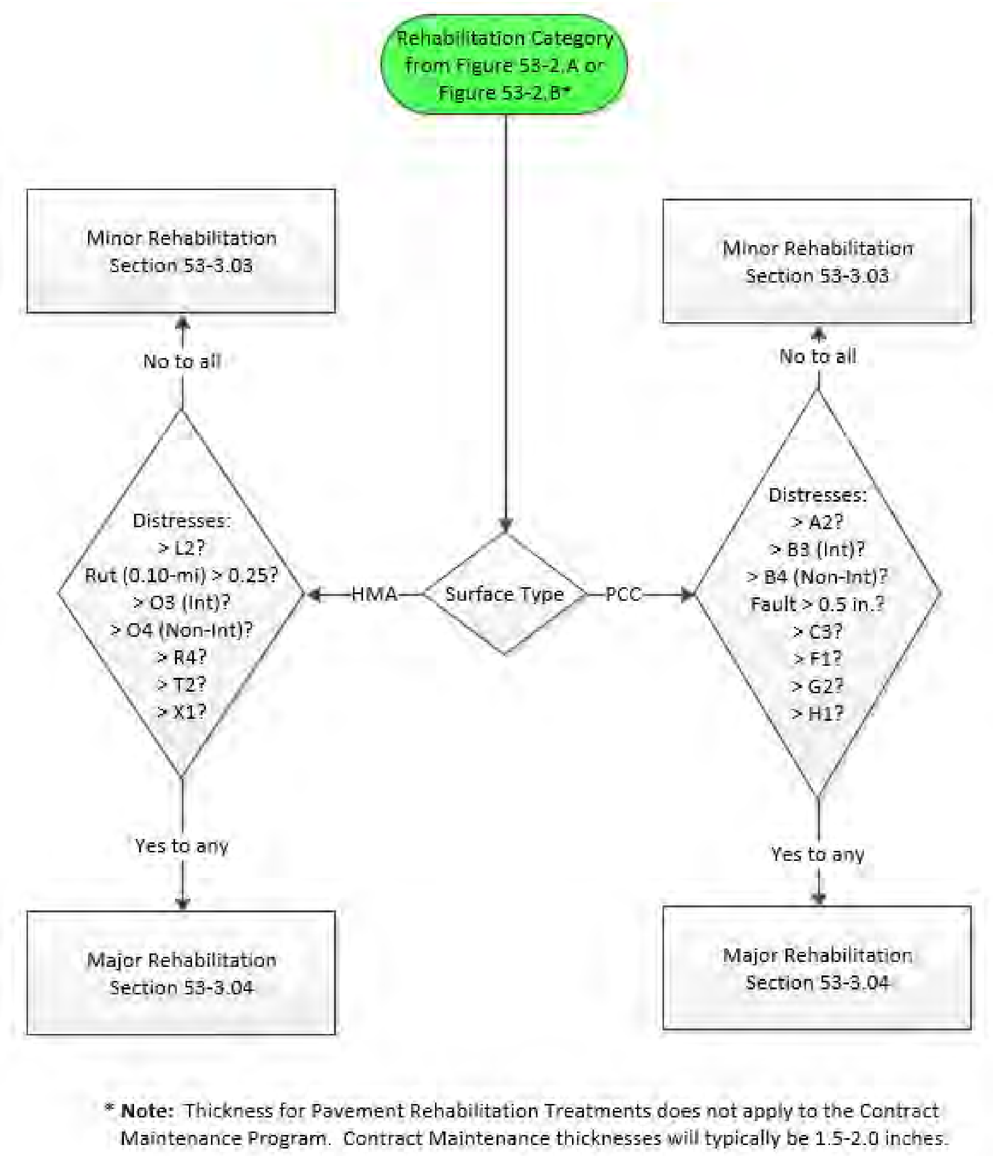
53-3.04(f) Timing Treatment Application

The weather limitations for the selected treatment must be considered when determining the letting date. Some treatments have small ranges of dates and/or temperatures in which they can be constructed. Schedule the letting at a time to avoid late season paving to promote proper cure of the treatment prior to the onset of winter.

53-4 PAVEMENT REHABILITATION TREATMENT SELECTION GUIDELINES

53-4.01 Select Appropriate Pavement Rehabilitation Treatment

Figure 53-4.A provides the decision tree for initial selection of the rehabilitation treatment based on the surface type of pavement and the presence of high severity structural distresses. Use this figure in conjunction with the PFI data as described in the Pavement Management and Evaluation Manual to make a final determination of rehabilitation subcategory (minor or major rehabilitation). Once the final subcategory has been established, utilize the guidance in the one-page treatment summaries to select the final treatment.



REHABILITATION TREATMENT SELECTION

Figure 53-4.A

53-4.02 Minor Pavement Rehabilitation Treatments

A rehabilitation strategy normally is developed and targeted to address specific deficiencies with a particular pavement type. The strategy usually will be a combination of a rehabilitation treatment and one or more mitigating activities that, when completed, will correct deficiencies (i.e., functional failure, structural failure, or both) in the most cost-effective manner. The following pages provide brief descriptions of the pavement rehabilitation treatments typically used by the Department. Use these descriptions to better understand each rehabilitation treatment's purpose and application when developing alternative rehabilitation strategies.

Minor rehabilitation options include standard HMA overlays and bonded concrete overlays on asphalt (BCOA).

1. For a Standard HMA Overlay, use the appropriate thickness guidelines presented in Section 53-4.02(a). HMA mixture design criteria must be met as outlined in Section 53-4.04.

2. When a BCOA is selected, the overlay should follow the guidelines in Section 53-4.02(b).

53-4.02(a) Standard HMA Overlay

If the projected CRS value for the pavement section is within the range for minor rehabilitation according to Figure 53-4.A and the PFI concurs, a standard HMA overlay may be selected.

1. Milling. For HMA-surfaced pavements, the milling depth should remove the entire existing surface lift. When determining milling depth, avoid milling within 0.50 in. of an HMA lift line or within 1.0 in. above underlying PCC whenever possible to eliminate scabbing.

   If there are constraints such as curb and gutter or other profile limits, take pavement cores to better define milling depth and required HMA lift thickness.

2. Number of Lifts. Full-depth HMA pavements may use a single lift of 2.00 in. (50 mm). All other pavement types will require the use of two lifts; however, a single 2-in. (50-mm) lift may be requested as an overlay policy exception according to Section 53-2.08.

3. Thickness. The resurfacing thickness for standard HMA overlays shall be according to the following.

   a. Interstates. Two lifts with a total thickness of 3.00 to 4.25 in.

   b. Other State Maintained Highways. Two lifts with a total thickness of 2.00 to 2.75 in. Bare PCC will require a minimum total thickness of 2.50 in.

53-4.02(b) Bonded Concrete Overlay on Asphalt (BCOA)

A bonded concrete overlay on asphalt is a rehabilitation strategy that involves a 3.0 in. to 6.0 in. portland cement concrete overlay over an existing HMA surface. The BCOA procedure does not apply to concrete thickness greater than 6.0 in. For thicker concrete slab designs, an unbonded concrete overlay, which is a pavement replacement option, should be considered. This alternative rehabilitation strategy shall apply to Class I, II, III, and IV pavements, but shall not be used when the traffic factor (based on the rigid pavement equations) exceeds 7.5.

The BCOA treatment requires bonding between the new PCC surface and the underlying HMA as well as selecting slab sizes to balance the number of joints with debonding potential and increased slab stresses.

The successful application of BCOA requires a thorough field evaluation of the existing pavement, as well as close attention to profile, elevation, pavement cross section, and utility adjustments. See the bonded concrete overlay on asphalt pavement evaluation information contained in the Pavement Management and Evaluation Manual for more details.

The existing pavement surface shall be milled to correct the longitudinal and transverse profile, remove surface irregularities, and to maintain an acceptable cross-slope. Milling will also promote better bonding between the HMA and new PCC layer. The existing HMA layer, or remaining HMA after milling, shall be a minimum of 2.5 in. thick. If the remaining HMA does not meet this requirement, mill the entire HMA layer and replace with 2.5 in. new HMA to provide a good surface for the new concrete.

If a portion of the BCOA in excess of 5% will be bonded directly to bare concrete, brick, or other old slabs of concrete, this rehabilitation method shall not be used. This 5% limitation allows for existing concrete patches or other existing pavement features. Construction may be hindered by complicated geometrics, utility obstructions, traffic demand, and condition of the existing pavement.

To ensure good performance, synthetic macrofibers are specified for all BCOA projects. Synthetic macrofibers increase the structural capacity of concrete overlays by increasing the concrete material toughness. Additionally, synthetic microfibers are used to minimize the effects of plastic shrinkage cracks.

1. Procedures. All proposed BCOA projects must be submitted to the Bureau of Research for approval. The request should be documented in a “BCOA Project Request Report” and should include the following:

    - Preliminary and detailed pavement investigations, including performance testing of the existing HMA surface to remain in place,
    - existing and proposed cross sections,
    - existing and projected traffic information,
    - construction sequencing and proposed traffic control,
    - a document summarizing why the BCOA option is preferred over other rehabilitation alternatives.

Guidelines regarding the items to be included in the report and other BCOA design details are provided in the following sections. The designer should review all requirements and conduct preliminary calculations to check for feasibility before proceeding with detailed assessments.

2. Identify Design Considerations. There are several design issues that must be considered before submitting a BCOA rehabilitation proposal for review and approval. Issues that the designers should accommodate for prior to design submission for review are as follows:

   a. Design Period. The design period to be used for this rehabilitation strategy is 15 years.

   b. Drainage Considerations. Maintaining proper drainage through design and during construction is important. During construction, maintaining drainage is especially critical for projects that include an inlay. Repairing inadequate surface, subsurface, and/or lateral drainage may be required in certain locations prior to placement of a BCOA.

   c. Thickness Design and Joint Spacing. Using macrofibers in the mix, the bonded concrete overlay thickness design is based on the traffic factor, the underlying HMA thickness, and the panel size. The concrete thickness shall be 3.0 in. to 6.0 in. with 0.50 in. increments allowed.

      The traffic factor shall be determined according to the applicable equation for each pavement class using the equations in Section 54-4.01(g). Based on the traffic factor, the thickness of the underlying HMA material, and panel size, the bonded concrete overlay thickness may be determined either from Figures 53-4.B through 53-4.I or by using a computer program which is available from BDE: www.dot.il.gov/desenv/pdp.html.

      This program allows the designer to input the traffic factor, the thickness of the underlying HMA material, panel size, and macrofibers residual strength to calculate the bonded concrete overlay thickness. The result from the program is rounded up to the nearest 0.50 in.

      The thicknesses shown in Figures 53-4.B through 53-4.I were calculated using the computer program with the following default values as design inputs:

      Elastic Modulus of HMA Layer (E_{AC}) = 350,000 psi
      Elastic Modulus of PCC Overlay or Inlay (E_C) = 3,600,000 psi
      Modulus of Rupture (*MOR*) = 750 psi
      Residual strength (F_{150}) = 150 psi
      Modulus of Subgrade (*k*)= 100 pci
      Coefficient of Thermal Expansion (*CTE*) = 5.5 x 10^{-6} in./in./°F
      Percent of Panels with Cracking (P_{cr}) = 20%
      Reliability Factor (*R*) = 85%
      Temperature Gradient (ΔT) = -1.4 °F/in.
      Occurrence of Temperature Gradient (*% Time*) = 58%

A key to the successful application of BCOA is longitudinal and transverse jointing. These joints are saw cut into hardened concrete to relieve stresses due to drying and thermal shrinkage as well as curling. The joints should be laid out on a regular pattern for both longitudinal and transverse directions (to form panels) based on the spacing used to determine the thickness. No skewed joints will be allowed.

Transverse and longitudinal joints should be laid out to match existing joints, utility obstructions, and geometrics of the existing pavement when PCC pavement is exposed during milling. When feasible, longitudinal joints should be laid out to avoid the wheelpath areas of the traveling lanes. Typically, this means 6 ft slab sizes should be selected to avoid longitudinal contraction joints in the wheelpath that occur with 4 ft panel sizes. The layout of all transverse and longitudinal joints should be detailed on the plan sheets.

The cost of sawing may significantly influence the cost of the BCOA. A thicker overlay may be more economical than a thinner one because the greater thickness may increase the joint spacing, resulting in less sawing.

The following list defines the variables shown in Figures 53-4.B through 53-4.I.

F_{150} = Residual Strength (psi) calculated at a net deflection of L/150 (L = span length) or 3 mm in accordance with ASTM C1609-12.

h_{ac} = Thickness of existing remaining HMA after milling.

h_c = Thickness of new bonded concrete overlay.

L = Maximum joint spacing in the longitudinal and transverse directions.

d. Final Finish. Locations with a posted speed limit greater than 40 mph shall use a Type A final finish. All other locations shall use a rough broom final finish struck perpendicular to the direction of traffic flow in lieu of a Type B final finish. The rough broom finish shall be used across the entire surface area of the PCC surface.

e. Traffic Control. The control of traffic through the project must be considered and well established prior to time of construction. The best alternative for traffic control is to completely close the project to traffic. This alternative may be difficult for urban projects; however, somewhat easier for rural projects. If closure to traffic is not possible, traffic control must be established that will effectively move traffic through the project with minimal disruption to construction operations and traffic flow. Traffic control that can be left unattended overnight must be anticipated for each stage of construction.

f. Construction Staging. Construction staging for a bonded concrete overlay on asphalt project must be considered with respect to the construction timeframe and traffic flow through the project. The project must be staged in such a way that continuous traffic flow will be maintained. Construction staging must also consider the geometrics of the project and any lane to lane drop off restrictions that may be present with the overlay thickness.

A PCC traffic opening strength of 550 psi flexural or 3,000 psi compressive is required. The current PCC mix design specified may obtain the opening strength in as little as three days if properly proportioned. If the BCOA must be opened to traffic in a shorter time frame, consult the District Materials Office for an acceptable high-early-strength PCC mixture. The risk of excessive shrinkage and debonding increases at higher cement contents and with thinner slabs.

3. Request for Review and Approval. Upon completion of the BCOA analysis, a completed "BCOA Project Request Report" should be submitted to the Bureau of Research for review and approval. Contact the Engineer of Pavement Technology in the Bureau of Research for an example of a "BCOA Project Request Report."

If the program is used in lieu of Figures 53-4.B through 53-4.I to determine the thickness, the BCOA Project Request Report must include screenshots of the program indicating the inputs used for the design.

53-4.03 Major Rehabilitation Treatments

Major Rehabilitation treatment options include Designed HMA Overlays and Structural Concrete Overlays (SCO).

1. For a Designed HMA Overlay, use the appropriate thickness guidelines presented in Section 53-4.03(a). HMA mixture design criteria must be met as outlined in Section 53- 4.04.

2. SCO is still considered experimental by the Department. Selection of this treatment as the rehabilitation method must be approved by the Bureau of Research. Design thickness and specification development for the overlay shall also be coordinated through the Bureau of Research.

53-4.03(a) HMA Designed Overlay

If the projected CRS value for the pavement section is within the range for major rehabilitation according to Figure 53-4.A and the PFI results concur, an HMA Designed Overlay may be selected as the rehabilitation treatment.

1. Milling. For HMA-surfaced pavements, consult the Pavement Investigation Report to determine the appropriate milling depth. When determining milling depth, avoid milling either within 0.50 in. of a HMA lift line or within 1.0 in. above underlying PCC whenever possible to eliminate scabbing. If proposed milling thickness exceeds the new overlay thickness, contact the Bureau of Research to confirm residual pavement structure and final milling thickness.

2. Number of Lifts. All pavement types will use a minimum of two lifts.

3. Thickness. A thickness design procedure is still under development. Until the procedure is completed, HMA Designed Overlays will use the following default thicknesses.

   a. Interstates. 5.00 in.

   b. Other State Maintained Highways. 3.75 in.

   The mixture gradations and lift thicknesses shall be selected from Figure 53-4.J.

53-4.03(b) Structural Concrete Overlay (SCO)

When a pavement section has experienced structural deterioration with a high frequency of working cracks, an HMA overlay may not be the best option due to the propensity for reflective cracking. At this point, the best option is a SCO. The SCO consists of placing a non-reinforced layer of PCC pavement that is sawed both longitudinally and transversely to create panels.

This treatment utilizes an interlayer that serves as a bond breaker over an existing distressed pavement which insulates the overlay from the underlying distresses. If the pavement has been previously resurfaced with HMA, the surface may be milled to correct profile irregularities and use the remaining existing HMA overlay as the interlayer. If the pavement is bare PCC, an interlayer shall be placed as a bond breaker.

Pavements that have high severity structural distresses (e.g., frequent, high severity transverse cracking) are suited for this treatment to reduce the potential for reflective cracking in the overlay.

This treatment has had limited use and is still considered experimental. The district must work with the Bureau of Research to design the PCC thickness, interlayer type and thickness, and joint spacing for the SCO.

Use of the SCO requires an experimental feature according to Construction Memo 02-2 and approval by the Bureau of Research. Contact the Engineer of Pavement Technology in the Bureau of Research for additional information on use and design of this treatment.

53-4.04 HMA Design Guidelines

These guidelines apply to all HMA construction.

53-4.04(a) Minimum HMA Lift Thickness

The mixture gradations and lift thicknesses shall be selected from Figure 53-4.J.

Mixture Gradation	Type of Lift	Minimum Compacted Lift Thickness (in.)
IL 4.75	Binder only	0.75 – Over HMA Surface 1.00 – Over PCC Surface
IL-9.5FG	Surface or Binder	1.25
IL-9.5, IL-9.5L	Surface or Binder	1.50
SMA-9.5	Surface or Binder	1.50
SMA 12.5	Surface or Binder	2.00
IL-19.0, IL 19.0L	Binder only	2.25

LIFT THICKNESS REQUIREMENTS FOR HMA OVERLAYS

Figure 53-4.J

53-4.04(b) HMA Mixture Requirements Table

Figure 53-4.K was designed to accommodate HMA mixtures and is required to be completed and inserted into the General Notes of the project plans for each HMA mixture application specified.

The following HMA mixture requirements are applicable for this project:

Location(s):	
Mixture Use(s):	
PG:	
Design Air Voids:	
Mixture Composition:	
Friction Aggregate:	
Mixture Weight:	
Quality Management Program:	
Sublot Size:	
Material Transfer Device (Required?)	

HMA MIXTURE REQUIREMENTS TABLE

Figure 53-4.K

Use the following guidelines to complete the table in Figure 53-4.K:

1. Location(s). Specify, by route number or stationing, the location(s) where the mix will be placed.

2. Mixture Use(s). Corresponds to the generic description of the mixture(s) (i.e., surface course, binder, base course, shoulders, etc.). On full-depth projects, specify the lift (e.g., "full-depth, lower binder," "full-depth, top binder," or "full-depth, surface").

3. PG. Specify the Performance-Graded (PG) binder for the mixture, including polymer modified asphalt binder (e.g., PG64-28, SBS-PG64-28, PG70-22, SBS-PG70-22). The PG binder grade shall be specified without consideration of RAP and/or RAS addition. Obtain the required PG binder designation from the District Materials Engineer.

4. Design Air Voids. Specify the target air void content for the mixture. For example, "4.0% @ N_{design} = 50", "4.0% @ N_{design} = 70", etc. All HMA mixtures will typically require 4.0% air voids; however, the N_{design} number will change. Obtain the N_{design} number from the District Materials Engineer.

5. Mixture Composition. Specify the aggregate gradation for the mixture design:

   - IL-19.0 – binder.
   - IL-19.0L – low volume binder.
   - IL-9.5 – surface or binder.
   - IL-9.5L – low volume surface.
   - IL-9.5FG – fine-graded surface or binder.

- IL-4.75 – binder.
- SMA-12.5 – surface or binder.
- SMA-9.5 – surface or binder.

6. Friction Aggregate. Specify the aggregate to be used to meet surface course friction requirements (i.e., Mixture C, Mixture D, Mixture E, Mixture F). Because there are no friction requirements for binder courses, leave this entry blank when specifying binder courses. Refer to Section 53-4.04(f) for additional information.

7. Mixture Weight. Specify the unit weight used to determine the plan quantities for HMA surface course. Use 112.0 lb/sq yd/in. thickness as the unit weight for typical standard mixes using natural aggregate. For a specialty mix design, such as those using synthetic aggregates with differing unit weights (e.g., air-cooled blast furnace slag (light) or steel slag (heavy)), the designer should consult the District Materials Engineer to determine the anticipated unit weight.

8. Quality Management Program. Specify which quality management program will be used for each mixture use listed in Item 2 above. If the same mixture has two QMPs, each QMP should be in separate columns in the mixture requirements table. Options include: Pay-For-Performance (PFP), Quality Control for Performance (QCP), and Quality Control/Quality Assurance (QC/QA).

   a. PFP. PFP utilizes pay adjustments based upon percent within limits statistical calculations. PFP should be specified for interstate, freeway and expressway resurfacing; and full-depth pavement projects having a minimum quantity of 8,000 tons per mix. PFP may also be considered for smaller projects where a more accurate measure of quality is desired. PFP should not be used on:

      - incidental surfacing (e.g., driveways, entrances, minor sideroads, and side road returns);
      - temporary pavements;
      - shoulders, unless they are used as auxiliary lanes;
      - patching;
      - turn lanes less than 500 ft in length; or
      - shared-use paths or bike lanes unless paved with the mainline pavement.

   b. QCP. QCP utilizes step-based pay adjustments and should be specified for:

      - mainline mixture quantities between 1,200 and 8,000 tons; or
      - shoulder applications that are greater than 8 feet wide and having quantities of 1,200 tons and greater.

      QCP should not be used on:

      - incidental surfacing (e.g., driveways, entrances, minor sideroads, and side road returns);
      - temporary pavements;

- patching;
- turn lanes less than 500 ft in length; or
- shared-use paths or bike lanes unless paved with the mainline pavement.

c. QC/QA. The use of QC/QA is limited to:

- mixtures with quantities less than 1,200 tons,
- shoulders placed with a road widener, and
- patching or incidental surfacing (e.g., entrances, minor sideroads).

9. Sublot Size. The sublot size for QCP and PFP will typically be 1,000 tons. On rare occasions, the sublot size may be reduced to lower the payment risk for smaller tonnage projects. Sublot size is not applicable when the QC/QA quality management program is used.

10. Material Transfer Device (MTD). Indicate whether or not the use of an MTD is required by placing either a "Yes" or a "No" in the box. MTDs are required for interstate HMA resurfacing and full-depth HMA contracts. For full-depth HMA contracts, an MTD is used for constructing all lifts of the pavement. MTDs may also be required in other types of HMA paving at the district's discretion.

    MTD have specific restrictions regarding travel on structures. The designer shall submit information to the Bureau of Bridges and Structures identifying the structures that will be crossed by a Category I MTD. The Bureau of Bridges and Structures will analyze the structures to verify that it has the capacity to safely carry an emptied Category I MTD and will provide the designer with recommendations. The recommendations provided by the Bureau of Bridges and Structures will identify any structure, which due to general deterioration or insufficient load carrying capacity, cannot be crossed by an emptied Category I MTD. The plans shall include notice to the contractor of special requirements and restrictions for structures that cannot be crossed by an emptied Category I MTD.

53-4.04(c) ESAL Calculation

Use Section 54-2.01(c) and Section 54-5.01(g) to calculate ESALs for the design lane. To select the PG binder and design compactive effort (N_{design}), the ESAL value, equivalent to the Traffic Factor (TF), is calculated according to the equations in Figure 54-5.B. Use a Design Period (DP) of 20 years. In this application, the calculation is purely to determine the mixture design parameters; actual pavement/thickness design may require a different design period and/or TF calculation. Minimum structural design traffic levels should be ignored for mixture design purposes.

It is recommended that each district designate a single individual to coordinate ESAL calculations. In instances where major routes cross district borders, it is recommended that the ESAL counts be confirmed between districts.

53-4.04(d) Design Compactive Effort

The design compactive effort is expressed as an N_{design} number, which is selected based on the estimated 20-year ESAL loading of the traffic lane.

Figure 53-4.L lists the design compactive effort (N_{design}) required for the different levels of traffic loading and describes the typical roadway application. Consult the District Materials Engineer for the appropriate N_{design} value.

Design ESALs (millions) (20-yr. Design)	N_{ini}[1]	N_{des}	N_{max}[1]	Typical Roadway Application
< 0.3	5	30	42	Roadways with very light traffic volume such as local roads, county roads, and city streets where truck traffic is prohibited or at a very minimal level. (Considered local in nature; not regional, intrastate, or interstate.) Special purpose roadways serving recreational sites or areas may also be applicable.
0.3 to 3	6	50	74	Includes many collector roads or access streets. Medium-trafficked city streets and the majority of county roadways.
3 to 10	7	70	107	Includes many two-lane, multi-lane, divided, and partially or completely controlled access roadways. Among these are medium-to-highly trafficked streets, many state routes, US highways, and some rural Interstates.
> 10	8	90	141	Includes Interstates, both urban and rural in nature. Special applications such as truck-weighing stations or truck-climbing lanes on two-lane roadways may also be applicable to this level. May also include the class of roadways in the row above which have a high amount of truck traffic.

[1] N_{ini} and N_{max} are for informational purposes only. It is recommended the air voids at N_{ini} be greater than 11% to avoid mix tenderness. Also, air voids at N_{max} should be greater than 2% to prevent premature rutting.

DESIGN COMPACTIVE EFFORT FOR VARIOUS TRAFFIC CONDITIONS

Figure 53-4.L

53-4.04(e) Asphalt Binder Selection

Selection of Performance-Graded (PG) binders is based on temperature and traffic conditions. Figure 53-4.M lists the appropriate PG binders for use with all HMA mixtures. Consider the following when selecting the asphalt binder:

1. Polymer Modified PG Binders. Where polymer modifiers are required, designate “SBS” in front of the PG binder requirements in the General Notes table. The following grades of asphalt binder must be polymer modified: PG 64-28, PG 70-22, PG70-28, PG76-22, and PG76-28.

2. Overlays of PCC or Composite Pavements. Overlays of PCC or composite pavements should use the grades shown in Figure 53-4.M for a standard traffic level. Adjustments to this grade are dependent upon conditions such as slow moving traffic, high ESALs, or standing traffic. These modifications should be made for the corresponding N_{design} number and/or ESAL number. The appropriate asphalt binder grade should then be reported on the General Notes table of the plans.

3. Full-Depth HMA Pavements or Overlays of Full-Depth HMA Pavements. Full-depth HMA pavements or overlays of full-depth HMA pavements should be designed using the PG binders shown in Figure 53-4.M. The appropriate binder grade should be reported on the General Notes table of the project plans.

53-4.04(f) Friction Aggregate

An HMA surface course must be specified for each rehabilitation/resurfacing project. Section 11-2.02(f) gives safety analysis procedures to determine risks contributing to substantive safety problems.

Before the appropriate mix is selected, determine whether or not pavement surface friction is contributing to a substantive safety problem at the site. Presence of “wet pavement” crashes alone is not sufficient, as other risks related to wet weather may be present. For example, inadequate warning signage or visibility of stop or maneuver areas, unexpected geometric conditions, rutting, lack of surface drainage, inadequate pavement cross slope, or excess spray from vehicle tires may be more important than surface friction for locations of wet pavement crashes. Review of crash reports including narratives and sketches, site reviews during wet conditions, and surface friction testing should be included in an analysis of wet pavement crashes. Pavement friction testing may be requested according to the Bureau of Research Pavement Technology Advisory- “Testing Pavement Friction” (PTA-T3), http://idot.illinois.gov/Assets/uploads/files/Transportation-System/Research/Pavement-Technology-Advisories/Testing-and-Data-Collection-Series/PTAT3.pdf.

If the segment demonstrates a pattern of wet pavement crashes, identification of the risks contributing to the crash pattern will help to indicate the appropriate countermeasures, possibly including improved positive guidance, geometric changes, surface to full-depth repairs of rutting, improved drainage or cross slope, or improved surface texture (pavement grooving) or resurfacing with appropriate friction aggregate.

Type of HMA Pavement	Layer	Illinois N_{design} Number	Design ESALs(1) (million)	PG Binder Grade(2)(3) Traffic Loading Rate: Standard(4)	Slow(5) or High ESALs(6)	Standing(7)
IL-4.75	Surface(8) and Binder	50	≤ 10	SBS PG 70-22	SBS PG 70-22	SBS PG 70-22

	Lower Binder	All	All Levels	PG 64-22	PG 64-22	PG 64-22

PG BINDER GRADE SELECTION - ALL APPLICATIONS

Figure 53-4.M (1 of 2)

1. *Design ESALs are the anticipated project traffic level expected on the design lane over a 20-year period. Regardless of the actual design life of the roadway, determine the design ESALs for 20 years and choose the appropriate N_{design} level.*
2. *The binder grade provided in the table is based on the recommendations given in Illinois-Modified AASHTO M 323, Table 1, "Binder Selection on the Basis of Traffic Speed and Traffic Level."*
3. *Consider increasing the high temperature grade by one grade and/or use polymer modified binder within 2,500 ft upstream of the exit terminal stub to 2,500 ft downstream of the entrance stub at weigh stations.*
4. *Standard Traffic - where the average traffic speed is greater than 43 mph.*
5. *Slow Traffic - where the average traffic speed ranges from 12 mph to 43 mph.*
6. *High ESALs – where ESALs are > 30 million.*
7. *Standing Traffic - where the average traffic speed is less than 12 mph.*
8. *For pavements with a posted speed limit ≤ 30 mph.*
9. *Consider increasing the high temperature grade by one grade for ESALs 10 to 30 million.*

PG BINDER GRADE SELECTION - ALL APPLICATIONS

Figure 53-4.M (2 of 2)

It is not desirable to specify short, closely spaced segments of special high-quality friction mixes (i.e., patchwork surfacing). If a higher-quality friction mix treatment is required at more than one location on a project and the distance between locations is less than 1,000 ft, the gaps should also be treated with the higher-quality mix. Also, if the special treatment is required on more than 50 percent of the project, it should be used throughout the entire project.

Four surface course mixtures have been developed that will provide adequate skid resistance for various Average Daily Traffic (ADT) levels: Mixtures C, D, E, and F. Figure 53-4.N designates the ADT levels allowable for each of the surface course mixtures.

It is expected that the application of friction aggregate according to Figure 53-4.N will address most pavement friction needs. However, some conditions create friction demands exceeding typical conditions anticipated by this tabulation. Examples include locations where problem identification shows a pattern of wet pavement related crashes and one of the following conditions:

- on grades exceeding 3.5%;
- locations with a heavy commercial vehicle (HCV) volume (Single Units plus Multiple Units) exceeding 400 per day and equal to 25% or more of the total ADT (Note – 25% HCV represents about 15% of State System mileage);
- locations that are shadowed or otherwise tend to remain wet for an extended time compared to typical locations; or
- other sites where similar friction demands or pavement conditions exist. At such locations, the Mixture designation may be increased by one step (e.g., from Mixture D to Mixture E).

Number of Lanes in Both Directions	**Frictional Requirements (ADT)**			
	Mixture C	**Mixture D**	**Mixture E**	**Mixture F**
≤ 2	≤ 5,000	> 5,000	N/A	N/A
4	≤ 5,000	5,001 to 25,000	25,001 to 100,000	> 100,000
≥ 6	N/A	5,001 to 60,000	60,001 to 100,000	> 100,000

Note: ADT levels are for the expected year of construction.

FRICTIONAL REQUIREMENTS FOR SURFACE MIXTURES

Figure 53-4.N

53-4.04(g) Longtidudinal Joint Sealant

Longitudinal Joint Sealant improves the performance of centerline and lane-to-lane joints of full-depth HMA pavements and HMA overlays. The specific lifts of HMA that will receive the sealant must be identified on the plans.

- Full-Depth HMA Pavements – under the surface lift and under the top binder lift
- Two-Lift Interstate HMA overlays – under both the surface and binder lifts
- Two-Lift Non-interstate HMA overlays – under the surface lift
- Single-Lift HMA Overlays – under the surface lift.

53-5 TREATMENT SUMMARIES

The following section contains one-page summaries of all pavement preservation treatments (proactive, low, and high), rehabilitation treatments (minor and major), pre-treatment activities, and other design considerations.

53-5.01 Flexible and Composite Pavement Preservation Treatment Summaries

FLEXIBLE AND COMPOSITE PAVEMENT PRESERVATION TREATMENT (PROACTIVE MAINTENANCE)

Name: Crack/Joint Filling

Application:

System:	Interstates and Non-Interstates
Pavement Type(s):	Full-Depth HMA and Composite Pavements
Distress Type(s):	Relates to both Functional and Structural Failures

Purpose. Crack filling is effective at reducing or delaying moisture damage, further deterioration, roughness, and rutting. However, crack/joint filling can also have a negative impact on roughness and friction.

Treatment Description. Crack filling is the process of placing material into non-working cracks to substantially reduce the infiltration of water and to reinforce the adjacent pavement. Crack filling is characterized by minimal crack preparation and the use of lower quality bituminous filler materials.

Pavement Conditions Addressed. Adds no structural benefit, but does reduce moisture infiltration through cracks. Only practical if extent of cracking is minimal and if there is little to no structural cracking.

Application Limitations. These treatments are not recommended when structural failures exist (e.g., extensive fatigue cracking, high-severity rutting) or if there is extensive pavement deterioration or little remaining life. Crack filling is appropriate for non-working (e.g., longitudinal, block) cracks 0.25 in. (6 mm) to 1.0 in. (25 mm) wide.

Non-working cracks narrower than 0.25 in. (6 mm) that do not exhibit spalling should not be filled. These cracks generally do not penetrate through the surface course nor do they pose a source of pavement deterioration. The practice of filling this type of crack by the method of pouring filler on the pavement surface is seldom of value. Perform a crack analysis to determine whether crack filling would be effective.

Letting/Construction Considerations. The project letting date should be selected to target construction during cool, dry weather conditions. Application during cool weather will allow for expanded crack widths.

Traffic Considerations. Performance is not significantly affected by varying ADT or truck levels. However, improper installation can permit the filler to fail.

Special Considerations/Comments: Crack filling may have negative effects. Undesirable visual impacts may occur, which include tracking of filling material by tire action, obscuring lane markings, and adversely affecting friction/skid resistance. Crack filling may result in a rougher pavement surface when the filler material is forced out of the cracks during warm months.

Performance Period. 2 to 4 years.

FLEXIBLE AND COMPOSITE PAVEMENT PRESERVATION TREATMENT (PROACTIVE MAINTENANCE)

Name: Crack/Joint Sealing

Application:

System: Interstates and Non-Interstates
Pavement Type(s): All Pavements
Distress Type(s): Relates to both Functional and Structural Failures

Purpose. Crack/joint sealing is effective at reducing or delaying moisture damage, further crack deterioration, roughness, and rutting. However, crack/joint sealing can also have a negative impact on roughness and friction.

Treatment Description. Crack/joint sealing is the process of placing higher-quality material into “working” cracks (i.e., those that open and close with changes in temperature) and construction joints in order to reduce water infiltration into a pavement. In contrast to crack “filling,” crack sealing requires crack routing and uses higher quality sealant materials. Thermosetting and thermoplastic materials are both used for crack/joint sealing.

Pavement Conditions Addressed. Adds no structural benefit, but does reduce future intrusion of incompressible materials, water, and soluble chemicals (e.g., salts, brines) into the cracks/joints. It is only practical if extent of cracking is minimal and if there is little to no structural cracking.

Application Limitations. These treatments are not recommended where structural failures exist (e.g., extensive fatigue cracking, high-severity rutting) or if there is extensive pavement deterioration or little remaining life. Crack/joint sealing is appropriate for cracks and joints 0.25 in. to 0.75 in. (6 mm to 19 mm) wide.

Non-working cracks narrower than 0.25 in. (6 mm) that do not exhibit spalling should not be routed and sealed. These cracks generally do not penetrate through the surface course nor do they pose a source of pavement deterioration. The practice of routing and sealing this type of crack can increase pavement roughness without gaining any benefit.

Letting/Construction Considerations. The project letting date should be selected to target construction during cool, dry weather conditions. Application during cool weather will allow for expanded crack widths.

Traffic Considerations. Performance is not significantly affected by varying ADT or truck levels. However, improper installation can cause the sealant to fail.

Special Considerations/Comments: Crack/joint sealing may result in a rougher pavement surface when the sealant material is forced out of the cracks during warm months. Sealing is best accomplished several months in advance of any other maintenance surface applications. If sealing quantities become excessive, the district may want to consider a higher level treatment.

Performance Period. 2 to 8 years.

FLEXIBLE AND COMPOSITE PAVEMENT PRESERVATION TREATMENT (LOW PRESERVATION)

Name: Cape Seal

Application:

System:	Non-Interstates
Pavement Type(s):	Full-Depth HMA and Composite Pavements
Distress Type(s):	Relates to Functional Failures

Purpose. A cape seal combines a chip seal with micro-surfacing to provide a smooth, quiet wearing surface at a lower cost than an HMA overlay.

Treatment Description. The treatment consists of a chip seal, followed within a few days by a micro-surfacing treatment to cover the chips and seal them in.

Pavement Conditions Addressed. Cape seal can be used to address longitudinal, transverse, and block cracking; friction loss; raveling/weathering (remove loose material); minor roughness; low- to medium-severity bleeding; and moisture infiltration. Adds no structural capacity. It is somewhat effective at sealing medium-severity fatigue cracks in comparison with other treatments.

Application Limitations. Not recommended for pavements with the following conditions: structural deficiency, unsealed cracks > 0.25 in. (6 mm) wide, medium- to high-severity alligator cracking, many potholes, rutting > 1 in. (25 mm) deep, and very rough surface.

Letting/Construction Considerations. The project letting date should be selected to target construction between May 1 and August 31.

Traffic Considerations. This treatment is not recommended for ADT greater than 10,000. Temporary pavement markings are required until permanent markings are applied. Because the application of the micro-surfacing removes the hazard of loose chips, the final surface of the cape seal leaves no concerns. However, keep traffic to slower speeds on high-volume or high-speed roadways until the chip seal portion has cured properly and/or it is covered by the micro-surfacing.

Special Considerations/Comments: Give special consideration to raised reflective pavement markers and bump grinding prior to treatment placement.

Performance Period. 4 to 7 years.

FLEXIBLE AND COMPOSITE PAVEMENT PRESERVATION TREATMENT (LOW PRESERVATION)

Name: Chip Seal (Bituminous Surface Treatment)

Application:

System:	Non-Interstates
Pavement Type(s):	Full-Depth HMA and Composite Pavements
Distress Type(s):	Relates to Functional Failures

Purpose. Chip Seals, also known as Bituminous Surface Treatments (BSTs), are effective at improving poor friction, inhibiting raveling, correcting minor roughness and bleeding, and sealing the pavement surface.

Treatment Description. Asphalt emulsion is applied directly to the pavement surface followed by the application of aggregate chips, which are then immediately rolled to imbed chips. Application rates depend upon aggregate gradation and maximum size. This treatment can be applied in multiple layers (e.g., double chip seals) and in combination with other surface treatments. For sections with ADT > 1,000, a fog seal shall be included with the treatment.

Pavement Conditions Addressed. Chip seals can be used to address longitudinal, transverse, and block cracking; raveling/weathering (remove loose material); friction loss; minor roughness; low-severity bleeding; and moisture infiltration. Adds no structural capacity. The flexible, impermeable HMA surface helps reduce cracking and is somewhat effective at sealing medium-severity fatigue cracks in comparison with other treatments.

Application Limitations. Chip seals are not recommended for pavements with structural deficiency, cracks greater than 0.25 in. (6 mm) wide, medium- to high-severity alligator cracking, many potholes, rutting greater than 1 in. (25 mm) deep, and very rough surface.

Letting/Construction Considerations. The project letting date should be selected to target construction between May 1 and August 31.

Traffic Considerations. With special design and proper placement, chip seals can perform well on high-volume roads. However, its use is sometimes limited to lower-speed, lower-volume roads because of the propensity for loose chips to crack windshields. This treatment is not recommended for ADT greater than 10,000. Use lightweight aggregate to help minimize claims. Flaggers may be needed at crossing intersections to control traffic.

Special Considerations/Comments: Temporary pavement markings are required until permanent markings are applied. Give special consideration to raised reflective pavement markers and bump grinding prior to treatment placement. Additional information is available from the BLRS Report, *Seal Coats (Oil & Chipping)*.

Performance Period. Single seals (A-1): 4 to 6 years; double seals (A-2): 5 to 7 years; triple seals (A-3): 6 to 8 years.

FLEXIBLE AND COMPOSITE PAVEMENT PRESERVATION TREATMENT (LOW PRESERVATION)

Name: Half-SMART Overlay

Application:

System:	Non-Interstates
Pavement Type(s):	Full-Depth HMA and Composite Pavements
Distress Type(s):	Relates to Functional Failures

Purpose. Placing a combination of HMA binder and a chip seal is a viable option for improving surface friction, profile, crown, and cross slope.

Treatment Description. Half-SMART overlays consist of placing a nominal 0.75 in. (19 mm) layer of HMA binder followed by a chip seal. Only place this treatment on a previously resurfaced pavement that is not in need of significant repair and is in good condition.

Pavement Conditions Addressed. Half-SMART overlays are applicable for low-severity cracking; raveling/weathering (remove loose material), friction loss, low-severity flushing/bleeding, and low-severity block cracking (may perform better with additional milling). Half-SMART overlays may also be used to correct minor rutting (depths less than 0.25 in. (6 mm)).

Application Limitations. Half-SMART overlays are not recommended where there are structural failures (e.g., fatigue cracking), extensive pavement deterioration, or if there is high-severity thermal cracking. If this treatment is being placed to correct rutting, evaluate the pavement to determine if the rutting is stable. Do not use half-SMART overlays on pavements that have unstable rutting due to stripping in the existing asphalt layers.

Letting/Construction Considerations. The project letting date should be selected to target construction of the chip seal portion between May 1 and August 31.

Traffic Considerations. Use of the Half-SMART overlay is sometimes limited to lower-speed, lower-volume roads because of the chip seal layer, which has the propensity for loose chips to crack windshields. This treatment is not recommended for ADT greater than 10,000. Lightweight aggregate can be used to help minimize claims. Flaggers may be needed at crossing intersections to control traffic.

Special Considerations/Comments. Repair localized distressed areas prior to the placement of the overlay. If milling is not used in conjunction with the Half-SMART overlay, give special consideration to bump grinding prior to treatment placement.

Consider using IL-9.5FG or IL-4.75 gradations for the binder lift to promote better performance.

Performance Period. 5 to 7 years.

FLEXIBLE AND COMPOSITE PAVEMENT PRESERVATION TREATMENT (LOW PRESERVATION)

Name: Micro-Surfacing

Application:

System:	Interstates and Non-Interstates
Pavement Type(s):	Full-Depth HMA and Composite Pavements
Distress Type(s):	Relates to Functional Failures

Purpose. Micro-surfacing is effective at correcting or inhibiting raveling and oxidation of the pavement surface, improving surface friction, sealing the pavement surface, and filling minor surface irregularities and average wheel ruts up to 0.25 in. (6 mm) deep over the entire project. Projects with isolated rut depths up to 1.25 in. (30 mm) deep may be addressed with a rut filling mix prior to full-width placement of the micro-surfacing.

Treatment Description. Applied in a process similar to slurry seals, micro-surfacing consists of a mixture of latex-modified emulsified asphalt, mineral aggregate, mineral filler, water, and additives. Micro-surfacing material is mixed in specialized, compartmented, self-powered trucks and placed on the pavement using an augured screed box.

Pavement Conditions Addressed. Micro-surfacing may be used to address block, transverse, and longitudinal cracking; raveling/weathering (remove loose material), bleeding, minor roughness, friction loss, and moisture infiltration.

Application Limitations. Micro-surfacing is not recommended when the pavement contains structural failures (e.g., significant fatigue cracking), high-severity thermal cracking, or extensive pavement deterioration.

Letting/Construction Considerations. The project letting date should be selected to target construction between May 1 and October 15.

Traffic Considerations. Micro-surfacing is very successful on both low-and high-volume roadways. However, avoid areas of heavy truck turning or downgrade locations as there is a high potential for early damage.

Special Considerations/Comments: Give special consideration to raised reflective pavement markers and bump grinding prior to treatment placement. All RRPMs shall be removed prior to placing micro-surfacing. Covering or masking RRPMs is not permitted.

Centerline/Longitudinal Joint micro-surfacing is permitted on full-depth HMA pavements and composite pavements. This treatment should only be considered if the distress is at low severity and limited to close proximity of the joint. If a pavement has three or more lanes and all longitudinal joints are in need of a longitudinal joint micro-surfacing, caution shall be used due to the potential for water to be trapped in the center lane(s) during heavy rain events. If the pavement has multiple distresses that would benefit from a full-lane micro-surfacing treatment, it is best to use that in lieu of treating only the longitudinal joints.

Performance Period. 4 to 7 years.

FLEXIBLE AND COMPOSITE PAVEMENT PRESERVATION TREATMENT (HIGH PRESERVATION)

Name: Longitudinal Joint Partial-Depth Repair

Application:

System:	Interstates and Non-Interstates
Pavement Type(s):	Full-Depth HMA and Composite Pavements
Distress Type(s):	Relates to Functional and Structural Failures

Purpose. The partial-depth removal and replacement of the longitudinal joint is a viable option for addressing raveling and spalling of the joint due to high permeability and reduces the potential for moisture infiltration into the pavement structure.

Treatment Description. This treatment consists of milling a 2- to 3-ft (600- to 900-mm) strip of the surface lift, centered over the longitudinal joint, and replacing with new HMA mix.

Pavement Conditions Addressed. Longitudinal Joint Partial-Depth Repair can be used to address low to medium severity longitudinal joint deterioration.

Application Limitations. This treatment is allowed if longitudinal joint deterioration is the only distress. If other distresses are present, a full-width treatment should be considered.

Letting/Construction Considerations. None.

Traffic Considerations. Performance is not affected by different ADT or percent trucks.

Special Considerations/Comments: When determining milling depth, it is recommended to mill 0.5 in. (13 mm) greater than the existing lift thickness to ensure all material is removed, which will minimize the potential for scabbing.

Performance Period. 7 to 10 years.

FLEXIBLE AND COMPOSITE PAVEMENT PRESERVATION TREATMENT
(HIGH PRESERVATION)

Name: Hot In-Place Recycling

Application:

System:	Non-Interstates
Pavement Type(s):	Full-Depth HMA and Composite Pavements
Distress Type(s):	Relates to Functional Failures

Purpose. Hot In-Place Recycling (HIR) is effective at correcting surface distresses that are limited to the top 1 in. to 2 in. (25 mm to 50 mm). Examples include rutting, corrugations, raveling, flushing/bleeding, loss of surface friction, minor thermal cracking, and minor load-associated cracking.

Treatment Description. HIR is a process of correcting HMA pavement surface distress by softening the existing surface with heat, mechanically loosening the pavement surface, mixing the loosened surface material with recycling agent, aggregate, rejuvenators, or HMA, and relaying the recycled material without removing it from the site. Different HIR processes include surface recycling (e.g., heater scarification), repaving, and remixing.

Pavement Conditions Addressed. HIR is effective at correcting surface distresses that are limited to the top 1 in. to 2 in. (25 mm to 50 mm). Examples include rutting, corrugations, raveling, flushing, loss of surface friction, and minor thermal and load-associated cracking.

Application Limitations. As the HIR equipment is relatively wide and long, short road sections, particularly in urban settings, are not suitable for HIR treatment.

This treatment must be approved by BDE and will require an experimental feature study according to Construction Memorandum 02-2. Good HIR candidates have no structural failures, limited variation in the existing HMA mix, no paving fabrics or interlayers in the anticipated treatment depth plus 25%, no deep ruts greater than one-half of the anticipated HIR treatment depth, and no large stone mixes. The presence of rubber in the surface lift, rubberized seal coats, and some crack fillers require special attention in the mix design process.

Letting/Construction Considerations. The project letting date should be selected to target construction when the air temperature is moderate (i.e., 50°F (10°C) or above). HIR pavement can remain tender for a number of days. Do not allow this treatment to remain exposed over the winter season without a surface treatment or HMA overlay as the final wearing surface.

Traffic Considerations. HIR is appropriate for very low to high traffic conditions. Only use the heater-scarification process for low volume traffic. The remixing and repaving processes can be used on high traffic volume roads.

Special Considerations/Comments: Remove crack sealant prior to the HIR operation to reduce flash fires or excessive blue smoke from the treatment placement.

Performance Period. 6 to 15 years, depending on method of HIR.

FLEXIBLE AND COMPOSITE PAVEMENT PRESERVATION TREATMENT (HIGH PRESERVATION)

Name: Surface Maintenance at the Right Time (SMART) Overlay

Application:

System:	Interstates and Non-Interstates
Pavement Type(s):	Full-Depth HMA and Composite Pavements
Distress Type(s):	Relates to Functional and Structural Failures

Purpose. The combination of cold milling and the application of a Surface Maintenance at the Right Time (SMART) overlay is a viable option for improving rideability, surface friction, profile, crown, and cross slope.

Treatment Description. SMART overlays may be continuous or intermittent and consist of placing a 1.50 in. (38 mm) (1.75 in. (44 mm) for F-mix) single-pass overlay on a previously resurfaced pavement that is not in need of significant repair and is in good condition. For Full-Depth HMA pavements, the single lift is 2.00 in. (50 mm) thick. If the SMART overlay is applied at the correct time, it can delay serious distresses, extend the life of the pavement, and decrease the overall cost.

Pavement Conditions Addressed. SMART Overlay can be used to address low-severity alligator cracking, stable rutting ≤ 0.25 in. (6 mm), medium-severity longitudinal and transverse cracking, medium-severity raveling/weathering, and medium-severity block cracking.

Cold milling is recommended to reduce pavement irregularities and to produce a uniform surface or to correct cross slope. Milling is required where: (1) rutting is continuous and, in isolated areas, exceeds 0.25 in (6 mm), (2) the CRS block cracking distress level is M3, and/or (3) CRS distress level W3 is present. Milling need not be continuous throughout the section.

Application Limitations. SMART overlays are not allowed on bare PCC pavements.

Letting/Construction Considerations. None.

Traffic Considerations. Performance is not affected by different ADT or percent trucks.

Special Considerations/Comments. During Phase I, the district shall review the project according to the requirements in Chapter 12 of this manual.

Repair localized distressed areas prior to the placement of the overlay. If milling is not used in conjunction with the SMART overlay, give special consideration to bump grinding prior to treatment placement.

Raised Reflective Pavement Markers shall be removed and replaced.

Performance Period. 7 to 10 years.

FLEXIBLE AND COMPOSITE PAVEMENT PRESERVATION TREATMENT (HIGH PRESERVATION)

Name: Ultra-Thin Bonded Wearing Course

Application:

System:	Interstates and Non-Interstates
Pavement Type(s):	All Pavements
Distress Type(s):	Relates to Functional and Structural Failures

Purpose. An ultra-thin bonded wearing course (UTBWC) is an alternative to chip seals, micro-surfacing, or thin HMA overlays as it effectively addresses minor surface distresses and increases surface friction.

Treatment Description. A UTBWC is formed in one pass with the application of a heavy, polymer-modified asphalt emulsion tack coat and a gap-graded, polymer-modified, 0.75 in. to 0.9 in. thick HMA layer.

Pavement Conditions Addressed. This treatment is applicable for low-severity cracking (high severity can be addressed with cold milling), raveling/weathering (remove loose material), high-severity friction loss, low-severity roughness, and low-severity flushing/bleeding. Retards fatigue cracking, but is not suited for rutted pavements.

Application Limitations. Ultra-thin bonded wearing courses are not recommended where structural failures exist (e.g., significant fatigue cracking, deep rutting) or if there is high-severity thermal cracking. They also are not appropriate where there is extensive pavement deterioration or little remaining life.

Letting/Construction Considerations. The project letting date should be selected to target construction when the air temperature is moderate (i.e., 50°F or above).

Traffic Considerations. It is capable of withstanding high ADT volumes and truck traffic better than other thin treatments.

Special Considerations/Comments: Give special consideration to bump grinding prior to treatment placement. Patching quantities should be included to repair localized structural problems prior to overlay application.

Avoid using on pavements with heavy turning movements or bus stops.

Performance Period. 7 to 12 years.

53-5.02 Rigid Pavement Preservation Treatment Summaries

RIGID PAVEMENT PRESERVATION TREATMENT
(PROACTIVE MAINTENANCE)

Name: Crack Sealing

Application:

System:	Interstates and Non-Interstates
Pavement Type(s):	All Rigid Pavements
Distress Type(s):	Relates to both Functional and Structural Failures

Purpose. Crack sealing is effective at reducing or delaying moisture damage, further crack deterioration, roughness, and rutting. However, crack sealing can also have a negative impact on roughness and friction.

Treatment Description. Crack sealing is an operation involving thorough crack preparation and placement of high-quality materials into or over candidate cracks to significantly reduce moisture infiltration and to retard the rate of crack deterioration. Sealed cracks in PCC pavements deteriorate less and contribute less to the overall deterioration of the pavement. PCC cracks are typically sealed with thermosetting bituminous materials.

Pavement Conditions Addressed. Crack sealing is effective at sealing low- or medium-severity transverse or longitudinal cracks where the crack width is ≤ 0.5 in. (13 mm). Full-depth working transverse cracks typically experience substantial movement; therefore, it is recommended that these cracks be sealed to reduce water and incompressibles.

Application Limitations. Crack sealing is most effective when performed on PCC pavements that exhibit minimal structural deterioration and in which the cracks are not showing other significant distress (e.g., faulting, spalling). Do not use crack sealing where there are unpatched pavement blowups, rocking slabs, pumping of water or fines through the crack, or full-depth punchouts. In these instances, use full-depth patching as a mitigating activity.

Letting/Construction Considerations. The project letting date should be selected to target construction during cool, dry weather conditions. Application during cool weather will allow for expanded crack widths.

Traffic Considerations. Performance is not significantly affected by varying ADT or truck levels, but sealant should be allowed to cure before opening to traffic.

Special Considerations/Comments: Crack sealing may result in a rougher pavement surface when the sealant material is forced out of the cracks during warm months. If sealing quantities become excessive, the district may want to consider a higher level treatment.

Performance Period. 4 to 8 years.

RIGID PAVEMENT PRESERVATION TREATMENT
(PROACTIVE MAINTENANCE)

Name: Diamond Grinding

Application:

System:	Interstates and Non-Interstates
Pavement Type(s):	All Rigid Pavements
Distress Type(s):	Relates to Functional Failures

Purpose. Diamond grinding is effective at removing joint faulting and other surface irregularities to restore a smooth-riding surface and increase pavement surface friction.

Treatment Description. Diamond grinding is the removal of a thin layer of concrete (generally up to about 0.25 in. (6 mm)) from the surface of the pavement, using special equipment outfitted with a series of closely spaced, diamond saw blades.

Pavement Conditions Addressed. Diamond grinding is used to remove joint faulting and other surface irregularities to restore a smooth-riding surface, increase pavement surface friction, and reduce noise.

Application Limitations. If the average faulting over the section is > 0.15 in. (4 mm) or other signs of structural failure (e.g., mid-panel cracks, corner breaks) exist, diamond grinding is not appropriate. The presence of materials-related distresses (e.g., D-cracking, ASR) may also preclude the use of diamond grinding. Soft aggregate will wear much quicker and require more frequent grinding.

Letting/Construction Considerations. None.

Traffic Considerations. Grinding may be used to remove faulting, which, if the mechanism is not addressed, can reoccur due to the continued application of truck traffic. If used to restore friction to a polished pavement (due to vehicle traffic), heavy volumes of traffic may cause the problem to recur.

Special Considerations/Comments: Note that diamond grinding is a surface repair method because it corrects the existing faulting and wear of PCC pavements. It does nothing to correct pavement distress mechanisms. Therefore, grinding usually is performed in combination with other rehabilitation methods to both repair certain pavement distresses and prevent their recurrence.

Performance Period. 8 to 15 years.

RIGID PAVEMENT PRESERVATION TREATMENT
(PROACTIVE MAINTENANCE)

Name: Diamond Grooving

Application:

System:	Interstates and Non-Interstates
Pavement Type(s):	All Rigid Pavements
Distress Type(s):	Relates to Functional Failures

Purpose. Diamond grooving is effective at increasing wet-pavement friction and reducing splash and spray in identified problem areas.

Treatment Description. Diamond grooving is the process of cutting narrow, discrete grooves in the PCC surface to reduce hydroplaning and wet-pavement crashes in localized areas. Grooving can be performed in both the longitudinal and transverse directions, but is more commonly performed longitudinally.

Pavement Conditions Addressed. Grooving is conducted to increase wet-pavement friction and reduce splash and spray. Diamond grooving is conducted in localized areas of a project where wet-pavement crashes have historically been a problem (e.g., curves, intersections).

Application Limitations. In general, candidate pavements for grooving should be structurally and functionally sound.

Letting/Construction Considerations. None.

Traffic Considerations. Performance is not affected by varying ADT or truck levels.

Special Considerations/Comments: Clearly indicate the areas to be grooved on the project plans. The entire lane area should be grooved; however, allowance should be made for small areas that were not grooved because of pavement surface irregularities. Grooving is most commonly performed longitudinally due to ease of construction; however, if the district would like to place the grooving transversely, the Bureau of Research should be contacted for assistance. This treatment can be used in conjunction with diamond grinding.

Performance Period. Remaining service life of the pavement structure.

RIGID PAVEMENT PRESERVATION TREATMENT
(PROACTIVE MAINTENANCE)

Name: Longitudinal Joint Sealing

Application:

System:	Interstates and Non-Interstates
Pavement Type(s):	All Rigid Pavements
Distress Type(s):	Relates to both Functional and Structural Failures

Purpose. Joint sealing helps keep moisture out of the pavement layers and incompressibles out of joints, which reduces spalling.

Treatment Description. Sealing longitudinal joints in PCC pavements is intended to minimize the infiltration of surface water into the underlying pavement structure and to prevent the intrusion of incompressibles into the joint.

Pavement Conditions Addressed. Joint sealing is effective in addressing low or medium severity joint spalling.

Application Limitations. Longitudinal joint sealing is most effective when performed on PCC pavements that exhibit minimal structural deterioration. Base material selection on the expected time until next treatment.

Letting/Construction Considerations. The project letting date should be selected to target construction during cool, dry weather conditions. Application during cool weather will allow for expanded crack widths.

Traffic Considerations. Performance is not affected by different ADT or percent trucks.

Special Considerations/Comments: Joint sealing is necessary when the existing sealant has deteriorated to the point that it readily allows water and incompressibles to enter the joint. The primary cause of sealant failure is improper installation (e.g., not preparing joint sidewalls, getting bonding).

Performance Period. 4 to 8 years for hot-poured asphalt sealant; approximately 8 years for silicone sealant.

RIGID PAVEMENT PRESERVATION TREATMENT
(HIGH PRESERVATION)

Name: Load Transfer Restoration

Application:

System:	Interstates and Non-Interstates
Pavement Type(s):	Jointed Plain Concrete Pavements
Distress Type(s):	Relates to Functional and Structural Failures

Purpose. Load transfer restoration, also known as dowel bar retrofit, is effective at mitigating medium severity transverse joint deterioration and faulting by re-establishing load transfer across the joint. This treatment should only be used on transverse joints.

Treatment Description. Load transfer restoration is the addition or replacement of dowel bars across a transverse joint. A gang saw is used to grind slots across the joints, a bar is placed in each slot, and then the slot is filled with a non-shrink grout. Once cured, the transverse joint is re-established and diamond grinding is performed to remove faulting, if present.

Pavement Conditions Addressed. This treatment should be used when the concrete pavement is in good condition and the only distresses are faulting and transverse joint deterioration.

Application Limitations. If significant faulting, other signs of structural failure (e.g., mid-panel cracks, corner breaks), or materials-related distresses (e.g., D-cracking, ASR) are present, load transfer restoration is not appropriate.

Letting/Construction Considerations. None.

Traffic Considerations. None.

Special Considerations/Comments: Contact the Bureau of Research for the latest special provision.

Performance Period. 8 to 15 years.

RIGID PAVEMENT PRESERVATION TREATMENT
(HIGH PRESERVATION)

Name: Ultra-Thin Bonded Wearing Course

Application:

System:	Interstates and Non-Interstates
Pavement Type(s):	All Rigid Pavements
Distress Type(s):	Relates to Functional and Structural Failures

Purpose. An ultra-thin bonded wearing course (UTBWC) effectively addresses minor surface distresses and increases surface friction.

Treatment Description. A UTBWC is formed in one pass with the application of a heavy, polymer-modified asphalt emulsion tack coat and a gap-graded, polymer-modified, 0.75 in. to 0.9 in. thick HMA layer.

Pavement Conditions Addressed. This treatment is applicable for low-severity D-Cracking, ASR, transverse cracking, and/or longitudinal joint deterioration; medium-severity transverse joint deterioration and/or longitudinal cracking; and surficial cracking such as map cracking and popouts/high steel.

Application Limitations. Ultra-thin bonded wearing course is not recommended where structural failures exist (e.g., significant D-cracking, ASR, excessive permanent patch deterioration) or where there is extensive pavement deterioration or little remaining life.

Letting/Construction Considerations. The project letting date should be selected to target construction when the air temperature is moderate (i.e., 50°F or above).

Traffic Considerations. It is capable of withstanding high ADT volumes and truck traffic better than other thin treatments.

Special Considerations/Comments: Give special consideration to bump grinding prior to treatment placement. Patching quantities should be included to repair localized structural problems prior to overlay application.

Avoid using on pavements with heavy turning movements or bus stops.

Performance Period. 7 to 12 years.

53-5.03 Minor Rehabilitation Treatment Summaries

PAVEMENT REHABILITATION TREATMENT (MINOR)
Name: Bonded Concrete Overlay on Asphalt (BCOA) **Application**: System: Interstates and Non-Interstates Pavement Type(s): HMA-Surfaced Pavements Distress Type(s): Relates to Functional and Structural Failures
Purpose. BCOA is suitable for HMA pavements that have a history of rutting and/or shoving. Intersections, with stopping, starting, standing, and turning actions of vehicles, are an example. Other roadways with volumes and types of vehicles that rapidly rut HMA pavements are also good candidates for BCOA. **Treatment Description**. A BCOA consists of placing 3.0 in. to 6.0 in. (75 mm to 150 mm) of PCC pavement over an existing distressed HMA pavement surface. The existing HMA is first milled to correct profile irregularities and provide a surface for bonding the overlay. **Pavement Conditions Addressed.** BCOA is effective in treating low- to medium-severity alligator cracking, rut depth < 0.25 in. (6 mm), low- to medium-severity transverse cracking, and low- to medium-severity reflective widening cracking. **Traffic Considerations.** The best alternative for traffic control is to completely close the project to traffic. This alternative may be difficult for urban projects; however, somewhat easier for rural projects. **Special Considerations/Comments.** Currently, this rehabilitation strategy is only allowed when the traffic factor does not exceed 7.5. If the district is interested in using this treatment on a project with a higher traffic factor, they must work with the Bureau of Research to design the thickness and joint spacing for the BCOA. Contact the Engineer of Pavement Technology in the Bureau of Research for additional information on design. Bare concrete or brick areas included in the rehabilitation area should not exceed 5% of the total area. The HMA layer shall be at least 2.50 in. (63 mm) thick. Consider complicated geometrics, utility obstructions, traffic demand, frequency of at-grade and overhead structures, and condition of the existing pavement when selecting this rehabilitation type. **Performance Period.** 10 to 15 years.

PAVEMENT REHABILITATION TREATMENT (MINOR)

Name: Cold In-Place Recycling

Application:

System: Non-Interstates
Pavement Type(s): Full-Depth HMA and Composite Pavements
Distress Type(s): Relates to Functional and Structural Failures

Purpose. Cold In-Place Recycling (CIR) is very effective at correcting distresses contained in the top 3 in to 6 in. (75 mm to 150 mm) of the pavement surface. Examples include poor friction and roughness, bleeding, raveling, rutting, and poor cross slope.

Treatment Description. Cold in-place recycling (CIR) is an in-situ process used to recycle the top 3 in to 6 in. (75 mm to 150 mm) of an existing HMA pavement to restore integrity of a flexible pavement layer. As the name suggests, the recycling process is conducted without the addition of heat. During the CIR process, the reclaimed asphalt pavement (RAP) is sized, mixed with additives (e.g., asphalt binder, emulsion, rejuvenator, virgin aggregate), and re-laid. The recycled pavement is then typically resurfaced with a surface treatment or HMA overlay. Note that the compacted thickness will be 5 to 10 percent thicker than the depth milled.

Pavement Conditions Addressed. CIR is effective where cracking is limited to the surface layers; profile, crown, and cross slope problems; poor ride quality and surface friction; rutting, corrugations, and bumps; raveling; and flushing/bleeding. This treatment may be used when transverse cracking level is O4 and the age of surface is greater than 12 years.

Application Limitations. This treatment must be approved by BDE and will require an experimental feature study according to Construction Memorandum 02-2. CIR is not an appropriate treatment for pavements with major or extensive structural deficiencies (e.g., severe alligator cracking, severe structural rutting) or distresses deeper than the CIR depth. CIR may also be difficult to conduct on steep grades, tightly curved roads, or on roads with many utility appurtenances.

Letting/Construction Considerations. The project letting date should be selected to target construction when the air temperature is moderate (i.e., 50°F (10°C) or above). CIR pavement can remain tender for a number of days. Do not allow this treatment to remain exposed over the winter season without a surface treatment or HMA overlay as the final wearing surface.

Traffic Considerations. CIR is most often used on secondary and low volume roads. This treatment is not recommended for ADT greater than 10,000.

Special Considerations/Comments: Remove and replace areas of weak material with suitable patching material prior to recycling to reduce the risk of the cold-planing machine or other CIR equipment breaking through the pavement. If excessive concrete patches are present at the pavement surface, this treatment should not be used.

Performance Period. 5 to 13 years.

PAVEMENT REHABILITATION TREATMENT (MINOR)

Name: Standard Hot-Mix Asphalt (HMA) Overlay
(Formerly known as the Policy Resurfacing Program)

Application:

System:	Interstates and Non-Interstates
Pavement Type(s):	All Pavements
Distress Type(s):	Relates to All Functional and Limited Structural Failures

Purpose. Standard HMA Overlays are used to reduce or eliminate distresses and restore serviceability on a pavement in fair to poor condition.

Treatment Description. Standard HMA Overlays consist of placing two lifts of HMA, unless otherwise noted. The mixture gradation and thickness shall be specified according to Section 53-4.03(a). HMA mixture design criteria must be met as outlined in Section 53-4.04.

Pavement Conditions Addressed. Standard HMA Overlays are effective in treating low- to medium-severity alligator cracking, rut depth < 0.25 in. (6 mm), low- to medium-severity transverse cracking, and low- to medium-severity reflective widening cracking.

Traffic Considerations. Roadway segments with extremely high multiple unit counts may want to consider a Stone-Matrix Asphalt mixture.

Special Considerations/Comments. If the district wants to use an alternative thickness range (increased or decreased) or a single lift, an exception request must be submitted to the Asset Management Engineer to coordinate with the Engineer of Pavement Technology for approval.

For existing HMA-surface pavements, cold milling and inlay may be used in conjunction with a Standard HMA Overlay to maintain existing grade elevation or gain clearance under overhead structures. More information on cold milling is available in the pre-treatment activity summaries (Section 53-5.05).

Performance Period. 10 to 15 years.

53-5.04 Major Rehabilitation Treatment Summaries

PAVEMENT REHABILITATION TREATMENT (MAJOR)
Name: Designed HMA Overlay (Formerly known as Structural Overlay) **Application**: System: Interstates and non-Interstates Pavement Type(s): All Pavements Distress Type(s): Relates to All Functional and Structural Failures
Purpose. Designed HMA overlays are used to restore serviceability and slow the propagation of underlying structural distresses on a pavement in poor condition. **Treatment Description.** Designed HMA overlays consist of placing two or more lifts of HMA. The mixture gradation and thickness shall be specified according to Section 53-4.04(a). HMA mixture design criteria must be met as outlined in Section 53-4.04(b). **Pavement Conditions Addressed.** For Interstate CRS values ≥ 4.0 and non-Interstate CRS values ≥ 3.5, designed HMA overlays may be effective in treating infrequent high-severity alligator cracking, high-severity transverse cracking, and high-severity reflective widening cracking. **Traffic Considerations.** Roadway segments with extremely high multiple unit counts may want to consider a Stone-Matrix Asphalt mixture. **Special Considerations/Comments.** For existing HMA-surface pavements, cold milling and inlay may be used in conjunction with a designed HMA overlay to maintain existing grade elevation. More information on cold milling is available in the pre-treatment activity summaries (Section 53-5.05). If milling depth is greater than designed overlay thickness, an exception request must be submitted according to Section 53-2.08. **Performance Period.** 10 to 15 years.

PAVEMENT REHABILITATION TREATMENT (MAJOR)

Name: Structural Concrete Overlay (SCO)

Application:

System: Interstates and Non-Interstates
Pavement Type(s): All Pavements
Distress Type(s): All Functional and Structural Failures

Purpose. The Structural Concrete Overlay (SCO) is designed to span underlying structural distresses while minimizing the potential for random cracking of the PCC slab.

Treatment Description. SCOs consist of placing a non-reinforced layer of PCC pavement over an existing distressed pavement. This treatment is sawed both longitudinally and transversely to create panels.

If the pavement has been previously resurfaced with HMA, the surface may be milled to correct profile irregularities. If the pavement is bare PCC, an interlayer shall be placed as a bond breaker between the existing PCC pavement and the SCO.

Pavement Conditions Addressed. Pavements that have high severity structural distresses (e.g., frequent, high severity transverse cracking) are suited for this treatment to reduce the potential for reflective cracking in the overlay.

Traffic Considerations. The best alternative for traffic control is to completely close the project to traffic. This alternative may be difficult for urban projects; however, somewhat easier for rural projects.

Special Considerations/Comments. This treatment has had limited use and is still considered experimental. The district must work with the Bureau of Research to design the PCC thickness, interlayer type and thickness, and joint spacing for the SCO.

Use of the SCO requires an experimental feature according to Construction Memo 02-2 and approval by the Bureau of Research. Contact the Engineer of Pavement Technology in the Bureau of Research for additional information on use and design of this treatment.

Performance Period. 12 to 15 years.

53-5.05 Pre-Treatment Activity Summaries

PRE-TREATMENT ACTIVITY SUMMARY

Name: Cold Milling / Fine Milling

Application:

Pavement Type(s): HMA Pavements, Composite Pavements

Distress Type(s): Relates to both Functional Failures and Structural Failures

Description and Purpose: Cold milling and fine milling are effective at mitigating functional distresses and providing a smoother surface by removing vertical deformations. It can also be used to restore proper grades and cross-slopes on existing pavement.

Cold milling involves the removal of part or all of an existing HMA surface to prepare an HMA surface for an HMA overlay or SMART overlays. Milling depth should match what is required to remove the entire HMA surface lift. Deeper milling may be required based on the findings of a pavement investigation report or project constraints.

Fine milling, which uses modified milling equipment, is used in preparation for a preservation treatment. Contact the Bureau of Research for the current version of the fine milling special provision.

Special Considerations/Comments:

Some rehabilitation treatments require a minimum thickness of HMA for construction purposes. See Section 53-4 for requirements.

PRE-TREATMENT ACTIVITY SUMMARY

Name: Full-Depth CRCP Patches (Class A)

Application:

Pavement Type(s): CRCP, HMA Overlaid CRCP
Distress Type(s): Structural Failures

Description and Purpose:

Class A patching consists of removing the failed pavement area and patching it with a full-depth, continuously reinforced PCC patch. Where CRCP facilities are to be patched, it is important to make every attempt to maintain the integrity of the continuous reinforcement. A decision that the pavement distress is so severe that continuity cannot be maintained must be justified by district field testing and subsequent review by the Central Office. In some cases, previous contracts or maintenance activities may have resulted in the use of non-tied PCC or HMA patches being placed on a CRCP facility. Such patches should be replaced with Class A patches when rehabilitation is justified. Obtain BDE approval prior to specifying other than Class A patching for CRCP facilities. Refer to the *Highway Standards* for Class A patching details. The minimum Class A patch dimensions will be a length of 4.50 ft and a width that includes half the width of the travel lane.

Special Considerations/Comments:

It is not desirable to create the large number of closely spaced joints in a pavement that would result from placing a large number of closely spaced patches. The minimum distance between patches is 15 ft. If less than 15 ft of existing pavement will remain, the entire area between the two patches should be removed and replaced.

For all Class A patching projects, review previous plans to determine the locations of any lug systems or wide-flange beam terminal joints.

PRE-TREATMENT ACTIVITY SUMMARY

Name: Full-Depth Dowelled Patches (Class B)

Application:
Pavement Type(s): JPCP, JRCP, HMA Overlaid JPCP, and HMA Overlaid JRCP
Distress Type(s): Structural Failures

Description and Purpose:

Class B patching consists of removing the failed pavement area and patching it with a full-depth dowelled PCC patch. For highways on the State system, including Interstate facilities, that have sound JPCP/JRCP and less than 2% of previously placed undowelled patching, specify Class B patching regardless of whether or not the pavement will be overlaid. Class B patching also should be specified on other low-ADT routes that have existing load transfer and sound plain concrete pavements with no previously placed undowelled patches. In general, use dowelled patches on sound JPCP/JRCP. Specify undowelled patching if field testing indicates that the concrete is so unsound as to preclude the use of Class B patching. Refer to the *Highway Standards* for Class B patching details. The minimum Class B patch dimensions will be a length of 6 ft and a width that includes the full width of the travel lane.

Special Considerations/Comments:

It is not desirable to create the large number of closely spaced joints in a pavement that would result from placing a large number of closely spaced patches. The minimum distance between patches is 6 ft. If less than 6 ft of existing pavement will remain, the entire area between the two patches or between a patch and the existing joint should be removed and replaced.

PRE-TREATMENT ACTIVITY SUMMARY

Name: Full-Depth Undowelled Patches (Class C and Class D)

Application:
Pavement Type(s): HMA Pavements, JPCP, JRCP, and HMA Overlaid JPCP/JRCP
Distress Type(s): Structural Failures

Description and Purpose:

Undowelled patching may consist of either Class C or Class D patches. Class C patching consists of removing the distressed pavement area and patching it with an undowelled PCC patch. Class D patching consists of removing the distressed pavement area and replacing it with an HMA patch. Specify “Pavement Patching” to permit the contractor the option of using either PCC or HMA unless there exists a justifiable reason to specify one or the other. If a particular patch material is specified, document the basis for the material selection in the district project files.

Special Considerations/Comments:

Use the following guidelines when specifying either Class C or Class D patching:

1. PCC Pavements. Undowelled patching for PCC pavements should only be specified when field testing indicates that the concrete is so unsound as to preclude the use of Class A or B patching.

2. Full-Depth HMA Pavements. Class D patching shall be specified for all full-depth HMA pavements.

3. Level of Existing Patching. Undowelled patches also may be specified if there exists 2% or more of previously placed undowelled patching and the undowelled patches are in good condition and performing well.

4. Emergency Patching. Except in an emergency, Class D patching should not be specified on the Interstate System or on any supplemental freeway constructed to Interstate criteria. On such facilities, replace emergency Class D patches with permanent Class A, B, or C patches as soon as practical.

5. Full-Depth Patching. Where the multiple unit (MU) traffic is greater than 200 ADT, the minimum dimensions for full-depth patches will be a length of 4 ft and a width of half the travel lane. Where the MU traffic is 200 ADT or less, the minimum patch dimensions for full-depth patches will be as shown in the *Highway Standards* for Class C and Class D patches.

PRE-TREATMENT ACTIVITY SUMMARY

Name: Partial-Depth Patches

Application:
Pavement Type(s): All Pavement Types
Distress Type(s): Structural and Functional Failures

Description and Purpose:

Partial-Depth patching is effective at removing distresses that are primarily in the top portion of the pavement (e.g., isolated unstable rutting, spalling of joints in a PCC pavement, distresses limited to the HMA portion of a composite pavement, etc.). This activity typically uses HMA patching material, but some applications may warrant using PCC patching material.

Special Considerations/Comments:

Areas for partial-depth patching shall be clearly identified on the plans using a detail or note near typical sections or clear typical sections to note milling depth in relation to the cross-sectional layers. For example, the removal depth can include only HMA, or the removal depth can include a combination of HMA and deteriorated concrete.

When patching an HMA or composite pavement, the minimum partial-depth patch size will be 4 ft by 4 ft at the necessary depth. If using HMA patching material, lift thickness requirements shall be followed to ensure good performance of the patch. Mixture requirements, lift thickness, and placement methods are determined by whether or not the patch will be resurfaced.

When patching a bare PCC pavement, the minimum partial-depth patch size will be 2 ft by 2 ft at a depth of 2 to 4 inches. If PCC patching material is used, all joints within patches shall be reestablished to prevent random cracking.

PRE-TREATMENT ACTIVITY SUMMARY

Name: Longitudinal Crack Repair

Application:
Pavement Type(s): All PCC and HMA Overlaid PCC Pavements
Distress Type(s): Structural Failures

Description and Purpose:

Longitudinal crack repair is a cost-effective method of prolonging the service life of a pavement which has distress along a longitudinal crack while the rest of the pavement is sound. The recurring special provision for Portland Cement Concrete Partial Depth Hot-Mix Asphalt Patching shall be used for this work.

Many CRC pavements exhibit longitudinal cracking with severe spalling and D-cracking adjacent to the cracks. The cost of placing a full-depth patch at these locations would be prohibitive. Instead, the crack can be milled to a depth of 2 in. to 3 in. with a width of 12 in. to 24 in. The milled area can then be filled with a HMA mixture without a need to overlay the pavement. This method can also be used to repair high severity longitudinal cracks in JPCP/JRCP and reflective cracks in HMA overlays.

In lieu of milling, the longitudinal crack may be sealed with an asphalt mastic product. If interested in this option, contact the Bureau of Research for the special provision.

Special Considerations/Comments:

When using this method on bare PCC pavements, it is important to limit the depth of the milling to just above the depth of the reinforcing steel so as not to damage the steel.

53-5.06 Additional Design Feature Summaries

ADDITIONAL DESIGN FEATURE SUMMARY
Name: Expansion Joints **Application**: Pavement Type(s): PCC Pavements, Composite Pavements Distress Type(s): Relates to both Functional Failures and Structural Failures
Description and Purpose: Expansion joints should be visually inspected to determine if they are in working order. If patching is an integral part of the rehabilitation strategy, closed expansion joints should be re-established regardless of the type of patching that is specified. **Special Considerations/Comments**: Consider the following guidelines when re-establishing expansion joints: 1. Jointed Pavements. Consider the following for JPCP and JRCP: a. Dowelled Patches. Where the pavement requires patching at or near a closed expansion joint, a new joint should be established using a dowelled expansion patch as shown in the *Highway Standards* for Class B patches. If the joint is closed, but does not require patching, an expansion joint may be formed by sawing the pavement and filling the saw cut with a preformed expansion joint filler material that meets the *Standard Specifications* for expansion joints. b. Non-Dowelled Joints. If other than dowelled patches are required and if the pavement is not being resurfaced, a new expansion joint may be formed by sawing the pavement and filling the saw cut with a preformed expansion joint filler material that meets the *Standard Specifications*. 2. CRC Pavements. If a CRC pavement is being patched with a Class A patch, whether or not the pavement is being resurfaced, existing expansion joints should be re-established using a saw cut filled with preformed expansion joint filler material that meets the *Standard Specifications* for expansion joints.

ADDITIONAL DESIGN FEATURE SUMMARY

Name: Lug Areas/Pressure Relief Joints

Application:
Pavement Type(s): CRC Pavements, HMA Overlaid CRC Pavements
Distress Type(s): Relates to both Functional Failures and Structural Failures

Description and Purpose:

Lug systems are typically located just prior to the approach pavement of a structure. When developing patching contracts, consult previous plans to determine actual locations.

Lug areas that do not show signs of tilting or other similar distresses should not be cut free. If they have previously been cut free and there is no sign of tilting, the continuity of the pavement should be restored through the use of a Class A patch.

Special Considerations/Comments:

If signs of tilting exist and the pavement surface over the lug area is excessively rough, a 4 in. wide pressure relief joint that is filled with a preformed expansion joint filler material should be provided 150 ft from the lug area. The entire lug system should be subsealed to fill voids, and the area over the lug should be resurfaced to complete the leveling process.

In extreme cases, the lug system should be removed and replaced with a lug system or wide flange beam expansion joint as shown in the *Highway Standards*.

ADDITIONAL DESIGN FEATURE SUMMARY

Name: Pipe Underdrains

Application:

Pavement Type(s): All Pavements

Distress Type(s): Relates to both Functional Failures and Structural Failures

Description and Purpose:

Drainage is an important pavement rehabilitation consideration. Water is a fundamental variable in most problems associated with pavement performance and is directly or indirectly responsible for many pavement distresses. A drainage survey may indicate that pipe underdrains are required to control one or more sources of water in the pavement, thus increasing pavement serviceability and life. Subsurface drainage systems should be designed and constructed with long-term performance and maintenance goals in mind, including periodic inspections to check performance.

Special Considerations/Comments:

The moisture that infiltrates the pavement/shoulder joint usually is the only moisture that can be readily drained. A benefit to installing retrofit pipe underdrains is that it will minimize the potential to trap moisture in the slab/base interface. A properly designed and constructed longitudinal edge drain system can, in some cases, improve the long-term load-carrying and distribution properties of the base and subgrade materials. Note that underdrains by themselves cannot restore a pavement that is structurally inadequate.

ADDITIONAL DESIGN FEATURE SUMMARY

Name: Wide-Flange Beam Terminal Joints

Application:
Pavement Type(s): CRC Pavements, HMA Overlaid CRC Pavements
Distress Type(s): Relates to both Functional Failures and Structural Failures

Description and Purpose:

Wide-Flange Beam Terminal Joints are typically located just prior to the approach pavement of a structure. When developing patching contracts, consult previous plans to determine actual locations.

Existing wide flange beam terminal joints should be closely inspected to determine if the joint is working properly both at the beam and at the expansion joint between the beam and the bridge approach or jointed pavement. In addition, the flange of the beam should be inspected for signs of fatigue cracking.

Special Considerations/Comments:

If the pavement in the area of these joints or the beam itself show signs of distress, special patching details may be required. Contact the BDE for assistance in preparing plans for the proper remedial treatment.

PAVEMENT DESIGN

54-1 GENERAL

54-1.01 Scope of Chapter

Following the AASHO Road Test Project, IDOT assessed the results and performed additional research to develop practical applications of the findings that would be applicable to all marked and all unmarked routes on the State highway system. In the late 1980's and early 1990's, mechanistic design concepts were investigated and developed into our first procedures using the actual stresses and strains from traffic to design our pavements. Since that time, extensive research, monitoring, and evaluation have occurred resulting in refinements in the late 2000s. As a result, the following structural pavement design methodologies were developed or updated for inclusion in Chapter 54:

- mechanistic design of rigid pavements,
- modified AASHTO design of rigid pavements (CRCP only),
- design procedures for unbonded concrete overlays,
- mechanistic design of flexible pavements,
- mechanistic design of flexible pavements over rubblized PCC pavements, and
- modified AASHTO design of composite pavements.

A flowchart is presented in Chapter 54 (Figure 54-1.A) that will assist in determining the appropriate structural pavement design methodology, pavement type, and design criteria. In addition to providing an analytical approach to structural pavement design, Chapter 54 presents an analytical method for selecting the most economical pavement design that can be expected to meet structural design requirements. The pavement design submittal serves as documentation to substantiate the recommendation of pavement type and thickness.

The pavement design procedures outlined in this chapter are for pavements on the state system only. The procedures in this chapter are inappropriate for non-state agency pavements and/or parking lots. Designs for local agencies should be developed using Chapter 44 of the BLRS Manual.

54-1.02 Definitions

The following definitions are typically used in pavement design:

1. Base Course. The layer(s) of material placed on a subbase or a subgrade to support the surface course.

2. Class I Roads and Streets. Roads and streets designed as a facility, or as part of a future facility, with four or more lanes, and all one-way streets with structural design traffic greater than 3,500 ADT.

3. Class II Roads and Streets. Roads and streets designed as a two-lane facility with structural design traffic greater than 2,000 ADT, and all one-way streets with structural design traffic less than 3,500 ADT.
