4. Class III Roads and Streets. Roads and streets with structural design traffic between 750 ADT and 2,000 ADT.

5. Class IV Roads and Streets. Roads and streets with structural design traffic less than 750 ADT.

6. Composite Pavement. A pavement structure having an HMA surface overlaying a PCC slab of relatively high bending resistance that serves as the principal load distributing layer. The PCC slab may be either a newly constructed base course or an existing rigid or composite pavement that is to be resurfaced.

7. Composite Pavement Structural Number (SN_C). An index number derived from an analysis of traffic and roadbed soil conditions that is used to determine the thickness of HMA surface and PCC base course, if required, for a composite pavement.

8. Construction Year Traffic. Construction year traffic is the ADT for the year the facility is to be opened to traffic.

9. Continuously Reinforced Concrete Pavement (CRCP). A rigid pavement structure having continuous longitudinal reinforcement. The continuous reinforcement is achieved by overlapping the longitudinal steel reinforcing bars.

10. Design HMA Microstrain. The design HMA microstrain is the tensile strain at the bottom of the HMA pavement layer used in the design of mechanistic flexible pavements.

11. Design E_{HMA} (HMA Mixture Modulus). The design E_{HMA} is the HMA mixture modulus in the pavement that corresponds to the design pavement HMA mixture temperature. E_{HMA} is selected from Figure 54-5.D and is based on the relationship between the design HMA mixture temperature and the asphalt binder type (i.e., PGXX-22 or PGXX-28) used in the design of mechanistic flexible pavements.

12. Design Lane. The lane carrying the greatest number of SU and MU vehicles for which the pavement section thickness will be based.

13. Design Pavement HMA Mixture Temperature. The design temperature of the HMA mixture to be used in the design of mechanistic flexible pavements is based on the pavement's geographical location. See Figure 54-5.C.

14. Design Period. The number of years that a pavement is to carry a specific traffic volume and retain a serviceability level at or above a designated minimum value.

15. Design Subgrade Support Rating (SSR). The design SSR is the rating of the subgrade support under mechanistically designed pavements. There are three classes of SSR: poor, fair, and granular. SSR is determined by the district geotechnical engineer and documented in the project soils report.

16. Equivalency Factor. A numerical factor that expresses the relationship of a given axle load to another axle load in terms of its effect on the serviceability of a pavement structure. In pavement design, all axle loads are equated in terms of an equivalent number of repetitions of an 18-kip, equivalent single-axle load (ESALs).

17. Existing Traffic. Existing traffic is the existing ADT of the facility.

18. Flexible Pavement. An HMA pavement structure which maintains intimate contact with and distributes loads to the subgrade which depends upon aggregate interlock, particle friction, and cohesion for stability.

19. Flexible Pavement Structural Number (SN_F). An index number derived from an analysis of traffic and roadbed soil conditions which may be converted to a flexible pavement thickness for modified AASHTO through the use of suitable factors related to the types and strengths of material being used within the pavement structure.

20. Full-Depth HMA Pavement. A flexible pavement structure that uses HMA throughout the entire thickness (binder course and surface course layers).

21. Future Traffic. Future traffic is the ADT of the facility at the end of the design period, typically 20 years.

22. Illinois Bearing Ratio (IBR). The IBR is a measure of the support provided by the roadbed soils or by unbound granular materials under modified AASHTO designed pavements or composite pavements. The IBR test procedure is a modification of the California Bearing Ratio (CBR) procedure and is a soaked laboratory test.

23. Improved Subgrade. A subgrade which has been modified with lime, by-product lime, cement, or other approved material or, alternatively, has been removed and replaced with aggregate.

24. Integral Curb and Gutter. A curb and gutter which is paved monolithically with the pavement. It is used to reduce edge stresses.

25. Jointed Plain Concrete Pavement (JPCP). A rigid pavement structure that uses doweled joints at 12 ft or 15 ft nominal intervals.

26. Jointed Reinforced Concrete Pavement (JRCP). A rigid pavement that uses distributed steel reinforcement and transverse contraction joints.

27. Limiting Strain Criterion Design Thickness. The full-depth HMA pavement thickness at which the tensile strain at the bottom of the HMA is reduced to such a level that fatigue is no longer a factor in the design. This thickness need not be exceeded.

28. Mechanistic Pavement Design. A structural pavement design procedure used to determine fatigue life based on actual conditions, including stresses, strains, and deflections. It can be used to suit any local condition and material.

29. Multiple-Unit (MU) Vehicles. MU vehicles include truck tractor semi-trailers, full trailer combination vehicles, and other similar combinations.

30. Passenger Vehicles (PV). PVs include automobiles, pickup trucks, vans, and other similar two-axle, four-tire vehicles.

31. Pavement Performance. The trend of pavement serviceability with respect to repetitive vehicular load applications.

32. Pavement Structure. The combination of subbase, base course, and surface course placed on a subgrade to support the traffic load and distribute it to the roadbed.

33. Present Serviceability Index (PSI). A number derived by formula for estimating the serviceability rating from measurements of certain physical features of the pavement.

34. Present Serviceability Rating (PSR). The mean value of the independent subjective ratings by members of a special panel for the AASHO Road Test as to the serviceability of a section of the highway.

35. Pumping. The ejection of foundation material through joints or cracks or along edges of rigid slabs due to vertical movements of the slab under traffic.

36. Ramp. A roadway that connects two or more legs at an interchange and includes at least one ramp terminal section. Roadways that connect two legs of freeway, and that are continuations of mainline lanes, or arise from tapers designed for high-speed operation are not considered ramps, but are considered part of the mainline for structural design.

37. Rigid Pavement. A pavement structure whose surface and principal load distributing component is a PCC slab of relatively high bending resistance (e.g., JPCP, CRCP, JRCP).

38. Roadbed. That portion of the highway within the side slopes that is graded and prepared as a foundation for the pavement structure and shoulders.

39. Serviceability. The ability of a pavement, at the time of observation, to serve automobile and truck traffic.

40. Single-Axle Load. The total load transmitted by all wheels whose centers may be included between two parallel transverse vertical planes 40 in. apart, extending across the full width of the vehicle.

41. Single-Unit (SU) Vehicles. SU vehicles include two- or three-axle trucks and buses having six tires.

42. Structural Design Traffic. The ADT that is estimated for the year that represents one-half of the design period which is then classified into PV, SU, and MU vehicles and assigned to the design lane to determine a traffic factor.

43. Subbase. The layer(s) of material (e.g., HMA, CAM II) placed on the subgrade to support the base course or, in the case of rigid pavements, the PCC slab.

44. Subgrade. The finished grade of earthwork upon which the pavement structure (i.e. the subbase, base course, surface course, or pavement slab) and shoulders are constructed. Due to the poor soils in Illinois, the subgrade is typically improved (see Improved Suggrade definition).

45. Surface Course. One or more layers of a pavement structure designed to accommodate the traffic load, the top layer of which resists skidding, traffic abrasion, and the disintegrating effects of climate. The top layer is sometimes called the “wearing course”.

46. Tandem-Axle Load. The total load transmitted to the road by two or more consecutive axles whose centers may be included between two parallel vertical planes spaced more than 40 in. but not more than 96 in. apart, extending across the full width of the vehicle.

47. Tied Curb and Gutter. A PCC curb and gutter, which is tied with reinforcing steel to the pavement. It is used to reduce pavement edge stresses.

48. Tied Shoulder. A PCC stabilized shoulder tied with reinforcing steel to the pavement. It is used to reduce pavement edge stresses.

49. Time-Traffic Exposure Factor. A numerical factor applied to the pavement design term indicated by the AASHO Road Test pavement performance equations (rigid and flexible) to modify the equations to be more representative of the behavior of pavements serving under similar conditions but over periods of time more typical of regular service life.

50. Traffic Factor (TF). The total number of 18-kip equivalent single-axle load applications (ESALs) to the design lane anticipated during the design period, expressed in millions. It is used as an equivalency factor for mixed traffic loads.

51. Untied Shoulder. Any shoulder which does not provide edge support. The shoulder may consist of earth, aggregate, HMA, or other materials.

54-1.03 Pavement Design Methodologies

54-1.03(a) Mechanistic

Since the completion of the AASHO Road Test Project, the Department has developed many new highway materials and procedures to improve pavement construction. This effort has resulted in improved material usage, construction procedures, and pavement designs which, although common practice today, were neither envisioned nor included in design procedures at the time of the AASHO Road Test. Therefore, to supplement the AASHO Road Test Project and better address modern pavement design, mechanistically based structural pavement design procedures were developed using structural mechanical analysis, computer modeling, and actual performance and response of existing pavement sections.

Mechanistic pavement design procedures are applicable to JPCP designs with nominal 12-ft or 15-ft panels and full-depth HMA designs with HMA surface and binder. The procedures use the actual stresses, strains, and deflections experienced by the pavement to determine its expected fatigue life. Factors that are considered in mechanistic designs include:

- design HMA strain,
- design pavement HMA mixture temperature,
- design HMA mixture modulus (E_{HMA}),
- subgrade support ratio (SSR),
- design reliability of 95% (HMA and PCC),
- degree of PCC edge support,
- degree of PCC base erosion,
- PCC joint spacing, and
- PCC stresses.

See Section 54-1.02 for definitions of these factors.

The "IDOT Mechanistic Pavement Design and Life-Cycle Cost Analysis" spreasheet (BDE 5401) is used to perform the design calculations and is available on the IDOT website.

54-1.03(b) Modified AASHTO

The modified AASHTO design procedures are based on the AASHO Road Test pavement performance equations, which correlate performance of test sections with pavement design, the magnitude and configuration of the axle load, and the number of axle-load applications. The AASHTO equations are necessarily limited to the following factors:

- physical environment of the Road Test Project,
- materials used in the test pavements,
- range of pavement thicknesses included in the experiments,
- axle loads used and number of axle-load applications experienced,

- specific times and rates of application of the test traffic,
- construction techniques employed, and
- climatic cycles experienced during construction and testing of the experimental facility.

To apply the AASHTO equations in design, it is necessary to make certain assumptions and extrapolations based on experience and engineering judgment. In developing the design procedures, modifications were made to the AASHTO equations to reflect the effect of the following variations on pavement performance:

- mixed truck and passenger car traffic axle loadings when compared with controlled traffic axle loadings in the AASHO Road Test,
- pavements subjected to traffic over longer periods of time when compared to the two years of traffic in the AASHO Road Test, and
- variations in the support strengths of the roadbed soils.

Variations in climatic conditions as they exist from one part of the State to another and particularly between the extreme northern and extreme southern portions undoubtedly affect pavement performance. The relative effects of these variations on pavement performance, however, are not sufficiently distinguishable at the present time to be taken into account in pavement structural design. Therefore, in developing the modified AASHTO structural design procedures, climatic effects were considered only on a state-wide basis.

Currently, the modified AASHTO design procedure is only used for CRCP, unbonded CRC overlays, and composite pavements. Composite pavements include HMA surfacing for both existing PCC pavements and new PCC base courses.

54-1.04 Selection of Design Methodology, Pavement Type, and Design Criteria

Figure 54-1.A presents a flowchart that will help to determine the appropriate structural pavement design methodology, pavement type, and design criteria. In general, the mechanistic structural pavement design methodology will be used for all projects involving new pavement construction, replacement of existing pavements, and widening greater than or equal to 6 ft. In addition to the above requirements, the following will apply:

1. New Construction/Replacement Projects. For new construction/replacement projects, the pavement selection will be based on a life-cycle cost analysis (see Section 54-7). This procedure uses a 45-year life cycle, a 3% discount rate, and a comparison of pavement types based on annualized costs.

   For pavement replacement projects, supplemental designs such as unbonded concrete overlay and full-depth HMA pavement over rubblized PCC will be added to the comparison with mechanistic designs for new rigid and flexible pavements to determine the most appropriate and economical strategy.

   If the economic analysis does not result in one design being more than 10% cheaper than the others, the pavement selection will be based upon an alternate pavement bidding process. The criteria and requirements shown below must be met/followed for use of the alternate pavement bidding process.

a. Project Criteria. The following criteria must be met for a project to be considered for the alternate pavement bidding process.

- The project length must be 2 lane-miles or more in length. Pavement projects less than 2 lane-miles in length may be developed for alternate bids with approval by the Bureau of Research. A standard lane-mile is defined as pavement 12 ft wide and 1 mile in length. Full-depth paved shoulder widths that have the same pavement type as the mainline should be proportionally included when calculating the overall project length in lane-miles [compared to 12-ft lane width].

- Projects involving widening cannot be considered for the alternate pavement bidding process.

- Life cycle costs for both the rigid and flexible designs must be based on a 45-year analysis with equal pavement design life.

- Traffic and construction staging for all pavement designs are considered an equal cost and therefore not included in the analysis.

b. Project Requirements. The following requirements must be completed for preparing a project for the alternate pavement bidding process.

- Plans for all projects with alternate pavements should contain typical cross-sections and multiple sets of quantities. One set will contain all items that are common for all pavement designs. The remaining sets will contain those items exclusive to the a particular design. Typical sections for each alternate pavement design, including station limits and all side road connections, must be presented in the contract plans. All pay items for alternate pavements must be in square yards for the entire pavement surface.

- The profile grade should always be designed for the thickest pavement design. The Contractor is responsible for maintaining the profile grade shown on the plans for the selected pavement with no additional compensation.

- Projects using lime modification for the improved subgrade must be scheduled for letting such that the subgrade improvement and placement of the pavement is completed in the same construction season. If the letting date is too late in the year to meet this requirement, the project start date needs to be delayed until the following construction season.

- Crossroad structures should be designed to accommodate a minimum cover based on the thickest pavement design.

- Cost adjustment special provisions which tend to benefit one alternative (e.g. Bituminous Materials Cost Adjustment) cannot be included in an alternate bidding project. Other cost adjustments which are of equal benefit (e.g. Fuel Cost Adjustment and Steel Cost Adjustment) should be included.

While alternate bidding is generally advantageous, circumstances occasionally arise which cause one pavement type to be preferred over the other. In such cases, the district can submit documentation to the Bureau of Research of the preferred pavement type and the reason(s) alternate bidding is not advantageous. The Pavement Selection Committee can then be convened to determine the final pavement design. Refer to Section 54-7.05 for more information on the Pavement Selection Committee.

2. Widening Projects Involving Resurfacing. For projects involving widening greater than or equal to 6 ft in width, where the existing pavement and widening are to be resurfaced, the following will apply.

- The thickness of resurfacing over the existing pavement should be determined first according to the Department's policy.

- The mechanistic pavement design procedure will then be used to determine the total thickness of pavement required for the full-depth HMA pavement widening. The thickness of the resurfacing will be subtracted from the total thickness to determine the thickness of the additional binder required.

- Procedures contained in Section 54-6 will be used to design the PCC base course thickness of the composite pavement alternative. The thickness of the HMA surface and top lift of binder over the PCC base course will be equal to that determined for the resurfacing of the existing pavement.

- The designer should review and consider the ability of the pavement to be matched in-kind. It is possible that the new pavement thickness is thinner than the original pavement and subsequent rehabilitations. The designer should review the cross-section to determine if drainage paths will be impacted or other factors exist that could lead to performance problems if a thinner section is placed next to a thicker section.

- The selection of the pavement type will then be based on first cost.

3. Widening Projects Not Involving Resurfacing. For projects involving widening greater than or equal to 6 ft in width, where the existing pavement and widening are not to be resurfaced, the following will apply:

- The mechanistic structural pavement design procedures will be used to determine the required thickness for both the rigid and full-depth HMA pavement alternatives.

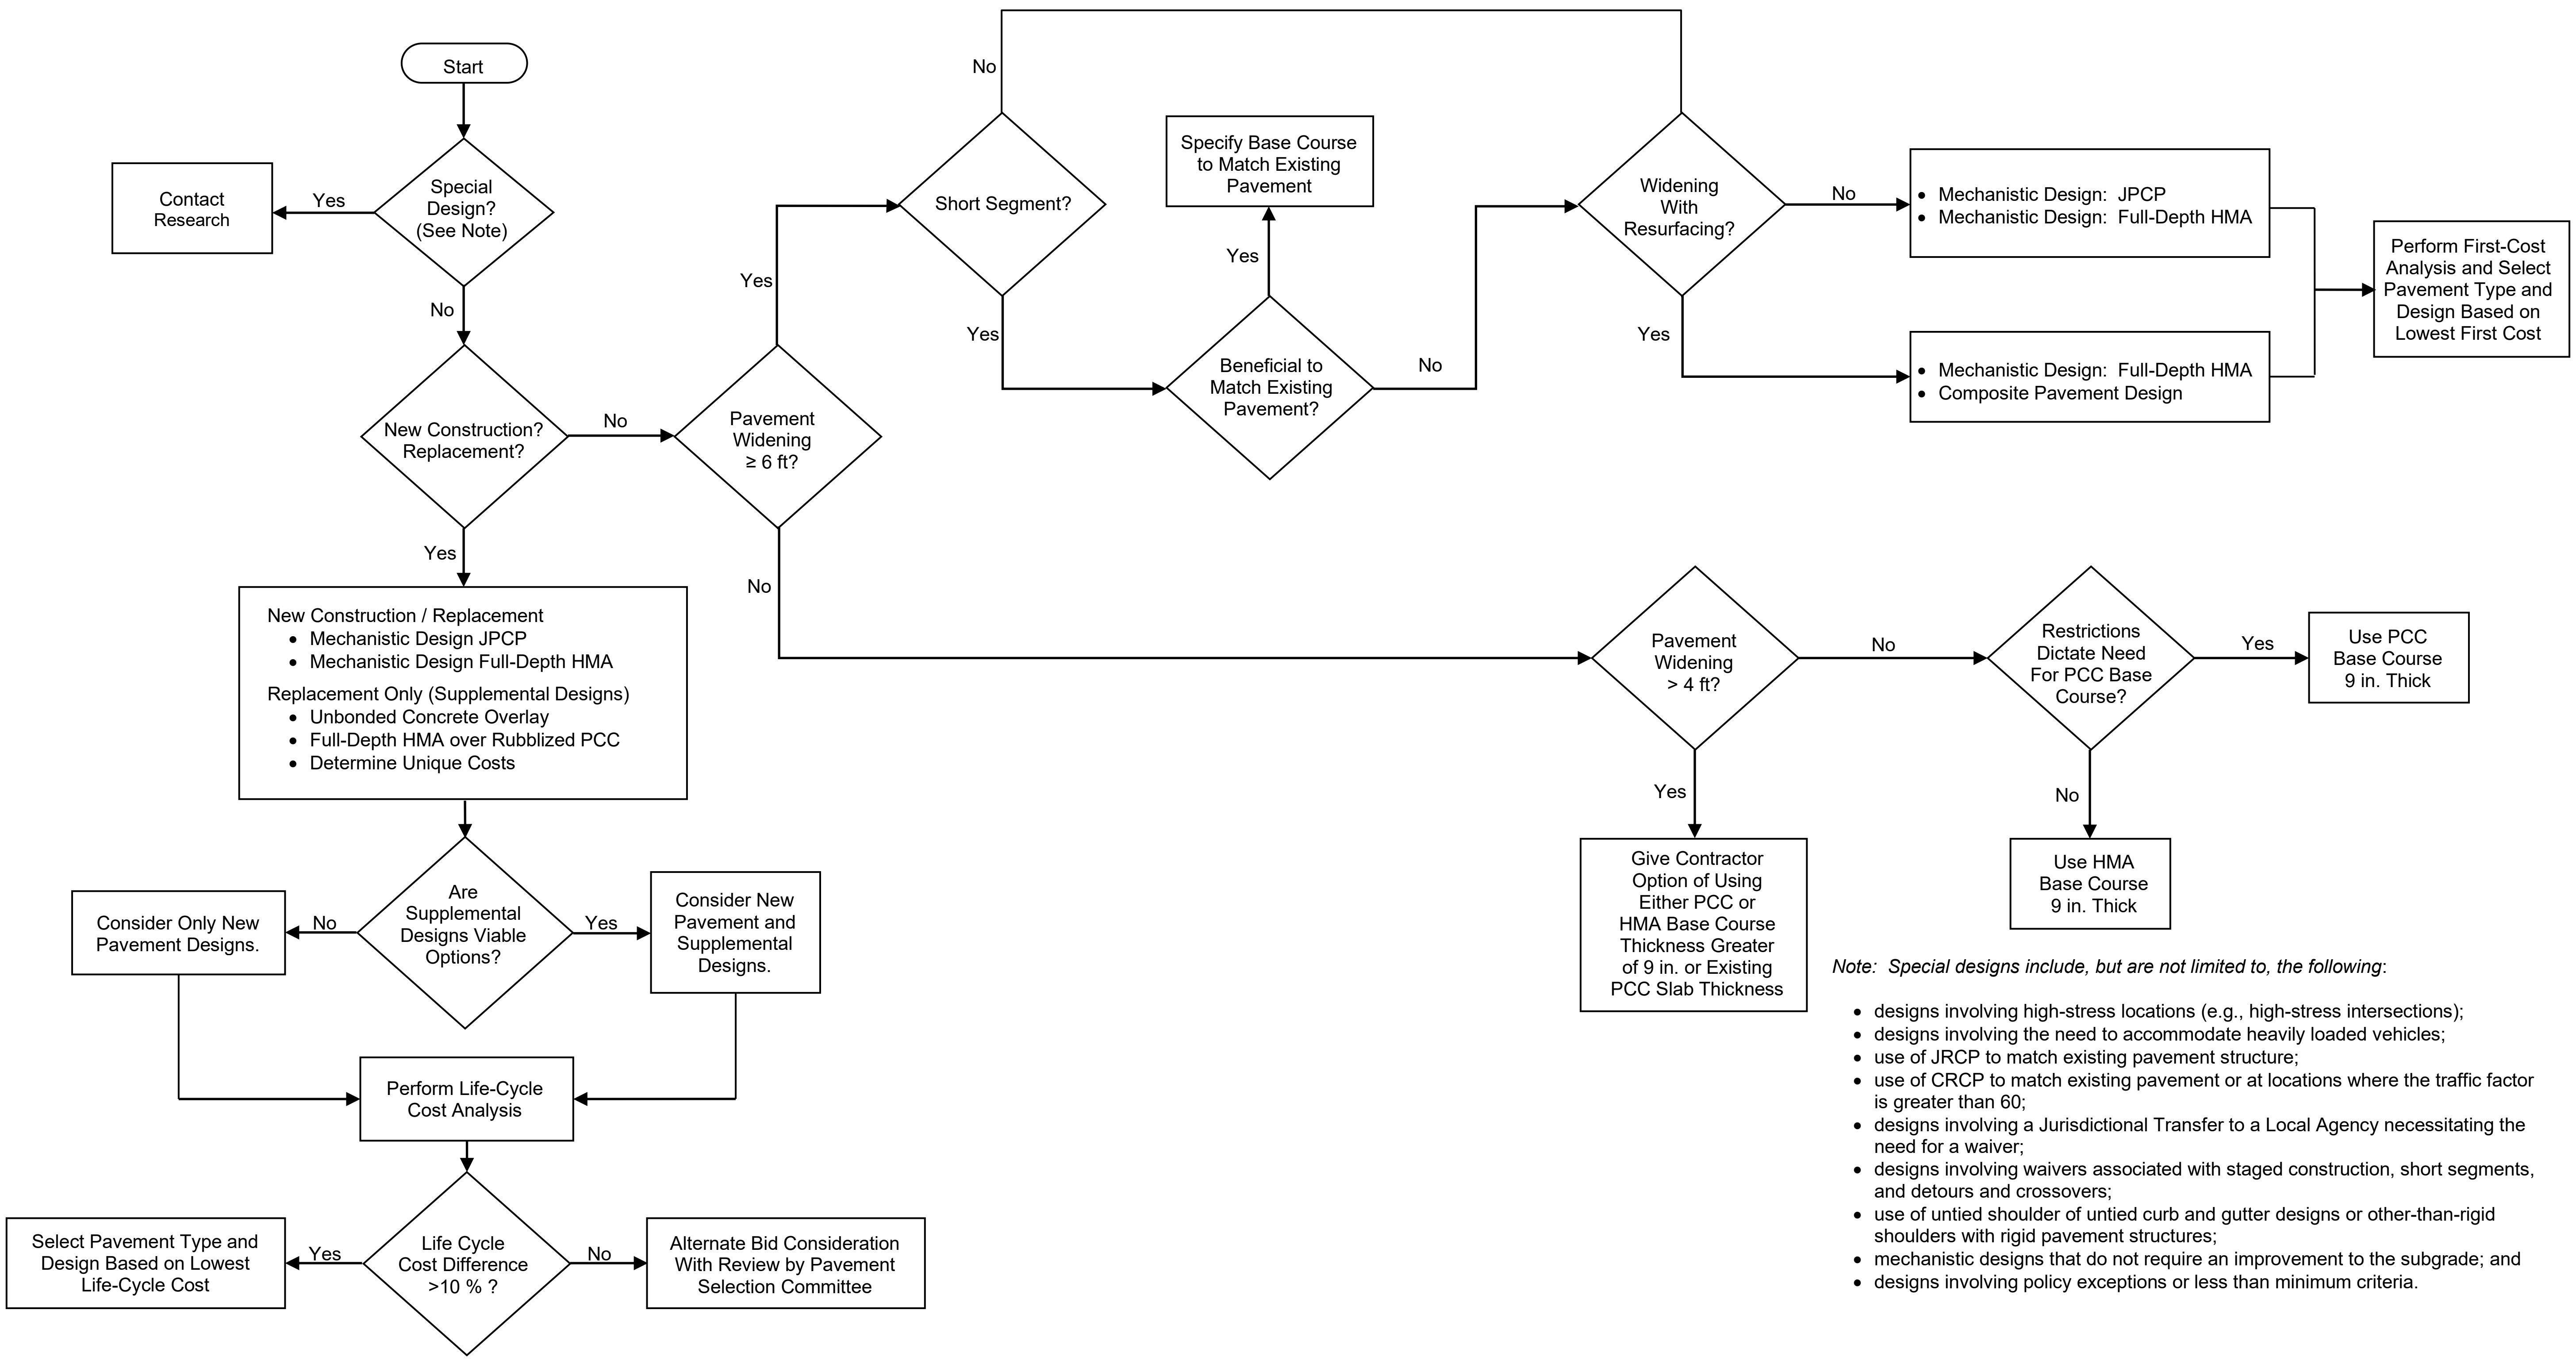
- The designer should review and consider the ability of the pavement to be matched in-kind. It is possible that the new pavement thickness is thinner than the original pavement and subsequent rehabilitations. The designer should review the cross-section to determine if drainage paths will be impacted or other factors exist that could lead to performance problems if a thinner section is placed next to a thicker section.

- The selection of the pavement type will then be based on first cost.

4. Special Considerations of Mechanistic Designs. The design charts used in the mechanistic design methodology provide several options for both rigid and flexible pavement designs. The following special considerations apply to mechanistic designs:

    a. Rigid Pavement Designs. Unless prior approval to use untied shoulders has been granted by the the Bureau of Research or if stabilized shoulders are not required, the rigid pavement design curve for the 12 ft lane with tied concrete shoulders will be used for determining the design thickness. If the rigid option is selected, plans will be prepared based on the thickness obtained with the 12 ft lane.

    b. Flexible Pavement Designs. For flexible pavements, the designer must select the appropriate asphalt binder grade(s) (i.e., PG XX-22 or PG XX-28) for the lower binder, upper binder, and surface lifts. This information is then included on the HMA Mixture Table in the plans. However the design thickness of the overall pavement is only based upon the asphalt binder grade of the lower binder which is PG 64-22 for all districts according to Figure 53-4.M. This is the only binder grade which should be used in the actual design.



Note: Special designs include, but are not limited to, the following:

- designs involving high-stress locations (e.g., high-stress intersections);
- designs involving the need to accommodate heavily loaded vehicles;
- use of JRCP to match existing pavement structure;
- use of CRCP to match existing pavement or at locations where the traffic factor is greater than 60;
- designs involving a Jurisdictional Transfer to a Local Agency necessitating the need for a waiver;
- designs involving waivers associated with staged construction, short segments, and detours and crossovers;
- use of untied shoulder of untied curb and gutter designs or other-than-rigid shoulders with rigid pavement structures;
- mechanistic designs that do not require an improvement to the subgrade; and
- designs involving policy exceptions or less than minimum criteria.

FLOWCHART FOR SELECTION OF DESIGN METHODOLOGY, PAVEMENT TYPE, AND DESIGN CRITERIA

Figure 54-1.A

54-1.05 Intersections

The type of pavement material selected for intersections will depend upon the existing pavement type and the volume and type of vehicles crossing or turning at the intersection. The following sections discuss the type and application of pavement materials typically used at intersections.

54-1.05(a) High-Stress Intersections

High-stress intersections are defined as those under stop control, either signal or signage, that have one or more of the following conditions:

- The approach grade on any stop-controlled leg of the intersection is greater than or equal to 3.5%.
- The design lane MU ADT is greater than or equal to 200 vehicles.
- The MU ADT for turning vehicles on any one lane of the intersection is greater than or equal to 200 vehicles. This also applies to sharp turning movements that are not under stop control.

Pavement types for high-stress intersections are limited to either of the following materials:

- PCC, or
- HMA $N_{design} \geq 90$ with polymer-modified binders.

Use these materials a minimum of 150 ft back from the location of the stop bar. The maximum length normally will be the length of the turn lane plus the taper. A greater length is permitted if a capacity study indicates a greater queue length.

If an existing intersection exhibits rutting and shoving of the HMA surface material, consider complete replacement rather than resurfacing the intersection.

54-1.05(b) Distress Treatment at Other Intersections

Intersections not meeting the criteria in Section 54-1.05(a) are not considered high-stress intersections. Nevertheless, they may exhibit, or have the potential to exhibit, pavement distress similar to that exhibited at high-stress intersections.

At intersections that do not meet high-stress criteria where the existing pavement type is bare PCC, PCC may be used if the improvement consists of minor widening without resurfacing.

Those intersections that are not considered high-stress but have an HMA pavement type exhibiting distress (e.g., rutting, shoving) should be investigated to determine the cause. Procedures outlined in the Pavement Management and Evaluation Manual should be used to determine the suitability of the existing HMA pavement. If the existing material is found to be unsuitable, remove and replace the unstable material prior to resurfacing. If the investigation indicates a stable mixture but experience indicates a problem with flexible or composite pavements, consider obtaining an exception to the criteria presented in Section 54-1.05(a). Example conditions which may allow an exception include the following:

- MU ADT less than 200 if all are required to stop or if the approach speed is greater than 40 mph.
- MU ADT less than 200 if the majority are fully loaded at intersections near warehouse facilities, landfills, grain elevators, etc.
- High levels of SU vehicles that are primarily fully loaded hauling vehicles (e.g., grain trucks, concrete trucks, coal trucks). In this case, the designer should add the SU ADT to the MU ADT.
- Demonstrated and repeated history of pavement life significantly below 15 years with shoving of an HMA overlay related to tight turning movements.

The above exceptions also apply to intersections not exhibiting distress if the intersection is being constructed or replaced. Any exception request needs Bureau of Research approval. Requests to use PCC pavement for intersections that are not high-stress and do not require an exception will be submitted for approval through the normal pavement selection process.

54-1.05(c) Side Road Approaches

The following will apply to the placement of pavement material at side road approaches:

- For side road approaches that have a surface type lower than HMA, surface the approach with HMA to the right-of-way line or to 50 ft beyond the edge of the traveled way, whichever is less.
- For side road approaches that have a surface equal to or greater than HMA, surface the approach with HMA to at least the edge of shoulder.

54-1.06 Interchange Ramps

The following will apply to the structural pavement design of interchange ramps:

1. Design Methodology. Use the mechanistic structural pavement design methodology for interchange ramp projects, regardless of whether or not the ramps are to be newly constructed, replaced, or widened. The minimum traffic criteria are given in Figure 54-1.B. Other pavement design methodologies (e.g., modified AASHTO designs, composite pavement designs) are rarely used for interchange ramp designs and will require Bureau of Research approval.
2. Ramp Pavement Type. Use a pavement type for interchange ramps that is the same as that of the contract being let for the mainline, except that ramps connected to entrance or exit ramp terminals shall be jointed PCC pavement if rigid pavement is used for the mainline.

3. Design Considerations. Typically, it is necessary to perform a structural pavement design for interchange ramps that is independent of that for the mainline pavement. Give adequate consideration to the requirements of high-stress locations during design.

54-1.07 Rest Areas

Design the rest area exit and entrance ramps, roadways, shoulders, and parking areas for the greater of: 1) the actual projected mainline 2-way ADT in the design year using P=16% and S=M=25%, or 2) the interstate/freeway minimums assuming lane distribution of P=32% and S=M=45%. Use a pavement type for rest areas that is the same as that of the contract being let for the mainline, except use jointed PCC pavement if rigid pavement is used for the mainline. The concentration of heavy trucks braking on the ramps and inner roadways and the sharp turning maneuvers to enter parking stalls require these facilities to be considered high-stress locations. If HMA is used for the pavement material, it may require a polymer modified asphalt binder and/or special mixture design. See Sections 54-1.05(a) and 54-1.06 for additional information. Design the shoulders to the same thickness and material as the pavement as shown in Figure 16-1.H.

54-1.08 Weigh Stations

Design the weigh station ramps and detention parking area to provide the same structural capacity as the adjacent freeway. Weigh stations are, by definition, high-stress locations for pavement design purposes. When flexible or composite pavements are selected, apply modifications to the HMA mixtures to the driving lane pavements beginning 2,500 ft upstream of the exit ramp terminal stub, and downstream to a point 2,500 ft beyond the entrance ramp terminal stub, as well as throughout all pavements in the weigh stations and ramps. See Section 54-1.05(a) for additional information.

Crossroad	Design Traffic Criteria		Lane Distribution Criteria	Traffic Factor Equation	
				Rigid	Flexible
Interstate or Freeway	Greater of:	Actual Ramp Traffic Projection for Design Year	PV = SU = MU = 100% in Design Lane of Ramp (assuming a 1-lane ramp)	54-4.1	54-5.1
		Interstate/ Freeway Minimum Traffic (Figure 54-2C)	Same distribution as used for the Design Lane of the Crossroad (Figure 54-2B)	54-4.1	54-5.1
Other State Marked Route or Unmarked Route	Greater of:	Actual Ramp Traffic Projection for Design Year	PV = SU = MU = 100% in Design Lane of Ramp (assuming a 1-lane ramp)	54-4.1	54-5.1
		Marked Route Minimum Design Traffic (Figure 54-2C)	Same distribution as used for the Design Lane of the Crossroad (Figure 54-2B)	54-4.2	54-5.2

[1] *Use the highest traffic factor of any ramp at a given interchange for all ramps at that interchange.*

DESIGN TRAFFIC CRITERIA FOR INTERCHANGE RAMPS[1]

Figure 54-1.B

54-2 BASIC DESIGN PARAMETERS (Mechanistic)

54-2.01 Development of Design Procedures

54-2.01(a) General

See Section 54-1.03(a) for a brief discussion of the mechanistic structural pavement design methodology.

54-2.01(b) Design Period

The level of traffic and type of facility to be constructed affect the selection of the design period. Generally, it is desirable to design highway pavements to carry traffic without necessitating the need for major rehabilitation for a period of 20 years. However, it may be advantageous to design lesser roadways (e.g., frontage roads) for shorter periods. Use the following guidelines when selecting an appropriate design period:

1. New Construction/Pavement Replacement Projects. For new construction/pavement replacement projects, see the following sections for the appropriate design period:

   - Rigid Pavement: Mechanistic Design — Section 54-4.01(e),
   - Rigid Pavement (CRCP only): Modified AASHTO Design — Section 54-4.02(b),
   - Flexible Pavement: Mechanistic Design — Section 54-5.01(e), or
   - Composite Pavement Design: Modified AASHTO Design — Section 54-6.02.

2. Widening Projects. Use the following guidelines when selecting the design period for widening projects:

   a. Widening Without Resurfacing. Use a design period of 20 years.

   b. Widening With Resurfacing. Use the Department's policy for the thickness of the resurfacing. Use a design period of 20 years for the total thickness of the widening.

54-2.01(c) Structural Design Traffic

Structural design traffic is an estimate, based on ADT, of the volume of PV, SU, and MU vehicles that will be in the design lane in the year that is one-half the design period from the established date of construction. For example, if the design period is 20 years, the structural design traffic will be projected for the year which is 10 years from the established date of construction. In all IDOT pavement design procedures, structural design traffic is used to calculate a traffic factor (i.e., a factor representing the anticipated traffic load in the design lane on the pavement structure). However, the procedures and equations used to calculate the traffic factor differ among pavement types (rigid pavements or flexible pavements). Use the following procedures to determine structural design traffic:

1. Estimate ADT of PV, SU, and MU Vehicles. Vehicular classification and traffic volume projections for structural design traffic are based on available traffic data (i.e., ADT). ADT

and vehicular classification data for various roadway classes may be obtained from published IDOT traffic maps. Contact the district Programming Section for traffic data. If traffic data is unavailable or if published data is dated or does not appear to reflect known conditions or field observations (e.g., land uses, directional distributions), traffic volume and classification studies may be needed to establish a representative base of existing conditions. Factors that compound annual growth typically are used in traffic projections. Other methodologies may apply. It is important to consider any future land development or land use changes that may affect the volume or composition of traffic that will use the facility. If vehicular classification data is not available for Class III or Class IV facilities, use the percentages in Figure 54-2.A to estimate the number of PV, SU, and MU vehicles from ADT. Also, give consideration to the potential impacts of heavily loaded vehicles, especially in areas near mines, grain elevators, factories, and river ports. It may be necessary to specifically design for such vehicles (see Section 54-2.01(e)).

Facility Class	**Percent of Total ADT**		
	PV	**SU**	**MU**
Class III	88%	7%	5%
Class IV	88%	9%	3%

VEHICULAR CLASSIFICATION FOR STRUCTURAL DESIGN TRAFFIC
(Class III and Class IV Facilities)

Figure 54-2.A

2. Assign Traffic to Design Lane. Although the sum of the PV, SU, and MU vehicular volumes determined in Step 1 represents the total ADT that will be carried by the highway facility in the year of the projection, the structural design of the pavement will be based on the lane which carries the greatest number of SU and MU vehicles (i.e., the design lane). Use the distribution factors in Figure 54-2.B to estimate the number of PV, SU, and MU vehicles that will be in the design lane. Use the total two-way ADT for multilane facilities when calculating the structural design traffic as the distribution factors account for directional traffic and the percentage of vehicles in the design lane. For example, if the total projected ADT for a rural 4-lane facility determined in Step 1 includes 300 MU vehicles, the estimated number of MU vehicles in the design lane will be 135 (i.e., 300 • 0.45). Note that the design lane distribution factors in Figure 54-2.B are based on previous traffic studies under average conditions. Unusual traffic control or design features may influence lane usage (e.g., lane restrictions of commercial vehicles, relatively close interchange spacing). Give consideration to such factors before applying the distribution factors in Figure 54-2.B. Adjustments may be necessary. Contact the Bureau of Research for additional guidance.

Number of Facility Lanes	Percent of Total Vehicular Class Volume (ADT) in Design Lane					
	Rural			Urban		
	PV	SU	MU	PV	SU	MU
2 or 3*	50%	50%	50%	50%	50%	50%
4	32%	45%	45%	32%	45%	45%
≥ 6	20%	40%	40%	8%	37%	37%

One-way roads and streets.

DESIGN LANE DISTRIBUTION FACTORS FOR STRUCTURAL DESIGN TRAFFIC

Figure 54-2.B

3. Determine Actual Structural Design Traffic. Steps 1 and 2 above are used to estimate the actual structural design traffic. The actual structural design traffic is used to calculate an actual traffic factor, which is a number representing an estimate of the total ESALs that will be in the design lane on the pavement structure during the design period. Unless other minimum criteria apply (e.g., see Item 4), this traffic factor will be used to design the entire pavement structure. In all IDOT pavement design methodologies it is necessary to calculate an actual traffic factor. There are two different sets of traffic factor equations, one for rigid and composite pavements and one for flexible pavements. Section 54-4.01(g) applies to rigid mechanistic, rigid modified AASHTO, and composite pavement designs. Section 54-5.01(g) applies to flexible pavement designs using either the mechanistic or modified AASHTO methodologies.

4. Determine Minimum Structural Design Traffic. The concept of using minimum structural design traffic to determine a minimum traffic factor applies only to mechanistic pavement designs. The minimum traffic factor is a factor that represents a minimum threshold below which the Department will not permit lesser pavement designs and is based on a set of minimum SU and MU vehicular volumes which are obtained from Figure 54-2.C. Figure 54-2.C applies to mechanistic designs of both rigid and flexible pavements. To obtain the minimum structural design traffic, enter Figure 54-2.C and select the set of minimum SU and MU vehicular volumes for the type of facility being designed, regardless of actual design traffic. Use the procedures discussed in Step 2 to distribute the minimum volumes obtained from Figure 54-2.C and determine the number of SU and MU vehicles in the design lane. The SU and MU vehicles assigned to the design lane will be used to calculate the minimum traffic factor. The minimum traffic factor is calculated in the same manner as the actual traffic factor calculated in Step 3. The only difference is that minimum, not projected actual, traffic volumes are used. The greater of the two traffic factors, actual or minimum, will be used to perform the mechanistic design of the pavement structure. Note that mechanistic designs of flexible pavements for unmarked routes have an overriding absolute minimum traffic factor of 0.5. For example, if the actual traffic factor calculated in Step 3 is less than the calculated minimum traffic factor, and the calculated minimum traffic factor is less than 0.5, the absolute minimum traffic factor of 0.5 will be used in the mechanistic design of the flexible pavement.

Facility Type	PV ①	SU ①	MU ①
Class I Interstates and Freeways	0	500	1500
Class I Other Marked State Routes	0	250	750
Class II, III, and IV Marked State Routes	0	250	750
Class I, II, III, and IV Unmarked State Routes	Use Actual Volumes ②		

Notes:

① *The minimum vehicular class volumes presented in Figure 54-2.C are given as ADT (i.e., two-way traffic) and must be assigned to the design lane using the procedures described in Step 2 in Section 54-2.01(c).*

② *Mechanistic designs of flexible pavements have an overriding absolute minimum traffic factor of 0.5. See Step 4 in Section 54-2.01(c).*

MINIMUM VEHICULAR CLASS VOLUMES FOR STRUCTURAL DESIGN TRAFFIC
(Mechanistic Design: Rigid and Flexible Pavements)

Figure 54-2.C

54-2.01(d) Mixed-Traffic Axle Loadings

To evaluate the effects of mixed-traffic axle loadings on pavement performance, a system was developed to convert these loadings into a traffic factor. The traffic factor represents the total number of 18-kip ESALs, expressed in millions, that a given pavement may be expected to carry throughout its entire service life.

In developing this system, equivalency factors for various groupings of single-axle and tandem-axle loadings were determined from the AASHO Road Test equations, statewide weigh survey data, and classification counts at weigh stations. The equivalency factor for any given single-axle or tandem-axle load expresses the number of 18-kip single-axle load applications that is equivalent in effect upon pavement performance to one application of the given axle load.

In determining the number of 18-kip ESALs that represents one application of each of the three classes of vehicles (i.e., PV, SU, and MU), consideration must be given to the differences in average axle weights of both SU and MU trucks operating on various highways (e.g., high volume major highways with heavy commercial truck traffic, low volume farm-to-market highways). Highways were divided into four general classifications to reflect these differences in average axle loads. Because rigid and flexible pavements respond differently to axle loadings, the equivalency factors reflect these differences. The 18-kip equivalencies per vehicular classification for Class I through Class IV roads and streets are presented in this chapter for each design methodology.

In areas that include mines, grain elevators, factories, river ports, and landfills, the impacts of heavily loaded SU and MU vehicles may become significant. See Section 54-2.01(e) for additional information on designing for heavily loaded vehicles.

54-2.01(e) Heavily Loaded Vehicles and High Volume Truck Routes

The equivalency factors for SU and MU vehicles that are incorporated in the IDOT pavement design methodologies presented in this chapter assume that traffic on the roadway is a typical mix of fully loaded, partially loaded, and empty vehicles. See Section 54-2.01(d) for additional information on equivalency factors for mixed-traffic axle loadings. Highway sections in some areas of the State provide access to businesses that utilize fully loaded trucks. Using typical SU and MU equivalency factors often will result in an inadequately designed pavement section. It only requires an increase in gross vehicle weight of approximately 10% to double the resulting damage to the pavement. Failure to consider the effects of heavily loaded vehicles can reduce pavement life significantly, in some cases by as much as one-half. It is therefore important to seriously evaluate pavement designs that will accommodate heavily loaded vehicles.

Typically, operations that involve moving bulk commodities and hauling large quantities of materials to and from ports and other locations use heavily loaded vehicles. Such operations may include mining operations, grain terminals, factories, river ports, landfills, etc. In general, designs should be adjusted where heavily loaded vehicles comprise 10% or more of the design truck traffic. The designer should refer to the Bureau of Research document *Pavement Technology Advisory PTA-D1: Designing for Heavily Loaded Vehicles*. If needed, contact the Bureau of Research for assistance in analysis of traffic and pavement sections.

When determining the type of pavement to be constructed, first calculate the rigid traffic factor. Projects with a rigid traffic factor greater than 60 should typically use continuously reinforced concrete pavement as discussed in Section 54-4.02(a). If a district has a project with a rigid traffic factor greater than 60 and another pavement type is desired (e.g., match adjacent cross-sections, ease of construction, etc.), the Bureau of Research must approve the design.

54-2.01(f) Roadbed Soils

Subsurface exploration is an essential part of the engineering survey for highway location and design. It includes soils investigation, sampling, testing, identification, and distribution with respect to the horizontal and vertical alignment of the highway. USDA county soils reports often are used in preliminary geotechnical investigations and in developing soil sampling surveys. Roadbed soil types, problem areas, recommendations, and corrective measures are compiled by the geotechnical engineer in the project geotechnical report, which will become a project design document for incorporation in the project plans and specifications. Consider the following guidelines when evaluating the need for subgrade improvements:

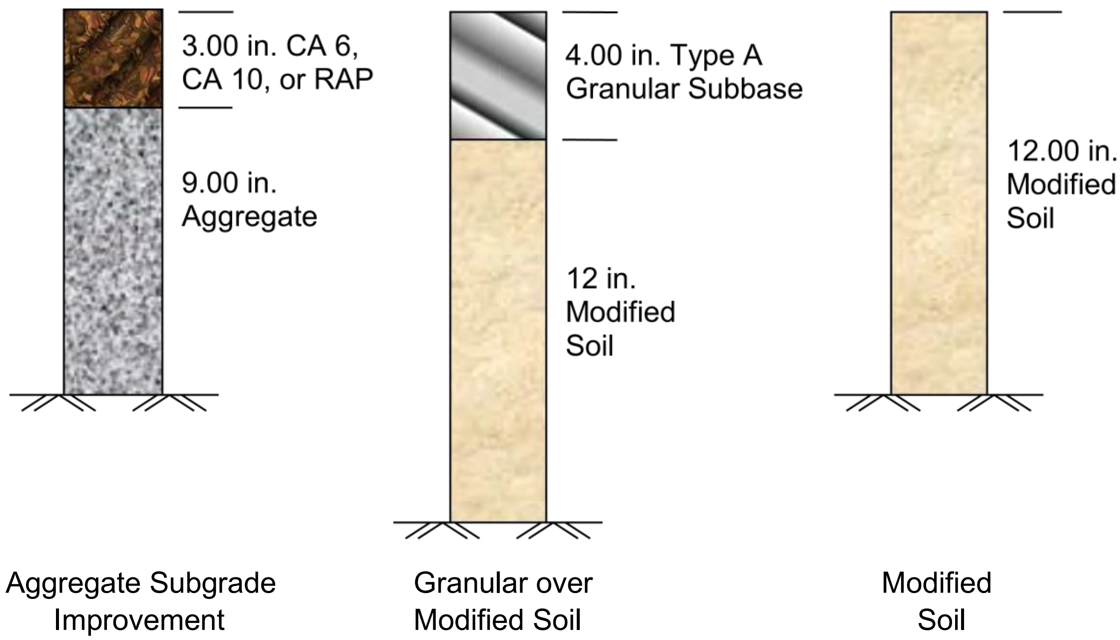
1. <u>Importance of Subgrade Stability</u>. Subgrade stability plays a critical role in the construction and performance of a pavement. Pavement performance is directly related to the physical properties of the roadbed soils and the materials used in the pavement structure. Subgrade stability is a function of a soil's strength and its behavior under repeated traffic loadings. Both properties significantly influence pavement construction operations and the long-term performance of the pavement structure. The pavement subgrade should be sufficiently stable to:

    - prevent excessive rutting and shoving during construction;

- provide uniform support for placement and compaction of pavement layers;
- minimize impacts of excessive volume change and frost;
- limit pavement resilient (i.e., rebound) deflections to acceptable limits; and
- restrict permanent deformation during pavement service life.

2. Department Policy. A subgrade that provides a stable working platform will minimize rutting and moisture related problems resulting in effective construction and a smoother pavement. Department policy was established to ensure that the pavement subgrade, in situ or improved, will provide a stable working platform for all pavement construction. Most Illinois soils are not capable of providing a subgrade that meets the criteria for a stable working platform. Although the negative effects of less satisfactory soils can, to some degree, be reduced by increasing pavement structure thickness, it usually is necessary to treat in situ soils to ensure adequate subgrade support for construction equipment operations and for the placement and compaction of pavement layers. At a minimum, it is required that a 12 in. improved subgrade layer be provided. Where in situ soils are found to be inadequate such that the 12 in. improved subgrade layer will not provide a stable working platform, the designer should include provisions to address the need for deeper treatment or removal and replacement per the *IDOT Subgrade Stability Manual*).

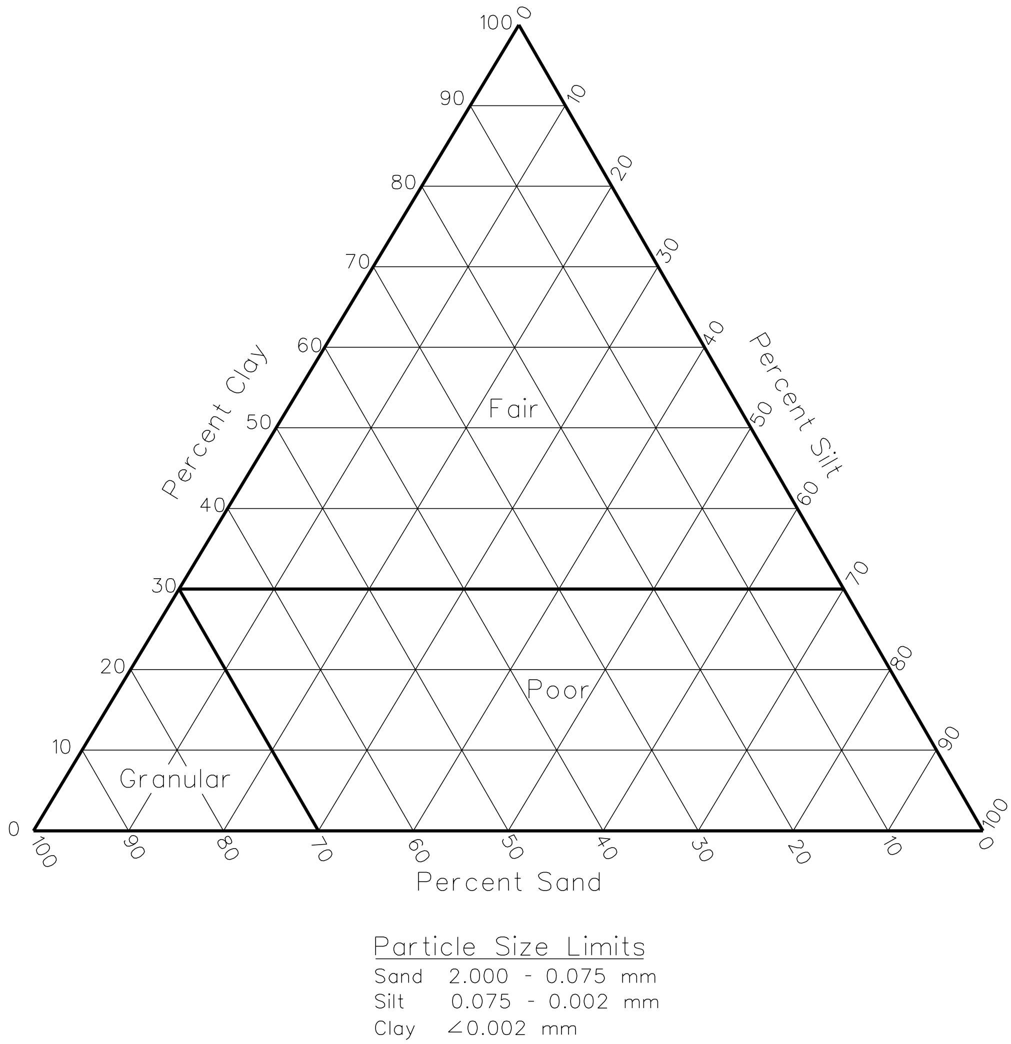
3. Design Considerations. Mechanistic structural pavement designs will provide structurally adequate pavements that are suited to local conditions and material selection. The mechanistic design methodology for both rigid and flexible pavement types assumes that a stable subgrade is present (in situ or improved) and that, if improved, the subgrade is constructed with the highest quality material. The subgrade, however, is not given additional credit during design nor is the cost of providing an improved subgrade included in the pavement selection process. If it is determined that an improved subgrade layer is needed to provide a stable working platform, no change will be made to the subgrade support rating that is used during design (see Item 4). For additional design guidance on providing a stable working platform, see the IDOT *Subgrade Stability Manual*. Provisions must be made for the entire thickness of the binder to be completed in a single construction season once the improved subgrade layer is in place. The Department has experienced repeated springtime pavement failures during construction of partially completed sections that have been exposed to winter conditions. Provisions for staging/completion may need to be used to prevent large sections of partially completed pavement being abandoned due to winter shutdown.



TREATMENT OPTIONS FOR IMPROVED SUBGRADE
(Mechanistic Design: Rigid and Flexible Pavements)

Figure 54-2.D

4. <u>Soils Evaluation (Subgrade Support Rating — SSR)</u>. Mechanistic pavement design procedures require that subgrade support ratings be determined for the project's in situ soils. These SSR values will be used to design the pavement structure. SSRs are based on information provided in the project geotechnical report. There are three SSR categories (i.e., poor, fair, and granular). Based on the percent clay, silt, and sand found in the in situ soil, SSR values are obtained from Figure 54-2.E. Note that Figure 54-2.E already assumes a high-water table and appropriate frost penetration. All project soils will be evaluated by the district geotechnical engineer to determine and verify what, if any, subgrade treatment is needed. It also is the responsibility of the geotechnical engineer to provide the designer with SSRs and their application limits within the project. Each SSR in the soils report will represent the average soil conditions within the specified limits of the project. For small projects, in the absence of laboratory tests, SSR values may be estimated using USDA county soils reports.



SUBGRADE SUPPORT RATING (SSR)
(Mechanistic Design)

Figure 54-2.E

5. Policy Deviations. Typical Illinois soils have poor to fair SSR values and require an improved subgrade layer. Although infrequent, an in situ soil (e.g., granular) may be found at a project location that will provide a stable working platform without improvement. Where marginally adequate soils are found, the district geotechnical engineer may recommend something less than a 12 in. thick improved subgrade layer. On the other hand, the geotechnical report may recommend a thicker improved subgrade layer. Where an improved subgrade layer is needed to provide a stable working platform, any deviation from the 12 in. thickness criteria must be supported by the geotechnical engineer,

documented in the project geotechnical report, and approved by the Bureau of Research. In such cases, ensure that supporting conclusions and recommendations are adequately documented in the pavement design submittal.

6. Subgrade Improvement Alternatives. Where the in situ soil has an SSR value of either poor or fair, the subgrade shall be improved to the required depth using the allowable alternatives shown in Figure 54-2.D.

   Consider the following when selecting from these alternatives:

   a. Typical Treatment. Where required, lime modification typically is used for the improved subgrade layer.

   b. Non Lime-Reactive Soils. Where in situ soils are found to not react with lime or by-product lime (e.g., organic and sandy soils), cement or fly ash modification typically is used for the improved subgrade layer. Laboratory testing may be required to determine the ability of cement or fly ash to be used as a modifier.

   c. Urban Areas. For dust control in urban areas, granular material may be specified for the improved subgrade layer.

   d. Granular Material Availability. If granular material is readily available, the district may elect to specify aggregate subgrade improvement in lieu of typical treatments. This decision will be made on a case-by-case basis.

   e. Alternatives Analysis. For the subgrade treatments being considered, determine the appropriate construction parameters for the subgrade alternatives analysis. This may include the following:

      - required thickness of the improved subgrade layer;
      - percentage of lime, by-product lime, fly ash, or cement required; and/or
      - required depth of undercut and granular backfill.

      Base the decision for selecting the subgrade treatment on factors that include material availability, constructability, economics, permanence of treatment, and pavement performance benefits. Select the alternative for the improved subgrade layer that is best suited for the project.

7. Embankment Settlement. Underlying soils can settle under the weight of a newly constructed embankment resulting in differential settlement and/or embankment failures. The settlements are expensive to fix and can result in pavement dips. For all classes of roads and streets, construction should be sequenced to assure that earthwork is completed during one construction season and that paving is initiated the next. If this cannot be accomplished with some degree of certainty, include special provisions in the contract that will assure adequate embankment settlement prior to subsequent pavement layers being placed. Consult the district geotechnical engineer for guidance in preparing such special provisions.

54-2.02 Structural Design

To select the proper type and thickness of mainline pavement for a particular project, first determine the following:

- the volume and composition of traffic to be carried by the pavement,
- the length of time the pavement is to service this traffic,
- the strength characteristics of the subgrade soils and pavement materials, and
- the minimum quality of service to be provided by the pavement during its lifetime.

See Section 54-1.06 for information on pavement designs for interchange ramps. Pavement designs for rest areas and weigh stations are discussed in Sections 54-1.07 and 54-1.08, respectively.

54-2.03 Limitations and Requirements

54-2.03(a) General

The procedures that are presented in this chapter will allow the designer to select an economically optimal pavement design that is most capable of carrying the anticipated traffic. To ensure that the selected design is both practical and adequate, the following sections present policy limitations and requirements that must be considered.

54-2.03(b) Adherence to Specifications

The design procedures that are presented in this Chapter are based on the assumption that material requirements, mixture designs, and construction procedures and controls will be in accordance with current IDOT specifications and practices. To ensure satisfactory performance, the strengths of structural components that are assumed during design must be achieved during construction. These strengths should be shown on the cover sheet or typical cross-sections of the plans, along with the structural design traffic; the percentage breakdown of the structural design traffic for PV, SU, and MU vehicles; the percentage of these vehicles in the design lane; and the SSR or IBR values of the roadbed soils. See Section 63-4.05 for additional information on placing structural design traffic on plans.

54-2.03(c) Structural Design Traffic

The equations used to convert structural design traffic into 18-kip ESALs are based on an average distribution of vehicle types and axle loadings and are directly applicable to most roads and streets. However, cases will arise in which these equations should not be used, and a special analysis will be necessary. One such case would be that involving a highway adjacent to an industrial site where the commercial vehicles entering and leaving the site generally travel empty in one direction and fully loaded in the other. Contact the Bureau of Research for assistance. It will be necessary for the district to furnish the structural design traffic and weight and classification count data in sufficient detail to permit a determination of the distribution of commercial vehicle types and the single-axle and tandem-axle loadings within each type. See Section 54-2.01(e) for additional information on designing for heavily loaded vehicles.

54-2.03(d) Terminal Service Level

At the end of the design period, the serviceability level of the pavement can be expected to have been reduced to a value of 2.5 for Class I roads and streets and to 2.0 for Class II, Class III, and Class IV roads and streets, and the pavement should be considered eligible for rehabilitation. The design period may or may not be the actual service life of the pavement. The actual service life may be longer or shorter than the design period depending upon the conditions under which the pavement actually serves and the conditions assumed for the design. Highly significant are the differences between the structural design traffic and the actual traffic carried by the pavement, and the difference between the design terminal serviceability level and the actual serviceability level at which the pavement is structurally upgraded.

54-3 BASIC DESIGN PARAMETERS (Modified AASHTO)

54-3.01 Development of Design Procedures

54-3.01(a) General

See Section 54-1.03(b) for a brief description of the modified AASHTO design procedures.

54-3.01(b) Design Period

Section 54-2.01(b) applies to the modified AASHTO design procedures.

54-3.01(c) Structural Design Traffic

Section 54-2.01(c) applies to the modified AASHTO design procedures, except for the requirement of calculating a minimum traffic factor based on minimum structural design traffic.

54-3.01(d) Mixed-Traffic Axle Loadings

Section 54-2.01(d) applies to the modified AASHTO design procedures.

54-3.01(e) Heavily Loaded Vehicles

Section 54-2.01(e) applies to the modified AASHTO design procedures.

54-3.01(f) Roadbed Soils

Section 54-2.01(f) does not apply to the modified AASHTO design procedures. The following material specifically relates to the modified AASHTO design methodology.

An A-6 (9-13) type of roadbed soil was used throughout the entire embankment of the AASHO Road Test Project. Because only one soil type was taken into consideration in the AASHO Road Test, it was necessary to modify the AASHO Road Test equations so that pavement thicknesses could be developed for other soil types. The modification makes use of the Illinois Bearing Ratio (IBR) of the soil, which is the only soil support value normally determined by the Department for modified AASHTO designs. Other soil strength test procedures can be used provided that the test results can be directly correlated with those obtained by the IBR test procedure.

The IBR selected for use in design should represent a minimum value for the soil to be used. Preferably, laboratory tests should be made on four-day soaked samples of the soils to be used in construction. It is recommended that a soil survey be made prior to all construction; however, when test data are not available, use the values presented in Figure 54-3.A.

Soil Classification	IBR
A-1	20
A-2-4, A-2-5	15
A-2-6, A-2-7	12
A-3	10
A-4, A-5, A-6	3
A-7-5, A-7-6	2

SUGGESTED IBR VALUES FOR VARIOUS SOIL CLASSIFICATIONS

Figure 54-3.A

Pavement performance is directly related to the physical properties and the support capacity of the materials used in the pavement structure and of the roadbed soils. The effect of less satisfactory soils, to some degree, can be reduced by increasing the thickness of the pavement structure, but it may be necessary to take other steps to ensure adequate pavement performance. The problems that can be encountered because roadbed soils are subject to permanent deformation, excessive volume changes, excessive deflection and rebound, frost susceptibility, and non-uniform support from wide variations in soil types within the State should be recognized in the design stage. Corrective measures should be included in the plans and in the special provisions for any and all small isolated areas of unsatisfactory soils. If such areas contain soils that are unsatisfactory for roadbed construction, the soils should be either removed and replaced with satisfactory soils or granular material or improved in-place with a suitable stabilizing agent. If such soils are unsatisfactory only from the standpoint of having an IBR less than the minimum selected for design, consider the following treatments:

- remove and replace with soils or granular material at or above the minimum value,
- remove and replace with additional subbase material to a depth that will compensate for the deficiency in support strength, or
- improve the material in-place with a suitable stabilizing agent.

See the IDOT *Subgrade Stability Manual* for further guidance.

54-3.02 Structural Design

Section 54-2.02 applies to the modified AASHTO design procedures.

54-3.03 Limitations and Requirements

54-3.03(a) General

Section 54-2.03(a) applies to the modified AASHTO design procedures.

54-3.03(b) Adherence to Specifications

Section 54-2.03(b) applies to the modified AASHTO design procedures.

54-3.03(c) Structural Design Traffic

54-3.03(d) Terminal Service Life

Section 54-2.03(d) applies to the modified AASHTO design procedures.

54-4 STRUCTURAL DESIGN OF RIGID PAVEMENTS

54-4.01 Mechanistic

54-4.01(a) Limitations

Jointed plain concrete pavement (JPCP) thickness designs may be obtained for thicknesses up to 12 in. and for traffic factors up to approximately 100. For traffic factors above 60, CRCP should typically be used, see Section 54-4.02 for design procedures. The use of doweled joints will be required for pavement thicknesses that are 7 in. and greater on all Class I, Class II, and Class III roads and streets and Class IV marked roads and streets. Doweled joints will not be required for Class IV unmarked roads and streets. Recommended dowel diameters are given in Figure 54-4.A. If designs for traffic factors greater than 100 or for pavement thicknesses greater than 12 in. are desired, contact the Bureau of Research.

Pavement Thickness (T) (inches)	Nominal Dowel Diameter (inches)
10 and greater	1.5
8.01 thru 9.99	1.25
8 and less	1

RECOMMENDED DOWEL DIAMETERS

Figure 54-4.A

54-4.01(b) Application of Design Method

The mechanistic design procedures for rigid pavements enable the designer to determine the type and thickness of PCC pavement that are required to carry a specified volume and composition of traffic for a designated period of time while retaining minimum serviceability. Use the procedures presented in Section 54-4.01(j) to determine pavement type and thickness and provide a subbase in accordance with Section 54-4.01(h).

54-4.01(c) Edge Support Conditions

The mechanistic design methodology gives the designer the option of selecting from the following two-edge support conditions:

1. Tied Shoulder. The tied shoulder condition consists of a 12 ft paved lane that is tied with reinforcing steel to a PCC shoulder or curb and gutter.

2. Untied Shoulder. Any 12 ft pavement that is not positively tied with reinforcing steel to the shoulder or curb and gutter is considered an untied shoulder condition. An untied shoulder may consist of earth, aggregate, or HMA materials.

The selection of edge support has a pronounced effect on edge stresses and pavement thickness. Department policy dictates exclusive use of tied shoulders, unless otherwise approved by the Bureau of Research.

54-4.01(d) Joint Spacing Limitations

Joint spacing between panels may need to vary to accommodate adjacent pavements, drainage structures, etc. See the *Highway Standards* for typical designs. The mechanistic design procedures may be used to design pavement thickness for a nominal panel length of 15 ft, except Class IV unmarked roads and streets may use 12-ft joint spacing. The panel length may be adjusted ±3 ft to accommodate discontinuities in pavement cross-section (e.g., intersections, medians). If designs for longer panel sections are required to match existing pavements, contact the Bureau of Research.

54-4.01(e) Design Period

The design period for all rigid pavements is typically 20 years.

54-4.01(f) Equivalency Factors

Section 54-2.01(d) describes the use of equivalency factors to convert mixed-traffic loadings to 18-kip ESAL applications. Equivalency factors for rigid pavements are presented in Figure 54-4.B. The factors in Figure 54-4.B were used to develop the traffic factor equations discussed in Section 54-4.01(g).

54-4.01(g) Traffic Factor

The traffic factor is the projected total 18-kip ESALs, expressed in millions, to be carried by the design lane during the design period. Based on the class of the facility, select the appropriate equation from Figure 54-4.C to calculate the traffic factor for rigid pavement designs. See Section 54-2.01(c) for information on structural design traffic.

Facility Class	18-kip ESAL Applications Per Vehicle		
	PV	SU	MU
Class I	0.0004	0.394	1.908
Class II	0.0004	0.372	1.554
Class III and IV	0.0004	0.355	1.541

EQUIVALENCY FACTORS
(Rigid Pavements)

Figure 54-4.B

Facility Class	Traffic Factor Equation	Equation Number
Class I	$TF = DP\left[\dfrac{(0.15 \bullet P \bullet PV) + (143.81 \bullet S \bullet SU) + (696.42 \bullet M \bullet MU)}{1x10^6}\right]$	Equation 54-4.1
Class II	$TF = DP\left[\dfrac{(0.15 \bullet P \bullet PV) + (135.78 \bullet S \bullet SU) + (567.21 \bullet M \bullet MU)}{1x10^6}\right]$	Equation 54-4.2
Class III and Class IV	$TF = DP\left[\dfrac{(0.15 \bullet P \bullet PV) + (129.58 \bullet S \bullet SU) + (562.47 \bullet M \bullet MU)}{1x10^6}\right]$	Equation 54-4.3

where:

PV, SU, MU = *structural design traffic expressed as the number of PV, SU, and MU vehicles.*
P, S, M = *percent of PV, SU, and MU in the design lane expressed as a decimal.*
DP = *design period — typically 20 years.*

TRAFFIC FACTOR EQUATIONS
(Rigid Pavements)

Figure 54-4.C

54-4.01(h) Improved Subgrade and Subbase Type and Thickness

Thicknesses determined through the mechanistic design process assume that an adequate construction platform exists at the time of construction and it will perform adequately over the life of the pavement. The platform consists of an improved subgrade, and subbase when necessary. The requirements for the improved subgrade and subbase are as follows:

1. Improved Subgrade. The improved subgrade provides a stable construction platform for placement of the subsequent courses. All classes of roads and streets shall have an improved subgrade of the required thickness according to Section 54-2.01(f).

2. Subbase. The subbase serves two purposes. First, the subbase provides a separation layer between the rigid pavement and pumpable subgrade soils. Second, the subbase is there to resist erosion of the fine-graded soils during the service life of the pavement.

Treatment options for improved subgrade and requirements for subbase type and thickness are shown in Figure 54-4.D.

54-4.01(i) Designating Structural Information on Plans

See Section 63-4.05 for information on designating structural information on plans.

Facility Type	Subbase ①		Improved Subgrade Type ② ③
	Type	Minimum Thickness (inches)	
Class I			
Interstate / Freeway	HMA or PCC Stabilized	4	ASI, GM, or MS
Other Marked Routes	HMA or PCC Stabilized	4	ASI, GM, or MS
Unmarked Routes (TF ≥ 2.0)	HMA or PCC Stabilized	4	ASI, GM, or MS
Unmarked Routes (0.7 < TF < 2.0)	Not required	n/a	ASI, GM ④
Unmarked Routes (TF ≤ 0.7)	Not required	n/a	ASI, GM, or MS
Class II			
Marked Routes	HMA or PCC Stabilized	4	ASI, GM, or MS
Unmarked Routes (TF ≥ 2.0)	HMA or PCC Stabilized	4	ASI, GM, or MS
Unmarked Routes (0.7 < TF < 2.0)	Not required	n/a	ASI, GM ④
Unmarked Routes (TF ≤ 0.7)	Not required	n/a	ASI, GM, or MS
Class III			
Marked Routes	HMA or PCC Stabilized	4	ASI, GM, or MS
Unmarked Routes (TF ≥ 2.0)	HMA or PCC Stabilized	4	ASI, GM, or MS
Unmarked Routes (0.7 < TF < 2.0)	Not required	n/a	ASI, GM ④
Unmarked Routes (TF ≤ 0.7)	Not required	n/a	ASI, GM, or MS
Class IV			
Marked Routes	HMA or PCC Stabilized	4	ASI, GM, or MS
Unmarked Routes (TF ≥ 2.0)	HMA or PCC Stabilized	4	ASI, GM, or MS
Unmarked Routes (0.7 < TF < 2.0)	Not required	n/a	ASI, GM ④
Unmarked Routes (TF ≤ 0.7)	Not required	n/a	ASI, GM, or MS

Notes:

① *For urban sections containing curb and gutter and a storm sewer system, the designer may omit the stabilized subbase when an ASI or GM improved subgrade is used, regardless of the traffic factor.*

② *Improved Subgrade Types include:*

ASI - Aggregate Subgrade Improvement (minimum of 12 in.)

GM – Granular over Modified Soil (4 in. CA 6 or CA 10 over 12 in. Modified Soil)

MS – Modified Soil (minimum of 12 in.)

③ *The minimum thickness of improved subgrade shall be according to Section 54-2.01(f).*

④ *Modified Soil may be used for the improved subgrade if a minimum 4-in. stabilized subbase is used.*

MINIMUM STRUCTURAL DESIGN REQUIREMENTS
(Rigid Pavement: Mechanistic Design)

Figure 54-4.D

54-4.01(j) Thickness Design Procedure

For a mechanistic design of a rigid pavement, use the following steps to determine thickness:

1. Determine Traffic Factor. Use the following procedures to determine the traffic factor:

   a. Determine the facility class (e.g., Class I, II, III, or IV).

   b. Determine the actual structural design traffic as described in Section 54-2.01(c).

   c. Determine the minimum structural design traffic as described in Section 54-2.01(c) and Figure 54-2.C.

   d. Based on the facility class, select the appropriate traffic factor equation from Figure 54-4.C.

   e. Calculate the actual traffic factor.

   f. Calculate the minimum traffic factor.

   g. Compare the actual traffic factor to the minimum traffic factor and use the greater of the two as the traffic factor for design.

2. Determine the SSR. Determine the SSR as described in Section 54-2.01(f) (e.g., poor, fair, granular).

3. Determine the Edge Support. Determine the edge support condition to analyze as discussed in Section 54-4.01(c) (e.g., tied shoulder).

4. Determine the PCC Thickness. Use one of the following two procedures to determine the PCC thickness depending on the route class:

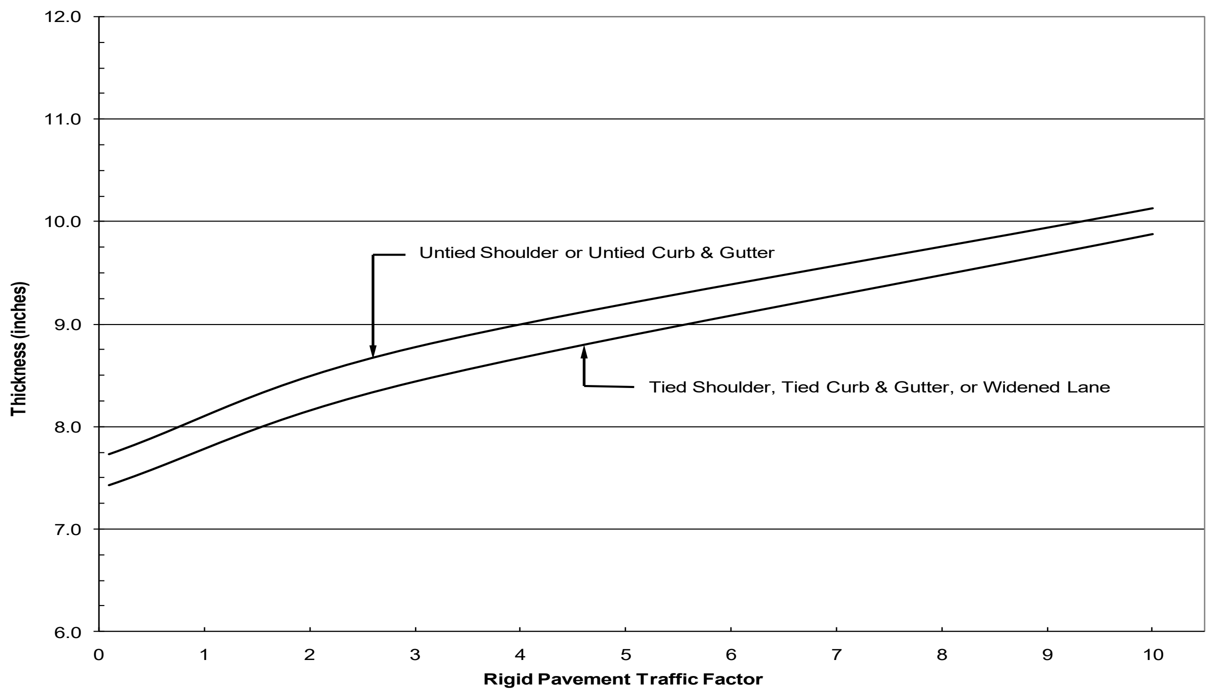
   a. For all Class I, II, III, and IV marked roads and streets, and for Class I, II, and III unmarked roads and streets, use the following procedures:

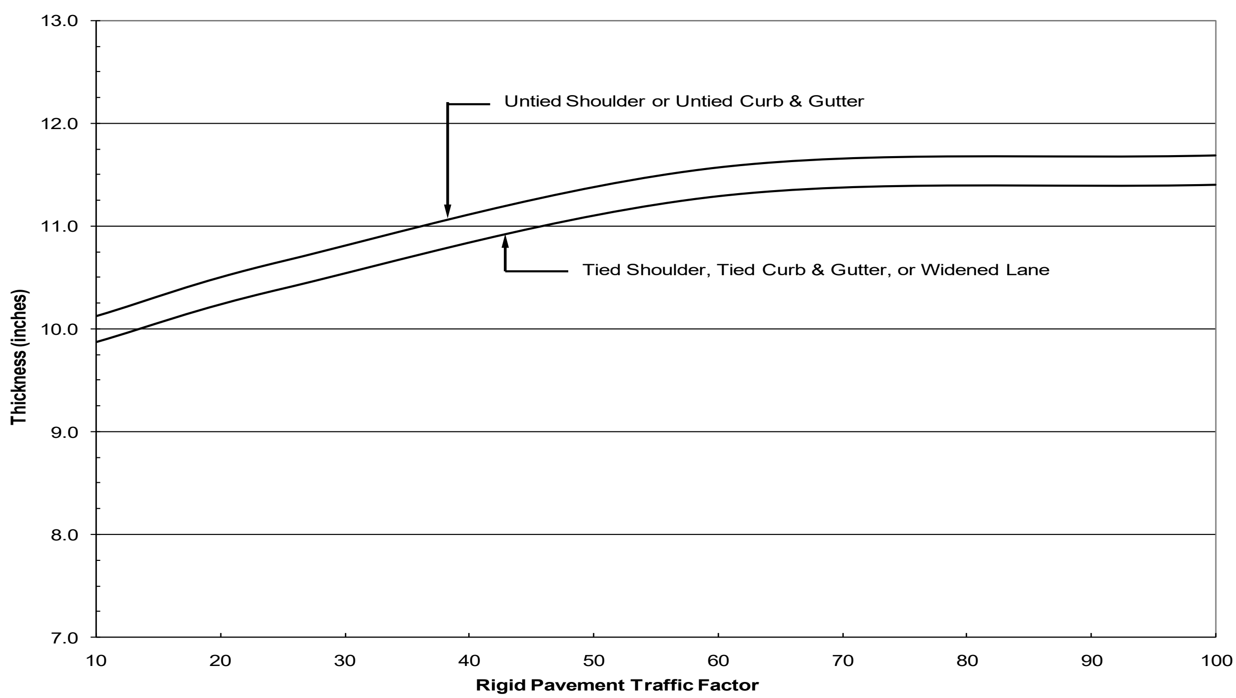
      (1) Based on the SSR (e.g., poor, fair, granular) determined in Step 2, select the appropriate rigid pavement mechanistic design chart from the following:

      - SSR = Poor, use Figure 54-4.E;
      - SSR = Fair, use Figure 54-4.F; or
      - SSR = Granular, use Figure 54-4.G.

      (2) Within the design chart, select the curve that represents the edge support condition, either tied or untied.

      (3) Enter the chart along the horizontal axis with the traffic factor determined in Step 1.

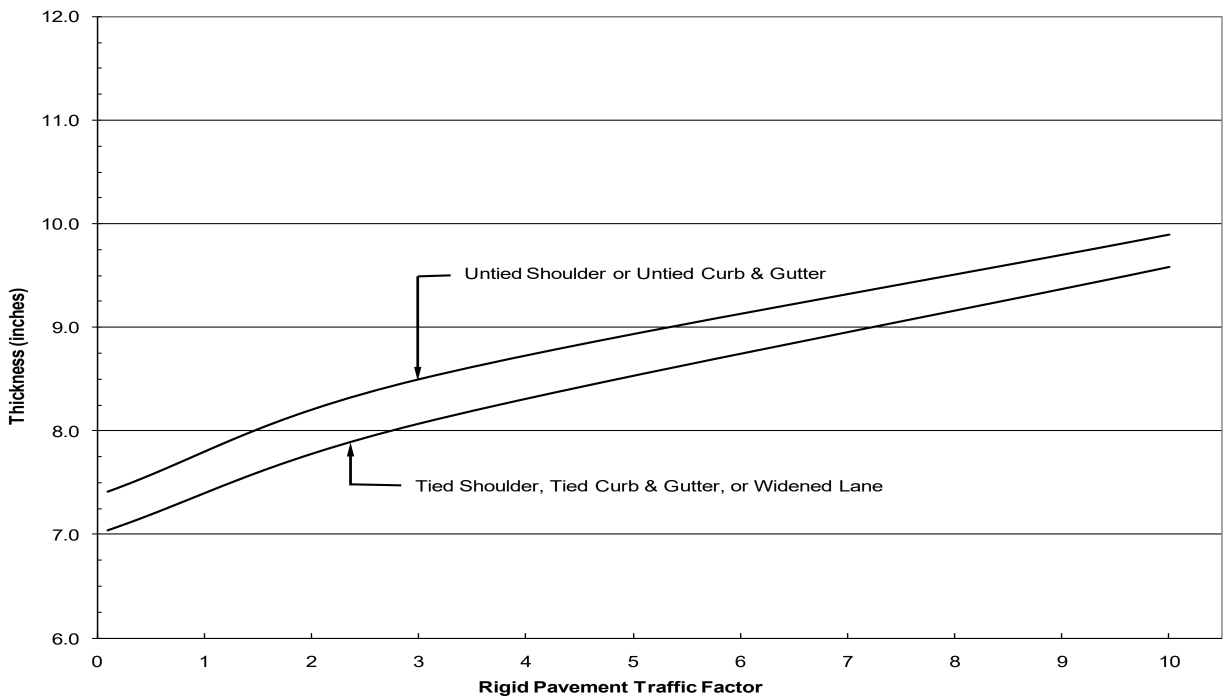


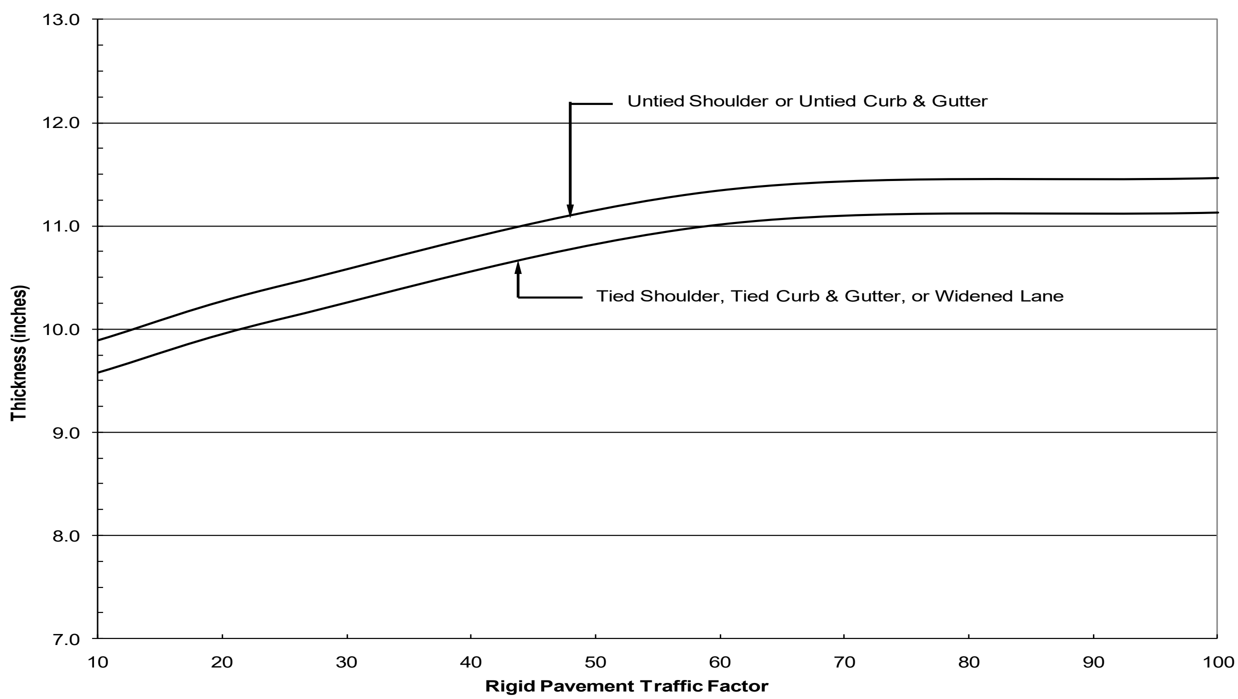


Note: Use of untied shoulder design requires Bureau of Research approval.

RIGID PAVEMENT DESIGN CHART
(Mechanistic Design: SSR = Poor)

Figure 54-4.E

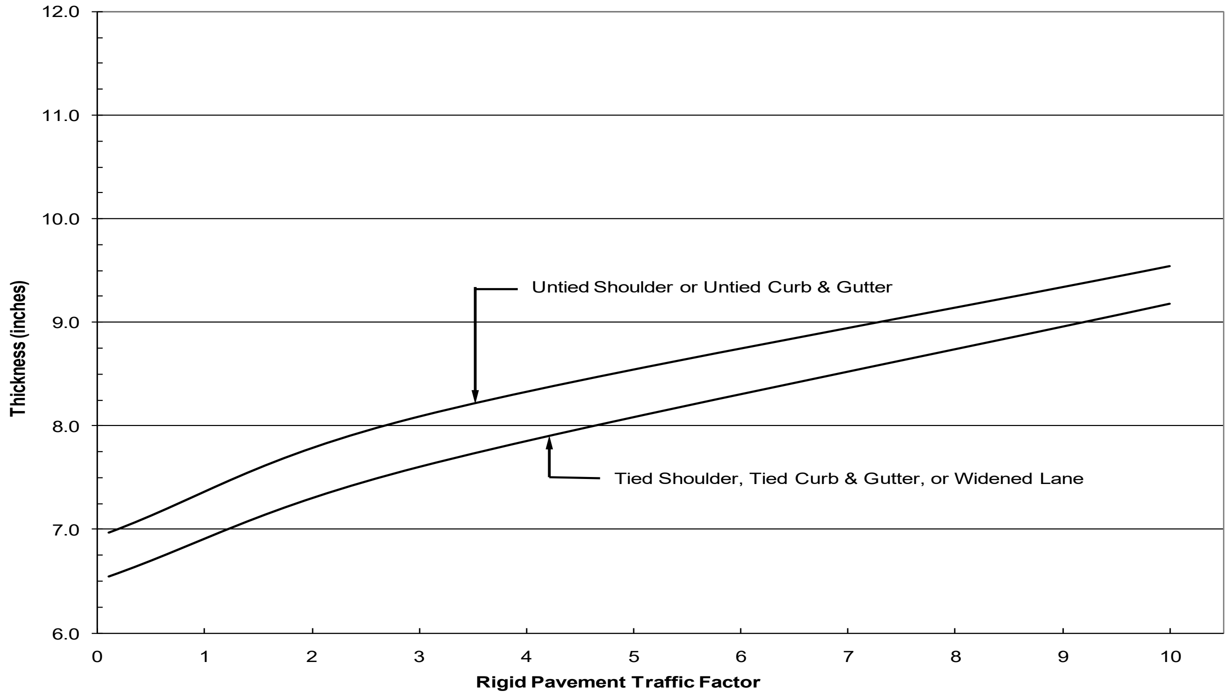


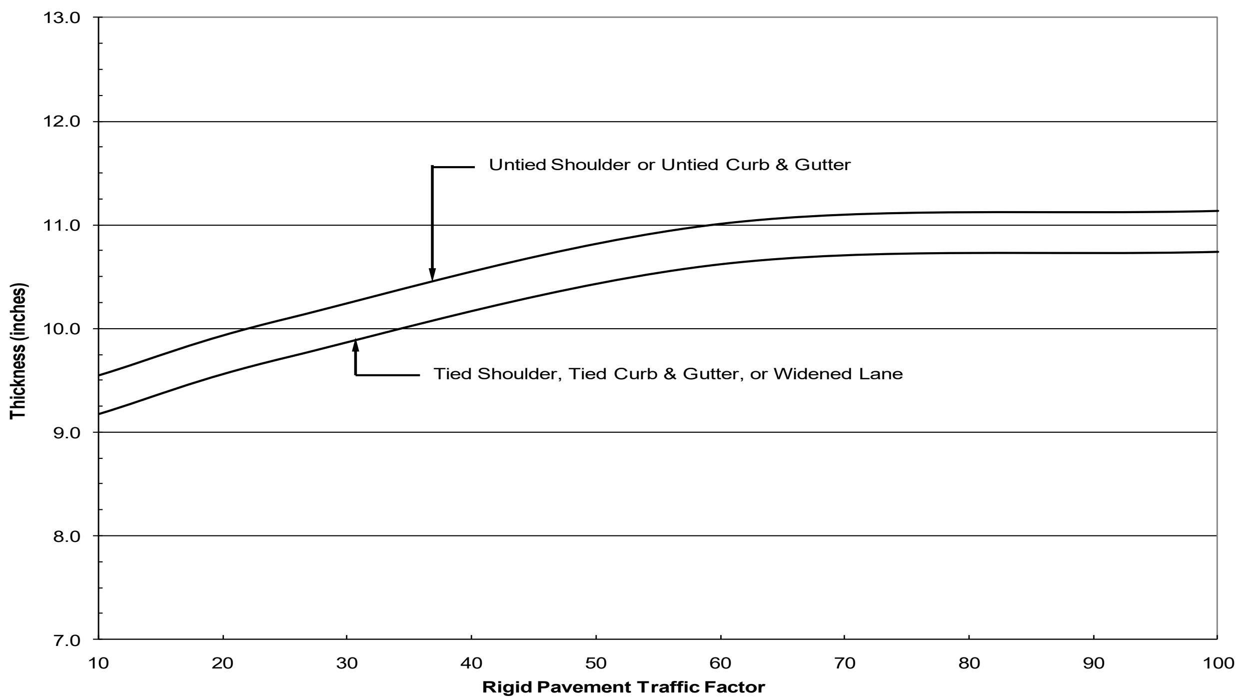


Note: Use of untied shoulder design requires Bureau of Research approval.

RIGID PAVEMENT DESIGN CHART
(Mechanistic Design: SSR = Fair)

Figure 54-4.F





Note: Use of untied shoulder design requires Bureau of Research approval.

RIGID PAVEMENT DESIGN CHART
(Mechanistic Design: SSR = Granular)

Figure 54-4.G

(4) Move up vertically until the curve selected in Step a.(2) is intersected.

(5) From the point of intersection, move left horizontally until the vertical axis is intersected.

(6) Read the thickness from the chart's vertical axis.

(7) Round the thickness up to the nearest 0.25 in.

b. For Class IV Unmarked Routes, use the following procedures:

(1) Determine the thickness according to Figure 54-4.H using the standard case of untied shoulders, no subbase, poor subgrade (k=50 psi/in.), panel length of 12 ft, and no dowels.

Traffic Factor	Thickness
0.025	6.75
0.05	7.00
0.10	7.25
0.50	7.50
1.00	7.75
2.00	8.00

PCC PAVEMENT THICKNESS
CLASS IV UNMARKED ROADS AND STREETS

Figure 54-4.H

(2) Adjust the pavement thickness according to Figure 54-4.I to account for differences in the cross-section from the standard case.

Option Different from Standard Case	Thickness Adjustment (inches)
Tied Concrete Shoulders	- 0.25
4 in. Granular Subbase	none
4 in. Stabilized Subbase	- 0.25
15 ft Slab Length	+0.50
Fair Subgrade (k = 100 psi/in.)	- 0.25
Good Subgrade (k = 200 psi/in.)	- 0.50

THICKNESS ADJUSTMENTS FOR
CLASS IV UNMARKED ROADS AND STREETS

Figure 54-4.I

54-4.01(k) Shoulder Type/Design

For new construction or pavement replacement rural projects, use a tied rigid shoulder with all mechanistic rigid pavement designs. The thickness of the shoulder will either match the pavement thickness or vary uniformly from the pavement thickness to a 6 in. minimum at the outside edge.

54-4.01(l) Design Example

See Section 54-9 for a design example.

54-4.01(m) Typical Sections

Figures 54-4.J through 54-4.L illustrate typical rural and urban pavement sections of rigid designs for various types of highway facilities.

54-4.01(n) Joint Placement

The proper placement of pavement joints greatly affects the overall performance of the pavement. Where joints are not properly designed, uncontrolled cracking can occur. Features that can affect joint spacing are turn lanes, drainage blockouts, medians, intersecting side streets, etc. This is especially true at large intersections. It is imperative that the designer and the construction engineer pay particular attention to joint placement in these areas.

Designers should provide jointing details in the plans, and construction engineers should make every effort to follow the joint layout. In many cases, it will be necessary to adjust the normal 15 ft spacing used by IDOT to accommodate other features. Joint spacing may be adjusted ±3 ft to match joints in intersecting pavements and/or to accommodate pavement discontinuities (e.g., drainage castings, median noses). In some cases, it also may be possible to adjust the location of pavement discontinuities so that they are located at a normal joint position. The American Concrete Pavement Association has published a bulletin entitled *Intersection Joint Layout*. Although this bulletin should not be construed as an IDOT policy or standard, it does contain helpful information on jointing intersections and can serve as a design reference.

The designer and construction engineer also must be aware of planned staged construction and its effect on joint layout. Where adjacent lanes are to be constructed in stages, it is important to plan the layout of the joints before any pavement is placed. Occasionally, new pavement is constructed adjacent to existing pavement that was designed using a different joint type and spacing. When this occurs, the designer must make provisions in the plans to match existing joints. A detailed joint survey prior to plan preparation can help eliminate problems during construction and throughout the life of the pavement.

TYPICAL URBAN SECTION: RIGID DESIGN WITH TIED CURB AND GUTTER
Figure 54-4.L

54-4.01(o) Surface Finish

The surface finish of a pavement provides skid resistance for the traveling public. The type of finish is dictated by the posted speed limit. As the posted speed limit increases, so does the need for higher skid resistance. The type of surface finish shall be indicated on the plans according to the following guidelines:

- Final finishing (of surfaces) on highways with posted speed limits in excess of 40 mph will be a Type A final finish as outlined in the *Standard Specifications for Road and Bridge Construction*.
- Final finishing (of surfaces) on highways with posted speed limits not exceeding 40 mph will be a Type A or Type B final finish as outlined in the *Standard Specifications for Road and Bridge Construction*.

54-4.02 <u>Modified AASHTO</u>

54-4.02(a) Application of Design Method

The modified AASHTO design procedures are used for new CRCP and unbonded concrete overlays using CRCP. These procedures are also used to match existing CRCP. Use the procedures presented in Section 54-4.02(e) to determine pavement type and thickness and provide a subbase in accordance with Section 54-4.02(f). CRCP designs should typically be used if the rigid traffic factor is greater than 60. CRCP designs for projects with rigid traffic factors greater than 60 will not require LCCA.

54-4.02(b) Design Period

Section 54-4.01(e) applies to modified AASHTO designs for rigid pavements.

54-4.02(c) Equivalency Factors

Section 54-4.01(f) applies to modified AASHTO designs for rigid pavements.

54-4.02(d) Traffic Factors

Section 54-4.01(g) applies to modified AASHTO designs for rigid pavements.

54-4.02(e) Pavement Type and Thickness

For a modified AASHTO design of a rigid pavement, use the following steps to determine thickness:

1. <u>Determine Traffic Factor</u>. Use the following procedures to determine the traffic factor:

    a. Determine the facility class (e.g., Class I, II, III, or IV).

b. Determine the actual structural design traffic as described in Section 54-3.01(c). Note that the minimum traffic as described in Section 54-2.01(c) does not apply to the modified AASHTO design.

c. Based on the facility class, select the appropriate traffic factor equation from Figure 54-4.C.

d. Calculate the actual traffic factor for design.

2. Determine the IBR. Determine the IBR as discussed in Section 54-3.01(f).

3. Determine the CRCP Thickness. Use the following procedures to determine the CRCP thickness:

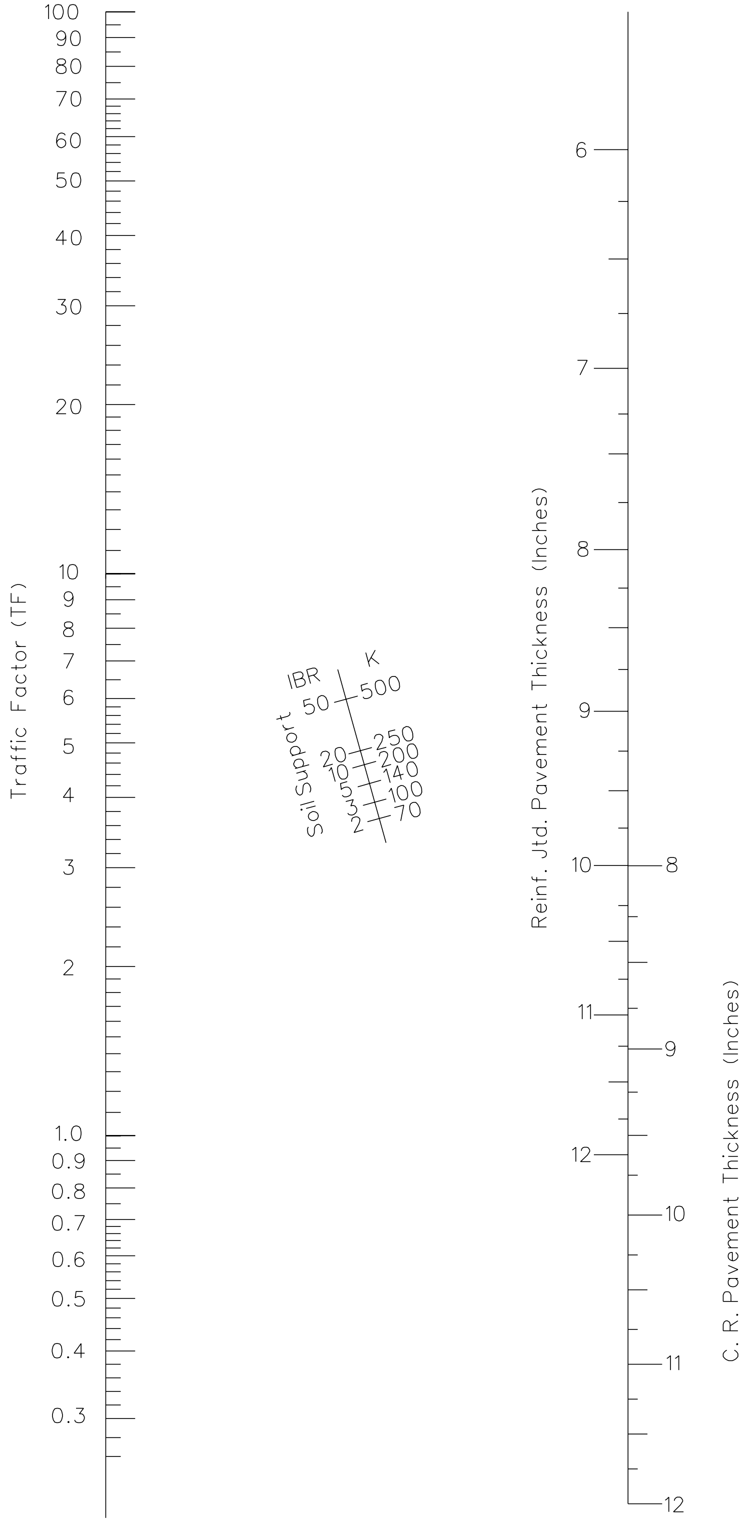
a. Based on the facility class determined in Step 1a, select the appropriate design nomograph from the following:

- Class I Facilities; use Figure 54-4.M; or
- Class II, III, and IV Facilities; use Figure 54-4.N.

b. Within the nomograph, project a line from the traffic factor determined in Step 1 through the IBR of the roadbed soil determined in Step 2 and intersect the CRCP pavement type and thickness axis of the nomograph.

c. Read the CRCP thickness from the point of intersection on the nomograph and round the thickness up to the nearest 0.25 in.

d. If design inputs produce values which exceed the chart's, the design's parameters should be forwarded to the Bureau of Research for design.



RIGID PAVEMENT DESIGN NOMOGRAPH

(Note: Ignore the Reinf. Jtd. Pavement thickness scale, it is not used.)

Figure 54-4.N

54-4.02(f) Subbase Type and Thickness

Section 54-4.01(h) applies to modified AASHTO designs for rigid pavements, except the stabilized subbase shall be constructed of HMA for CRCP.

54-4.02(g) Designating Structural Information on Plans

See Section 63-4.05 for information on designating structural information on plans.

54-4.02(h) Joints and Concrete Lug End Anchorages

The following guidelines should be used when CRCP is placed between structures that are in close proximity to each other.

Where the slab length of CRCP between bridges or other pavement types is less than 1,500 ft, use a doweled expansion joint. Where the slab length is between 1,500 ft and 2,000 ft, contact the Bureau of Research. For sections of CRCP longer than 2,000 ft, use a lug system. A wide-flange beam terminal may be used in place of a lug system.

54-4.02(i) Typical Sections

See Section 54-4.01(m) for typical rural and urban pavement sections of rigid designs for various types of highway facilities.

54-4.02(j) Surface Finish

See Section 54-4.01(o) for guidance on the type of surface finish that is required.

54-4.03 Unbonded Concrete Overlay

54-4.03(a) Limitations

Unbonded concrete overlays (UCOs) have a proven history in Illinois. Research in Illinois has shown that UCOs are a viable alternative to complete removal and replacement when a pavement has deteriorated beyond the point that a standard patch and overlay will not perform. However, some pavements may not be the best candidates for UCOs. Pavements with existing HMA and/or undoweled PCC patches are not good candidates. The UCO is not able to bridge over unstable slabs or rocking or pumping patches. UCOs are not experimental; however, use of this type of pavement requires approval from the Bureau of Research using economic justification.

54-4.03(b) Application of Design Method

A UCO consists of an existing concrete pavement, an interlayer, and a JPCP or CRCP overlay. The overlay relies on minimal structural contribution from the existing pavement and the two layers function independently. The existing pavement acts as the subbase. The interlayer separates the two pavements and retards reflective cracking in the overlay. HMA is an effective interlayer. A minimum HMA interlayer thickness of 4 in. is recommended.

54-4.03(c) Pavement Type and Thickness

When designing a UCO, use the same design parameters for design period, traffic factors, and pavement thickness as shown in Section 54-4.02 for rigid pavements. If using a CRCP, determine the UCO thickness by calculating the thickness of a new CRCP and subtracting 1 in.

Though several other States use JPCP pavements for UCOs, the Department does not have any experience with designing or constructing a UCO with that type of pavement. If the district is interested in using a JPCP for the UCO, the project will require assistance from Bureau of Research for the design of the overlay and an experimental feature according to Construction Memorandum 02-2.

54-4.03(d) Special Considerations/Comments

Due to the increase in pavement elevation, the following must be considered: the grade/elevation of mainline structures, vertical clearances at overhead structures, and adjustments of earth front-slopes. These issues may involve exceptions to policy which must be approved by the FHWA, BDE, or Bridges and Structures. Terminal treatments (e.g., lug systems, wide-flange beams, and special treatments that taper into existing sections) may need to be detailed to connect the adjacent pavement or bridge section to the overlay.

Contact the Bureau of Research for assistance in developing UCO designs (i.e., overlay and interlayer thickness requirements, UCO thickness, terminal treatments). The suitability of a UCO depends on many factors, and each set of conditions warrants an individualized design. Costs must be considered on a case-by-case basis. Rural sections without overhead structures are ideal locations for UCOs because vertical clearance will not become an issue.

54-5 STRUCTURAL DESIGN OF FLEXIBLE PAVEMENTS

54-5.01 Mechanistic

54-5.01(a) Limitations

Thickness designs may be obtained for traffic factors ranging from 0.5 to approximately 100 and for pavement thicknesses ranging from 6 in. to 18 in. However, the absolute minimum traffic factor of 0.5 will control the design thickness at the lower limits and the Limiting Strain Criterion Design Thickness will control the maximum design thickness. Limiting Strain Criterion Design thicknesses will only be allowed on those projects for which the design thickness calculated in Figures 54-5.F, 54-5.G, or 54-5.H exceeds the thickness shown in Figure 54-5.I.

54-5.01(b) Minimum Material Quality

The mechanistic full-depth HMA design procedures require, and are limited to, the use of HMA surface and binder courses with 4% air voids. HMA (4% voids, $N_{design} \geq 90$) mixtures will be specified for Interstates and freeways. HMA (4% voids, $N_{design} \leq 70$) mixtures may be specified for all other highway classifications. Any combination of surface course and binder course may be used to total the design HMA thickness. However, for the purpose of providing the most economical design, a surface course thickness of 2 in. should be used for new construction (see Section 54-5.01(i)). If there is any question as to the use of any HMA mixture in the procedure, contact the Bureau of Materials. The HMA mixture design criteria must be met as outlined in Section 53-4.04.

54-5.01(c) Asphalt Binder Selection

The mechanistic design procedures give the designer the option of selecting an appropriate asphalt binder type within the limits of current IDOT policy. The designer should be aware that in northern Illinois the use of a softer asphalt binder will reduce the effects of thermal cracking. On lower volume roads, a softer asphalt binder may be desired to reduce weathering and raveling and improve durability. On high volume roads and in areas of slower moving or standing loads, a stiffer asphalt binder should be used. In some cases, it may be desirable to use one asphalt binder grade for the binder course and another asphalt binder grade for the surface course. Where more than one asphalt binder grade is used, the design thickness will be based on the grade used for the lower binder course. Information on design asphalt binder grade selection is provided in Section 53-4.04(e). The design asphalt binder grade will be provided by the district and will be noted on the plans.

Project location and traffic volume are the main factors affecting the performance of HMA pavements. Consult with the district materials engineer to determine the proper asphalt binder grade.

54-5.01(d) Application of Design Method

The mechanistic design procedures enable the designer to determine the material types and thicknesses for the various layers of a flexible pavement that are required to carry a specified volume and composition of traffic for a designated period of time while retaining a serviceability level at or above a selected minimum value. Use the procedures presented in Section 54-5.01(i) to determine the thickness design for full-depth HMA pavement.

54-5.01(e) Design Period

The design period for all Class I and Class II roads and streets and for Class III State primary highways is typically 20 years. Other Class III and all Class IV roads and streets may be designed for less than 20 years.

54-5.01(f) Equivalency Factors

Section 54-2.01(d) describes the use of equivalency factors to convert mixed-traffic loadings to 18-kip ESAL applications. Equivalency factors for flexible pavements are given in Figure 54-5.A. These equivalency factors have been used to develop the equations presented in Section 54-5.01(g).

Facility Class	**18-kip ESAL Applications Per Vehicle**		
	PV	**SU**	**MU**
Class I	0.0004	0.363	1.322
Class II	0.0004	0.307	1.056
Class III and IV	0.0004	0.299	1.053

EQUIVALENCY FACTORS
(Flexible Pavements)

Figure 54-5.A

54-5.01(g) Traffic Factor

The traffic factor is the projected total 18-kip ESALs, expressed in millions, to be carried by the design lane during the design period. Figure 54-5.B presents the traffic factor equations that should be used for flexible pavement designs.

Facility Class	Traffic Factor Equation	Equation Number
Class I	$TF=DP\left[\frac{(0.15 \bullet P \bullet PV)+(132.50 \bullet S \bullet SU)+(482.53 \bullet M \bullet MU)}{1x10^6}\right]$	Equation 54-5.1
Class II	$TF=DP\left[\frac{(0.15 \bullet P \bullet PV)+(112.06 \bullet S \bullet SU)+(385.44 \bullet M \bullet MU)}{1x10^6}\right]$	Equation 54-5.2
Class III and Class IV	$TF=DP\left[\frac{(0.15 \bullet P \bullet PV)+(109.14 \bullet S \bullet SU)+(384.35 \bullet M \bullet MU)}{1x10^6}\right]$	Equation 54-5.3

where:
DP = design period in number of years.
PV, SU, MU = structural design traffic expressed as the number of PV, SU, and MU vehicles.
P, S, M = percent of PV, SU, and MU in the design lane expressed as a decimal.

TRAFFIC FACTOR EQUATIONS
(Flexible Pavements)

Figure 54-5.B

54-5.01(h) Improved Subgrade

The improved subgrade serves as a stable construction platform for placement of the subsequent layers of HMA pavement. All classes of roads and streets shall have an improved subgrade of the required thickness according to Section 54-2.01(f). Treatment options for improved subgrade are shown in Figure 54-2.D.

54-5.01(i) Thickness Design Process for Full-Depth HMA

For a mechanistic design of a flexible pavement, use the following steps to determine thickness:

1. Determine Traffic Factor. Use the following procedures to determine the traffic factor:

    a. Determine the facility class (e.g., Class I, II, III, or IV) and the design period (see Section 54-5.01(e)).

    b. Determine the actual structural design traffic as described in Section 54-2.01(c).

c. Determine the minimum structural design traffic as described in Section 54-2.01(c) and shown in Figure 54-2.C.

d. Based on the facility class, select the appropriate traffic factor equation from Figure 54-5.B.

e. Calculate the actual traffic factor.

f. Calculate the minimum traffic factor.

g. Compare the actual traffic factor to the minimum traffic factor and select the greater of the two. Compare the resulting traffic factor to 0.5. If less than 0.5, use 0.5 as the absolute minimum traffic factor for design.

2. Determine the SSR. Determine the SSR as described in Section 54-2.01(f) (e.g., poor, fair, granular).

3. Determine the Asphalt Binder Grade. Determine the asphalt binder grade for the lower binder, upper binder, and surface lifts as discussed in Section 54-5.01(c).

4. Determine the HMA Mixture Temperature. Use the following steps to determine the HMA mixture temperature:

   a. On Figure 54-5.C, identify and mark the location where the pavement section will be constructed.

   b. Using the temperature contours on Figure 54-5.C, interpolate the temperature and round up to the nearest 0.5°F at the marked location, except that the minimum HMA mixture temperature will be 73°F.

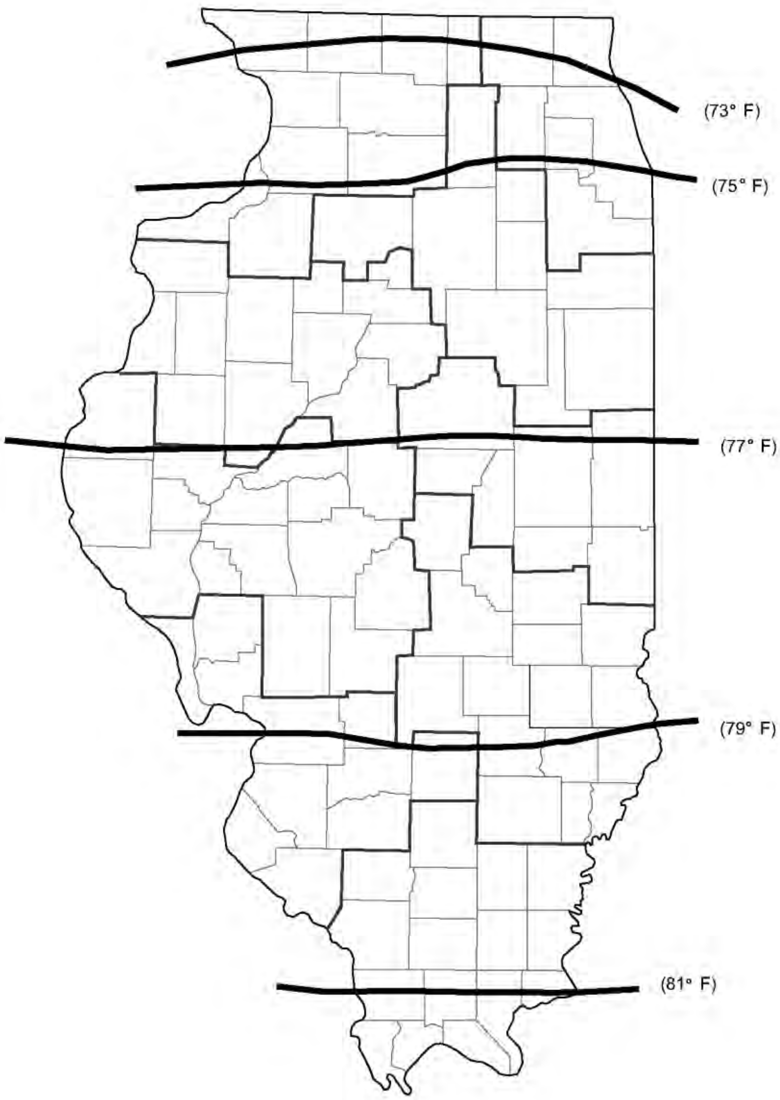
5. Determine HMA Mixture Modulus (E_{HMA}). Use the following procedures to determine the HMA mixture modulus (E_{HMA}) for pavement design:

   a. Along the horizontal axis of Figure 54-5.D, locate the value of the HMA mixture temperature determined in Step 4.

   b. Move up vertically and intersect the curve that represents the asphalt binder grade for the lower binder lifts determined in Step 3.

   c. Move left horizontally from the point of intersection on the asphalt binder grade curve and intersect the vertical axis of the HMA mixture modulus (E_{HMA}).

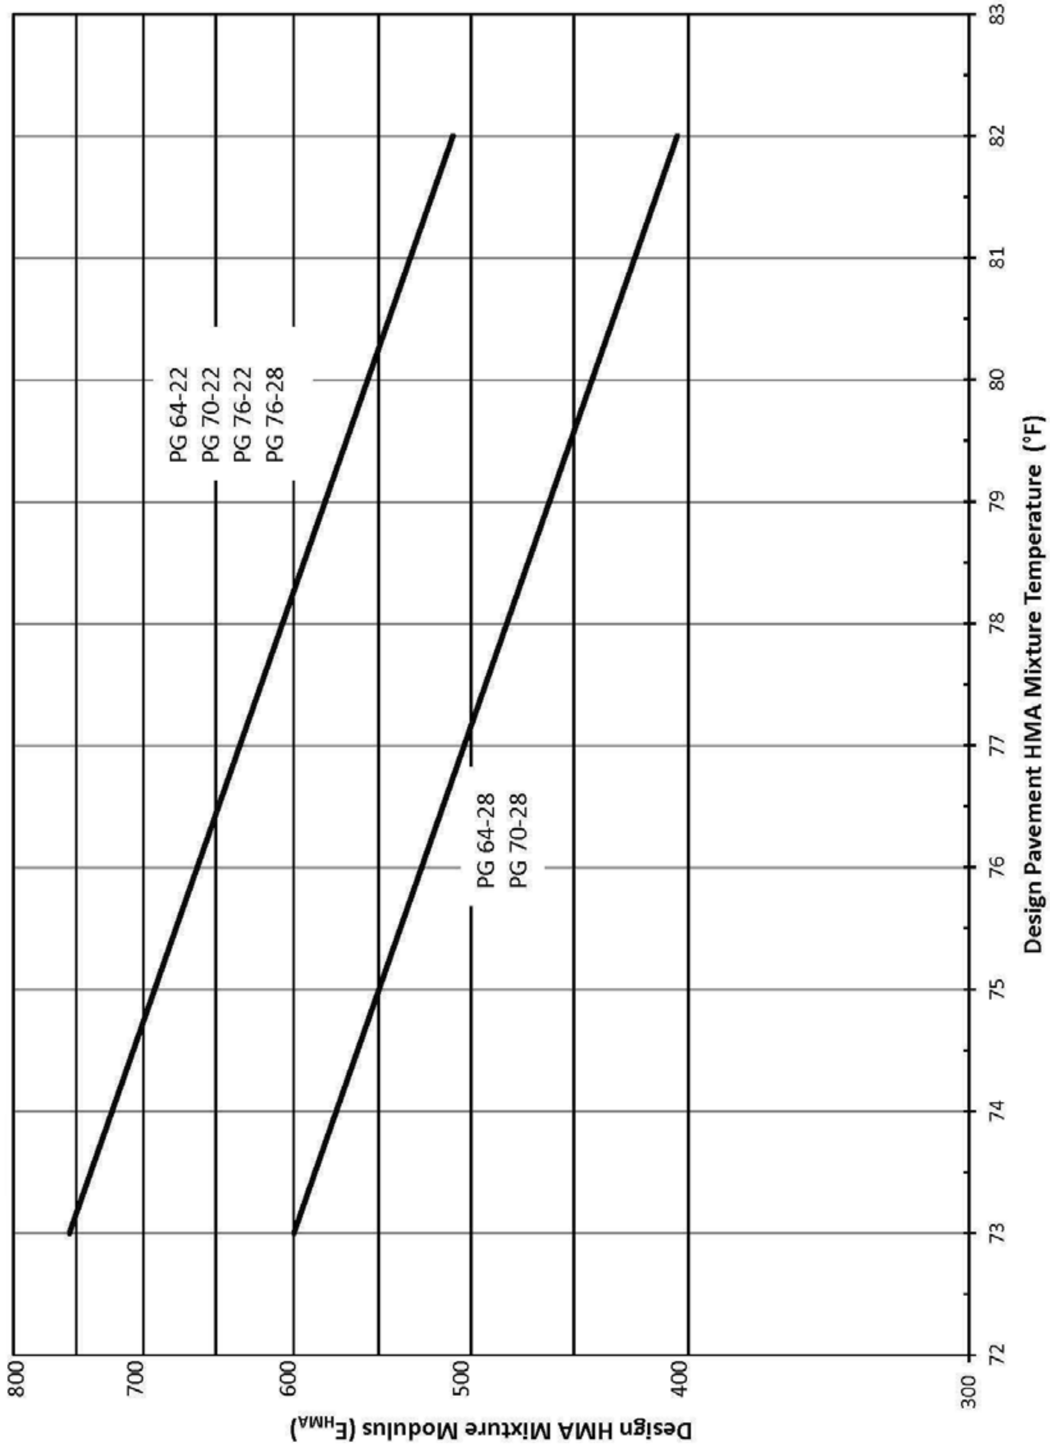
   d. At the point of intersection with the vertical axis, read the HMA mixture modulus (E_{HMA}) and round the value to the nearest 10 ksi. This will be the HMA mixture modulus for use in the design of the flexible pavement thickness (see Figures 54-5.F, 54-5.G, or 54-5.H).



Note: The minimum design HMA mixture temperature will be 73°F.

HMA MIXTURE TEMPERATURE
(Mechanistic Design: Flexible Pavement)

Figure 54-5.C



HMA MIXTURE MODULUS (E_{HMA})

HMA THICKNESS DESIGN CHART
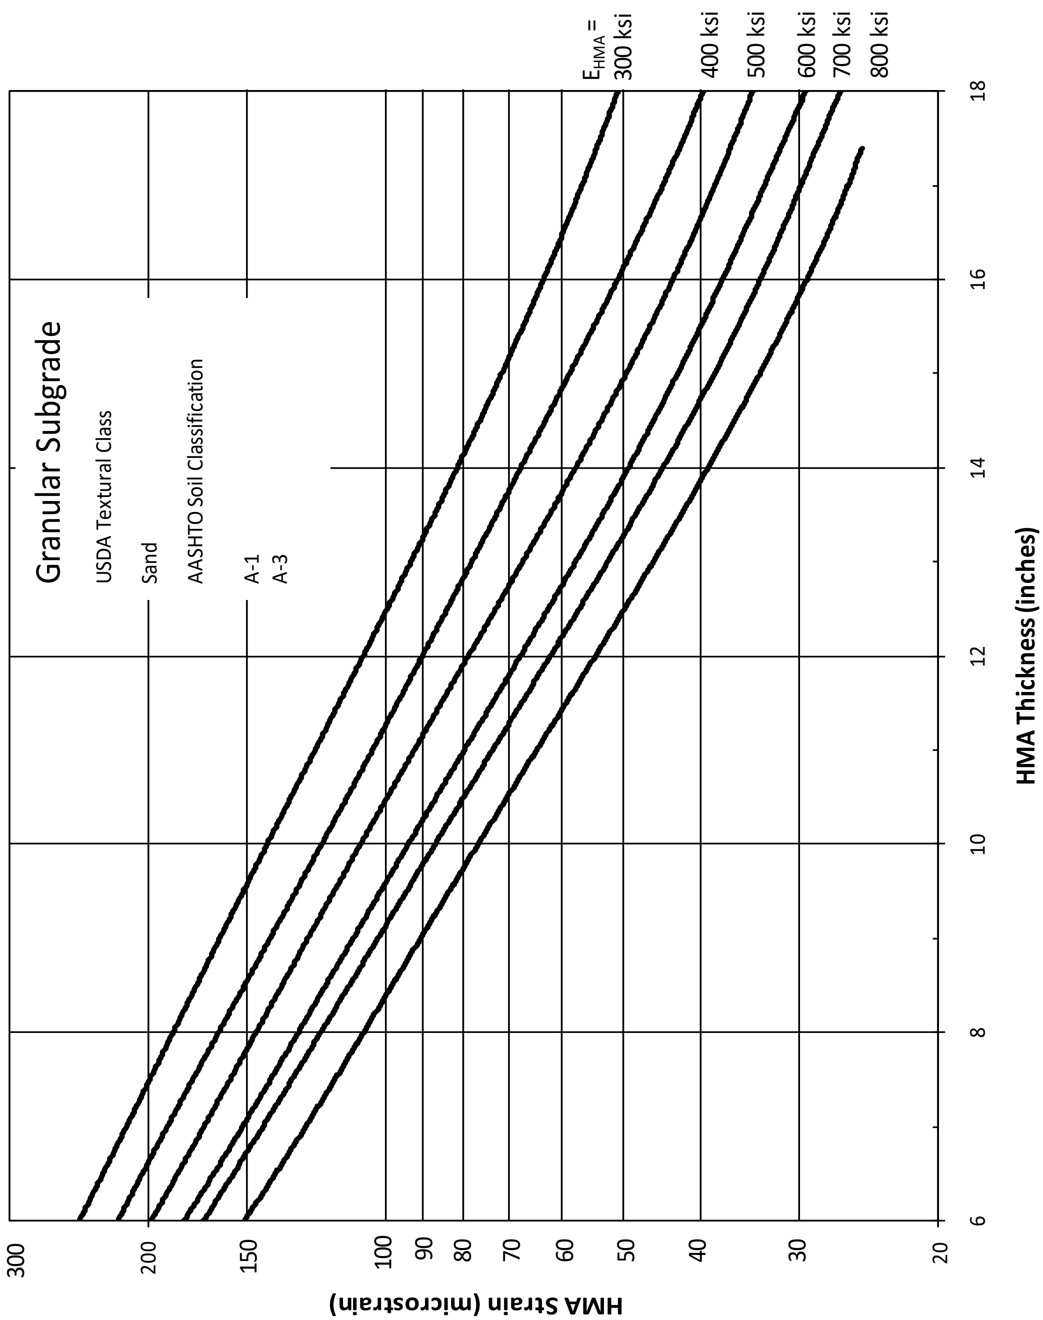
(Mechanistic Design: Flexible Pavement: SSR = Fair)

Figure 54-5.G



HMA THICKNESS DESIGN CHART
(Mechanistic Design: Flexible Pavement: SSR = Granular)

Figure 54-5.H

6. Determine Design HMA Strain. Use the following procedures to determine the design HMA strain:

   a. Along the horizontal axis of Figure 54-5.E, locate the value of the traffic factor determined in Step 1.

   b. Move up vertically and intersect the curve.

   c. Move left horizontally from the point of intersection on the curve and intersect the vertical axis of the design HMA strain (i.e., microstrain).

   d. At the point of intersection with the vertical axis, read the design HMA strain and round the value to the nearest unit microstrain. This will be the HMA strain to use in the design of the flexible pavement thickness (see Figures 54-5.F, 54-5.G, or 54-5.H).

7. Determine Pavement Thickness. Use the following procedure to determine the pavement thickness:

   a. Using the SSR determined in Step 2 (e.g., poor, fair, granular), select from Figures 54-5.F, 54-5.G, or 54-5.H, the one chart that represents the SSR for use in design.

   b. On the chart selected in Step 7a, there is a set of six curves that represents HMA mixture moduli (E_{HMA}) from 300 ksi to 800 ksi. Using the value of E_{HMA} that was determined in Step 5, interpolate and draw a parallel curve that will represent the HMA mixture modulus for use in design.

   c. Along the left vertical axis of the selected chart, locate the value of the design HMA strain determined in Step 6.

   d. Move right horizontally and intersect the design E_{HMA} curve interpolated and drawn in Step 7b.

   e. Move down vertically and intersect the horizontal axis of the selected chart.

   f. Read the thickness from the point of intersection on the horizontal axis and round this value up to the nearest 0.25 in. This will be the total thickness for the pavement design.

   g. Use the following guidelines to determine the proper surface course thickness for full-depth pavements:

      - New or replaced pavements where the pavement selection is based on life-cycle costs will have a surface course thickness of 2 in.

      - Additional lanes, pavement widening, and short replacement segments where the pavement selection is based on first cost will have a surface course thickness equal to the surface course thickness of the resurfacing if the adjacent pavement is being resurfaced. Otherwise, the surface course will be 2 in.

8. Limiting Strain Criterion Design Thickness Check. Use the following procedure to check the thickness determined in Step 7 against the limiting strain criterion design thickness for the project location.

   a. Determine the limiting strain criterion design thickness for the project location from Figure 54-5.I and round up to the nearest 0.25 in.

      If PG64-28 or PG70-28 is used in the lower binder lifts, add 1.00 in. of thickness to the value obtained from Figure 54-5.I and round up to the nearest 0.25 in.

   b. Compare the value obtained in Step 8a against the value obtained in Step 7 and select the lower value as the final design thickness.

9. Surface Friction Aggregate. See Section 53-4.04(f) for guidance on the selection of the appropriate surface friction aggregate.

   The use of an SMA surface course for projects with design TF greater than 10 is encouraged.

54-5.01(j) Use of Limiting Strain Criterion Design Cross-Section

Per Section 54-5.01(i), the surface course thickness for limiting strain criterion designs should be 2 in.

Limiting strain criterion designs should only need surface renewal throughout their design life. Material selection and attention to construction are critical to ensure that the design assumptions are met. Limiting strain criterion designs must incorporate the following mixture characteristics and construction requirements.

1. Mix Characteristics. The use of an SMA surface course is encouraged.

2. Construction Requirements.

   - Positive Dust Control-The use of positive dust control is required.

   - MTD-The use of a Material Transfer Device is required.

   - Auger-Paver Mainframe Extensions-The use of mainframe extensions in addition to auger extensions is required.

   - Tack Coats-The use of tack coats on all HMA lifts is required. Specify use of polymer tack coats on the top two lifts and non-polymer tack coats on all other lifts.

- Joint Construction-The use of echelon or full-width paving is required for all lifts. For situations where this is not possible, longitudinal joint sealant is required at the centerline joint under the surface lift and under the top binder lift.

Potential increases to costs as a result of material selection and improved construction requirements must be factored into the life-cycle cost analysis discussed in Section 54-7.

54-5.01(k) Designating Structural Design Information on Plans

See Section 63-4.05 for information on designating structural design information on plans.

54-5.01(l) Shoulder Type/Design

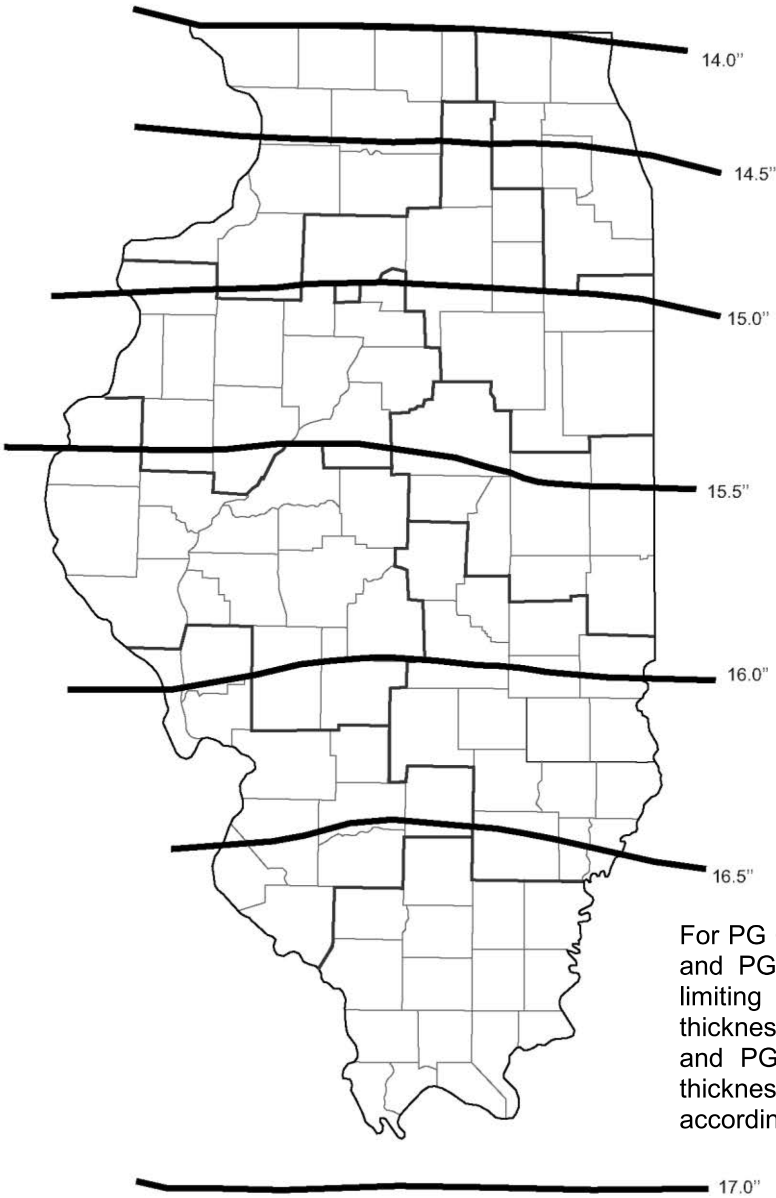
Use flexible shoulders with flexible pavement designs. The shoulder should be of constant thickness to a depth determined by the designer, but should not be less than 8 in. Give particular consideration to the need to provide a greater-than-minimum shoulder thickness along heavily traveled truck routes.

54-5.01(m) Design Example

See Section 54-9 for a design example.

54-5.01(n) Typical Sections

Figures 54-5.J through 54-5.L illustrate typical rural and urban pavement sections of flexible designs for various types of highway facilities.



For PG 64-22, PG 70-22, PG 76-22, and PG 76-28 binder grades, read limiting strain criterion design thickness off of map. For PG 64-28 and PG 70-28 binder grades, the thickness should be corrected according to Section 54-5.01(i)8a.

Note. Thickness values based upon Mean Monthly Pavement Temperature at 4 in. depth correlated to July Mean Monthly Air Temperature, axle load of 20,000 lb, strain of 70 με, and E_{Ri} of 2 ksi.

Figure 54-5.L

54-5.02 HMA Pavement (Full-Depth) on Rubblized PCC Pavement

54-5.02(a) Application of Design Method

The following procedures are to be used to determine the appropriate full-depth HMA pavement thickness to be placed over rubblized PCC pavement. Rubblization is an alternative to complete removal and replacement in which the existing PCC pavement is broken (in-place) into small pieces and compacted to create a uniform base for the new full-depth HMA pavement.

These guidelines encompass the evaluation of an existing pavement structure to determine if the section can support the rubblizing process, as well as the design and construction steps needed to successfully use this option. The use of rubblizing requires close attention to subgrade support. This technique requires sufficient thickness of the rubblized pavement and subbase structure to protect the subgrade during construction operations.

54-5.02(b) Review of the Existing Pavement Structure

The selection of HMA pavement (full-depth) on rubblized PCC pavement as a viable alternative should be the result of a thorough investigation of the existing pavement structure and subsurface conditions. This technique requires adequate support from the subgrade, subbase, and rubblized pavement for each of the various construction activities. If conditions exist that would result in extensive removal and replacement of the existing pavement, or the subgrade is weak and would result in construction problems, the designer should consider other options.

1. Preliminary Soils Review. Before ordering an extensive subgrade investigation, the designer should contact the district's geotechnical engineer to discuss the proposed rubblizing section. From the typical pavement sections, soil maps, and typical Immediate Bearing Values (IBVs) of soils in the area, the designer and geotechnical engineer should determine if the rubblized section will protect the subgrade, as outlined in the Department's *Subgrade Stability Manual*.

   If the rubblized pavement will not provide adequate cover for potentially soft subgrades, rubblizing should not be considered as an option. Rubblizing destroys the slab action of the PCC pavement; and if an unstable subgrade is encountered, the pavement section may require expensive change orders during construction.

   If it appears that the pavement can be rubblized, then a detailed pavement and subsurface investigation is needed to verify constructability of the pavement.

2. Detailed Pavement and Subsurface Investigation. After passing a preliminary review, a detailed investigation of the existing pavement and subsurface conditions should be conducted and a report prepared to specifically address the following points:

   - condition/thickness of PCC slab and HMA overlay(s) (if present);
   - subbase condition and thickness (if present);
   - subgrade IBV from Dynamic Cone Penetrometer (DCP) tests;

- subgrade soil samples (if needed for further evaluation);
- survey of existing drainage conditions;
- shoulders' ability to carry traffic while under construction;
- identification of locations where pavement removal and replacement, or alternative rehabilitation is recommended; and
- subgrade stability during rubblization.

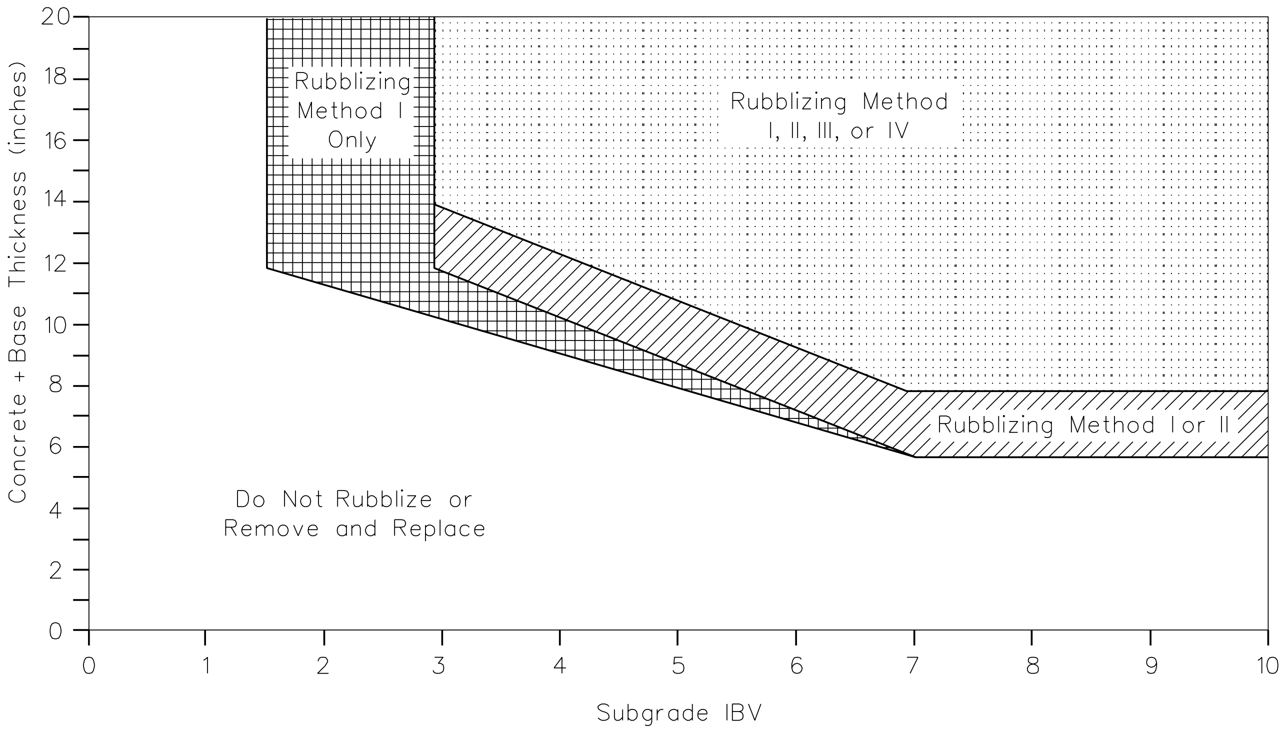
The district's geotechnical engineer should develop a coring, DCP, and soil sampling plan for the section. If the total thickness of existing concrete and base (i.e. stabilized subbase and/or granular layers) exceeds 12 in. and rubblizing Method I will be used, then DCP testing is optional. In general, a minimum of two cores per lane-mile should be taken. Core locations should be in representative cut and fill locations, and staggered between lanes. Additional coring and testing may be needed to define limits of weak subgrade areas.

The condition of any recovered stabilized material should be noted as being sound (intact and like new), slightly deteriorated (20% or less unsound or missing material), or deteriorated (more than 20% unsound or missing material). The overall condition of the subbase should be reported as a percentage of cores in each of these groups (i.e., 60% – sound, 30% – slightly deteriorated, and 10% – unsound).

After the core is removed, the DCP should be run in the hole for subgrade IBV. It is preferable to record single blow increments, to a depth of approximately 30 in. below the bottom of the pavement. If a granular base exists, the DCP may be driven through it and the depth determined from the change in IBV. A 6-lb to 8-lb soil sample should be taken and stored in an air-tight container for later testing if required. Forms BC 334 and BBS 2640 shall be used for documentation.

After the field survey is complete, typical IBVs should be developed, along with cross section data and condition of each layer. The data from each test location should be presented in table form including depth, penetration, and calculated IBV.

For the 12 in. of subgrade directly below the pavement, additional analysis is required. The top of the subgrade is broken into two layers, from 0 in. to 6 in. and 6 in. to 12 in. The average IBV is determined for each layer and plotted on Figure 54-5.M, using the pavement cross-section information. Once the data is plotted, a determination should be made as to what type of rubblizing method should be specified.



SUBGRADE RUBBLIZING GUIDE

Figure 54-5.M

For very limited areas of very soft subgrades, the designer may remove and replace the pavement, omit rubblizing, or perform a cracking and seating operation so the pavement can bridge weak subgrade areas where undercutting is not cost-effective. These areas should be identified on the plans. If it is found that several short or a few substantial segments of the project require rubblizing omissions, or removal and replacement of the pavement, then rubblization is not a viable alternative.

The pavement and subsurface investigation report should include the following:

- existing typical pavement section(s),
- core soundness and condition,
- summarized results of subsurface investigation,
- data plotted on Subgrade Rubblizing Guide (Figure 54-5.M),
- number and locations of transitions to meet mainline structures,
- clearances for overheads,
- utilities and culverts,
- location of any buildings or structures within 50 ft of the rubblization, and
- location and condition of underdrains.

54-5.02(c) Design Issues

The following design issues must be considered before the project can be submitted for review and approval:

1. Equipment Selection. A pavement breaker and self-propelled rollers are the major equipment necessary to rubblize a PCC pavement. The pavement breaker should be selected to meet the project's needs with respect to traffic control, staging, and subgrade support limitations. The following equipment characteristics should be considered when making a decision on breaker selection:

   a. Method I—Multi-Head Breaker (MHB). The MHB is a self-propelled unit with multiple drop-hammers mounted at the rear of the machine. The hammers are set in one or two rows, and strike the pavement approximately every 4.5 in. The hammers have variable drop heights and variable cycling speeds.

      The equipment has the ability to break pavement up to 13 ft wide, in one pass. The rate of production depends on the type of base/subbase material, and is approximately 1.0 lane-mile per day.

      The Z-pattern steel grid roller, a vibratory roller with a grid pattern, must be used in conjunction with the MHB to complete the breaking process. A Z-pattern grid is attached transversely to the drum surface. This roller further breaks flat and elongated material into more uniform pieces. The vibratory roller is self-propelled, with a minimum gross weight of 10 tons.

      Method I should be specified if there is any question of the rubblized section's ability to support construction equipment. The rubblized section and subgrade still must be able to support compaction equipment and loaded trucks without rutting or dislodging the rubblized PCC pavement.

      The MHB should be specified if the roadway is to remain open to traffic and encroachment into the adjacent lane cannot be accommodated. Encroachment of the MHB into the adjacent lane is similar to the rolling operation of HMA paving.

      The paving operation may work directly behind the breaking operation, in such a manner that the lane may be rubblized and overlaid for opening to traffic at the end of the day.

      Caution should be used if buildings are within 50 ft of the rubblizing operation, especially in an urban setting. Buildings that may be sensitive to vibration should be identified in the project report, with an alternative method of localized pavement breaking recommended. Alternative breaking methods (e.g., skid steer mounted jack hammer) should be considered or pavement rubblizing omitted near vibration sensitive buildings.

Underground utilities and drainage structures must be identified for protection. An omission in the breaking operation may be required over utilities and drainage structures. These omitted areas shall be broken with an alternative breaking method.

b. Method II—Resonant Frequency Breaker with High Flotation Tires. This method uses a resonant frequency breaker with tires, which have pressures below 60 psi. This allows operation on pavement sections that are thinner or have soft subgrades.

A resonant frequency breaker is a self-propelled unit that uses high frequency, low amplitude impacts with a shoe force of 2,000 lb to fracture the PCC pavement. The shoe, or hammer, is located at the end of a pedestal, which is attached to a beam and counter weight. The breaking principle is that low amplitude, high frequency resonant energy is delivered to the concrete slab, resulting in high tension at the top. This causes the slab to fracture on a shear plane, inclined at about 35 degrees from the pavement surface. The shoe, beam size, operating frequency, loading pressure, and speed of the machine can all be varied.

The breaking begins at the centerline and proceeds to the outside edge of the pavement. The breaking pattern is approximately 8 in. wide, and requires 18 to 20 passes to break a 12 ft lane width. The rate of production depends on the type of base/subbase material, and is about 1.0 lane-mile per day.

The resonant breaker has very heavy wheel loads of 20,000 lb. The broken pavement, shoulder, and subgrade must be adequate to support multiple passes of the equipment. The resonant breaker encroaches 3 ft to 5 ft into the adjacent lane to rubblize pavement near the centerline. The pavement section/shoulder must be structurally adequate for traffic to be moved 7 ft to 8 ft from the centerline and onto the shoulder. The use of the resonant breaker is best suited on roads that can be closed to traffic and support the breaker's weight.

The resonant breaker produces limited vibrations. Caution should be used with vibration sensitive buildings that are within 10 ft of the rubblizing operation.

Utilities or culverts within 6 in. of the PCC pavement bottom need to be protected, as described in Method I.

c. Method III—Resonant Frequency Breaker. This is the same basic machine as in Method II. However, it does not utilize the high flotation tires. This results in limiting usage as shown in Figure 54-5.M.

d. Method IV—Breaking Device Not Specified. This method can be specified if Methods I, II, and III could be used without restrictions to subgrade support, traffic, staging, or structures as noted above.

2. Drainage Considerations. The Department's longitudinal underdrain policy (see Section 53-2.07(c)1.) should be followed. Installation of new underdrains is strongly recommended. At a minimum, sag areas of vertical curves must be addressed. French drains, which are capable of draining the entire depth of the section, are acceptable for isolated areas. Existing underdrains that will remain in place shall be thoroughly investigated to ensure that they are functioning properly. For sections where underdrains will not be installed, the designer should consider limiting the amount of time the rubblized pavement may be left without an overlay, to minimize delays from rain saturation.

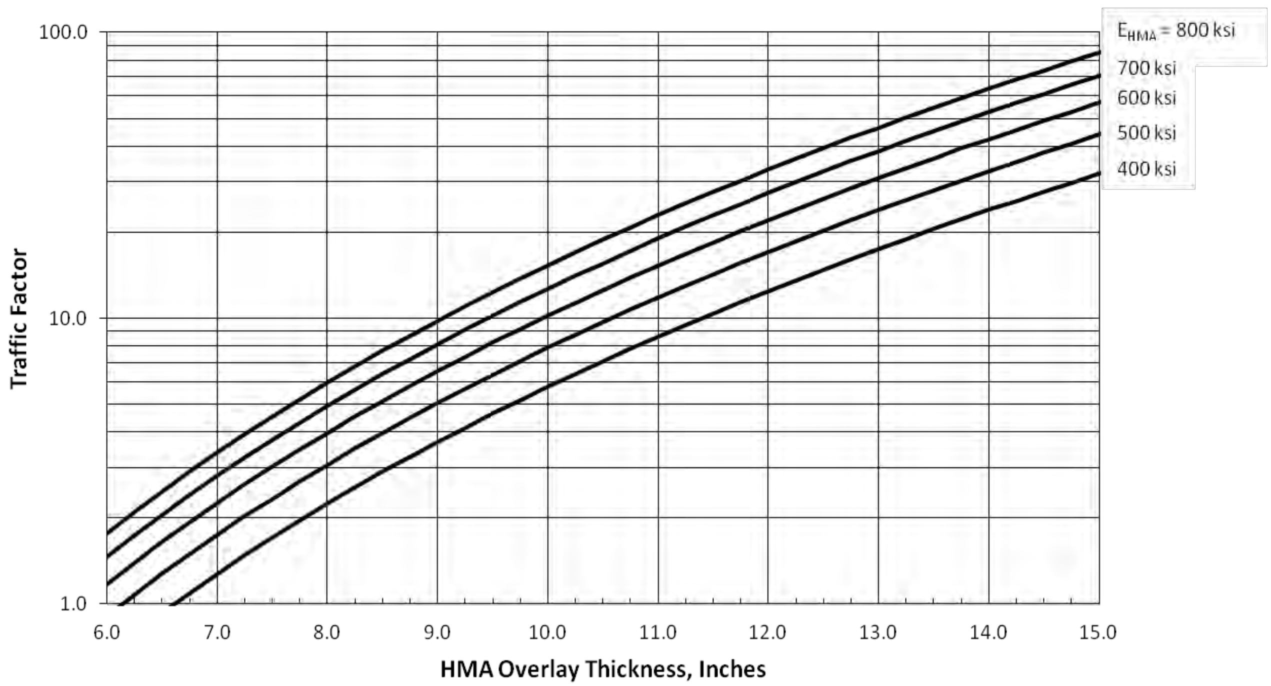
3. Priming. The rubblized surface should be overlaid without priming. Priming adds an extra step and curing period, which delays construction with no benefit to the finished product.

4. HMA Overlay Thickness Design. Use the following procedure to determine the HMA overlay thickness.

   a. Overlay Thickness Design Based on Actual Traffic. The designer should determine the required Traffic Factor (TF) needed for the design period (see Section 54-5.01(g)) using a recommended design period of 20 years. Design periods less than 10 years should not be considered. Asphalt binder grade for the HMA overlay is selected according to Section 53-4.04(e) using the requirements for a full-depth HMA pavement (Figure 53-4.M). The thickness of the HMA overlay needed on top of the rubblized section is determined using Figure 54-5.N. All designs are rounded up to the next 0.25 in. The design thickness, as a function of HMA mixture modulus and traffic factor, is determined as follows:

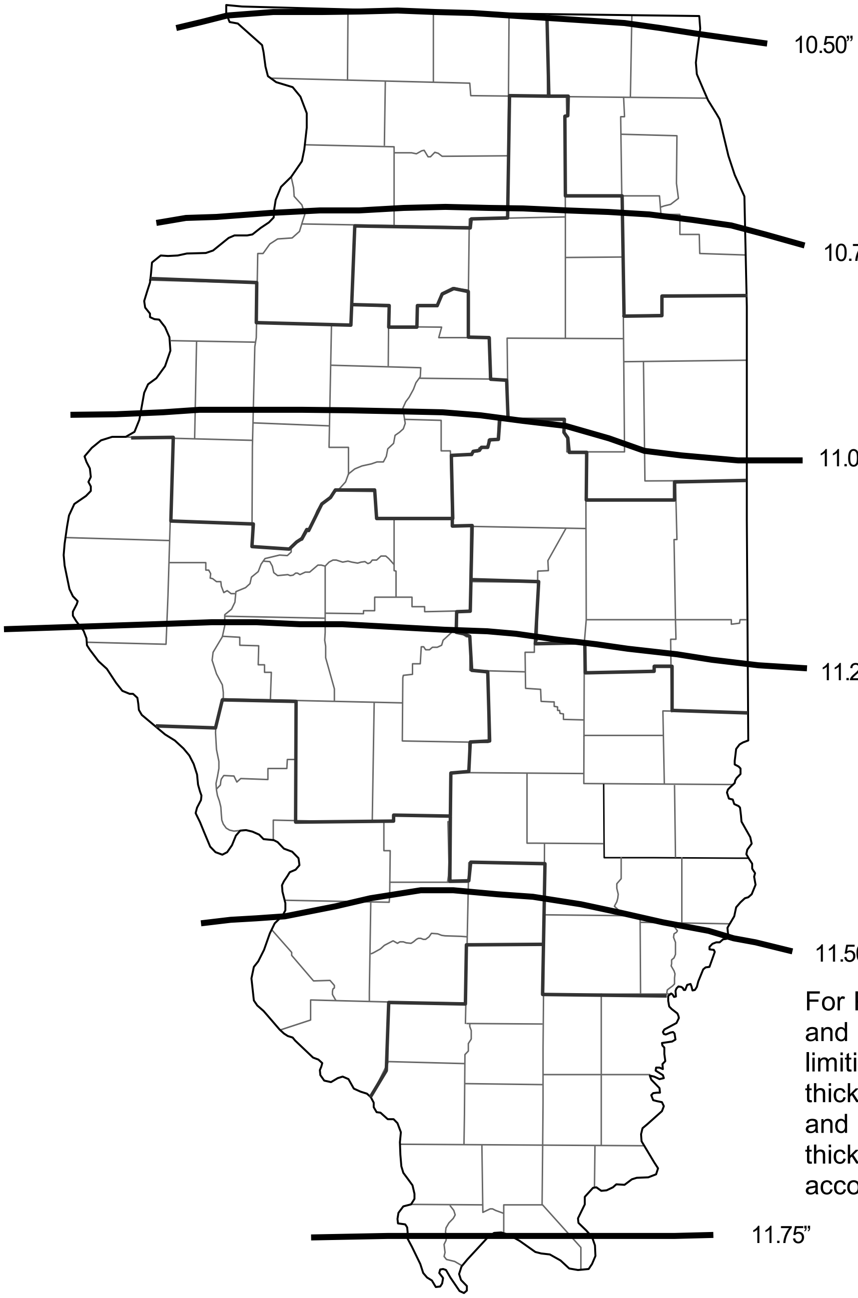
      - Determine the HMA mixture modulus (E_{HMA}) using the procedure described in Section 54-5.01(i)5.
      - Using the TF and E_{HMA} determined above, obtain the design thickness using Figure 54-5.N. An overall maximum thickness of 15 in. applies regardless of TF.
      - Determine the limiting strain criterion design thickness for the project location from Figure 54-5.O and round up to the nearest 0.25 in. If PG 64-28 or PG 70-28 is used in the lower binder lifts, add 1.00 in. of thickness to the value obtained from Figure 54-5.O. Compare the values obtained from Figures 54-5.N and 54-5.O and select the lower value as the final design thickness.

b. Minimum HMA Overlay and Lift Thicknesses. The minimum HMA overlay thickness for rubblized pavement is 6 in. The first lift of the overlay should be 3 in. to 4 in. This thickness allows good compaction on and minimizes dislodging of the rubblized base. The surface lift should be 2 in. For pavement overlays that are 7 in. or less, surface lifts of 1.5 in. are allowable. Contact the Bureau of Materials if first lifts less than 3 in. are desired.



HMA OVERLAY THICKNESS FOR RUBBLIZED PAVEMENTS

Figure 54-5.N



For PG 64-22, PG 70-22, PG 76-22, and PG 76-28 binder grades, read limiting strain criterion design thickness off of map. For PG 64-28 and PG 70-28 binder grades, the thickness should be corrected according to Section 54-5.02(c)4a.

Note. Thickness values based upon Mean Monthly Pavement Temperature at 4 in. depth correlated to July Mean Monthly Air Temperature, axle load of 20,000 lb, strain of 70 με.

MAXIMUM PAVEMENT THICKNESS
(Limiting Strain Criterion Design: HMA Overlay of Rubblized PCC Pavement)

Figure 54-5.O

5. Traffic Control. Traffic may be maintained during much of the construction process. The road may be used after the installation of underdrains and the milling of any existing HMA overlay. The safety of open trenches, lane to lane drop-offs, high shoulders, and the condition of the exposed pavement surface should be considered when determining if the road can be reopened to traffic.

   No traffic (including unnecessary construction traffic) should be allowed on the fractured pavement surface once the breaking operation begins. All HMA binder lifts should be paved before traffic is allowed onto the section. If staging requires that the pavement be opened to traffic before all the binder layers are in place, contact the Bureau of Research to review the structural impacts.

   Edge differentials in elevation of rubblized pavements can be substantially greater than standard overlays, and may require additional traffic control measures. The designer should evaluate the overall design and traffic staging to determine if any additional traffic control may be required. The designer should also evaluate differentials in elevation if milling to bare pavement is needed.

6. Specification of Material Transfer Devices (MTDs). The use of MTDs on the rubblized base must be evaluated on a case-by-case basis, due to the weights and axle configurations of the equipment. Contact the Bureau of Research to perform an analysis.

7. Construction Sequence. The general sequence of construction should be as follows:

   - Install underdrains or French drains, as required.
   - Remove any existing HMA overlay to the staged width.
   - Remove and replace any existing unsound HMA repair materials.
   - Rubblize the pavement.
   - Compact the broken pavement.
   - Pave the binder lifts of the HMA overlay.
   - Allow traffic on sections that have adequate thickness, as shown on the plans (if needed).
   - Pave the surface of the HMA overlay.

8. Other Design Issues. Any HMA material on the pavement from pothole patching may be left in place. If there are any full-depth HMA patches in the section, soundness of the patch material should be determined. HMA patches should be rated in the same manner as subbase in Section 54-5.02(b). Visually indeterminate patches may be investigated with a limited coring program. If an HMA patch is unsound, the material should be removed. When traffic is maintained during the patching operation, the

replacement material should be a Class C or D patch. If concrete is the replacement material, it shall be rubblized.

If the unsound patch is greater than 10 sq ft, HMA binder mixture shall be used. When the road is closed to traffic and the unsound patch is less than or equal to 10 sq ft, the replacement material may otherwise be aggregate. The aggregate shall be a Class D Quality (or better) crushed stone, crushed slag, crushed concrete, or crushed gravel meeting a CA 6 or CA 10 gradation; according to Section 1004 of the *Standard Specifications*.

Partial-depth HMA patches may be left in place during rubblization. If partial-depth patches prevent proper breaking of the PCC pavement, a skid steer loader (with a jack hammer attachment or similar device) may be used to complete breaking in these areas.

The rubblizing process will increase the pavement width 1 in. to 3 in. per 2-lane width, and encroach slightly into the underdrain trench. This has not caused performance problems with sand trench and pipe type underdrains to date. If the resonant breaker is used, the driving of heavy wheel loads directly over the underdrain trench should be avoided as much as possible. Wheel loads directly over the underdrain trench are of less concern if the existing shoulder is in sound condition.

54-6 STRUCTURAL DESIGN OF COMPOSITE PAVEMENTS

54-6.01 Application of Design Method

The design procedures for composite pavements enable the designer to select:

- the thickness of HMA surface needed to structurally rehabilitate an existing rigid or composite pavement, or

- the thickness of both HMA surface and PCC base course for a new composite pavement.

The resulting composite pavement will be capable of carrying a specified volume and composition of traffic for a designated period of time while retaining a serviceability level at or above a selected minimum value.

The composite design method assumes that the existing rigid or composite pavement has reached the end of its design life and is in need of structural rehabilitation. If the existing pavement has not reached the end of its design life, as may be the case when a resurfacing is being designed in conjunction with a lane addition, higher strength coefficients than those discussed in Section 54-6.06 may be appropriate. Such cases should be referred to the Bureau of Research.

Application of the composite design method involves the following steps:

1. Determine Traffic Factor. Use the following procedures to determine the traffic factor:

    a. Determine the facility class (e.g., Class I, II, III, or IV).

    b. Determine the actual structural design traffic as described in Section 54-2.01(c).

    c. Based on the facility class, select the appropriate traffic factor equation from Figure 54-4.C.

    d. Calculate the actual traffic factor to use in design.

2. Determine the IBR. Determine the IBR of the roadbed soil (see Section 54-3.01(f)).

3. Determine the Structural Number (SN_C). Determine the composite pavement structural number (SN_C) using the appropriate design nomograph for the facility class (i.e., Figure 54-6.A for Class I facilities or Figure 54-6.B for Class II, III, and IV facilities).

4. Determine Thickness. Select the appropriate equation from Section 54-6.06 as follows:

    - first resurfacing, use Equation 54-6.1;
    - second resurfacing, use Equation 54-6.2; or
    - new composite pavement, use Equation 54-6.3.

Using the appropriate equation and Figure 54-6.C, calculate the thickness of surface and base course, if applicable. Round the thickness(es) up to the nearest 0.25 in. For pavements that are in need of a third resurfacing, see Section 54-6.06.

5. Compare with Minimum Criteria. Compare the calculated thickness(es) with the minimum requirements presented in Figure 54-6.D. Use the larger of the values for design.

54-6.02 Design Period

The design period for all composite pavements is typically 20 years. See Section 54-3.01(b).

54-6.03 Equivalency Factors

Section 54-3.01(d) describes the use of equivalency factors to convert mixed-traffic loadings to 18-kip ESAL applications. Because the main structural layer of a composite pavement is a rigid slab, the equivalency factors are the same as for rigid pavement (see Section 54-4.02(c)).

These equivalency factors have been used to develop the traffic factor equations discussed in Section 54-6.04.

54-6.04 Traffic Factors

The traffic factor is the projected total 18-kip ESALs, expressed in millions, to be carried by the design lane during the design period. Because the main structural layer of a composite pavement is a rigid slab, the equivalency factors are the same as for rigid pavement (see Section 54-6.03). The traffic factor equations discussed in Section 54-4.02(d) also apply to composite pavement designs.

54-6.05 Composite Pavement Structural Number

Having calculated the traffic factor, only the IBR of the roadbed soil (see Section 54-3.01(f)) is needed to determine the composite pavement structural number. The composite pavement structural number (SN_C) is obtained by projecting a line through the traffic factor and the IBR of the roadbed soil on the appropriate design nomograph, either Figure 54-6.A for Class I facilities or Figure 54-6.B for Class II, III, and IV facilities.

MINIMUM DESIGN REQUIREMENTS FOR COMPOSITE PAVEMENTS
(Composite Pavement Design)
Figure 54-6.D

54-6.06 Thickness Design Equations

The composite pavement structural number (SN_C), an abstract number related to the strength required of the total pavement structure, is a summation of layer thicknesses multiplied by their corresponding strength coefficients. Three design equations incorporate the composite pavement structural number as follows:

1. First Resurfacing. For the initial HMA surfacing over an existing rigid pavement, use the following equation:

$$D_S = \frac{SN_C - 0.26D_C}{0.40}$$ Equation 54-6.1

2. Second Resurfacing. For a second HMA surfacing over an existing resurfaced rigid pavement, use the following equation:

$$D_S = \frac{SN_C - 0.25D_E - 0.17D_C}{0.40}$$ Equation 54-6.2

3. New Composite Pavement. For the design of a new composite pavement, use the following equation:

$$SN_C = 0.40\ D_S + 0.33\ D_B \qquad \text{Equation 54-6.3}$$

where:
- SN_C = composite pavement structural number
- D_S = thickness of HMA policy overlay (inches)
- D_C = equivalent thickness of existing PCC slab (inches)
- D_E = thickness of existing HMA surface (inches)
- D_B = thickness of new PCC base course (inches)

Note that the above equations do not include provisions for a third resurfacing. Pavements that are in need of a third resurfacing for structural reasons often are badly deteriorated and may no longer be functioning as a rigid pavement. Contact the Bureau of Research for guidance in selecting the appropriate strength coefficients for such pavements.

In the case of an existing JRCP/JPCP of uniform thickness, the equivalent thickness of the PCC slab (D_C) is the actual slab thickness. For a CRCP, D_C is the slab thickness multiplied by 1.25. Figure 54-6.C presents the equivalent thickness (D_C) of the non-uniform PCC pavements formerly constructed by the Department.

Use Equation 54-6.3 to develop designs for totally new composite pavements composed of an HMA surface and a PCC base course. The application of this pavement design procedure is restricted as follows:

- to changes in horizontal or vertical alignment for short segments of rural pavement,
- to lane additions,
- to replacement of short segments of urban pavement, and
- as an option to flexible base materials.

Equation 54-6.3 requires determination of two unknowns (i.e., the surface and the base course thicknesses). To develop a design, it becomes necessary, therefore, to assume the thickness of one pavement component and compute the required thickness of the other. In most cases, it will be best to initially assume the surface course thickness. The surface course thickness selected should be the standard policy resurfacing thickness or the thickness of the resurfacing being placed on the adjacent pavement.

54-6.07 Minimum Design Requirements

The composite design procedures are used to analyze PCC slabs that are surfaced with high-type HMA and are therefore limited to HMA surfacing materials that meet the requirements of the *Standard Specifications* for HMA. To ensure practical and adequate designs, adhere to the minimum criteria presented in Figure 54-6.D for composite pavements.

54-6.08 Designating Structural Design Information on Plans

See Section 63-4.05 for information on designating structural design information on plans.

54-6.09 Design Example

See Section 54-9 for a design example.

54-7 PAVEMENT SELECTION ANALYSIS

54-7.01 Introduction

The life-cycle activities for mechanistically designed pavements that are presented in this section were developed by a panel of Department experts who have experience in the areas of design, construction, materials, and maintenance of Illinois pavements. The expert group established rehabilitation, patching, and maintenance strategies for a 45-year analysis period for typical rigid and flexible pavements.

A framework for data collection has been established to gather actual data on maintenance activities and costs. As these data are collected, appropriate modifications to the life-cycle strategies will be made where needed.

54-7.02 Selection Basis

The selection of pavement design alternatives is based on the following criteria:

1. Widening Projects. Pavement design alternatives for widening projects are evaluated based on a first-cost analysis. The alternative with the lowest first cost is selected for construction.

2. New Construction/Pavement Replacement Projects. Pavement design alternatives for new or replaced pavements are evaluated based on a life-cycle cost analysis. The analysis will consider the following alternatives:

   a. New Construction Projects. The analysis for a new pavement shall consider mechanistic designs for rigid and flexible pavements. If the difference in life-cycle costs between alternatives is greater than 10%, the alternative with the lowest life-cycle cost is selected for construction.

      If the difference in life-cycle costs is 10% or less, the selection will be based upon the alternate pavement bidding process described in Section 54-1.04. However if the project does not fit the criteria for alternate pavement bidding, or one pavement type is preferable, the project will be referred to the Pavement Selection Committee. If the Committee agrees alternate pavement bidding is not appropriate, the Committee will select the pavement type.

   b. Replacement Projects. The analysis for a replaced pavement shall consider new pavement mechanistic designs for rigid and flexible pavements; as well as supplemental pavement designs for unbonded JPC/CRC overlay and full-depth HMA pavement on rubblized PCC pavement. When developing the supplemental designs, the designer shall review the criteria provided in Sections 54-4.03 and 54-5.03 to determine which supplemental designs are viable options.

When comparing the new pavements designs to the viable supplemental designs, the life-cycle cost analysis must include costs that are unique to this type of comparison. For example, the cost of removing the existing pavement must be added to the new pavement alternatives and the cost of preparing the existing pavement, additional earthwork, etc. must be added to the supplemental designs. If the difference in life-cycle cost between one alternative and the others is greater than 10%, then that alternative with the lowest life-cycle cost is selected for construction.

If the difference in life-cycle costs is 10% or less, the selection will be based upon the alternate pavement bidding process described in Section 54-1.04 with only those alternatives within the 10% being taken forward to bidding. However if the project does not fit the criteria for alternate pavement bidding, or one pavement type is preferable, the project will be referred to the Pavement Selection Committee. If the Committee agrees alternate pavement bidding is not appropriate, the Committee will select the pavement type.

3. Waivers. Although the guidelines presented in Item 1 and Item 2 will apply in most cases, a waiver based on issues related to policy, Local Agency requests, or constructability may need to be considered. Such cases will be referred to the Bureau of Research for approval.

54-7.03 Life-Cycle Activities

Figures 54-7.A through 54-7.C present the maintenance and rehabilitation activities during 45 years of service. Figure 54-7.A illustrates the activities for mechanistically designed JPCPs and unbonded JPC overlays. Figure 54-7.B illustrates the activities for CRCPs and unbonded CRC overlays. Figure 54-7.C illustrates the activities for mechanistically designed full-depth HMA pavements and full-depth HMA pavements on rubblized PCC pavements.

54-7.04 Cost Estimating

The estimation of unit prices of all major pay items must be documented and must be based upon the anticipated quantities for the contract. Contact the BDE for the Department's procedures for cost estimation.

54-7.05 Life-Cycle Cost Analysis

The life-cycle cost analysis for new construction/pavement replacement type projects is performed using the "IDOT Mechanistic Pavement Design and Life-Cycle Cost Analysis" spreasheet (BDE 5401). The analysis is based on the following equation which annualizes the costs of initial construction and life-cycle activities amortized over the 45-year service life of the pavement. A discount rate of 3% is used to determine annual costs and no adjustment for inflation is required.

$$A = D + M + CRF_n [C + R_1(PWF_{n1}) + R_2(PWF_{n2}) + ... + R_n(PWF_{nn})] \qquad \text{Equation 54-7.1}$$

where: A = total annual cost per mile

D = annual administrative and overhead cost per mile (assumed to be equal for all pavement types; therefore, do not include in analysis)

M = total annual maintenance cost per mile (assumed to be equal for all pavement types; therefore, do not include in analysis)

CRFn = capital recovery factor for year n calculated as follows (see Figure 54-7.D):

$$= \frac{i(1+i)^n}{(1+i)^n - 1} \qquad \text{Equation 54-7.2}$$

i = discount rate (assumed to be 0.03 (i.e. 3%))

n = year within analysis period in number of years after initial construction

C = initial construction cost per mile

R1 = first rehabilitation cost per mile

R2 = second rehabilitation cost per mile

Rn = n^{th} rehabilitation cost per mile

PWF_{nn} = present worth factor for the n^{th} number of years after initial construction that the n^{th} rehabilitation activity is performed, calculated as follows (see Figure 54-7.D):

$$= \frac{1}{(1+i)^{nn}} \qquad \text{Equation 54-7.3}$$

n1 = number of years after initial construction that the first rehabilitation activity is performed

n2 = number of years after initial construction that the second rehabilitation activity is performed

nn = number of years n after initial construction that the nth rehabilitation activity is performed

If the difference in life-cycle cost between one alternative and the others is greater than 10%, select the alternative with the lowest life-cycle cost. If the difference in life-cycle costs is 10% or less, the selection will be based upon the alternate pavement bidding process described in Section 54-1.04 with only those alternatives within the 10% being taken forward to bidding. However if the project does not fit the criteria for alternate pavement bidding, or one pavement type is preferable, the project will be referred to the Pavement Selection Committee. If the Committee agrees alternate pavement bidding is not appropriate, the Committee will select the pavement type.

The Pavement Selection Committee consists of five Department personnel (i.e., three from the Central Office and two from the district). Regional Engineers, Deputy Directors, and other high-ranking personnel are excluded from the Committee. Committee meetings usually are held by conference calls. Factors that are considered by the Committee during the selection process are documented in the AASHTO *Guide to Design of Pavement Structures*. Committee deliberations are considered confidential and only the Committee's recommendation as to the final pavement selection is recorded.

Figure 54-7.D

54-8 PAVEMENT DESIGN SUBMITTALS

54-8.01 Submittal Requirement

Pavement designs for projects involving new construction, pavement replacement, or widening greater than or equal to 6 ft will be submitted to the Bureau of Research for approval if the project involves:

- more than 4,750 sq yds of pavement;
- more than $500,000 in pavement costs (see 20 ILCS 2705/2705-590);
- high stress intersections, experimental pavements, or special designs;
- exceptions to policy; or
- an expired pavement design (see Section 54-8.03).

Once approved, pavement designs will be posted on the IDOT website for public information. Approved pavement designs shall also be included in the Phase I project report or file.

54-8.02 Submittal Content

All pavement design submittals will include the following items:

1. Transmittal Memorandum. Include a memorandum of transmittal with the submittal. The memorandum should include information such as the route, section, county, description of the project, the district's recommendation for the pavement design, and the basis for that recommendation.

2. Location Map. Include a location map of the subject improvement showing the limits of the pavement work.

3. Typical Sections. Include typical sections for the proposed pavement types and for any special or unusual pavement treatment. Typical sections should include information detailing the number of lanes, shoulders, curbs and gutters, and other information as appropriate. Usually, only one typical section is required.

4. Subgrade Stability Chart. If the soil condition is found to be fair or granular, include the subgrade stability chart used in the analysis. Also, include documentation for any unusual soil conditions that affect pavement design (e.g., laboratory test results). If the soil is found to be poor, it is not necessary to include detailed information to substantiate this fact as this is the assumed condition.

5. Design Calculations. For most submittals, simply include a copy of the "IDOT Mechanistic Pavement Design and Life-Cycle Cost Analysis" spreasheet (BDE 5401). For designs not covered by the spreadsheet (e.g. composite pavement designs), include all design calculations and assumptions (e.g., traffic factor calculations, thickness calculations, thickness nomographs and related charts).

6. Economic Analysis. For most submittals, simply include the life-cycle cost analysis portion of spreadsheet BDE 5401. For designs based upon a first-cost analysis, include all calculations and assumptions related to the economic analysis. For special designs, an economic analysis is not required.

7. Unit Cost Sheets. Provide unit cost computation sheets that document the unit costs used for each major pay item involved in each of the economic designs. The unit costs must be based on the total anticipated quantities of the major pay items involved for the entire contract section.

8. Other Information. Include adequate documentation that describes any unusual factors affecting design or that influenced the pavement selection (e.g., construction staging, high-stress locations, Local Agency requests, unusual traffic volumes, traffic count summary sheets, memoranda from other District Bureaus, etc.).

54-8.03 Shelf-Life of Approved Pavement Designs

To ensure the department is using relevant data in the design and selection of pavements as required by the Department of Transportation Law, 20 ILCS 2705/2705-590, the approval of a pavement design will expire after 5 years.

To avoid having a pavement design expire in close proximity to a project’s anticipated construction letting date, the submittal of pavement designs for approval should be coordinated with the letting date; or the design should be updated and re-submitted for approval sufficiently in advance of the letting date.

54-9 DESIGN EXAMPLES

The following examples illustrate typical IDOT pavement designs:

* * * * * * * * * * *

Example 54-9.1

Given: New rural 4-lane State highway in central Sangamon County
ADT (Design Year Traffic) PV = 17,225 SU = 360 MU = 360
Subgrade Support Rating (SSR) = Poor
Asphalt Binder Type = PG64-22

Because this involves new construction, it will be necessary to perform both a rigid and flexible mechanistic design. See Figure 54-1.A.

Solution:

Step 1: Determine the actual traffic factor using Equations 54-4.1 and 54-5.1.

TF_R (Actual)

$$TF_{R(A)} = 20\,\frac{(0.15 \bullet 0.32 \bullet 17{,}225) + (143.81 \bullet 0.45 \bullet 360) + (696.42 \bullet 0.45 \bullet 360)}{1\text{x}10^6}$$

= 2.74

TF_F (Actual)

$$TF_{F(A)} = 20\,\frac{(0.15 \bullet 0.32 \bullet 17{,}225) + (132.50 \bullet 0.45 \bullet 360) + (482.53 \bullet 0.45 \bullet 360)}{1\text{x}10^6}$$

= 2.01

Step 2: Check minimum traffic factor.

TF_R (Minimum)

$$TF_{R(M)} = 20\,\frac{(143.81 \bullet 0.45 \bullet 250) + (696.42 \bullet 0.45 \bullet 750)}{1\text{x}10^6}$$

= 5.02

TF_F (Minimum)

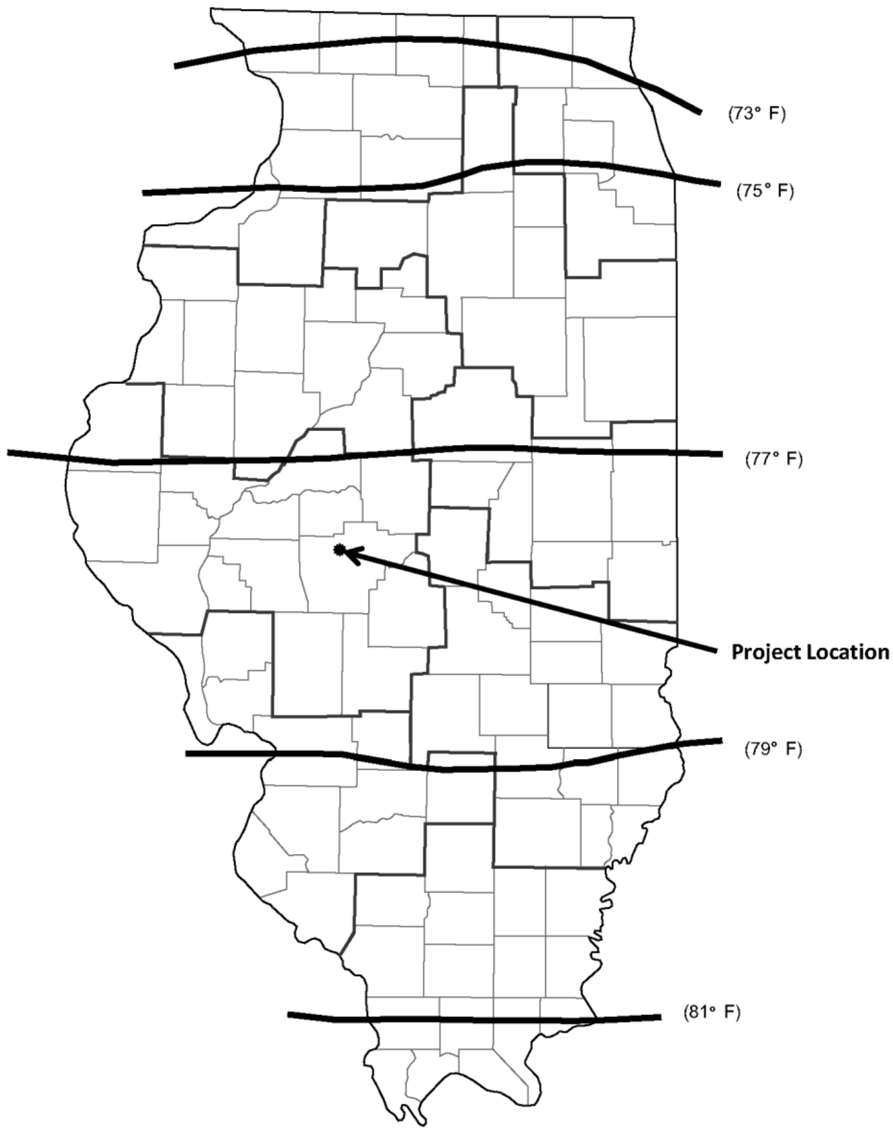
$$TF_{F(M)} = 20\,\frac{(132.50 \bullet 0.45 \bullet 250) + (482.53 \bullet 0.45 \bullet 750)}{1\text{x}10^6}$$

= 3.56

Because the minimum traffic results in a higher traffic factor, use the minimums.

Step 3: Determine the pavement HMA mixture temperature from Figure 54-5.C and round up to the nearest 0.5 degree. See Figure 54-9.A.

HMA Mix Temperature = 78.0°F



Note: The minimum design HMA mixture temperature will be 73°F.

HMA MIXTURE TEMPERATURE
(Mechanistic Design: Flexible Pavement)

Figure 54-9.A

Step 4: Determine Design E_{HMA} from Figure 54-5.D and round to nearest 10. See Figure 54-9.B.

Design E_{HMA} = 610 (i.e., 607 rounded to 610)

Step 5: Determine the Design HMA strain using the $TF_{F(M)}$ and Figure 54-5.E. See Figure 54-9.C.

Design HMA strain = 84

Step 6: Using the Design E_{HMA} and the Design HMA strain, determine the flexible thickness from Figure 54-5.F for a poor subgrade and round up to the nearest 0.25 in. See Figure 54-9.D.

Thickness = 10.75 in. (i.e., 10.74 in. rounded up to 10.75 in.)

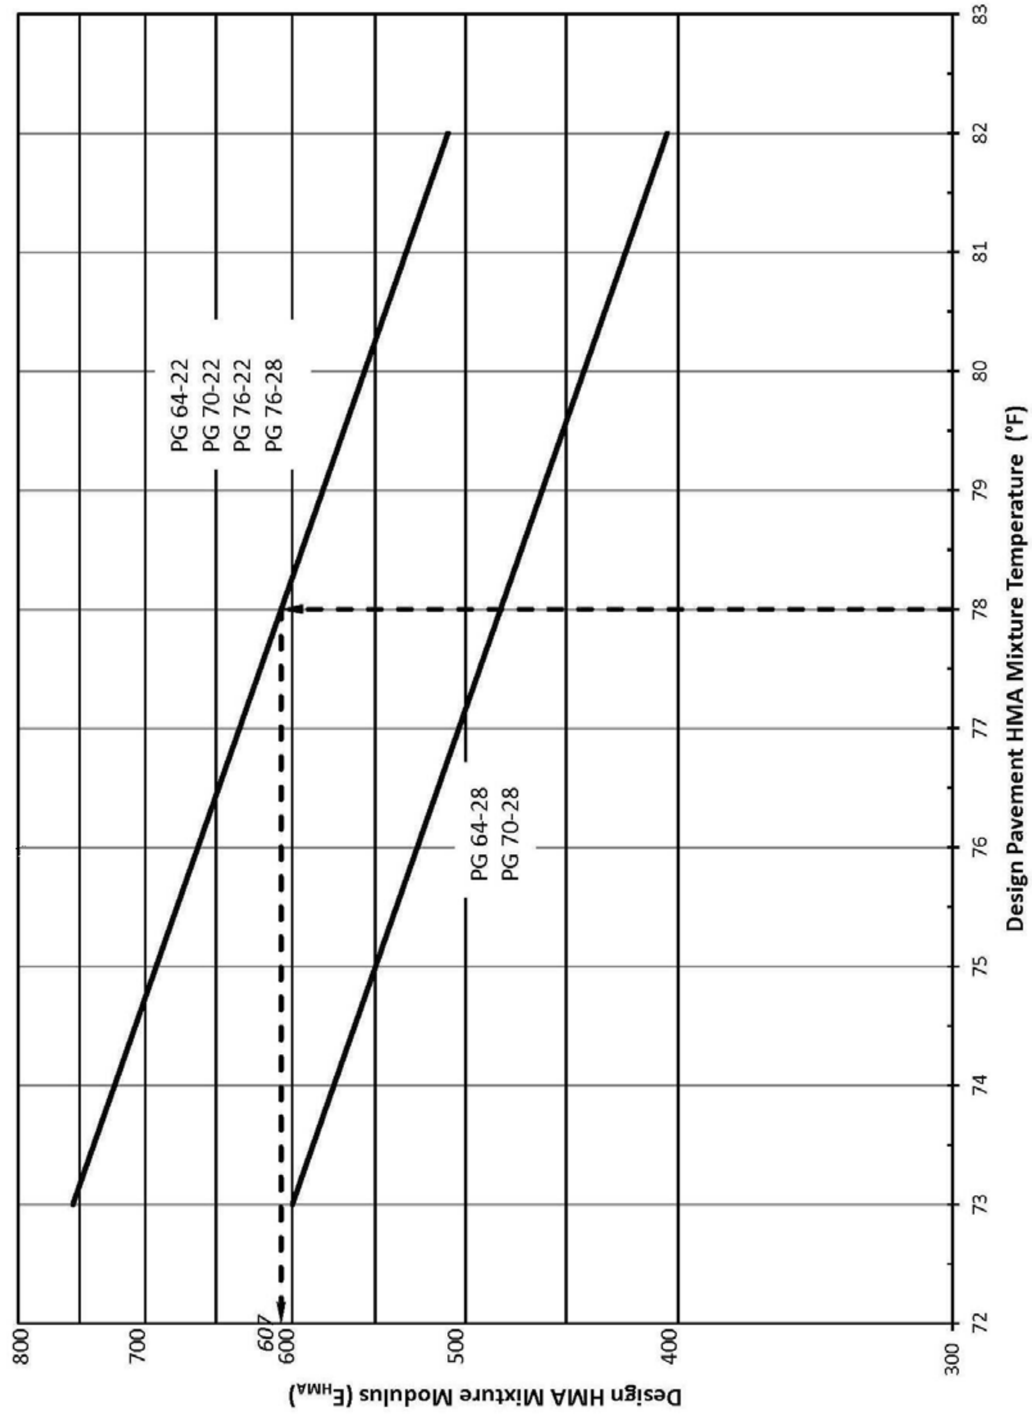
Step 7: Determine the limiting strain criterion (LSC) design thickness from Figure 54-5.I and round up to the nearest 0.25 in. See Figure 54-9.E.

LSC Thickness = 16.00 in. (i.e., 15.78 in. rounded up to 16.00 in.) is greater than standard design thickness – use HMA thickness of 10.75 in.

Step 8: Using the $TF_{R(M)}$ and Figure 54-4.E for a poor subgrade, determine the rigid thickness. Round up to the nearest 0.25 in. See Figure 54-9.F.

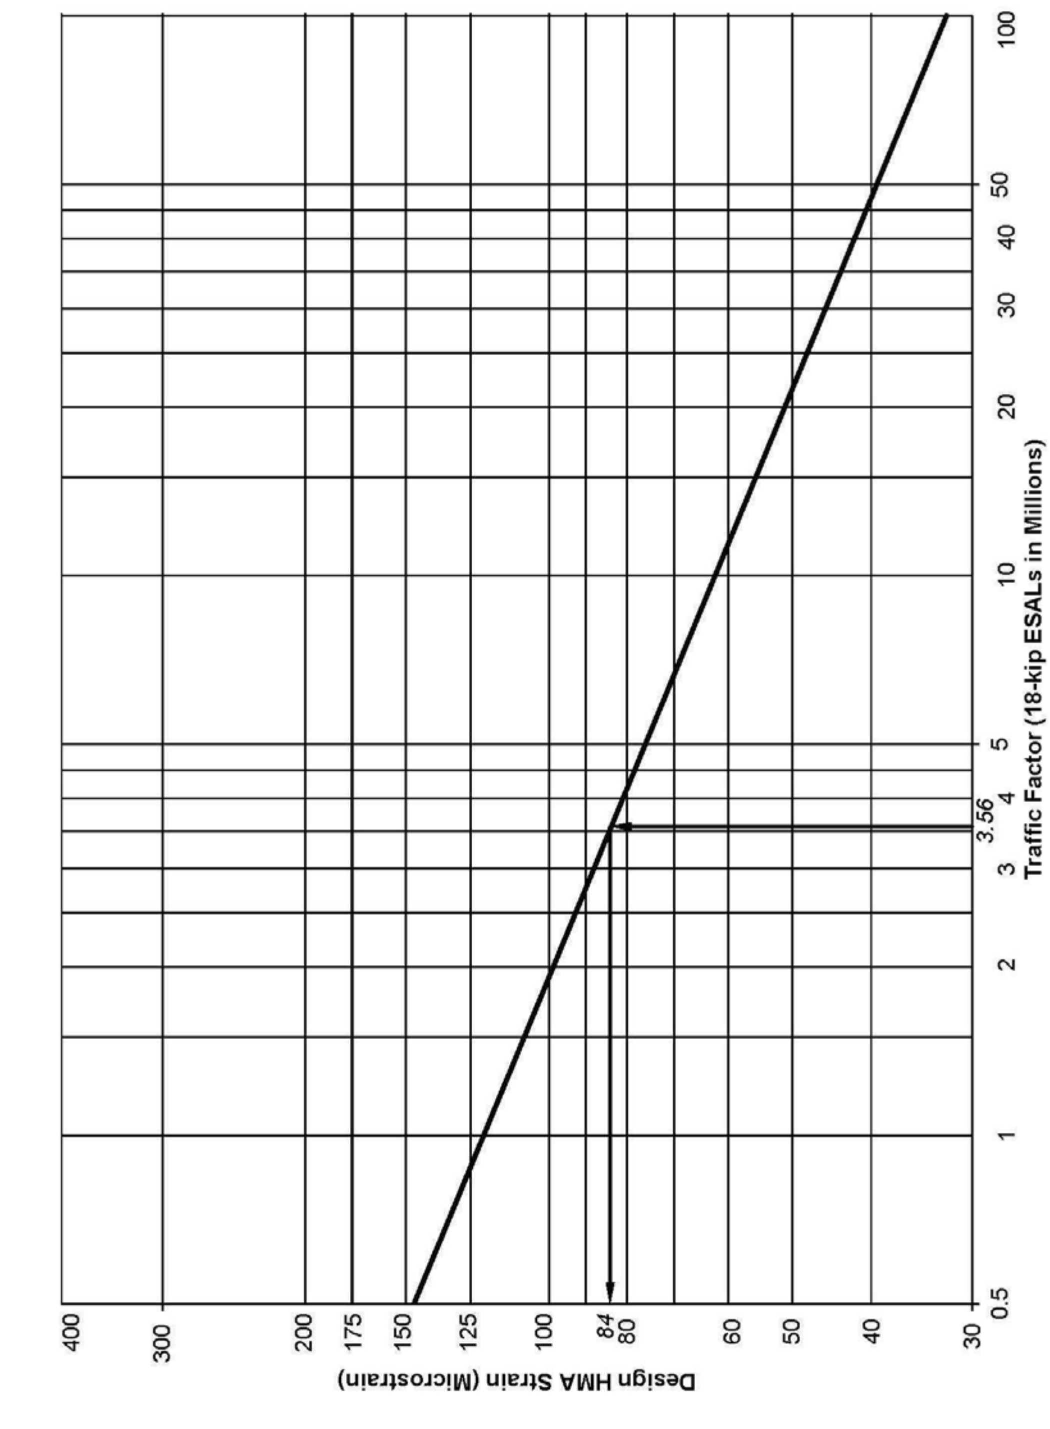
Thickness = 9.00 in. for tied shoulder (i.e., 8.87 in. rounded up to 9.00 in.)

Results: For the design thickness, use a 10.75 in. full-depth HMA pavement or a 9.00 in. JPCP with tied PCC shoulders. A 45-year life-cycle cost analysis must be performed to determine the pavement type.



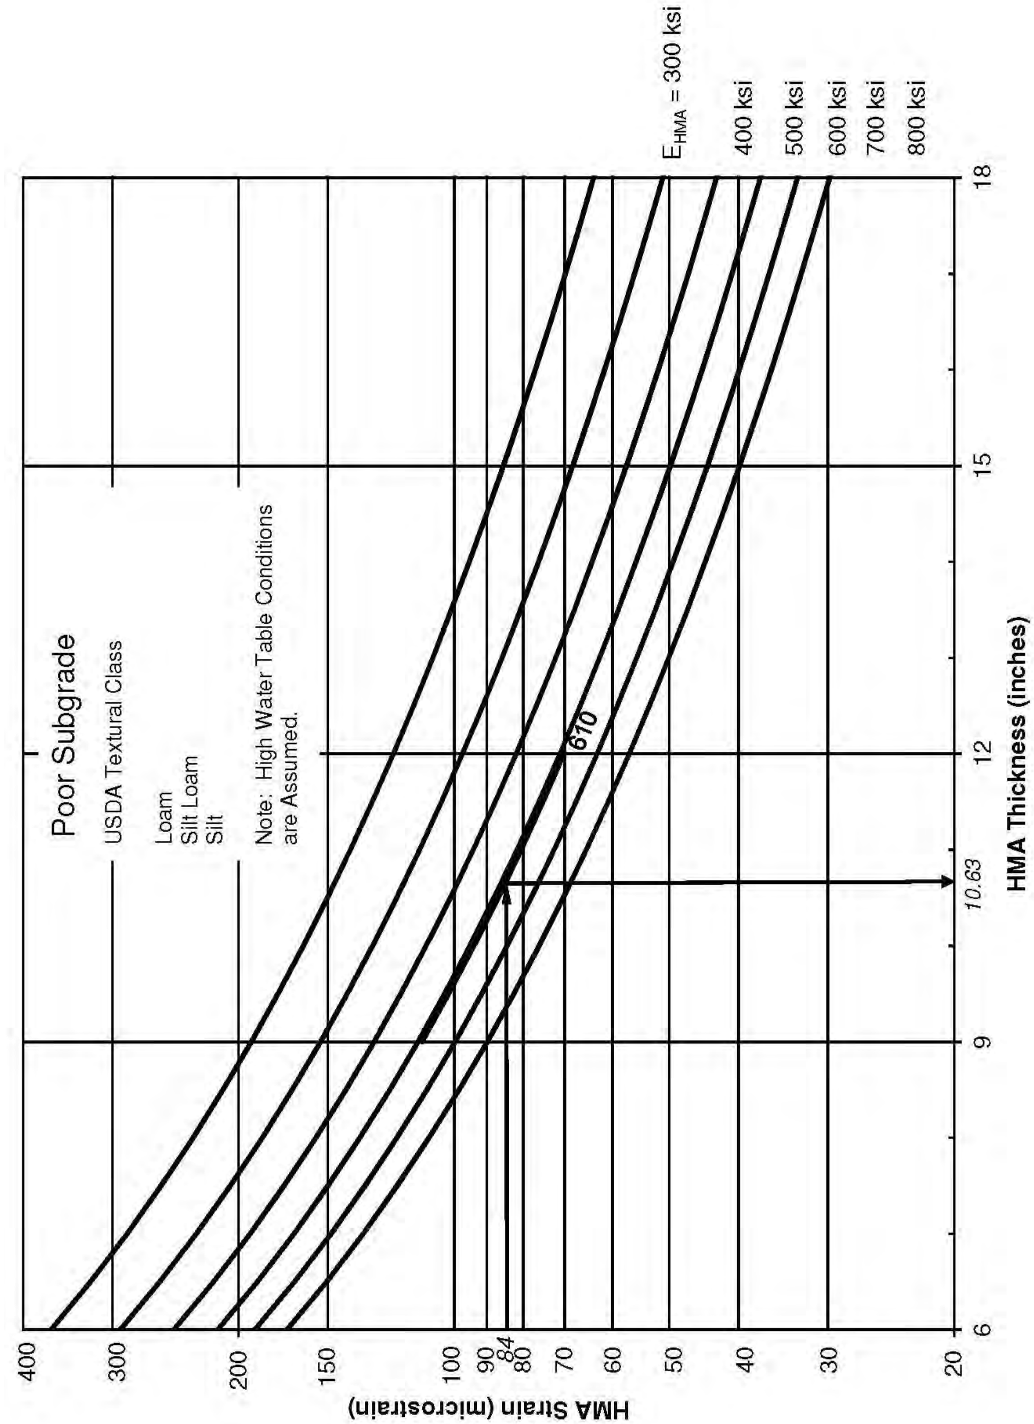
HMA MIXTURE MODULUS (E_{HMA})
(Mechanistic Design: Flexible Pavement)

Figure 54-9.B



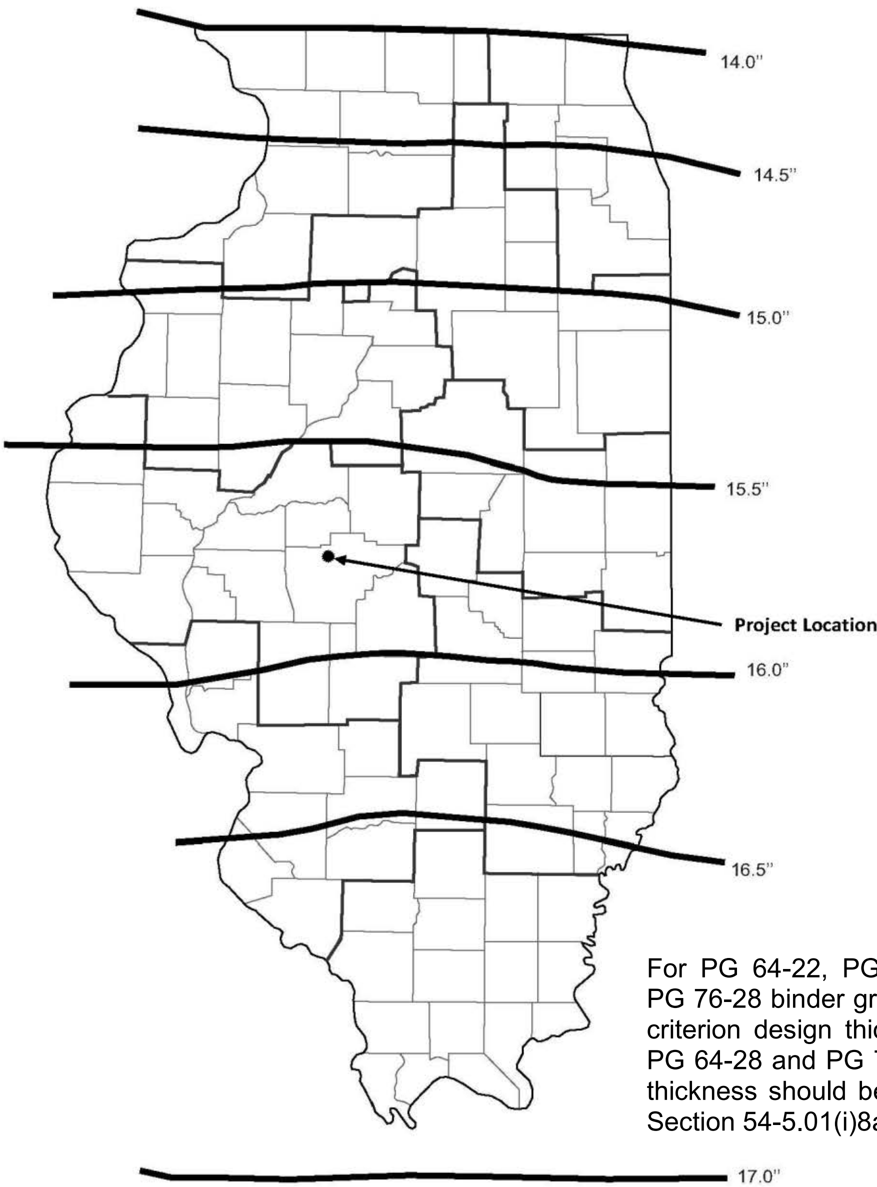
DESIGN HMA STRAIN
(Mechanistic Design: Flexible Pavement)

Figure 54-9.C



HMA THICKNESS DESIGN CHART
(Mechanistic Design: Flexible Pavement: SSR = Poor)

Figure 54-9.D

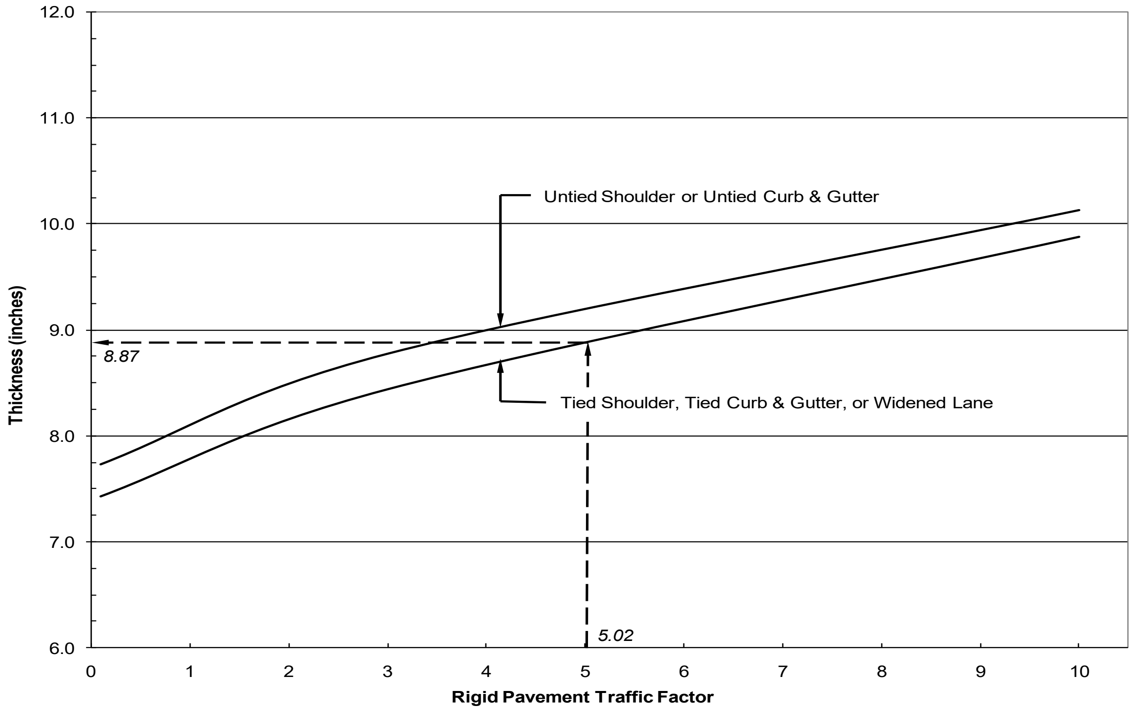


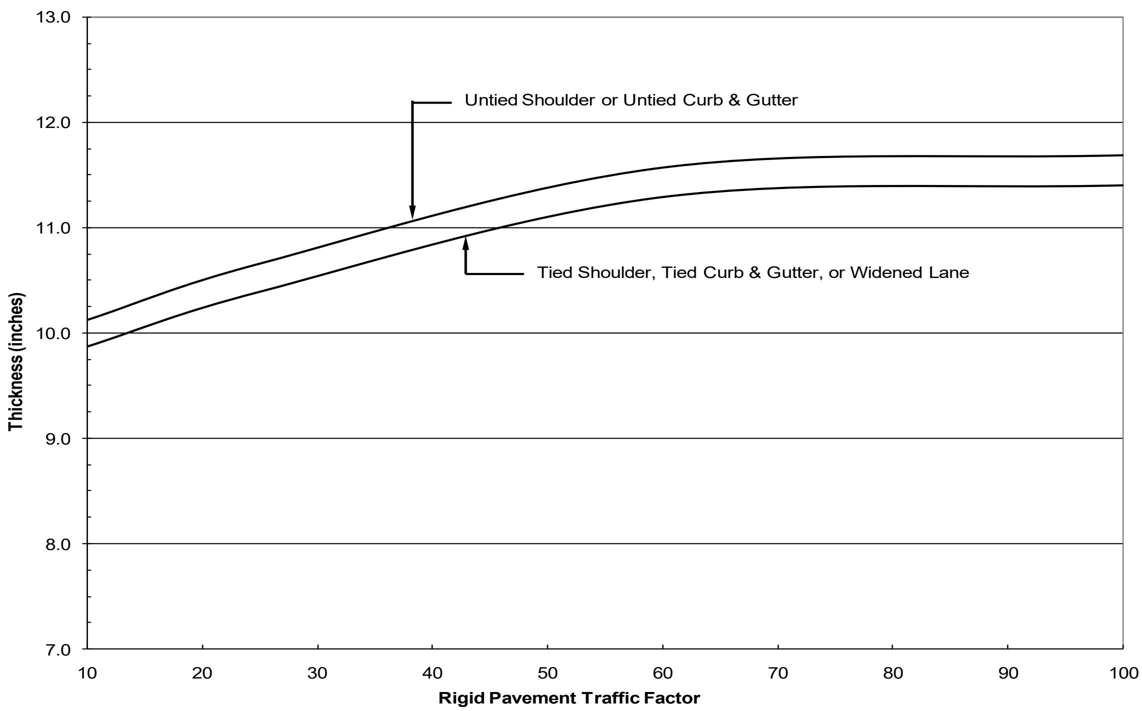
For PG 64-22, PG 70-22, PG 76-22, and PG 76-28 binder grades, read limiting strain criterion design thickness off of map. For PG 64-28 and PG 70-28 binder grades, the thickness should be corrected according to Section 54-5.01(i)8a.

Note: Thickness values based upon Mean Monthly Pavement Temperature at 4 in. depth correlated to July Mean Monthly Air Temperature, axle load of 20,000 lb, strain of 70 με and E_{Ri} of 2 ksi.

MAXIMUM PAVEMENT THICKNESS
(Limiting Strain Criterion Design: Flexible Pavement)

Figure 54-9.E





Note: Use of untied shoulder design requires Bureau of Research approval.

RIGID PAVEMENT DESIGN CHART
(Mechanistic Design: SSR = Poor)

Figure 54-9.F

Example 54-9.2

Given: Existing 2-lane rural State highway in central Sangamon County being widened to 4 lanes – 12 ft widening each side (with resurfacing)
ADT (Design Year Traffic) PV = 17,225 SU = 360 MU = 360
Subgrade Support Rating = Poor IBR = 4
Asphalt Binder Type = PG 64-22

Because the design requires widening with resurfacing, the solution will involve preparing a mechanistic flexible design and a composite design. See Figure 54-1.A.

Solution:

Step 1: The mechanistic flexible design will be the same as in Example 54-9.1.

Step 2: Determine the composite design. A mimum traffic factor does not apply so the actual traffic factor will be used.

$TR_{R(A)}$ = 2.74 (from Example 54-9.1)

From Figure 54-6.A, determine the composite pavement structural number (SN_C).

SN_C = 3.55 (See Figure 54-9.G)

Using Equation 54-6.3, determine the layer thickness:

$$SN_C = 0.40\ D_S + 0.33\ D_B$$

$$D_B = \frac{3.55 - (0.4 \bullet 2.5)}{0.33}$$

D_B = 7.72 in. From Figure 54-6.D, minimum thickness is 8 in.

Results:

Mechanistic Flexible:	10.75 in. Full-Depth Flexible using PG64-22 12 in. Improved Subgrade
Composite Design:	2.5 in. HMA Surface Course 8 in. PCC Base Course

A first-cost economic analysis must be performed to determine the pavement type.

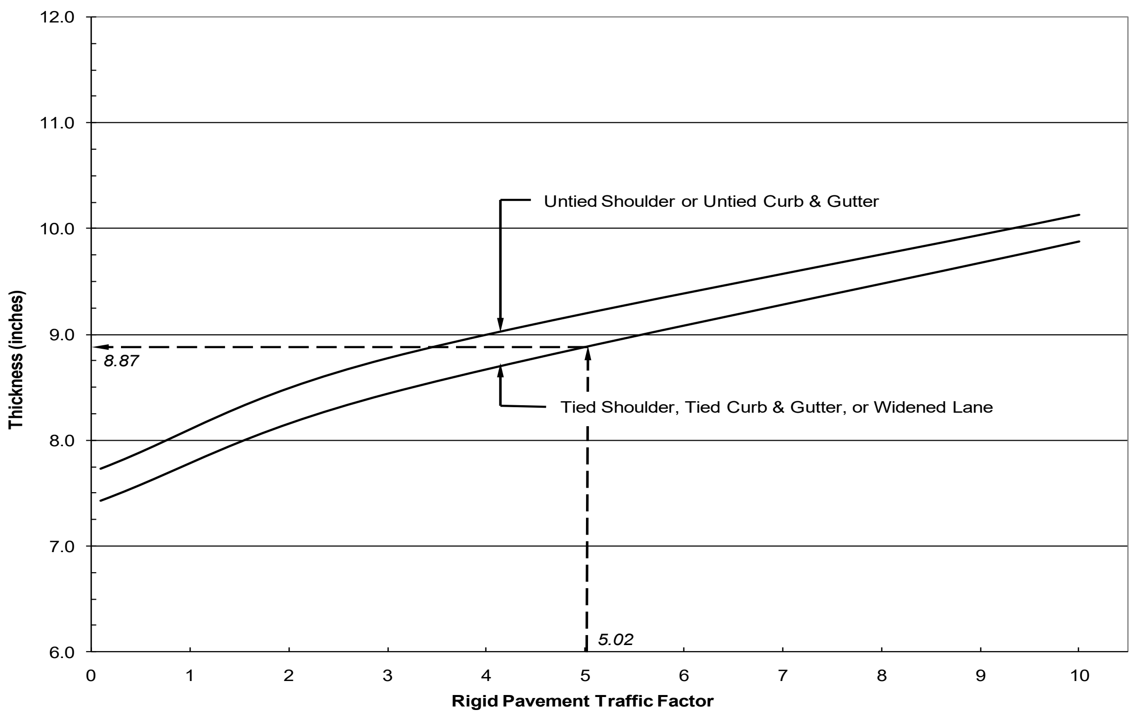
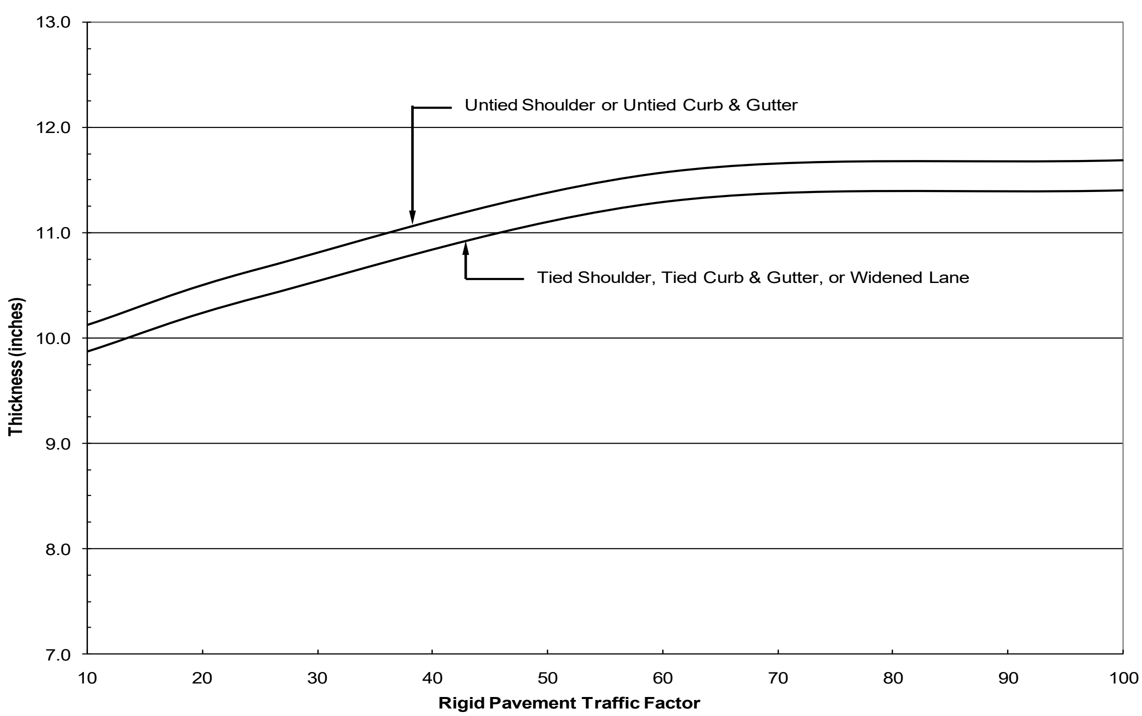
COMPOSITE PAVEMENT DESIGN NOMOGRAPH
(Class I Facilities)

Figure 54-9.G





Note: Use of untied shoulder design requires Bureau of Research approval.

RIGID PAVEMENT DESIGN CHART
(Mechanistic Design: SSR = Poor)

Figure 54-9.F

<u>Example 54-9.2</u>

<u>Given</u>: Existing 2-lane rural State highway in central Sangamon County being widened to 4 lanes – 12 ft widening each side (with resurfacing)
ADT (Design Year Traffic) PV = 17,225 SU = 360 MU = 360
Subgrade Support Rating = Poor IBR = 4
Asphalt Binder Type = PG 64-22

Because the design requires widening with resurfacing, the solution will involve preparing a mechanistic flexible design and a composite design. See Figure 54-1.A.

<u>Solution</u>:

<u>Step 1</u>: The mechanistic flexible design will be the same as in Example 54-9.1.

<u>Step 2</u>: Determine the composite design. A mimum traffic factor does not apply so the actual traffic factor will be used.

$TR_{R(A)}$ = 2.74 (from Example 54-9.1)

From Figure 54-6.A, determine the composite pavement structural number (SN_C).

SN_C = 3.55 (See Figure 54-9.G)

Using Equation 54-6.3, determine the layer thickness:

$$SN_C = 0.40\ D_S + 0.33\ D_B$$

$$D_B = \frac{3.55 - (0.4 \bullet 2.5)}{0.33}$$

D_B = 7.72 in. From Figure 54-6.D, minimum thickness is 8 in.

Results:

Mechanistic Flexible:	10.75 in. Full-Depth Flexible using PG64-22 12 in. Improved Subgrade
Composite Design:	2.5 in. HMA Surface Course 8 in. PCC Base Course

A first-cost economic analysis must be performed to determine the pavement type.

Chapter Fifty-five

WORK ZONE TRAFFIC CONTROL

BUREAU OF DESIGN AND ENVIRONMENT MANUAL

Chapter Fifty-five
WORK ZONE TRAFFIC CONTROL

Table of Contents

Table of Contents
(Continued)

Chapter Fifty-five
WORK ZONE TRAFFIC CONTROL

Highway construction often disrupts the normal flow of traffic and may pose safety hazards to motorists, bicyclists, pedestrians, and workers. Therefore, to mitigate potential operational and safety problems, IDOT requires that a Transportation Management Plan (TMP) be prepared for highway construction projects to consider work zone impacts upon the traveling public.

A Traffic Control Plan (TCP) is a plan to safely guide traffic through a construction project through the use of traffic control devices and project coordination. The TCP focuses on the mobility and protection of traffic within the construction zone. The TCP, part of the TMP, may range in scope from very detailed design plans and special provisions; to the incorporation of Special Provisions, Recurring Special Provisions, and/or Contract Special Provisions; or to merely referencing the *Highway Standards*, *Standard Specifications,* and detailing their use and location.

Chapter 55 provides the necessary information to develop a well-conceived TCP that minimizes the adverse effects of traffic disruption and hazards. This chapter draws heavily on the reader's knowledge of the work zone criteria in Part 6 of the *Illinois Manual on Uniform Traffic Control Devices* (ILMUTCD), *Highway Standards,* and *Standard Specifications*. Work zone traffic control practices and motorist driving patterns are constantly changing and these publications are kept as current as practical.

The key for effective traffic control is consistency. By providing traffic control consistently throughout the State, drivers will recognize the significance of the devices used and react accordingly. When problems or unique situations arise in the development of the traffic control plan, the designer should consult with the District Traffic Control Supervisor. This position is the district contact responsible for resolving unique work zone traffic control issues. Information also applicable to the maintenance and protection of traffic through work zones is included in the following chapters:

- Chapter 13 discusses IDOT's Work Zone Safety and Mobility Rule and provides guidelines for selecting the appropriate traffic control strategy and preparation of a Transportation Management Plan.
- Chapters 31, 32, 33, and 34 provide guidance on the geometric design elements that are also applicable to work zones.
- Chapter 38 provides guidelines on roadside safety.
- Chapter 57 provides guidance on permanent pavement markings, highway signing, and traffic signals.
- Chapter 58 provides guidance on highway lighting.

- Chapter 63 provides guidelines on the preparation of construction plans, including construction and traffic control sheets.

- Chapter 66 provides information and guidelines on the preparation of *Standard Specifications*, Special Provisions, Recurring Special Provisions, Contract Special Provisions, and *Highway Standards*.

55-1 PLAN DEVELOPMENT

55-1.01 Transportation Management Plan

Each Phase I report should contain a TMP that provides the preferred overall strategy for accommodating traffic during construction. The TMP should provide an initial, proposed strategy for addressing traffic control through a work zone (e.g., detour, runaround, crossovers). For many projects, the TMP will not only address the alternatives confined to the project site, but may also address the impact traffic will have on the entire corridor. The earlier in the design process potential traffic control problems are identified, the earlier solutions can be developed and incorporated into the overall project.

Chapter 13 provides guidance on the issues that should be considered during the preparation of the TMP. The goals that directly impact design and planning are:

1. Safety. When analyzing work zone safety measures, consider the following:

    - zero worker fatalities for traffic-related work zone crashes,
    - reduce the number of motorist fatalities in traffic-related work zone crashes by 10% each year with the eventual goal of eliminating all fatalities,
    - eliminate crashes and resulting fatalities and serious injuries caused by queuing, and
    - reduce the number of work zone crashes by 5% from each prior year.

2. Mobility. Consider the following:

    - delays caused by work zones should not exceed more than 5 minutes per mile (3 minutes per km) of project length with a maximum of 30 minutes above the normal recurring traffic delay, and
    - queues caused by work zones should be no more than 1.5 miles (2.5 km) beyond pre-existing queues.

Even if the TMP has been fully developed in the Phase I report and has satisfied the goals, the designer should check to ensure the TMP is still applicable. This is especially true for projects that may have been several years in the development process. If the TMP needs to be modified, present the project at a coordination meeting. If the TMP is acceptable and satisfies the delay and queuing goals, then the development of the final plans for Phase II can be prepared. If the goals are not met, then submit a “Request for Exception to Compliance” to the Bureau of Safety Programs and Engineering for further approval; see Chapter 13.

If the project is on a significant route and did not require a Phase I report, or if the TMP was not completely developed in Phase I, then a TMP should be developed in accordance with Chapter 13 to address safety and mobility goals.

If the project did not require a project report and the project is not on a significant route, it will be the designer’s responsibility to prepare a TMP in Phase II consistent with the requirements presented in this chapter and Chapter 13.

55-1.02 Transportation Management Plan Content

The TMP should include the preferred traffic control method for accommodating traffic during construction and the expected work zone impacts. Depending on whether a project is on a significant route or not, a TMP can have the following three components:

1. Traffic Control Plan (TCP). A TCP is a plan to safely guide traffic through a construction project through the use of traffic control devices and project coordination. The TCP focuses on the mobility and protection of traffic within the work zone.

2. Transportation Operations Plan (TOP). A TOP is a plan that consists of strategies that mitigate work zone impacts through the use of improved transportation operations and management of the transportation system.

3. Public Information Plan (PIP). A PIP is a plan that consists of strategies to inform those affected road users including the surrounding community of the expected impact of a project, of changing conditions, and available travel options.

A TCP is required on all IDOT highway projects. A TOP and PIP are required on projects designated as significant routes, but should be considered on all projects. See Chapter 13 for guidance on significant routes.

Figure 55-1.A illustrates the format and required opening paragraphs for the TCP that are placed in the special provisions. Include these paragraphs, or similar paragraphs, on every project. See Chapter 66-1.03 for additional guidance on preparation of the special provisions.

Traffic Control Plan
Effective 1985 Revised 1/2/97
9-107T1-97

Traffic control shall be according to the applicable sections of the Standard Specifications for Road and Bridge Construction, the guidelines contained in the Illinois Manual on Uniform Traffic Control Devices for Streets and Highways, the Supplemental Specifications, these Special Provisions, and any special details and highway standards contained herein and in the plans.

Special attention is called to Articles 107.09 and 107.14 of the Standard Specifications for Road and Bridge Construction and the following traffic control related (1) Highway Standards; (2) Supplemental Specifications and Recurring Special Provisions; and (3) Other Special Provisions which are included in this contract:

1. Standards: (*List applicable traffic control standards)*

2. Supplemental Specifications and Recurring Special Provisions:
   (List titles of applicable Recurring Specs which relate to traffic control)

3. Special Provisions: *(List titles of traffic control related special provisions)*

SPECIAL PROVISIONS FOR CONSTRUCTION PROJECTS
(Sample Format)

Figure 55-1.A

55-2 DESIGN CONSIDERATIONS

The objective of the traffic control plan (TCP) is to provide an implementation strategy that will minimize the adverse effects of traffic disruption on motorists, pedestrians, and bicyclists and provide a safe work area for workers. The following sections present design criteria that apply to temporary crossovers on divided highways, existing roadways through work zones, and detours specifically designed for construction projects (e.g., crossovers, runarounds). These criteria do not apply to detours over existing routes, which are presented in Section 55-3.04.

Consider the following engineering elements when developing the TCP:

1. Geometrics. The TCP should provide adequate facilities for drivers to maneuver safely through the construction area, day or night. The design should avoid frequent and abrupt changes in roadway geometrics (e.g., lane narrowing, lane drops, transitions that require rapid maneuvers). Section 55-2 presents the geometric design criteria applicable to work zones.

2. Roadside Safety. Motorist, pedestrian, bicyclist, and worker safety is a high priority element of any TCP and should be an integral part of each phase of the construction project (i.e., planning, design, and construction). Section 55-4 addresses the roadside safety issues typically encountered during construction.

3. Highway Capacity. The TCP should, where practical, provide the capacity necessary to maintain an acceptable level-of-service for the traveling public. This may require converting shoulders to travel lanes, eliminating on-street parking, constructing temporary lanes, limiting lane closures to hours when the capacity can be maintained, or expanding public transportation. Section 13-3.02(b) provides further information on highway capacity issues.

4. Special Traffic Control Devices. Special traffic control devices not included in the *Highway Standards* are included in the TCP to safely direct vehicles through or around the work zone. Coordinate the selection and location of these special traffic control devices with the Bureau of Safety Programs and Engineering and the Bureau of Operations. Section 55-5 provides guidance on the selection and location of traffic control devices in work zones.

5. Overhead Lighting. The designer should maintain existing overhead lighting and, on a case-by-case basis, consider the need for supplemental roadway lighting at potentially hazardous sites within the work area. Section 55-5.05 discusses the use of work zone lighting.

55-2.01 Constructability

55-2.01(a) Worksite

Evaluate the construction sequence of the proposed TCP to identify any safety, operational, or logistical problems and to facilitate the timely completion of the project. Special attention must be focused on provisions for contractor accessibility to the work site, the delivery and storing of materials, and worker parking. Consider a worksite delivery plan for complex projects (e.g., turnouts in temporary longitudinal traffic barrier for delivery trucks to accelerate and decelerate safely into and out of the traffic flow).

Some of the elements that should be evaluated include:

- the maneuverability of traffic through the horizontal and vertical alignment during all construction phases;
- the separation of opposing traffic, workers, equipment, and other hazards;
- the work areas that will be used for equipment maneuverability and construction inspection;
- oversize and overweight load requirements for construction; and
- the access points to work and material storage sites.

55-2.01(b) Construction Design

Several construction options are available that may reduce construction time or modify the time of construction. These options allow flexibility in planning the work to allow the TMP to better meet safety and mobility goals. Consider the following:

- the use of special materials (e.g., quick-curing concrete that can support vehicular loads within hours after placement);
- the use of special designs (e.g., using precast box culverts instead of cast-in-place box culverts or bridges);
- special scheduling requirements that will reduce traffic disruptions (e.g., working at night and during off-peak hours);
- project phasing that will allow traffic to use the facility prior to project completion; and
- contractor cost incentives/disincentives for early/late completion of construction for facilities with a high ADT; see Section 66-2.04.

55-2.01(c) Economic/Business

Review the TCP to ensure that it does not restrict access to businesses during peak periods. Consider access for large trucks to businesses for deliveries or from manufacturers that generate high truck traffic. Review the discussion for a Public Information Plan in Section 13.4.

55-2.01(d) Pedestrians/Bicyclists

The safe accommodation of pedestrians/bicyclists through the work zone should be addressed early in project development. Whenever possible, work should be done in a manner that does not disrupt existing pedestrian/bicycle facilities; however when such disruption is necessary, the MUTCD requires alternate routes to be provided. Further, the alternate routes shall be detectable and shall include accessibility features consistent with the features present in the existing facility.

Consider the following guidelines when addressing pedestrian/bicycle accommodation through work zones:

1. Separation. Physically separate pedestrians/bicyclists and vehicles where practical.

2. Construction. Plan the construction so the disruption of pedestrian/bicycle facilities will occur in the shortest practical time or during non-peak times.

3. Detours. Pedestrian detours should be avoided since pedestrians rarely observe them, and the cost of providing an accessible detour might outweigh the cost of maintaining the existing access route. When detours are used, they should be designed to minimize adverse travel and the number of pedestrian street crossings.

4. Temporary Sidewalks. Where temporary sidewalks are provided, consider the following:

    a. Width. The width of temporary sidewalks should be equal to the existing sidewalk; however the minimum continuous clear width will be 4 ft (1.2 m). Wider sidewalks should be considered where there are high pedestrian volumes. For temporary sidewalks with clear widths less than 5 ft (1.5 m), a 5 ft x 5 ft (1.5 m x 1.5 m) passing space should be provided at least every 200 feet (60 m).

    b. Surface. The surface of temporary sidewalks must be firm, stable and slip resistant. If the temporary sidewalk is to remain-in-place for more than four weeks, provide a 2 in (50 mm) Portland cement or asphalt surface. The material selection should be at the contractor’s option. For temporary sidewalks to remain-in-place less than four weeks, a 3 in (75 mm) compacted aggregate surface may be provided.

55-2.02 Geometrics and Work Zone Design Speed

The TCP should provide adequate facilities for drivers to maneuver safely through the construction area, day or night. The design should avoid frequent and abrupt changes in roadway geometry (e.g., lane narrowing, lane drops, transitions that require rapid maneuvers). The work zone design speed applies to the design of the geometric elements through the work zone. It does not apply to the regulatory speed limits that are used for posting the speed limit through the work zone and construction site.

When selecting the work zone design speed, consider the following factors:

1. Posted Speed Limit. The work zone design speed should reflect the following:

    - the existing posted speed limit of the facility before construction begins,
    - the anticipated posted speed limit through the work zone, and
    - the posted speed limit of the facility immediately prior to the work zone.

    The work zone design speed normally should not be more than 10 mph (15 km/h) below the posted speed limit prior to construction. Speed reductions greater than 10 mph (15 km/h) may be warranted by the complexity of the work zone; see the Bureau of Operations "Policy on Establishing and Posting Speed Limits on the State Highway System."

2. Urban/Rural. Work zone design speeds in rural areas are generally higher than those in urban areas. This is consistent with the typically fewer constraints in rural areas (e.g., less development).

3. Terrain. Lower work zone design speeds may be applicable for rolling terrains. This is consistent with the typically higher construction costs as the terrain becomes more rugged.

4. Traffic Volumes. For some facilities, the work zone design speed may vary according to the traffic volumes (i.e., use higher design speeds as traffic volumes increase).

See the Bureau of Operations "Policy on Establishing and Posting Speed Limits on the State Highway System" for further guidance on regulatory and work zone speed limits.

55-2.03 Lane/Shoulder Widths

In general, avoid reductions in the roadway cross section width through the construction and work zones. However, this is often not practical given the constraints of the project. When determining lane and shoulder widths in work zones, consider the following guidelines:

1. Divided Highways. For freeways and other divided highways, desirably use 12 ft (3.6 m) wide lanes; but as a minimum, maintain an 11 ft (3.3 m) lane width with 2 ft (600 mm) wide right and left shoulders. Under restrictive urban conditions, a 10 ft (3.0 m) lane width may be considered if an alternative detour route is provided for wide vehicles.

2. Undivided Highways. For undivided highways, maintain a minimum 10 ft (3.0 m) lane width and 1-ft (300-mm) wide shoulders.

3. Single-Lane Facilities. For single-lane roadways that are less than 14 ft (4.2 m) wide, evaluate the need for an alternative wide-load detour route. Ensure the wide-load detour is adequately marked in advance of the work zone.

4. Runarounds. Figure 55-3.C provides the minimum roadway widths for runarounds.

5. Temporary Crossovers. In addition to the above minimum criteria for lane widths, Section 55-3.02 presents the minimum lane widths for the crossover portion.

6. Options. In most cases, it will be more desirable to reduce the shoulder widths versus reducing the traveled way width.

55-2.04 Drop-Off Exposure

A drop-off is defined as an elevation difference between lanes or the edge of the traveled lane and shoulder as traversed by the wheel of a motor vehicle. Changes in elevation along highways present exposure of risk for highway users, especially vulnerable users (e.g., motorcyclists). Exposure can be limited by reducing speed, increasing lateral distance to the drop-off, providing a transition, or installing a barrier.

Refer to the most current Bureau of Safety Programs and Engineering's Policy Memorandum BSE-04 for guidance on mitigating longitudinal drop-offs.

55-2.05 Transition Taper Rates

Lane closures, lane width reductions, and lane shifts require the use of transition tapers to safely maneuver traffic around the encroaching restriction. These taper rates are shown in Figure 55-2.A., Figure 55-2.B and Figure 55-2.C and illustrate the minimum taper lengths for various taper applications in work zones (e.g., lane closures, lane shifts). The *Highway Standards* also present the minimum taper lengths for various taper applications in construction zones (e.g., lane closures, lane shifts). Use the design speed when selecting the appropriate taper rate.

55-2.06 Sight Distance

When considering sight distance in work zones, review the following:

1. Approaches. For the approach to the first physical indication of the work zone, the sight distance available to the motorist should be desirably based on the decision sight distance criteria provided in Section 31-3 and, at a minimum, on the stopping sight distance criteria provided in Section 31-3.

2. Construction Site. Through the construction site itself, ensure that at least the minimum stopping sight distance is available to the driver at all times.

3. Design Features. The location of many design features are often dictated by construction operations. Locate lane closures and transitions where the approaching driver has decision sight distance available to the lane closure.

4. Horizontal Curves. For horizontal curves in the work zone, check the horizontal clearance (i.e., the middle ordinate) of the horizontal curve using its radius and the minimum stopping sight distance for the work zone design speed; see Section 32-4.

Design Speed	**Taper Rate**
50 mph (80 km/h) or less	50:1
55 mph (90 km/h)	55:1
60 mph (100 km/h)	60:1
65 mph (110 km/h)	65:1

Note: L = W x Taper Rate,

where: L = minimum taper length, ft (m)
W = width, ft (m)

TAPER RATES FOR LANE REDUCTIONS/CLOSURES

Figure 55-2.A

Type of Taper	**Taper Length**
Upstream Tapers	
Merging Taper	L Minimum
Shifting Taper*	0.5 L Minimum
Shoulder Taper	0.33 L Minimum
Two-way Traffic Taper	100 feet (30 m) Maximum
Downstream Tapers (*Optional*)	100 feet (30 m) per lane

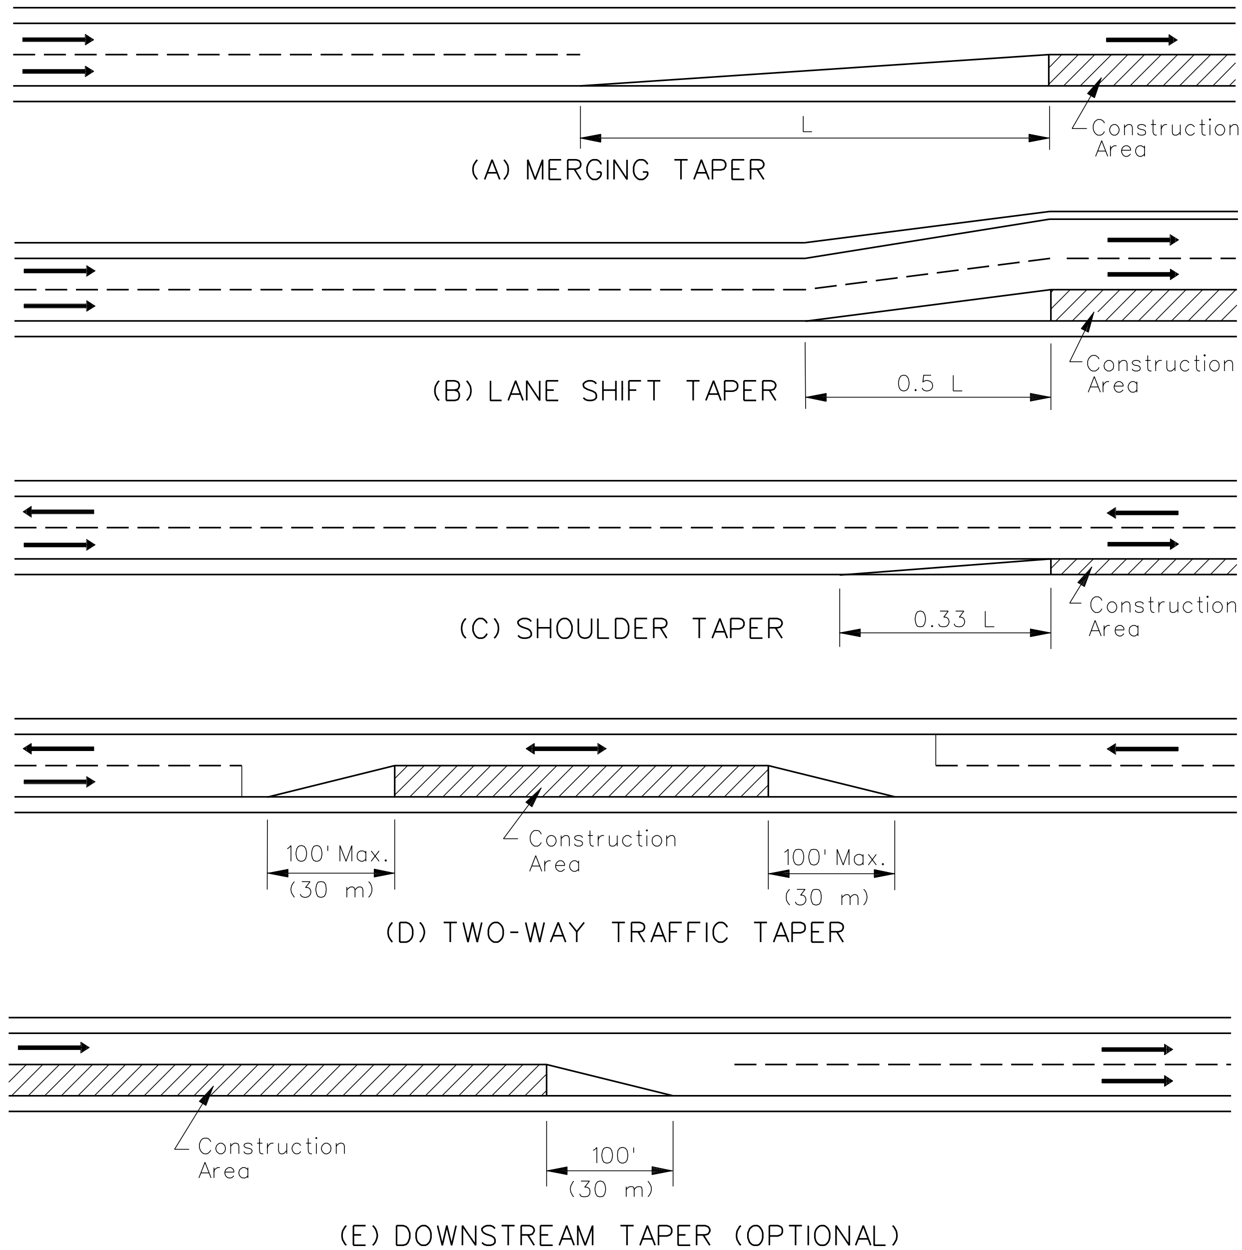
**May be used for determining buffer zone length.*

Notes:

1. *Length "L" is determined from Figure 55-2.C.*
2. *Figure 55-2.E illustrates the various taper types.*

TAPER LENGTH CRITERIA FOR CONSTRUCTION ZONES

Figure 55-2.B



Note: Length "L" is determined from Figure 55-2.C.

TAPER LENGTH CRITERIA FOR CONSTRUCTION ZONES
(Application)

Figure 55-2.C

55-2.07 Horizontal Curvature

Design the horizontal curvature using the selected design speed for the work zone (Section 55-2.02) and AASHTO Method 2 for distributing superelevation and side friction to determine the radius and superelevation rate of the horizontal curve. In this Method, superelevation is introduced only after the maximum allowable side friction has been reached. When compared to AASHTO Method 5, this approach typically results in no superelevation on flatter curves (i.e., maintaining the normal crown through the curve) and reduced rates of superelevation on the majority of other curves. Figure 55-2.F provides the minimum radii for retention of the normal crown section for horizontal curves through work zones based on AASHTO Method 2 and a typical cross slope of ¼ in/ft (2%). Figure 55-2.G allows the designer to determine the proper combination of curve radius and superelevation rate to meet the work zone design speed where the normal section cannot be retained. For other horizontal curvature elements (e.g., superelevation transition lengths), the criteria presented in Chapter 32 are applicable to work zones, as practical.

Where it is necessary to use the shoulder as a travel lane in the work zone, the shoulder cross slope may create a problem on horizontal curves; i.e., the shoulder slope may need to be modified for superelevation based on Figure 55-2.G, although the traveled way portion can retain the normal crown section through the curve based on Figure 55-2.F. Consider one or more of the following options to alleviate this problem:

- rebuild the shoulders to provide a cross slope equal to that of the adjacent travel lane;
- install advisory speed plate signs for the horizontal curve based on Figure 55-2.G;
- install rumble strips in advance of the temporary travel lane on the shoulder;
- restrict large vehicles (e.g., trucks, buses) from using the temporary travel lane; and/or
- detour large vehicles to other facilities.

55-2.08 Vertical Curvature

Design sag vertical curves in work zones using the selected work zone design speed and the comfort criteria presented in Section 33-4. The comfort criteria are based on the comfort effect of change in vertical direction through a sag vertical curve due to the combined gravitational and centrifugal forces. In general, riding through a sag vertical curve is considered comfortable when the centripetal acceleration does not exceed 1 ft/s^2 (0.3 m/s^2).

55-2.09 Cut and Fill Slopes

Where practical, design temporary cut and fill slopes to meet the design criteria presented in Chapter 34. However, for work zones, 1V:3H front slopes may be used where there is sufficient clear zone available at the bottom of the slope; see Section 55-4.03. The use of steeper front slopes may be considered on a case-by-case basis but may require the installation of roadside barriers or vertical panels.

US Customary			
Work Zone Design Speed, V	**f_{max} (Open-Roadway Conditions)**	**Normal Crown Section Minimum Radii, R_{min} (e = -1.5% to -2%)**	**Superelevated Section**
20 mph	0.27	105 ft	See Figure 55-2.G
25 mph	0.23	200 ft	
30 mph	0.20	335 ft	
35 mph	0.18	510 ft	
40 mph	0.16	760 ft	
45 mph	0.15	1040 ft	
50 mph	0.14	1390 ft	
55 mph	0.13	1835 ft	
60 mph	0.12	2400 ft	
65 mph	0.11	3130 ft	
Metric			
Work Zone Design Speed, V	**f_{max} (Open-Roadway Conditions)**	**Normal Crown Section Minimum Radii, R_{min} (e = -1.5% to -2%)**	**Superelevated Section**
30 km/h	0.28	27 m	See Figure 55-2.G
40 km/h	0.23	60 m	
50 km/h	0.19	116 m	
60 km/h	0.17	189 m	
70 km/h	0.15	297 m	
80 km/h	0.14	420 m	
90 km/h	0.13	580 m	
100 km/h	0.12	787 m	
110 km/h	0.11	1059 m	

Notes:

1. *Curve Radii. Radii for both Figures 55-2.F and 55-2.G are calculated from the following equation:*

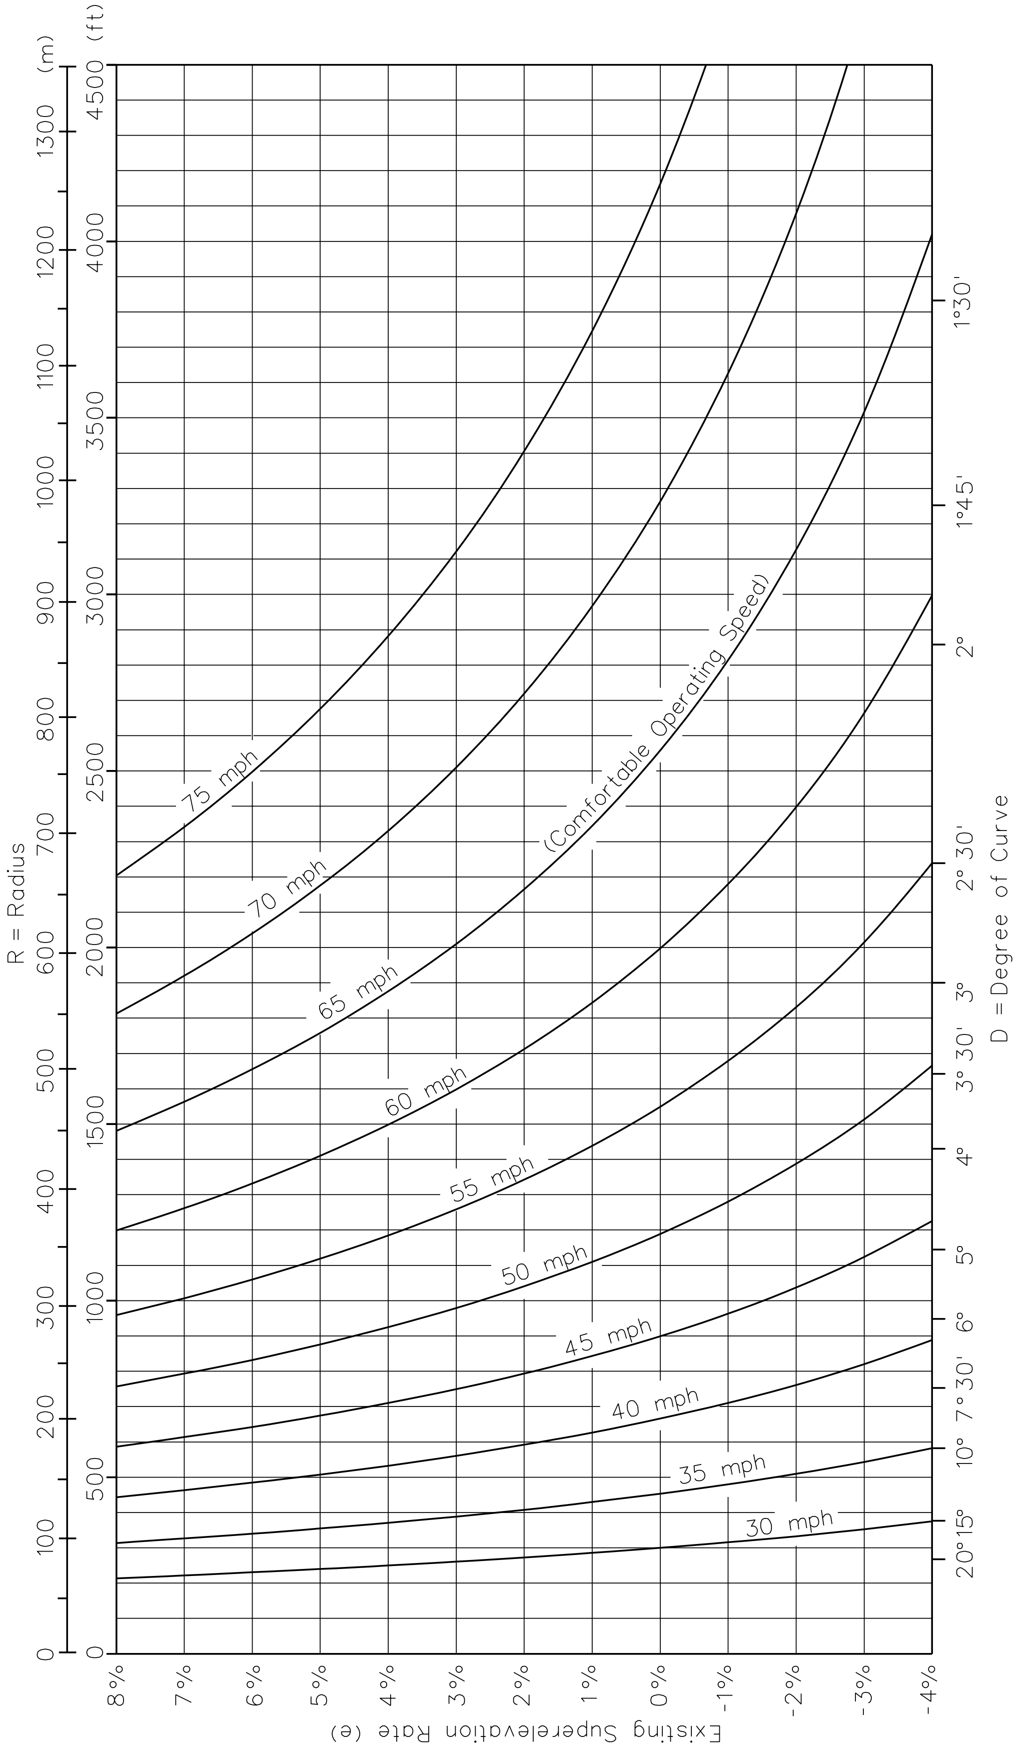
$$R = \frac{V^2}{15\ (e + f)} \quad \text{(US Customary)} \qquad R = \frac{V^2}{127\ (e + f)} \quad \text{(Metric)}$$

Values for design in Figure 55-2.F have been rounded to the nearest 5 ft (1 m) increment.

2. *Normal Crown Section. The data in the above chart is provided based on the normal crown section being maintained throughout the horizontal curve (to the left), a superelevation rate of -2%, and assuming a typical cross slope of ¼ in/ft (2%). Therefore, the R_{min} column with e = -2% presents the minimum radii that can be used when retaining the normal section through the horizontal curve.*

MINIMUM RADII FOR HORIZONTAL CURVES RETAINING NORMAL CROWN SECTION (Work Zones)

Figure 55-2.D



MINIMUM RADII AND SUPERELEVATION RATES FOR HORIZONTAL CURVES
(Work Zones)

Figure 55-2.E

- Although detours rarely involve excavation (i.e., cut), 1V:3H cut slopes are generally acceptable in place of the flatter slopes presented in Chapter 34. The use of slopes steeper than 1V:3H for cut depths less than 10 ft (3.0 m) may be acceptable under restrictive conditions. Soil conditions in cut sections will require an investigation to determine their stability.

The anticipated traffic volumes and the length of time the detour will be in place should be weighed in determining final cut and fill slopes. In all cases, stable embankment material must be used and placed according to the *Standard Specifications*.

55-2.10 Pavement Design

The pavement design objective for crossovers, runarounds, local route detours, etc., is to provide, as practical, maintenance-free pavement for its intended life. Note that the pavement for crossovers and runarounds needs to support the expected truck traffic through the work zone. An indication of the required pavement depth can be obtained by preparing a structural pavement design according to Chapter 54 and by using a minimum design period of three years for a single-season detour or five years for over-the-winter detour. The final pavement thicknesses will be based upon a pavement design analysis and previous district experience with similar detour conditions (e.g., soil types, seasons of detour use, truck volume, initial cost, restoration costs).

Typically, crossovers and runarounds are designed using a hot-mix asphalt surface. In high-volume situations, it may be advisable to use full-depth hot-mix asphalt on the detour. Medium-volume situations may warrant a stabilized granular base or an aggregate base with a hot-mix asphalt surface course. In low-volume situations, an aggregate base with some type of surface treatment (e.g., oil and chip) may be an acceptable design to provide maintenance-free pavement. A minimum thickness of 8 in (200 mm) is recommended for aggregate bases and a minimum 3 in (75 mm) of Superpave or Class B is recommended where a HMA surface course is used. As an alternative, a non-reinforced concrete pavement may be used. If non-reinforced concrete pavement is used, investigate the practicality of using lesser quality, local materials in the concrete. Long-term performance is usually not critical in these situations. If the detour will be used through winter, then a HMA surface is recommended.

55-2.11 Temporary Bridges

Where a temporary bridge is required and complete plans for the temporary bridge are not furnished, specify in the traffic control plans or special provisions the general location, roadway width, distance to be spanned, required load capacity, and any other known pertinent design features for the temporary bridge. This information will allow the contractor to bid and submit plans for the Engineer's approval after an award is made, as specified in the *Standard Specifications*.

In special cases, where the district determines the situation dictates a special design, the district may include in the project plans complete design plans for the temporary bridge. Upon request, the Bureau of Bridges and Structures will prepare these. However, because most contractors are equipped with precast bridge elements and can readily bid and furnish temporary bridges that will meet the Department's criteria, keep the preparation of these special designs by the Department to a minimum.

55-2.12 Crossovers to Remain in Place

A cost savings may be realized if some crossovers on freeway projects are left in place after the project is completed. Because these crossovers are designed to carry Interstate traffic, they are constructed with a high-type pavement that adds to the cost. If crossovers are left in place, this cost may be partially recovered as a cost savings to future construction. Crossovers also leave options open for emergency construction and remain available for future transportation operations plans, including incident management.

Crossovers left in place must be closed with positive separation when not in use, unless the opening is designed to be left open and an exception is obtained from FHWA. Consult the AASHTO *Roadside Design Guide* for information on the design, cost, and maintenance of openings in median barriers for openings in crossovers.

The following are some examples where it may be advisable to leave temporary crossovers in place:

1. Major River Crossings. At these locations, there is usually one preferred location where a crossover can be placed and any future work would require the rebuilding of the same configuration.

2. Locations With Physical Constraints. In some instances, certain factors (e.g., sight distance problems, closely spaced structures, nearby interchanges, elevation differences between lanes) limit where a crossover can be built. Even though projects may be at different locations, the location of a crossover may be set by these limitations.

3. Future Projects in Same Area. If structure work is scheduled for one year and roadway work anticipated in the next five years, the same crossover may be used for both projects. Another example would be a series of structures that are rehabilitated over several years.

   When encountering situations as outlined above, the designer should:

   - give consideration to leaving the temporary crossovers in place after the project is completed,
   - include provisions in the contract to close the crossover during the time it is not in use,
   - discuss these provisions at the regular coordination meeting, and
   - obtain FHWA and Central Office concurrence.

55-3 DESIGN RECOMMENDATIONS

The following are specific design recommendations for lane and shoulder closures, two way traffic on divided highways, runaround detours, local route detours, stage construction of two lane two way bridges and multilane bridges, reduced traffic control for road closure, and Interstate work zones.

55-3.01 Lane/Shoulder Closures

Lane and/or shoulder closure is often the most common type of traffic control. The *Highway Standards* provide several Traffic Control Standards for lane and shoulder closures. In addition, consider the following:

1. Traffic Control Devices. Section 55-5 and the *Highway Standards* provide Department criteria for the placement of traffic control devices.

2. Speeds. See the Bureau of Operations "Policy for Establishing and Posting Speed Limits on the State Highway System" for guidance on posting speeds in work zones.

3. Tapers. Lane closures, lane width reductions and lane shifts require the use of transition tapers to safely shift traffic around the encroaching restriction. Section 55-2.05 and the *Highway Standards* provide the criteria for taper rates and lengths for work zones.

4. Lane Widths. Section 55-2.03 provides the Department's criteria for reduced lane widths.

5. Sight Distance. Desirably, provide decision sight distance to the beginning of the lane closure or transition; see Sections 31-3.02, 32-4, and 33-4.

6. Lane Closure Length. Keep the length of a lane closure to a minimum so that motorists are not passing long sections of closed lanes where no work activity is occurring.

7. Roadside Safety. Do not use roadside barriers as transition devices. Where temporary roadside barriers are used, provide sufficient distance between the channelization devices and the roadside barrier to allow an errant motorist to safely return to the traveled way. Roadside barriers (e.g., temporary concrete barrier) may be used as channelization devices beyond the taper. When shifting traffic next to roadside barriers, the shy distance, as discussed in Section 38-6.02, desirably should be provided.

8. Bridges. Sections 55-3.05 and 55-3.06 discuss the criteria for lane closures on bridges.

9. Interstate Projects. Section 55-3.08 discusses additional factors to consider on Interstate projects.

55-3.02 Two-Way Traffic on Divided Highways

Because of the higher traffic volumes and higher speeds on multilane facilities, use special care in the design of these work zones. In these cases, safety considerations are usually more important than costs. In addition to Traffic Control Standard 701416, the following provides several design considerations for this application:

1. Design Speed. The design speed should be no more than 10 mph (15 km/h) below the posted speed limit before the construction zone. See the Bureau of Operations "Policy for Establishing and Posting Speed Limits on the State Highway System" for guidance on posting speeds in work zones.

2. Length. The optimum segment length of two-way traffic on divided highways is less than 4 miles (6 km). Where segments exceed 4 to 5 miles (6 to 8 km), operational efficiency may be reduced as traffic backs up behind slower vehicles.

3. Sight Distance. Adequate sight distance should be provided for motorists approaching the crossover. Desirably, this should be decision sight distance. For additional guidance, see Sections 31-3.02, 32-4, and 33-4. Traffic should not be diverted over to other lanes at locations not clearly visible to approaching motorists (e.g., near bridges, at crest vertical curves).

4. Interchanges. For interchanges, consider the following:

    a. Access. Desirably, maintain access to all interchange ramps even if the work space is in the lane adjacent to the ramps. Additional crossovers for the purpose of maintaining full interchange access may be required. If interchange access is not feasible or presents a capacity problem, close the ramp and provide detour signing for alternative routes. The designer should review the safety aspects and conduct a capacity analysis to determine the appropriate action.

    b. Local Coordination and Emergency Services. Where ramp closures are deemed necessary, conduct early coordination with local officials and emergency service having jurisdiction over the affected crossroads or streets. Use newspapers, radio, television, and changeable message signs to alert commuting motorists.

    c. Deceleration and Acceleration Lengths. Ensure that sufficient deceleration and acceleration distances are maintained where there is work in the vicinity of interchange ramps. If this is not practical, additional traffic control devices or ramp closure may be required.

5. Crossovers. Because of the unexpected movements, special care must be given to the design of crossovers. Temporary concrete barriers and the excessive use of traffic control devices cannot compensate for a poor geometric design of crossovers. Consider the following when designing crossovers:

    a. Design Speed. The crossover should have a design speed that is no more than 10 mph (15 km/h) below the posted speed limit before the construction zone.

b. Transitions. Tapers for lane drops should not be contiguous with the crossover (i.e., provide a buffer area between the lane closure and the crossover). See Section 55-2.05 for acceptable taper rates and lengths.

c. Width. For one-lane, one-way operations, the lane width through the crossover portion should be 16 ft (5.0 m) with 2-ft (600-mm) wide left and right shoulders. For multilane and/or multidirectional operations, each lane width should be 12-ft (3.6-m) wide with 2 ft (600 mm) left and right shoulders.

d. Pavement Design. Section 55-2.10 presents guidelines for determining the pavement design of the crossover.

e. Roadside Safety. Provide a clear recovery area or buffer area adjacent to the crossover prior to the work zone.

f. Crossovers to Remain In Place. Under some circumstances, it may be cost effective to retain the crossover after the project has been complete. See Section 55-2.12 for additional guidance.

6. Roadside Safety Appurtenances. Where traffic is diverted onto the opposing roadway, consider the effect this will have on the operational characteristics of roadside safety appurtenances. For example, existing trailing ends of unprotected bridge rails may require an approach guardrail transitions or impact attenuators, or blunt guardrail end terminals may require protection with an acceptable end treatment if these appurtenances are within the work zone clear zone. Appurtenances are discussed in Section 55-4.02 and chapter 38 for additional guidance.

7. Signing. In addition to the signing shown in the Highway Standards, include signing prior to the crossover to indicate the length of the two-way, two-lane section. In addition, provide signing within the two-lane section to indicate the remaining distance of the two-lane section (e.g., NEXT X MILES). Place this sign below the two-way traffic signs.

8. Channelization Devices. Traffic Control Standards 701416 and 701431 present the general criteria for the placement of channelization devices within and between crossovers. Temporary longitudinal traffic barriers, barricades or drums may be used to channel traffic within the crossovers. Between crossovers, temporary longitudinal traffic barrier is used to separate traffic between the crossovers except as discussed below. Signs, centerline striping, and raised pavement markers, either alone or in combination, are not considered separation devices. Consider the following:

a. Short-Duration Projects (120 Consecutive Hours or Less). Type II barricades or drums may be used as separators. Cones may be used for daylight only operations.

b. Longer-Duration Projects (Greater than 120 Consecutive Hours). Use temporary longitudinal traffic barrier on all projects other than those listed in Item c. below.

c. Urban (Typically Posted Speed 40 mph or less). Cones, drums, barricades, or tubular markers may be used as separators for urban projects. Under special circumstances (e.g., winter work), it may be necessary to omit devices to allow for snow removal.

d. Ramps. Where ramps or side roads intersect a two-lane, two-way operation, special traffic-accommodation details must be developed. Consult the Bureau of Operations for guidance in these situations.

9. Nighttime Safety for Crossovers. Positive guidance is needed in crossovers. Consider the use of temporary highway lighting, or wet reflective pavement markings within the crossover in addition to other traffic control measures and devices.

a. Lighting. Consider providing temporary highway lighting where the crossover will be in place for longer than three weeks and one or more of the following conditions exist:

- Existing continuous highway lighting will be removed because of the construction activities at or adjacent to the proposed median crossover.

- The median crossover will be located adjacent to a lighted interchange.

- The absence of highway lighting will contribute to an already less than desirable condition (e.g., inadequate sight distance, inadequate geometrics) required by existing conditions that will not allow an adequate design through the median crossover.

- The crossover will be used on a roadway section having an ADT of 10,000 or more.

The crossover should be capable of safe operations during blackouts caused by construction activities, adverse weather, or traffic crashes.

See Chapter 56 and/or contact BDE for details on the lighting design. The request for the lighting design should include the:

- location of power source,
- location of any existing lighting units,
- geometrics of proposed median crossovers, and
- length of time it is anticipated that the temporary lighting will be required.

b. Wet Reflective Pavement Markings. Consider the use of wet reflective pavement markings for crossovers that meet the following conditions:

- temporary highway lighting is impractical due to cost or geometrics; and

- adverse geometrics, complexity of the crossover, or previous experience indicate a need for greater positive guidance to the motorist.

10. Emergency Access. Work with local emergency service agencies to ensure access throughout the project. It is important that police, fire, ambulance, and towing services have access without having to travel excessive adverse miles.

55-3.03 Runaround Detours

In addition to the criteria in the *Highway Standards*, runarounds and specially built detours should meet the geometric and roadside safety criteria presented in Sections 55-2 and 55-4 and the following guidelines:

1. Layout. Figure 55-3.A illustrates a typical layout for a runaround detour. Figure 55-3.B illustrates typical cross sections for a runaround detour.

2. Design Speed. The runaround should have a design speed that is no more than 10 mph (15 km/h) below the posted speed limit before the construction zone.

3. Width. At a minimum, provide a 22 ft (6.6 m) traveled way width. If there are significant multiple-unit trucks to affect the design, use the traveled way widths presented in Figure 55-3.C. Also, provide a minimum 2 ft (600 mm) shoulder on each side.

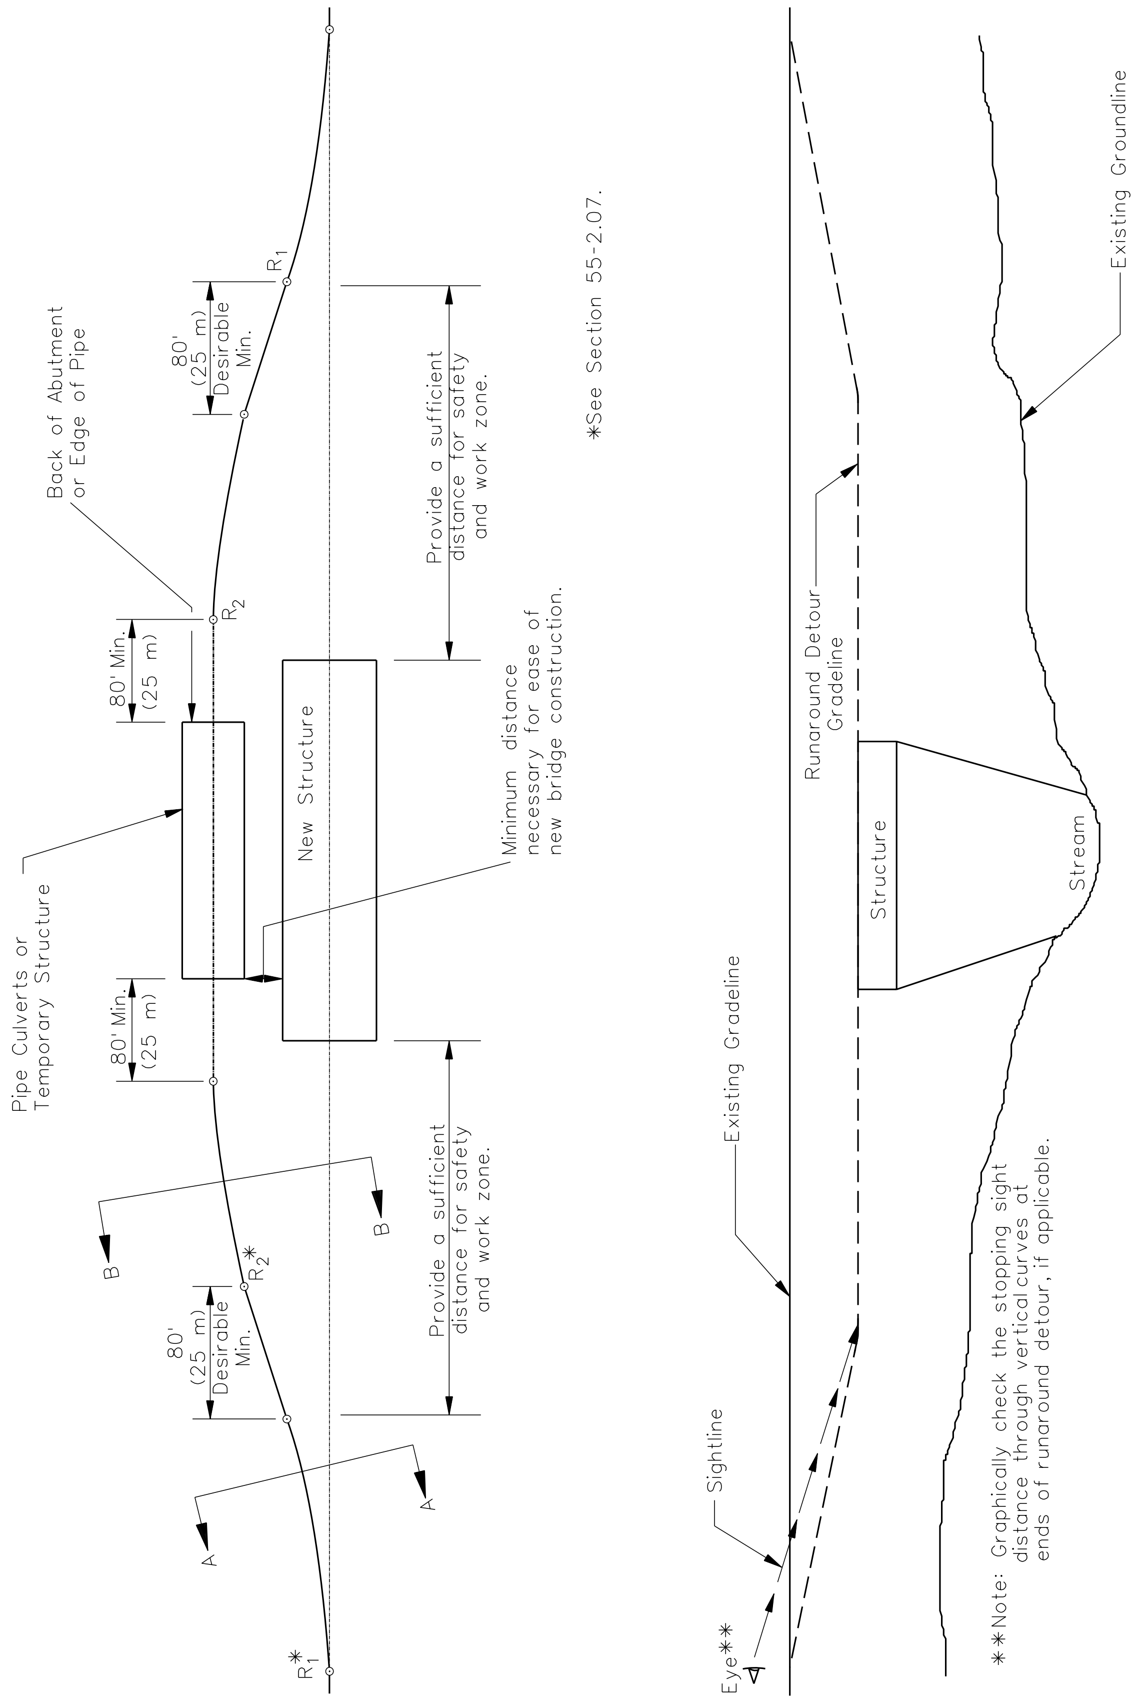
4. Pavement Design. Section 55-2.10 presents guidelines for determining the pavement design.

5. Horizontal Alignment. Desirably, the horizontal curve connecting the runaround to the existing roadway should be sufficiently flat so that superelevation will not be required. See Section 55-2.07 for the design of horizontal curves in work zones.

6. Vertical Alignment. See Section 55-2.08 for the minimum vertical curvature criteria that may be used on runarounds.

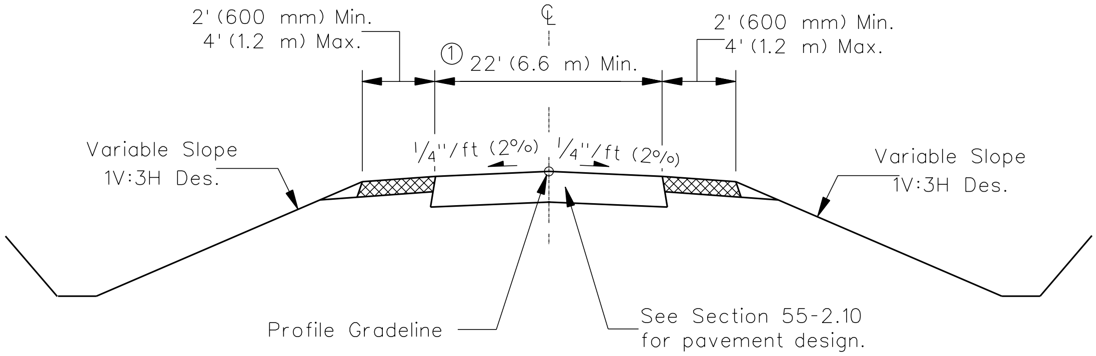
7. Sight Distance. Design the runaround to meet the sight distance criteria in Section 55-2.06. Check to ensure that adequate sight distance is available through the horizontal and vertical curves.

8. Traffic Control Devices. Traffic Control Standard 701331 and the Standard Specifications provide the minimum criteria for placement of traffic control devices prior to and through the runaround. Temporary rumble strips, reflectors, and/or additional warning devices may be required where unusual site conditions warrant and/or where the design speed on the runaround is more than 15 mph (25 km/h) less than the approach posted speed.



TYPICAL RUNAROUND LAYOUT

Figure 55-3.A



Section A - A

TYPICAL CROSS SECTIONS FOR RUNAROUND DETOUR

Figure 55-3.B

US Customary			
Roadway Width (ft)			
Radius on Inner Edge of Traveled Way (ft)	Traffic Condition A	Traffic Condition B	Traffic Condition C
150	26	29	32
200	26	28	30
300	25	28	29
400	25	27	28
500	22	22	22
Tangent	22	22	22
Metric			
Roadway Width (m)			
Radius on Inner Edge of Traveled Way (m)	Traffic Condition A	Traffic Condition B	Traffic Condition C
50	7.9	8.8	9.5
75	7.7	8.5	8.9
100	7.6	8.3	8.7
125	7.6	8.2	8.5
150	6.6	6.6	6.6
Tangent	6.6	6.6	6.6

Note:

Traffic Condition A — Predominantly P vehicles, but some consideration for SU vehicles.

Traffic Condition B — Sufficient SU vehicles to govern design, but some consideration for semitrailer vehicles (5%-10% SU and 0%-3% semitrailer vehicles).

Traffic Condition C — Sufficient semitrailer vehicles to govern design (over 3% semitrailer vehicles).

RUNAROUND DETOUR ROADWAY WIDTHS
(Two-Way, Two-Lane Operations)

Figure 55-3.C

9. Bridges. Temporary structures should be at least 2 ft (600 mm) wider than the approach runaround roadway. Provide appropriate roadside safety protection at the ends of temporary bridges. Design waterway openings based on the criteria of the Bureau of Bridges and Structures.

10. Ditches. Where construction of a runaround detour is over an existing ditch that involves minimal cuts and fills, undercut the ditch by a minimum of 2 ft (600 mm) to remove any unstable material. However, each site must be examined on a project-by-project basis to determine if additional excavation will be required.

11. Side Slopes. For large streams or rivers, the runaround may be in a cut section. Ensure that adequate sight distance is available through the cut section. For additional guidance on side slopes, see Section 55-2.09.

55-3.04 Local Route Detours

Once it has been determined to use a local road as a detour, the designer should consider the following guidelines for local route detours:

1. Widths. Figure 55-3.D presents the minimum and desirable traveled way and roadway widths for a local route detour. These widths are based on the expected average daily traffic during the detour and the detour posted speed.

2. Intersections. Existing rural intersections may need to be converted from a yield or a no-control intersection to a stop-controlled intersection. Note that local drivers may be accustomed to using the route without stop conditions. Therefore, provide adequate advance warning of the new stop condition.

3. Pavement Design. The pavement design of existing local routes may need to be upgraded to meet the increased traffic and truck volumes. See Section 55-2.10 to determine the acceptable pavement design for local detour routes.

4. Agreements. Before a local road can be used as a detour, a Joint Agreement or Letter of Understanding must be executed with the local officials having jurisdiction over the road. This will require conducting a joint inspection with the officials prior to construction to determine the existing condition of the road and reaching an agreement on plans for restoration of the local route to an acceptable condition after the detour is removed. See Chapter 5 for further guidance on agreements.

MINIMUM TRAVELED WAY AND ROADWAY WIDTHS

Figure 55-3.D

5. Bridges. Examine all structures on the local detour route to ensure that they are structurally adequate to accommodate the expected traffic and truck volumes. When determining the structural adequacy, consider the following:

   a. Widths. Where two-way operation is proposed, the minimum horizontal clearance for structures to remain in place along the detour route is 24 ft (7.2 m). Where low truck volumes are anticipated (i.e., where semitrailers are less than 5% and SUs are less than 10% of ADT) and expected traffic volume on the detour route is less than 1,000 ADT, the minimum horizontal clearance that may remain is 22 ft (6.6 m).

   b. One-Lane Bridges. Where it has been determined that it is feasible to retain a one-lane bridge on a local route detour, ensure that the appropriate traffic control devices and signing are provided to delineate the transitions and bridge.

   c. Design Load. Where the load-carrying capacity of a structure on the detour route is questionable, request the Bureau of Bridges and Structures to analyze the structure to determine if it is acceptable. In some cases, it may be necessary to specify weight restrictions (e.g., load limit, one truck at a time) for the bridge. However, where feasible, avoid specifying weight restrictions. When it is not feasible to use a bridge for truck traffic, provide a marked alternative truck route.

d. New Structures. Where an existing structure does not meet either the load limit requirements and/or width requirements necessary to remain in place, a new structure should be provided and designed according to the bridge policies in the *Bureau of Local Roads and Streets Manual*. Design traffic will be the current ADT on the local route rather than the ADT on the route during its use as a detour. If this is not feasible, provide a marked alternative truck route.

6. Ditches. To improve drainage and increase subgrade stability, existing ditches may need to be cleaned and deepened before the new pavement structure is built.

7. Roadside Safety. Review the local route to determine if new or upgrading existing roadside safety hardware is necessary. Any improvements to the existing roadside protection should be consistent with the local road classification, the temporary nature of the detour route, and the detour design speed. For additional guidance, see Section 55-4 and Chapter 38.

55-3.05 Stage Construction of Two-Lane, Two-Way Bridges

Traffic Control Standards 701316 and 701321 present the general traffic control criteria for stage construction on a two-lane, two-way structure (i.e., alternating traffic using one lane). In addition to the *Highway Standards*, consider the following guidelines:

1. Maximum Distance. Figure 55-3.E presents the recommended maximum closure distance, excluding tapers, that should be considered for this operation. Where longer distances are necessary, evaluate additional methods to improve operations.

2. Width. Section 55-2.03 presents the minimum widths that should be considered for one-lane roadways.

3. Structure Type. Section 13-2.02(b) contains guidelines for stage construction of various structure types.

4. Temporary Traffic Signals. The required method for alternating traffic across the structure is with temporary traffic signals. Section 55-5.04 and the Standard Specifications provide the criteria for these traffic signals.

5. Rumble Strips. Consider providing temporary rumble strips and/or additional warning devices in addition to the standard traffic control devices where there is restricted alignment and/or sight distance.

6. Temporary Bridge Rails. Under some circumstances, it will be necessary to provide temporary bridge rails, temporary concrete barriers, or temporary concrete barriers on the structures. Before using temporary concrete barrier across a structure, consult with the Bureau of Bridges and Structures to ensure the bridge deck can adequately support the barriers. Request the details for temporary bridge rails or temporary concrete barriers on the structure from the Bureau of Bridges and Structures.

Detour ADT	Recommended Maximum Distance
> 8000	300 ft to 500 ft (100 m to 150 m)
≥ 5000 to ≤ 8000	500 ft to 800 ft (150 m to 250 m)
< 5000	800 ft to 1000 ft (250 m to 300 m)

RECOMMEND MAXIMUM DISTANCE FOR STAGE CONSTRUCTION (Bridges)

Figure 55-3.E

55-3.06 Stage Construction of Multilane Bridges

In addition to Traffic Control Standard 701401, consider the following guidelines when using stage construction on multilane bridges:

1. Widths. See Section 55-2.03 for the minimum lane widths allowed.

2. Traffic Control Devices. In addition to the criteria presented in the Highway Standards, consider providing additional traffic control devices (e.g., wing barricades, regulatory speed signs, changeable message signs) where there are high-traffic volumes and/or restricted geometric conditions.

55-3.07 Reduced Traffic Control for Road Closed to Through Traffic

Where a highway or bridge is closed to through traffic, the *Illinois Highway Code* allows the Department to specify alternative procedures, if desired, for flagging and controlling the local traffic through the work zone. The designer must specify the option for reduced traffic control in the plans and provide the average daily local traffic in the contract, otherwise the contractor will be required to provide the same level of traffic control within the section of road closed to through traffic as would be required for open-highway conditions.

The Department's criteria in the *Standard Specifications* for reduced traffic control are based on the expected traffic volumes through the work zone. The designer will be responsible for determining these traffic volumes and incorporating this information within the traffic control plans. The estimated traffic volumes may vary at different locations within the work zone or during separate construction phases. For these situations, list the expected traffic volumes for each location and/or phase. This will allow the contractor to adjust the traffic control accordingly.

55-3.08 Interstate Work Zones

Incorporate the following items, as appropriate, into traffic control plans for Interstate projects involving lane closures:

1. Communication with Motorists. To inform motorists of possible backups, delays, closures, etc., review Section 13-3.02 for on-site strategies.

2. Other Traffic Control Device Requirements. In addition to the criteria presented in Section 55-4, provide extra attention to the following:

   a. Lighting. Provide temporary lighting at all Interstate crossovers for two-way, two-lane operations; see Chapter 56 and/or contact BDE for details on the lighting design. The request for the lighting design should include the:

      - location of power source,
      - location of any existing lighting units,
      - geometrics of proposed median crossovers, and
      - length of time it is anticipated that the temporary lighting will be required.

   b. Temporary Longitudinal Traffic Barriers. Use temporary longitudinal traffic barrier to separate two-way, two-lane traffic and to extend work space as required for positive protection. See Section 55-4.01 for positive protection guidelines.

   c. Guide Signs. In two-way, two-lane operations include signing with the distances remaining in the two-lane section (e.g., NEXT X MILES). This can reduce motorist frustration level. Place this sign below the two-way traffic signs.

   d. Review. If the TCP is not part of a TMP that will be reviewed by the Bureau of Safety Programs and Engineering, request the Bureau of Operations to review the traffic control plans prior to advertisement to ensure the above requirements are met.

3. Reducing Lane Closures. Develop the traffic control plan so that lane closures can be kept to a minimum. Consider the following to reduce the time and length of lane closures and to meet mobility goals.

   a. Overnight Closures. Where practical, specify the use of Traffic Control Standard 701406 (Daylight Work Only) versus Traffic Control Standard 701401 (Overnight Closures). Resurfacing, shoulder work, most underdrains, and moving work can be accomplished under Standard 701406. Do not allow contractors to use Standard 701401 in lieu of Standard 701406 at their expense.

   b. Time Restrictions. Consider the scheduling strategies listed in Section 13-3.04.

   c. Special Provisions. Figure 55-3.F provides a sample Special Provision that may be used for lane closures to limit the number of days of lane closure by the contractor.

Lane closures under Traffic Control Standard 701401, except those for structure repairs, shall be limited to a total of ___*a.*___ lane closure days. A day is defined as any day or portion thereof including Saturdays, Sundays, and Holidays, in which a lane closure is in effect. If more than one closure is in effect simultaneously, a day will be charged against each individual lane closure in determining the number of lane closure days used. When adverse weather prevents work from being performed, a day will not be charged.

If quantities for the following pay items are increased, days for lane closures will be increased at the following daily rates:

Pay Item	Daily Rate

b.

Increases in lane closure days will only be allowed for the specified pay items and at the specified rates. No additional increases will be considered.

If the Contractor fails to open all lanes to traffic within the lane closure days allowed, the Contractor shall be liable to the Department in the amount of $ ___*c.*___ for each full or partial day of overrun not as a penalty but as liquidated damages. These damages shall be in addition to any liquidated damages charged in accordance with Article 108.09.

Any additional cost to comply with these provisions shall be included in the cost of Traffic Control and Protection, Standard 701401.

Notes to the designer:

a. The total days should be calculated using those pay items that require overnight closures (e.g., concrete patching, shoulder reconstruction). Items such as resurfacing, bituminous patching, pipe underdrains, cold milling, etc., can typically be done using Standard 701406 and the lanes opened at the end of each day. Once the applicable pay items are determined, working days can be calculated using daily production rates; see Section 66-2.03 Working days would then be multiplied by 7/5 to obtain the calendar days.

b. List the pay items and daily rates used to determine the total days here.

c. The daily road user delay cost can be determined according to Section 66-2.04. The length used should be the estimated lane closure length; normally this would be 5 miles (8 km) for concrete patching and 3 miles (5 km) for other operations.

SPECIAL PROVISION FOR STANDARD 701401 LANE CLOSURES

Figure 55-3.F

55-4 ROADSIDE SAFETY

Through a work zone, drivers are often exposed to numerous hazards (e.g., restrictive geometrics, construction equipment, opposing traffic). A total elimination of work zone hazards is impractical. Therefore, the designer must devote special attention to reducing a motorist's exposure to potential hazards. The following sections offer roadside safety criteria that apply only to the roadside elements within the work zone. These criteria do not apply to detours over existing routes.

55-4.01 Positive Protection

Positive protection devices are the devices that contain and/or redirect errant vehicles and meet the crashworthiness evaluation criteria contained in NCHRP Report 350 or the Manual on Assessing Safety Hardware (MASH). This can include approved longitudinal barriers or truck/trailer-mounted attenuators (TMA). Positive protection devices shall be considered in work zone situations that place workers at increased risk from motorized traffic and where positive protection devices offer the highest potential for increased safety for workers and road users.

Desirably, the designer should consider traffic control designs that do not require the use of positive protection, while both minimizing the hazard exposure and maximizing the separation of workers and traffic. However, in many work zones, positive protection is needed.

Positive protection is required for the following conditions where work is conducted under traffic:

1. Mobile Operations. Mobile operations are defined as work that moves intermittently or continuously (at approximately 1 mph (1.6 km/h), a walking pace). A mobile operation may be accomplished using the following:

    a. Multi-lane Highways. Mobile operations on multi-lane highways may be accomplished using a stationary standard lane closure as shown in the *Highway Standards* (or *IDOT Work Site Protection Manual* for IDOT employees) where the lane is closed using signing, arrow boards, and channelizing devices. If such a stationary standard lane closure is not used, then positive protection devices (e.g., TMA) shall be used to close the lane in advance of the workers. The use of additional signing would be dependent upon the normal posted speed limit, and the duration and length of the work, and will be in accordance with the *Illinois Manual on Uniform Traffic Control Devices* (ILMUTCD).

    b. Two-lane, Two-way Highways. Mobile operations on two-lane highways will require the use of a positive protection device (e.g., TMA) in advance of the work.

    TMAs are acceptable for limited daily work hours consistent with the *IDOT Work Site Protection Manual*.

2. Stationary Operations. Stationary operations are defined as work that occupies a location for more than one hour. In these cases, the work would require a lane closure in accordance with an appropriate *Highway Standard*.

Positive protection devices will be required for stationary operations conducted under traffic in areas that offer no means of escape from motorized traffic (e.g., tunnels, bridges, bridge painting, narrow medians). For multi-lane and two-lane two-way highways, please see additional guidance below regarding use of temporary longitudinal traffic barriers:

- Multi-lane highways with work that occupies a location for more than 24 hours, or requires multiple days/nights setups exceeding 24 hours to complete, will require the use of temporary longitudinal traffic barriers.

- Two-lane two-way highways with work that occupies a location for more than four days per stage will require the use of temporary longitudinal traffic barriers.

Additionally, for long duration stationary locations, with high speed and workers near a traffic lane:

> Temporary longitudinal traffic barriers will be required for stationary operations where the normal posted speed limit is 45 mph or greater, the duration of the stationary operation is two weeks or more, and workers are present within one lane width of the open traffic lane, except when the project is outside of an urban area and the annual average daily traffic (AADT) is less than 2400 vehicles.

The following are locations where the designer should consider using positive protection:

- exposed ends of temporary concrete barriers;
- untreated guardrail ends in two-way, two-lane operations;
- bridge piers;
- bridge rail or parapet ends;
- structure foundations (e.g., bridge falsework, sign foundations);
- excavations and rock cuts;
- gap in median between dual bridges;
- excessive pavement edge and shoulder drop-offs (see Figures 55-2.A and 55-2.B); and
- other locations where construction will increase the potential hazards of existing conditions.

Consider the following factors when assessing the need for positive protection:

- duration of construction activity,
- traffic volumes (including seasonal and special event fluctuations),
- nature of hazard,
- length and depth of drop-offs,

- work zone design speed,
- highway functional class,
- length of hazard,
- proximity between traffic and construction workers,
- proximity between traffic and construction equipment,
- adverse geometrics which may increase the likelihood of run-off-the-road vehicles,
- two-way traffic on one roadway of a divided highway,
- transition areas at crossovers, and
- lane closures or lane transitions.

Other factors may apply, and the above list is not considered all inclusive.

Positive protection devices shall be used in accordance with the *Highway Standards*, *ILMUTCD*, manufacturers' requirements, NCHRP Report 350 or MASH, and the most current Bureau of Safety Programs and Engineering Policy Memorandum BSE-04. See Section 55-4.02 for more information. Their use provides greater protection for workers than normal channelizing devices; however, workers should be aware of the limitations of positive protection devices.

When developing the Transportation Management Plan, designers should take emergency situations into consideration. Emergency situations and traffic incidents should consider use of positive protection devices in accordance with Chapter 6 of the *ILMUTCD*. Incidents lasting more than 24 hours should be evaluated for appropriate use of positive protection devices.

55-4.02 Appurtenance Types

In addition to Chapter 38 and the *Highway Standards*, the following sections provide additional information on the roadside safety appurtenances used by the Department in work zones.

55-4.02(a) Guardrail

Temporary guardrail installations must meet the permanent installation criteria in Chapter 38 and the *Highway Standards*, except as modified in Section 55-4.02(c). For short-term construction projects, the installation of a new temporary guardrail is usually not practical.

55-4.02(b) Temporary Longitudinal Traffic Barrier

Temporary longitudinal traffic barrier provides protection by separating motorists from the construction site and/or opposing traffic. Temporary longitudinal traffic barrier may consist of temporary concrete barrier (TCB) or shifting, portable, or movable barrier systems.

When considering temporary longitudinal traffic barrier, evaluate the following:

1. Purpose. The primary functions of temporary longitudinal traffic barrier are:

    - to prohibit traffic from entering work areas (e.g., excavations, storage sites);

- to protect workers and pedestrians;
- to separate two-way traffic;
- to shield construction elements (e.g., bridge falsework, exposed objects); and
- to protect motorists from hazards in the clear zone.

2. Flare Rates. Temporary longitudinal traffic barrier located along a tapered alignment should be flared at the rates shown in Figure 55-4.A using the selected work zone design speed. If field conditions are such that these flare rates cannot be used, then consider using a flare rate between 4:1 and 8:1. The length of the taper will be determined based on the length of need requirements; see Section 55-4.03. The approaching end of the temporary longitudinal traffic barrier along the tapered alignment should desirably extend to a point beyond the construction clear zone. Under restrictive conditions, however, the designer may reduce this offset to the outside edge of the shoulder with an applicable end treatment.

3. **Work Zone Design Speed**	**Flare Rate**
45 mph (70 km/h) and above	12:1
Less than 45 mph (70 km/h)	8:1

TEMPORARY LONGITUDINAL TRAFFIC BARRIER FLARE RATES

Figure 55-4.A

4. End Treatment. Shield the approach end of temporary longitudinal traffic barrier with an approved end treatment meeting the requirements of NCHRP Report 350 or MASH, regardless of placement within or outside of the clear zone. Place all end treatments on level ground 1:10 or flatter.

5. Test Level. The application of temporary longitudinal traffic barrier must match the test level of the product. Consult the *AASHTO Roadside Design Guide*, NCHRP Report 350 or MASH, and the Bureau of Safety Programs and Engineering for further guidance.

6. Offset and Deflection. Check the expected deflection of the temporary longitudinal traffic barrier against the proposed use. The deflection should not allow the barrier to fall from a drop-off or bridge deck, or intrude into oncoming traffic. However, some barriers, including temporary concrete barriers, may be pinned to reduce deflection. Contact the Bureau of Safety Programs and Engineering for information on temporary longitudinal traffic barrier deflection data or potential barrier systems to be considered for use. Also, see the most current Bureau of Safety Programs and Engineering Policy Memorandum BSE-04 for guidance on pinning and anchoring when using temporary concrete barrier. Contact the Bureau of Bridges and Structures for guidance on anchoring barriers to bridge decks.

55-4.02(c) End Treatments

Locate any unprotected approach guardrail end (e.g., at breaks for crossovers, emergency vehicle access, or contractor access) at or beyond the construction clear zone or shield it with an appropriate end treatment. Shield the approach end of a temporary traffic barrier as discussed in Section 55-4.02(b). The following discusses several end treatments that can be used:

1. Attenuating Devices. Attenuating devices meeting the requirements of NCHRP Report 350 or MASH are acceptable protective end treatments. They also may be considered at point obstacles (e.g., bridge piers) where space is limited. Contact the Bureau of Safety Programs and Engineering for guidance on attenuating devices available and physical space requirements needed for installation.
2. Guardrail. The treatments for exposed ends of guardrail include:
   - connection to existing barriers,
   - overlapping barriers,
   - using an approved end terminal,
   - attaching an impact attenuator, or
   - burying the end in the backslope.
3. Sand Barrels. Sand barrels are commonly used to protect the driver from point obstacles (e.g., bridge piers, temporary longitudinal traffic barrier ends). Due to the size of the array, sand barrels should only be used outside of the traveled way (e.g., on shoulders, in medians). Arrays vary according to the obstacle width and the design speed. The Highway Standards illustrate typical sand barrel applications; however, the designer must confirm that the Highway Standards are applicable to the site. Information on alternative NCHRP Report 350 or MASH approved array arrangements can be obtained from the manufacturers' literature. Also note that single-row arrays are not allowed by IDOT policy. Use attenuating devices for areas with limited allowable width.

55-4.02(d) Glare Screens

Glare screens may be used in combination with temporary longitudinal traffic barrier to reduce headlight glare from opposing traffic. Typical applications in work zones are at crossover transitions and in two-way, two-lane operations. In addition to crossovers, consider providing glare screens where:

- the travel lane is within 2 ft (600 mm) of the barrier,
- a high amount of peripheral ambient light exists,
- there is a high volume of truck traffic, and/or
- the vertical or horizontal alignment of the roadway may create a headlight glare problem.

If glare screens are used on curvilinear alignments, ensure that the glare screen installation will not produce below minimum stopping sight distances. For additional glare screen design criteria, see Section 38-7.05.

55-4.03 Design/Layout

Where practical the designer should locate and design temporary roadside safety appurtenances based on the criteria in Chapter 38 (e.g., deflection distance, length of need). However, it is usually not practical nor cost effective to meet these criteria for permanent installations due to the limited time traffic is exposed to construction hazards and the space constraints that are required during construction. The designer must evaluate the exposure time of the hazard in determining the need for installing a roadside safety appurtenance. The following offers several alternatives that should be considered in designing and locating temporary roadside safety appurtenances within work zones:

1. Work Zone Clear Zones. Applying the clear zone distances from Chapter 38 to work zones is often impractical. Therefore, the Department has developed revised work zone clear zone distances, which are presented in Figure 55-4.B. However, the potentially hazardous conditions typically found within work zones warrant the use of considerable judgment when applying these clear zone distances. Note that it is not necessary to adjust the clear zone values presented in Figure 55-4.B for horizontal curvature.

   Treat hazards within the work zone clear zone in the same manner as they would be in a conventional clear zone.

2. Embankment Warrants. Figure 55-4.C presents barrier warrants for embankments in work zones.

3. Length of Need. As with new installations, provide a sufficient distance of full-strength barrier prior to the hazard to minimize the potential for a vehicle to run behind the barrier and impact the hazard. For temporary layouts, the length of need can be determined by using an angle of 10° to 15° from the back of the hazard or from the work zone clear zone distance off the traveled way.

4. Flare Rates. Desirably, flare temporary traffic barrier terminals beyond the traveled way to a point outside of the work zone clear zone. Figure 55-4.A presents the desirable flare rates for barrier based on the selected work zone design speed. Use these flare rates unless documented extenuating circumstances render this impractical (e.g., stop conditions, driveways, intersections).

Approach Posted Speed Limit[4]	ADT	Front Slopes			Back Slopes		
		1:6 or Flatter	1:5 to 1:4	1:3	1:3	1:5 to 1:4	1:6 or Flatter
		Work Zone Clear Zone Distances (ft)					
35 mph or less	Under 750	4 – 6	4 – 6	**	4 – 6	4 – 6	4 – 6

	Over 6000	10	10 – 12		10	10	10
35 - 50 mph	Under 750	6 – 8	6 – 10		4 – 6	4 – 6	6 – 8
	750-1500	10	10 – 14		6 – 8	8 – 10	10
	1500-6000	10 – 12	12 – 16		8 – 10	10	10 – 12
	Over 6000	12 – 14	16 – 18		10	12	12 – 14
55 mph	Under 750	6 – 8	10 – 12		6	6 – 8	6 – 8
	750-1500	10 – 12	12 – 16		6 – 8	10	10 – 12
	1500-6000	12 – 14	16 – 18		10	10 – 12	12 – 14
	Over 6000	14 – 16	16 – 20*		10 – 12	12 – 14	14 – 16
60 mph	Under 750	10 – 12	12 – 16		6 – 8	8 – 10	10
	750-1500	12 – 16	16 – 20*		8 – 10	10 – 12	12 – 14
	1500-6000	16 – 18	20 – 24*		10 – 12	12 – 14	16
	Over 6000	18 – 20*	22 – 28*		12 – 14	16	16 – 18
65 mph	Under 750	12	12 – 16		6 – 8	10	10
	750-1500	16	18 – 22*		8 – 10	12	12 – 14
	1500-6000	18 – 20*	22 – 26*		10 – 12	14 – 16	16 – 18
	Over 6000	18 – 22*	24 – 28*		14 – 16	16 – 18	18

* *Clear zones may be limited to 18 ft for practicality.*
** *See procedure in Section 38-3.02(b).*

Notes:

1. *All distances are measured from the edge of the traveled way.*
2. *For clear zones, the "ADT" will be the total ADT on two-way roadways and the directional ADT on one-way roadways (e.g., interchange ramps and one roadway of a divided highway). Traffic volumes will be the expected traffic volume through the work zone.*
3. *The values for " back slopes" only apply to a section where the toe of the back slope is adjacent to the shoulder. See Figure 38-3.B(d). For sections with roadside ditches, see Section 38-3.03.*
4. *Approach posted speed limit prior to the work zone.*

WORK ZONE CLEAR ZONE DISTANCES (US Customary)

65 mph	Under 750	3.5 - 4.0	4.0 - 5.0		2.0 - 2.5	3.0	3.0
	750-1500	4.5 - 5.0	5.5 - 7.0*		2.5 - 3.0	3.5 - 4.0	4.0
	1500-6000	5.5 - 6.0*	6.5- 8.0*		3.0 - 4.0	4.0 - 4.5	5.0 - 5.5
	Over 6000	5.5 - 6.5*	7.0- 8.5*		4.0 - 4.5	5.0 - 5.5	5.5

* *Clear zones may be limited to 5.5 m for practicality.*

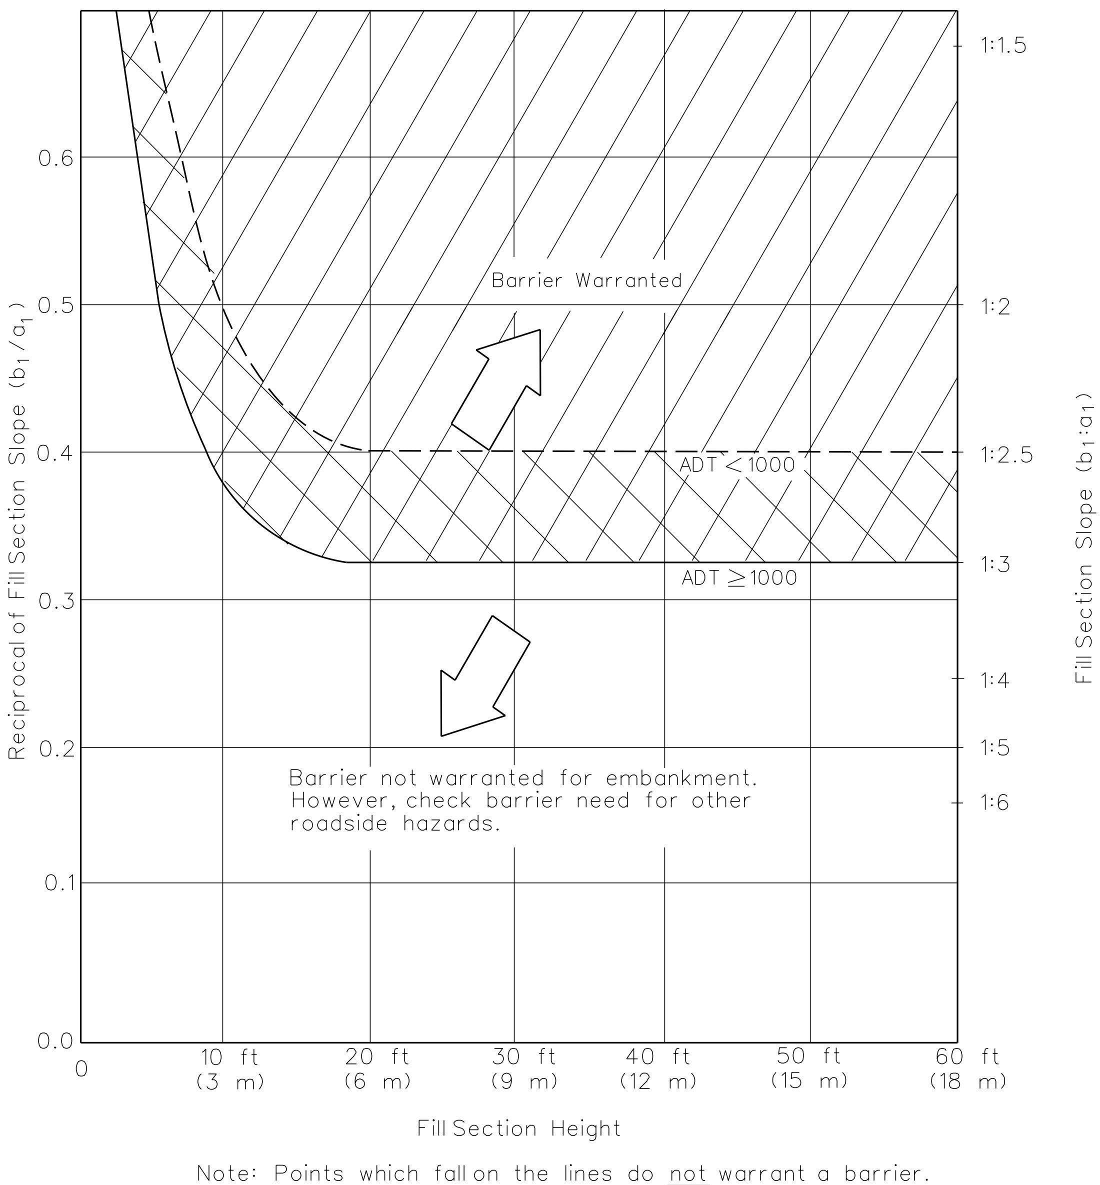
** *See procedure in Section 38-3.02(b).*

Notes:

1. *All distances are measured from the edge of the traveled way.*
2. *For clear zones, the "ADT" will be the total ADT on two-way roadways and the directional ADT on one-way roadways (e.g., interchange ramps and one roadway of a divided highway). Traffic volumes will be the expected traffic volume through the work zone.*
3. *The values for " back slopes" only apply to a section where the toe of the back slope is adjacent to the shoulder. See Figure 38-3.B(d). For sections with roadside ditches, see Section 38-3.03.*
4. *Approach posted speed limit prior to the work zone.*

WORK ZONE CLEAR ZONE DISTANCES
(Metric)

Figure 55-4.B



BARRIER WARRANTS FOR EMBANKMENTS
(Work Zones)

Figure 55-4.C

5. Openings. Avoid openings in the barriers. Where openings are necessary, provide a NCHRP Report 350 or MASH approved end treatment at the barrier ends and proper signing.

6. Sand Barrels. Sand barrel arrays for temporary installations are the same as for permanent installations, except for the shielding of the hazard. Permanent sand barrel installations require a minimum 30 in (750 mm) offset between the hazard and the outside edge of the sand barrel array. For temporary installations, this distance can be reduced to 15 in (375 mm) where a greater offset would cause unacceptable interference with traffic. The preferable alternative is to use an attenuator system.

55-5 WORK ZONE TRAFFIC CONTROL DEVICES

The proper use of traffic control devices is critical to both public and worker safety and has been proven to significantly reduce crashes in work zones. The district Bureau of Operations will be responsible for the selection and design of traffic control devices. This section provides supplemental information on these devices and presents specific Department policies and procedures.

55-5.01 Highway Signs

55-5.01(a) General

In construction zones, regulatory signs are used to temporarily override an existing mandate or prohibition (e.g., reduced speed limit). Warning signs are used in advance of the construction area to indicate potentially hazardous conditions, and guide signs are used at various locations to inform drivers of detour routes, destinations, and points of interest.

In general, the *Highway Standards*, the *Standard Specifications*, and Part 6 of the *Illinois Manual of Uniform Traffic Control Devices* (ILMUTCD) provide the Department's criteria for the design, application, and placement of these signs in construction zones. In addition, the designer should review the applicable sections for permanent signs in Chapter 57 of the *BDE Manual,* the Bureau of Operation's *Policies and Procedures Manual*, and the *ILMUTCD*.

55-5.01(b) Speed Limit Signing

Signs are used to alert the traveling public of the speed limit within a work zone. The signs must comply with *the Highway Standards* for the work zone speed limit to be enforceable. The Work Zone Speed Limit Sign is the regulatory sign that is used to establish the speed limit in a construction or maintenance zone, as well as legally establish the zone for enforcement and fines. Use the Bureau of Operations "Policy on Establishing and Posting Speed Limits on the State Highway System" to establish speed limits in work zones.

The work zone speed limit will be determined based on the work zone design speed, traffic volumes, construction work type, geometrics, project length, etc. Where there is no lane closure or apparent hazard, maintain the existing speed limit.

See the *Standard Specifications* and *Highway Standards* for details on sign placement.

55-5.01(c) Guide Signs

The references in Section 57-1.02 provide the Department's criteria for the design, application, and placement of guide signs. The following provides supplemental information on the use of guide signs in construction zones:

1. Panel Signs. Guide signs are typically warranted in construction zones and on alternative routes where temporary route changes are necessary. For example, the designer may consider using large panel signs or changeable message signs for ramp and lane closures (e.g., “Ramp 2A Closed, Use Ramp 2B,” “Ramp 4A Closed May 9”).

2. Other. Standard route markings, street name signs, special information signs, directional, and detour signs may also be warranted based on the particular work on the facility.

55-5.01(d) Portable Changeable Message Signs

Portable changeable message signs (PCMS) are very effective in communicating the construction zone information to the general public. The use of PCMS will be determined on a project-by-project basis based on road alignment, traffic routing, or other situations requiring advance warning and information.

PCMS can be an effective temporary traffic control device when used appropriately. However, PCMS should not replace any of the signing required by IDOT policy or the *ILMUTCD*. The positive effect of PCMS may be diminished if the device is overused. PCMS should not be employed when they do not add any value to the total traffic control plan.

For all facilities, the following are some typical applications where the PCMS device may be effectively used in construction zones:

- to provide advance notice of upcoming construction;
- where significant traffic queuing and delays are expected;
- where changes in road alignment or surface conditions are present;
- to provide advance notice of ramp, lane, or road closures;
- incident management;
- a change in construction activities (e.g., bridge beam placement, change in alignment);
- to notify or direct motorists to alternative routing; and
- to provide additional information on high-volume, urban projects.

Messages shown on PCMS signs should convey current conditions and as up to date information to the traveling public as possible, especially for incident management. On projects where numerous PCMS signs will be used, the designer should plan for locations and messages to be used on the signs. PCMS messages should be limited to two, with a maximum of three phases. PCMS messages must be carefully planned to be short, understandable, and have “news value” to the motorist. Do not provide information that is redundant to static signing.

PCMS signs are required to be remote programmable. Include provisions for monitoring and changing the messages as necessary to provide current information. Investigate new and emerging technologies for monitoring and changing the messages that can be done by computer in the district, field office, or from a remote location.

See the FHWA *Portable Changeable Message Sign Handbook* and the *ILMUTCD* for specific information on the placement, operation, acceptable messages, and acceptable abbreviations for PCMS.

55-5.01(e) Arrow Boards

In some construction areas, arrow boards are used to supplement conventional traffic control devices. They are used as directional information to assist in merging traffic. The *Highway Standards* and Part 6 of the *ILMUTCD* provide the Department's criteria for the placement, design, and application of arrow boards.

55-5.02 Channelization Devices

The *Highway Standards*, the *Standard Specifications*, and Part 6 of the *ILMUTCD* provide the Department's criteria for the selection, application, and placement of channelization devices. Part 6 of the *ILMUTCD* and the *Highway Standards* also illustrate several typical application diagrams for the use of these devices.

There are numerous types of channelization devices available, each having its specific application in construction operations (e.g., crossovers, runarounds, lane closures, road closures, two-lane, two-way operations). Avoid mixing devices, as it may be confusing to the driver. The following channelization devices are typically used by IDOT in construction zones:

1. Barricades:

    a. Type I Barricades, Type II Barricades, and Vertical Barricades. Type I or Type II barricades or vertical barricades may be used for channelization or to delineate a specific condition. Vertical barricades are not to be used for lane closure tapers or as check barricades.

    b. Type III Barricades. Types III barricades are used for road and lane closures.

    c. Directional Barricades. Directional Barricades may only be used in merging and shifting tapers.

2. Drums. Drums are most commonly used in a linear series to channelize traffic.

3. Cones. Traffic cones are channelization devices used only during daylight hours.

4. Tubular Markers. Also known as flexible delineators, these devices are used to channelize traffic, including the division of opposing lanes of traffic, and to delineate the edge of pavement drop-off, in lieu of drums where space is limited. Tubular markers have less visible area than other devices. Therefore, only use tubular markers where space restrictions do not allow for the use of more visible devices.

5. Vertical Panels. These devices are used to channelize traffic in lieu of drums where space is limited but are not used for the division of opposing lanes of traffic. Vertical panels have less visible area than other devices. Therefore, only use vertical panels where space restrictions do not allow for the use of more visible devices.

6. Temporary Longitudinal Traffic Barriers. Only use temporary longitudinal traffic barriers where positive protection is desired; do not use based on channelization needs. If used, locate the temporary longitudinal traffic barrier behind and in conjunction with other supporting channelization devices, delineators, and/or pavement markings. Section 55-4.02(b) provides information on the application and placement of temporary traffic barrier. Delineators, reflectors, and steady-burning lamps may be required by the *Highway Standards* or *Standard Specifications*.

7. Reflectors. Reflectors provide retro-reflection from headlights and are supplemental devices that may be used to indicate the roadway alignment and the intended path through a construction zone, or to delineate hazards within the construction zone. Reflectors are commonly installed on delineator posts or on channelizing devices such as barrier wall, guardrail, or curbs.

These channelization devices are used extensively in work zones to warn drivers of work activities in or near the traveled way, to protect workers in the area, and to guide drivers and pedestrians safely through and around the work zone. Because each construction project differs, the selection, application, and location of these devices should be determined on a project-by-project basis.

55-5.03 Pavement Markings

The *Highway Standards* and Part 6 of the *ILMUTCD* provide the Department's criteria for the selection, application, and placement of pavement markings in work zones. The *Standard Specifications* provide additional information on pavement markings. Also, review Section 57-3 for applicable information on permanent pavement markings. The following sections provide supplemental guidelines to these sources.

55-5.03(a) Types

The following types of pavement markings are typically used by IDOT in work zones:

1. Temporary Paint. Quick-drying paint is a low-cost, temporary pavement marking that may be used on construction projects. To improve reflectivity, glass beads are required. The Department does not normally allow the use of temporary paint markings on final pavement surfaces.

2. Temporary Raised Pavement Markers. In high-volume locations, the designer may consider using raised temporary pavement markers as a supplemental device to improve delineation through the work zone. Typical locations include lane lines, gore

areas, and other areas where there are changes in the alignment (e.g., lane closures, lane shifts). For lane lines, temporary raised pavement markers are placed mid-point in the gap (i.e., every 40 feet (12 m)). For tapers, gore markings, lane transitions, etc., space the raised markers at 20-ft (6 m) intervals. Temporary raised pavement markers must be removed prior to placing of the next pavement course.

3. Temporary Pavement Marking Tape. Temporary pavement marking tape is an excellent material choice where there are changes to the traffic pattern during construction (e.g., lane shifts, crossover switches). Temporary tape can be easily and quickly installed and, when necessary, easily removed. One disadvantage is that this tape tends to move and/or breakup under heavy traffic volumes. Black tape is also available to temporarily remove lane lines. Wet reflective tape should be considered to improve guidance in long term work zones, poorly lit locations, and high volume areas.

4. Thermoplastic Markings. Thermoplastic markings are generally used in construction zones only if traffic volumes are high and the traffic pattern will be in place for a long duration (e.g., over one year).

5. Temporary Rumble Strips. Temporary rumble strips are used on high-speed, stop conditions to warn motorists of the impending change. The Highway Standards illustrate the typical layout for temporary rumble strips with a lane closure.

55-5.03(b) Application

The application of pavement markings in work zones depends on facility type, project duration, project length, and anticipated traffic volume. The *Standard Specifications* provide the criteria for the use of pavement markings in work zones.

55-5.04 Traffic Signals

55-5.04(a) Location

The use of temporary traffic signals in work zones will be determined on a project-by-project basis. Use the warrant criteria for permanent installations in Section 57-4 of the *BDE Manual* to assist in determining if a temporary traffic signal is warranted. However, use the actual traffic volumes expected during construction for the warrant analysis. Common locations where temporary signal installations may be used include:

- intersections where an existing signal must be maintained,
- existing non-signalized intersections and driveways where construction patterns and volumes now warrant a signal,
- at a temporary haul road or other temporary access points, and

- at crossroad/ramp intersections where there is an increase in traffic or there is a decrease in capacity due to the construction.

Temporary signals are required at long-term, one-lane, two-way traffic operations (e.g., stage bridge construction).

55-5.04(b) Application

Consider the following:

1. Design. Determine the impacts a construction activity has on existing signal operations and attempt to maximize the level-of-service. For example, consider:

   - re-timing or re-phasing the signal to compensate for changes in traffic volume, mix, or patterns and for changes in lane designations or intersection approach geometrics; or

   - physically relocating poles or adjusting signal heads to maintain compliance with the ILMUTCD.

   Section 57-4 and Part 4 of the *ILMUTCD* provide design information on traffic signals.

2. Bridges. The Highway Standards require a temporary signal installation for a bridge lane closure. However, in some situations, the use of a flagger may be more cost effective.

3. Plan Sheets. Show all temporary signal installations on the Stages of Construction and Traffic Control Sheets.

55-5.05 Highway Lighting and Nighttime Construction

55-5.05(a) Types

The designer should maintain existing overhead lighting and, on a case-by-case basis, consider the need for supplemental roadway lighting at potentially hazardous sites within the work area.

Give special consideration to lighting of the traveled way during construction. Construction activities present unexpected road geometry, alignment, and hazards to the motoring public. The designer should maintain existing overhead lighting, and consider the need for supplemental roadway lighting at potentially hazardous sites within the work area.

The following lighting devices are used in construction areas:

- hazard identification beacons,
- steady-burning warning lamps,
- flashing warning lights,
- floodlights, and
- conventional highway lighting.

55-5.05(b) Warrants

Hazard identification beacons and warning lights are typically used to supplement signs, barriers, and channelization devices and emphasize specific signs, hazard areas, and the desired travel path. The warrants for these lighting devices should meet the criteria in Part 6 of the *ILMUTCD* and the *Highway Standards*.

For conventional highway lighting, the need for temporary lighting will be determined on a project-by-project basis. Maintain the existing highway illumination on all projects unless discontinuance of the highway illumination is specifically permitted. Review the warrants presented in Chapter 56 for permanent highway lighting to assist in determining the need for temporary lighting. Consider the use of temporary lighting at construction areas with the following characteristics:

- high-traffic volumes;
- high-traffic speeds;
- heavy queuing or congestion;
- areas with complicated traffic maneuvers (e.g., freeway crossovers, intersections); and
- other areas where hazardous locations may exist.

If existing light standards are removed or shut off during construction, consider providing temporary lighting until permanent light standards are reinstalled. In construction areas, the Department typically uses high-pressure sodium lamps mounted on temporary wood posts. However, the designer may wish to consider using portable lighting as an option. Chapter 56 provides additional information on the design of highway lighting.

55-5.05(c) Lighting for Nighttime Construction

Night construction presents additional challenges to both the contractor and the motoring public. The contractor needs adequate light to perform the work in a safe and efficient manner, and the motoring public requires additional guidance to safely transition the night work zone environment. As well, the motoring public must be protected from glare. Floodlights or other supplemental lighting may be used to illuminate the work area during night operations (e.g., flagger stations, equipment crossings, areas requiring supplemental lighting) and are the responsibility of the Contractor.

Table of Contents
(Continued)

Chapter Fifty-six
HIGHWAY LIGHTING

56-1 GENERAL

The general purpose of roadway lighting is to provide improved safety, security, and aesthetics for the various users of the roadway and associated facilities. Lighting enables the driver to recognize the geometry and condition of the roadway at extended distances, thereby simplifying the driving task at night. This, in turn, increases driver visual comfort and reduces driver fatigue, which contributes to highway safety.

Due to the large and diverse volume of highway lighting information, it would be impractical for this Chapter to present a complete design guide. Instead, the intent is to provide the user with a synopsis of the highway lighting design process and to present Illinois Department of Transportation (IDOT) criteria, policies, and procedures on this issue.

56-1.01 Responsibilities

Each district is responsible for the highway lighting projects within their respective jurisdictions (e.g., information gathering, plan preparation). See Chapter 63 for additional information on plan preparation.

The district will contact the Electrical and Mechanical Unit in the Central Office to design the project lighting. If it is mutually decided to have the project lighting designed by a consultant, a pre-design discussion will be held with the consultant to outline the lighting design parameters for the project.

The consultant lighting design criteria must be submitted and approved by the Electrical and Mechanical Unit before lighting plans are prepared. The district will submit all consultant preliminary and final lighting plans to the Central Office for review and approval by the Electrical and Mechanical Unit. See Chapter 11 for additional information on the local agency highway lighting improvement projects that must be submitted for review.

District 1 is responsible for highway lighting projects within their jurisdiction. This includes both lighting design and plan review for approval.

56-1.02 Definitions

The following definitions are for a common understanding of terms in the lighting field; consult listed references for detailed definitions:

1. Average Initial Illuminance. The average level of horizontal illuminance on the pavement area of a traveled way at the time the lighting system is installed, when luminaires are new

and clean; expressed in average footcandles (lux) for the pavement area. See definition of Illuminance.

2. Average Maintained Horizontal Illuminance (E_{ave}). The average level of horizontal illuminance on the roadway pavement when the output of the lamp and luminaire is diminished by the light loss factor (LLF); expressed in average footcandles (lux) for the pavement area; see definition for LLF.

3. Beacon Lighting. One or two luminaires that will identify the presence of an isolated intersection or potential conflict with other traffic and physical features and will serve as a warning or marker.

4. Bikeway. Any road, street, path, or way that in some manner is specifically designated as being open to bicycle travel, regardless of whether such facilities are designated for the exclusive use of bicycles or are to be shared with other transportation modes.

5. Candela (cd). A measure of the luminous intensity of a light source as seen by the eye (a.k.a., “candle”). For example, because the eye is less sensitive to blue light than to green light, a blue light source must radiate more power in watts (W) than a green light source if the two are to have the same luminous intensity. Most light sources have different luminous intensities when viewed from different directions and so the luminous intensity for a light source may vary with the angle at which it is viewed (1 cd = 1 cp).

6. Candela per Square Meter (cd/m^2). The metric unit of luminance (photometric brightness) that is equal to the uniform luminance of a perfectly diffusing surface emitting or reflecting light at the rate of one lumen per square meter (lm/m^2) or the average luminance of any surface emitting or reflecting light at that rate ($1\ cd/m^2 = 0.2919$ fl).

7. Candlepower (cp). The luminous intensity in a specific direction; expressed in candelas (cd). It is no indication of the total light output (1 cp = 1 cd).

8. Conflict Area. An area of a roadway where the motorist’s special attention is required in order to interpret the functional features and/ or activities of the roadway, in order to make a decision on their driving routine. It is that area which encompasses all of the conflict points.

9. Correlated Color Temperature (CCT). Relates to the color appearance of a white LED. CCT is defined in degrees Kelvin. A warm light is around 2700K, moving to neutral white at around 4000K, and cool white is 5000K or more. Commercially available light sources usually range from 2200 K to 6500 K. CCT values are used by the lighting industry to give specifiers a general indication of the apparent "warmth" or "coolness" of the light emitted by the source.

10. Disability Glare. Glare resulting in reduced visual performance and visibility. It often is accompanied by discomfort. See definitions for Discomfort Glare and Glare.

11. Discomfort Glare. Glare producing discomfort. It does not necessarily interfere with visual performance or visibility; see definition for Glare.

12. <u>Driver</u>. The power supply used to supply voltage and current to an LED system for operation per the luminaire design goals.

13. <u>Equipment Factor (EF)</u>. Light loss factors that are not dependent on time, relate mostly to the characteristics of the specific equipment selected. While some may not be correctable, it is possible that one more may have an important effect upon the light level produced. Care should be taken in selecting equipment appropriate to the service conditions.

14. <u>Footcandle (fc)</u>. The US Customary unit of measurement for illuminance on a surface one square foot (ft^2) in area where there is uniformly distributed a light flux of one lumen (lm) (1 fc = 10.76 lx).

15. <u>Footlambert (fl)</u>. The US Customary unit of luminance (photometric brightness) equal to the uniform luminance of a perfectly diffusing surface emitting or reflecting light at the rate of one lumen per square foot (lm/ft^2) or the average luminance of any surface emitting or reflecting light at that rate (1 fl = 3.426 cd/m^2).

16. <u>Glare</u>. The optical sensation produced by luminance within the visual field that is sufficiently greater than the luminance to which the eyes are adapted and causes annoyance, discomfort, or loss in visual performance and visibility. See definitions for Disability Glare and Discomfort Glare.

17. <u>House Side</u>. The horizontal direction away from the roadway or behind the nadir of the luminaire. See definitions for Street Side and Nadir.

18. <u>Isolux Diagram</u>. A diagram plotted on any appropriate set of coordinates to show all points on a surface where the illuminance is the same, represented by a series of isolux line curves.

19. <u>Illuminance</u>. The density of the luminous flux, lumen (lm), incident on a surface. It is the quotient of the luminous flux by the area of the surface, ft^2 (m^2) when the latter is uniformly illuminated. It is measured in footcandles (lux). Footcandle (fc) and lux (lx) are units of illuminance expressed in lumens (lm) per square foot (ft^2) and lumens per square meter (m^2), respectively.

20. <u>LED Array or Module</u>. An assembly of LED packages (components), or dies on a printed circuit board or substrate, possibly with optical elements and additional thermal, mechanical, and electrical interfaces that are intended to connect to the load side of an LED driver. Power source and ANSI standard base are not incorporated into the device. The device cannot be connected directly to the branch circuit.

21. <u>LED Lamp</u>. An assembly comprised of LED packages (components) or LED arrays (modules), LED driver, ANSI standard base and other optical, thermal, mechanical and electrical components. When integrated with an ANSI standard lamp-holder (socket), the device is intended to connect directly to the branch circuit.

22. <u>LED Light Engine</u>. An integrated assembly comprised of LED packages (components) or LED arrays (modules), LED driver, and other optical, thermal, mechanical and electrical

components. The device is intended to connect directly to the branch circuit through a custom connector compatible with the LED luminaire for which it was designed and does not use an ANSI standard base.

23. Light Emitting Diode (LED). A semiconductor device (p-n junction device) that converts electrical energy directly into incoherent optical radiation when forward biased. Their energy band gaps can span the ultraviolet, visible, or infrared wavelength regions. Also known as a chip, diode or die, it conducts electric current in one direction only. LEDs are typically created from formulations of III-V compounds (combinations of elements from columns III and V in the periodic table).

24. Light Loss Factor (LLF). A factor used in a lighting calculation after a given period of time and under given conditions. It takes into account temperature and voltage variations, dirt accumulation on luminaire surfaces, lamp lumen depreciation, maintenance procedures, equipment and driver variations (LLF = Lamp Lumen Depreciation (LLD) • Luminaire Dirt Depreciation (LDD) • Equipment Factor (EF)).

25. Luminaire Depreciation Factor (LLD). A depreciation factor that indicates the decrease in a light sources's initial lumen output over time. For design calculations, the initial lamp lumen value is reduced by LLD to compensate for the anticipated lumen reduction. See definition for Maintenance Factor.

26. Light Standard (Pole). A vertical structural support provided with the necessary internal attachments for wiring and the external attachments for the bracket arm and luminaire.

27. Longitudinal Roadway Line (LRL). A line along the roadway parallel to the curb or shoulder line. See definition for Transverse Roadway Line.

28. Lumen (lm). The unit of luminous flux. It is equal to the flux through a unit solid angle (steradian), from a uniform point source of one candela (cd), or to the flux on a unit surface, all points of which are at unit distance from a uniform point source of one candela.

29. Luminaire. A complete lighting unit consisting of LED-based light emitting elements and a matched driver together with parts to protect the light emitting elements. The LED driver is the power regulator for the system. The LED based light emitting elements may take the form of LED packages (components), LED arrays (modules), LED Light Engine, or LED lamps. The LED luminaire is intended to distribute light to the target area and to connect directly to a branch circuit.

30. Luminaire Dirt Depreciation Factor (LDD). A depreciation factor that indicates the expected reduction of a luminaire's initial lumen output due to the accumulation of dirt on or within the luminaire over time. See definition for Light Loss Factor.

31. Luminance. The luminous intensity, candela (cd), of any surface in a given direction per unit of projected area, ft^2 (m^2), of the surface as viewed from that direction. It is measured in footlamberts (candelas per square meter).

32. Luminous Efficacy (lm/W). The quotient of the luminous flux (lm) emitted by the total light source power input. It is expressed in terms of lumens per watt (lm/W).

33. Luminous Efficiency (%). The ratio of the total luminous flux emitted by a luminaire to that emitted by the bare light source.

34. Luminous Intensity. See definition of Candela.

35. Lux (lx). The metric unit of illuminance on a surface one square meter (m^2) in area on which there is uniformly distributed light flux of one lumen (lm), or the illuminance produced on a surface where all points are at a distance of one meter (m) from a uniform point source of one candela (cd) (1 lx = 1 lm/m^2 = 0.0929 fc).

36. Mounting Height. The vertical distance between the roadway surface and the center of the light source in the luminaire.

37. Nadir. The vertical axis that passes through the center of the luminaire light source.

38. Overhang. The horizontal distance between a vertical line through the nadir of a luminaire and the edge of traveled way or edge of the area to be illuminated.

39. Partial Lighting. Partial lighting refers to lighting installed at the decision areas of isolated interchanges and intersections whereby it provides visibility of potential conflicts with other traffic and physical features.

40. Pedestrian Crosswalk. An area designated by pavement markings for pedestrians to cross the roadway.

41. p-n Junction. The actual junction of the two types of semiconductor materials used in the construction of the LED die.

42. Setback. The horizontal distance between the face of a light pole and the edge of traveled way.

43. Spacing. The distance in feet (meters) between successive light poles.

44. Street Side. The horizontal direction toward the roadway from the nadir of the luminaire. See definition of House Side.

45. Transverse Roadway Line (TRL). Any line across the roadway that is perpendicular to the curb or shoulder line. See definition of Longitudinal Roadway Line.

46. Uniformity Ratio. Uniformity ratios are calculated as follows: the average-to-minimum ratio is determined by dividing the average luminance or Illuminance of all grid points by the grid point having the lowest value; the maximum-to-minimum ratio (applies to luminance only) is determined by dividing the grid point having the highest luminance value in a calculation grid by the grid point with the lowest luminance value in the calculation grid.

47. Utilization Curve. A plot of the quantity of light falling on the horizontal surface both in front (street side) and behind (house side) the luminaire. It shows only the percent of bare lamp lumens that fall on the horizontal surface and is plotted as a ratio of width of area to mounting height of luminaire.

48. Veiling Luminance. A luminance superimposed on the retinal image which reduces its contrast. It is this veiling effect produced by bright sources or areas in the visual field that results in decreased visual performance and visibility.

56-2 GUIDELINES FOR JUSTIFYING HIGHWAY LIGHTING

Providing lighting for all highway facilities is neither practical nor cost effective. It is generally IDOT's practice only to provide highway lighting where justified based on sound engineering judgment and on the criteria, warrenting guidelines presented in the American Association of State Highway and Transportation Officials (AASHTO) publication *Roadway Lighting Design Guide,* NCHRP Report No. 152 *Warrants for Highway Lighting*, and as set forth herein.

The Department will assess the economic feasibility of lighting on roadway projects and prioritize potential lighting projects. A location that appears to justify lighting does not necessarily obligate the Department to provide funding. Local agencies may provide lighting within their respective jurisdictions provided they find sufficient benefit in the forms of convenience, safety, policing, community promotion, public relations, etc., to participate in an appreciable percentage of the cost of, or wholly finance, the installation, maintenance, operation, and energy needs of the lighting facilities; see Chapter 5.

For a highway lighting facility to be considered for funding by IDOT, the lighting system must be both economically feasible and justified based on the applicable criteria presented in the following sections. The impacts of local conditions (e.g., frequent fog, ice, snow, roadway geometry, ambient lighting, sight distance, signing) should also be considered when analyzing highway lighting needs.

56-2.01 Analyzing Highway Lighting Needs

The AASHTO publication *Roadway Lighting Design Guide* presents an empirical approach to analyzing highway lighting needs with primary application to freeway-type facilities. The principal considerations are vehicular traffic volume, interchange spacing (i.e., an indicator of the relative frequency of vehicular traffic maneuvers), land development and artificial lighting conditions in the area surrounding the freeway, and the night-to-day crash ratio. The effect of these factors on driver visibility should be considered in the lighting needs analysis.

A supplemental approach to analyzing highway lighting needs, based primarily on an analytical evaluation of driver information, is published in NCHRP Report No. 152 *Warrants for Highway Lighting*. This publication has application to both urban-type facilities (e.g., streets, arterials, intersections) and freeway-type facilities (e.g., Interstates). In urban areas where the analyst may find difficulty in applying the AASHTO empirical approach, Report No. 152 offers an alternative approach for analyzing highway lighting needs. Additional information for analyzing partial interchange lighting is available in NCHRP Report No. 256.

56-2.02 Freeways

Use the criteria presented in the following sections when analyzing the lighting needs for State-maintained freeway facilities.

56-2.02(a) Continuous Freeway Lighting

Continuous lighting consists of all mainline and direct connections and provides for complete lighting of all associated interchanges. Lighting may be provided through high-mast facilities, conventional, or both. Continuous freeway lighting (CFL) should be considered under the following conditions:

1. Freeway Volume. On those freeway sections in and near cities where the current average daily traffic (ADT) is 30,000 or more, CFL should be considered.
2. Interchange Spacing. CFL should be considered where three or more successive interchanges are located with an average spacing of 1.5 miles (2.5 km) or less, and adjacent areas outside the right-of-way are substantially urban in character.
3. Land Development/Lighting Conditions. Consider CFL where, for a length of 2 miles (3 km) or more, the freeway passes through a substantially developed suburban or urban area where one or more of the following conditions exist:
    - local traffic operates on a complete street grid having some form of street lighting, parts of which are visible from the freeway;
    - the freeway passes through a series of developments (e.g., residential, commercial, industrial areas, civic areas, colleges, parks, terminals), which include facilities (e.g., roads, streets, parking areas, yards) that are lighted;
    - separate cross streets, with and without connecting ramps, occur with an average spacing of 0.5 miles (1 km) or less, some of which are lighted as part of the local street system; or
    - freeway cross-section elements (e.g., median, shoulders) are substantially reduced in width below desirable criteria in relatively open country.
4. Night-To-Day Crash Ratio. CFL should be considered where the night-to-day ratio of crash rates is at least 2.0 or higher than the statewide average for all unlighted similar sections, and a study indicates that lighting may be expected to result in a significant reduction in the night crash rate. The number of nighttime crashes should also be evaluated.
5. Local Agency Needs. CFL should be considered where the local agency finds sufficient benefit in the forms of convenience, safety, policing, community promotion, public relations, etc., to pay an appreciable percentage of the cost of, or wholly finance, the installation, maintenance, and operation of the lighting facilities. See Chapter 5 for additional information on local agencies' lighting responsibilities.
6. Local Conditions. CFL should be considered where local conditions (e.g., frequent fog, ice, snow, roadway geometry, ambient lighting, sight distances, or frequent advertising signing) could justify lighting.

56-2.02(b) Complete Interchange Lighting

Complete interchange lighting (CIL) consists primarily of lighting the freeway's through traffic lanes within the interchange area, the traffic lanes of all ramps, the acceleration and deceleration lanes, all ramp terminals, and the crossroad between the outermost ramp terminals. Consider CIL at interchanges under the following conditions:

1. Ramp Volume. CIL should be considered where the total current ADT ramp traffic entering and exiting the freeway within the interchange area exceeds 10,000 for urban conditions, 8000 for suburban conditions, or 5000 for rural conditions.
2. Crossroad Volume. Consider CIL where the current ADT on the crossroad exceeds 10,000 for urban conditions, 8000 for suburban conditions, or 5000 for rural conditions.
3. Land Development/Lighting Conditions. Consider CIL at locations on unlighted freeways where existing substantial commercial or industrial development, which is lighted during hours of darkness, is located in the immediate vicinity of the interchange, or where the crossroad approach legs are lighted for 0.5 miles (1 km) or more on each side of the interchange.
4. Night-to-Day Crash Ratio. CIL should be considered where the night-to-day ratio of crash rates within the interchange area is at least 1.5 or higher than the statewide average for all unlighted similar sections, and a study indicates that lighting may be expected to result in a significant reduction in the night crash rate. The number of nighttime crashes should also be evaluated.
5. Local Agency Needs. CIL should be considered where the local agency finds sufficient benefit in the forms of convenience, safety, policing, community promotion, public relations, etc., to pay an appreciable percentage of the cost of, or wholly finance, the installation, maintenance, and operation of the lighting facilities. See Chapter 5 for additional information on lighting responsibilities of local agencies.
6. Continuous Freeway Lighting. Provide CIL at interchanges where continuous freeway lighting is provided; see Section 56-2.02(a).

56-2.02(c) Partial Interchange Lighting

Partial interchange lighting (PIL) generally is a lighting configuration that defines lighting for the decision-making areas. It consists of a few luminaires located in the vicinity of all ramp terminals. The usual practice is to light those general areas where the exit and entrance ramps connect with the through traffic lanes of the freeway and generally those areas where the ramps intersect the crossroad. Consider PIL at interchanges under the following conditions:

1. Ramp Volume. Consider PIL where the total current ADT ramp traffic entering and exiting the freeway within the interchange area exceeds 5000 for urban conditions, 3000 for suburban conditions, or 1000 for rural conditions.

2. Freeway Volume. Consider PIL where the current ADT on the freeway through traffic lanes exceeds 25,000 for urban conditions, 20,000 for suburban conditions, or 10,000 for rural conditions.

3. Night-to-Day Crash Ratio. PIL should be considered where the night-to-day ratio of crash rates within the interchange area is at least 1.25 or higher than the statewide average for all unlighted similar sections, and a study indicates that lighting may be expected to result in a significant reduction in the night crash rate. The number of nighttime crashes should also be evaluated.

4. Local Agency Needs. PIL should be considered where the local agency finds sufficient benefit in the forms of convenience, safety, policing, community promotion, public relations, etc., to pay an appreciable percentage of the cost of, or wholly finance, the installation, maintenance, and operation of the lighting facilities. See Chapter 5 for additional information on local agencies' lighting responsibilities.

5. Continuous Freeway Lighting. Consider PIL where continuous freeway lighting is justified, but not initially installed. See Section 56-2.02(a). The freeway section should be in or near a city where the current ADT is 30,000 or more, or the interchange should be among three or more successive interchanges located with an average spacing of 1.5 miles (2.5 km) or less with adjacent areas outside the right-of-way being substantially urban in character.

6. Complete Interchange Lighting. Where complete interchange lighting is justified, but not initially fully installed, a partial lighting system, which exceeds the normal partial installation in number of lighting units, is considered to be justified; see Section 56-2.02(b).

NCHRP Report No. 256 *Partial Lighting of Interchanges* provides additional information on analyzing the need for partial interchange lighting.

56-2.02(d) Crossroad Ramp Terminal Lighting

Lighting of the crossroad ramp terminal should be considered regardless of traffic volume where the crossroad ramp terminal design of freeway interchanges incorporates raised channelizing or divisional islands, where there is poor sight distance, or roadway alignment constitutes curvature or severe slopes.

56-2.03 Streets and Highways Other Than Freeways

Urban and rural conditions, traffic volumes (both vehicular and pedestrian), intersections, turning movements, signalization, channelization, and varying geometrics are factors that should be considered when determining the lighting needs of streets and highways other than freeways. Consider the following when assessing the lighting needs of such State-maintained facilities. NCHRP Report No. 152 *Warrants for Highway Lighting* provides additional information analyzing the need for lighting.

1. <u>Facilities with Raised Medians</u>. Consider highway lighting along sections of State-maintained facilities that have raised medians.

2. <u>Major Urban Arterials</u>. Consider highway lighting along all major arterials that are located in urban areas.

3. <u>Intersections</u>. Consider intersection lighting at rural intersections that meet any one of the following conditions:

   - there are 2.4 or more crashes per million vehicles in each of three consecutive years;
   - there are 2.0 or more crashes per million vehicles per year and 4.0 or more crashes per year in each of three consecutive years;
   - there are 3.0 or more crashes per million vehicles per year and 7.0 or more crashes per year in each of two consecutive years;
   - the intersection is signalized and in the past year the day-to-night crash ratio is at least 1.25 or higher than the Statewide average for similar signalized intersections;
   - substantial nighttime pedestrian volume exists;
   - less than desirable alignment exists on any of the intersection approaches;
   - intersection approach roadway leg has less than the required Safe Sight Stopping Distance (SSSD) at the intersection;
   - the intersection is an unusual type requiring complex turning maneuvers;
   - commercial development exists in the vicinity, which causes high nighttime traffic peaks;
   - distracting illumination exists from adjacent land development; and/or
   - there exists recurrent fog or industrial smog in the area.

   Isolated intersections located within the fringe of corporate limits that are suburban or rural in character may be illuminated at the State's expense provided they meet the above criteria. Every effort should be made to have the local agency accept ownership of the system after installation and assume all operational and maintenance costs. See Chapter 5 for additional information on lighting responsibilities of local agencies.

4. <u>High-Conflict Locations</u>. Consider lighting along roadway sections with high vehicle-to-vehicle interactions (e.g., sections with numerous driveways, where driveway separation is less than one SSSD, significant commercial or residential development, driveways with larger percentage of turning traffic, large complex intersection with more than one turning

lane in one direction, intersection with raised medians, high percentage of trucks). Lighting generally improves traffic safety and efficiency at such locations.

5. Complex Roadway Geometry. Consider lighting at spot locations in rural areas where the driver is required to pass through a roadway section with complex or substandard geometry.

6. Night-to-Day Crash Ratio. Lighting should be considered at locations or sections of streets and highways where the night-to-day ratio of crash rates is higher than the statewide average for similar locations, and a study indicates that lighting may be expected to significantly reduce the night crash rate.

7. Local Agency Needs. Lighting should be considered where the local agency finds sufficient benefit in the forms of convenience, safety, policing, community promotion, public relations, etc., to pay an appreciable percentage of the cost of, or wholly finance, the installation, maintenance, and operation of the lighting facilities. See Chapter 5 for additional information on lighting responsibilities of local agencies.

8. Pedestrian Sidewalk. Consider lighting the sidewalk along the roadway section. Properly designed highway lighting may provide adequate pedestrian lighting without the need for supplemental or separate sidewalk lighting.

56-2.04 Rest Areas

Provide lighting at rest areas that offer complete rest facilities (e.g., comfort station, information kiosk, picnic areas). Illuminate all areas within the facility that have pedestrian activities (e.g., parking areas, immediate area of building). Provide lighting at rest area ramps, gore areas, other decision points, and traffic conflict areas.

56-2.05 Weigh Stations

Provide lighting and overheight detectors at all permanent truck weigh stations. Illuminate the weighing area, parking areas, speed change lanes, ramps, and gore areas.

56-2.06 Bridge Structures and Underpasses

Because of their typical configuration and length-to-height ratio, underpasses generally have good daylight penetration and do not require supplemental daytime lighting. Underpass lighting generally is installed to enhance driver visibility after daylight hours. When the underpass length-to-height ratio approaches 10:1, it usually is necessary to analyze specific geometry and roadway conditions, including vehicular and pedestrian activity, to determine the need for supplemental daytime lighting. For more information on daytime lighting see the *Recommended Practice: Lighting Roadway and Parking Facilities, RP-8* produced by the American National Standards Institute (ANSI) and by the Illuminating Engineering Society (IES).

On highways that are not continuously lighted, consider providing underpass lighting where frequent nighttime pedestrian traffic exists through the underpass or where unusual or critical geometry exists within or on an approach to the underpass.

Provide underpass lighting on all highways that are continuously lighted. Favorable positioning of conventional highway luminaires adjacent to a relatively short underpass often can provide adequate illumination within the underpass without a need to provide supplemental lighting. If this action is considered, ensure that shadows cast by the conventional luminaires do not become a visibility problem within the underpass.

56-2.07 Tunnels

Provide lighting for tunnels to create adequate roadway visibility necessary for safe and efficient traffic operation. Daytime tunnel lighting is recommended when driver visibility requirements are not satisfied without the use of a daytime lighting system to supplement natural daylight. Visibility requirements vary considerably with such items as:

- portal to portal tunnel length (i.e., short or long);
- tunnel portal design;
- geometry of tunnel and its approaches;
- vehicular and pedestrian traffic characteristics;
- treatment of pavement, portal, interior, and environmental reflective surfaces;
- climate and orientation of tunnel; and
- visibility objectives to provide for safe and efficient tunnel operation.

The AASHTO publication *Roadway Lighting Design Guide* provides tunnel lighting guidelines. For additional tunnel lighting requirements, consult the *ANSI/IES RP-8*.

56-2.08 Roundabouts

Provide lighting at roundabouts, including rural roundabouts, as recommended by the AASHTO publication *Roadway Lighting Design Guide*. Additional lighting requirements are outlined in *ANSI/IES RP-8*.

Lighting should be located in consideration of the following:

- Lights should be located so that they provide good illumination on the approach nose of splitter islands, at all conflict areas where traffic is entering the circulating stream, and at all places where the traffic streams separate to exit the roundabout.
- Particular attention should be given to the lighting of the pedestrian crossing areas.
- Avoid placing light poles within splitter islands, on the central island, or on the right-hand perimeter immediately downstream of an exit point.

56-2.09 Other Locations

Provide lighting for pedestrian crosswalks and all pedestrian underpass and pedestrian tunnel facilities. In addition, lighting for the following facilities will be considered on a case-by-case basis:

- commuter park-and-ride lots,
- bike paths,
- pedestrian walkways, and
- pedestrian overpasses.

56-2.10 Highway Sign Illumination

Overhead highway signs fitted with long-lasting, highly reflective sheeting may be adequately illuminated by vehicular headlights. Signs with non-reflective lower grade sheeting must be externally illuminated by a direct light source. Roadway lighting adjacent to signs does not provide adequate intensity to meet the requirements for external sign illumination.

Provide sign illumination where background (roadway and/or non-roadway) lighting obscures the legend of the sign or the sign is not adequately visible by vehicular headlights. In urban areas with high-ambient lighting, the external illumination of overhead sign panels generally is warranted.

External lighting for all other overhead sign panels along lighted highway facilities will be illuminated on a case-by-case basis. See *ANSI/*IES RP-8 for additional information on when to light signs. Also, apply the requirements of this manual when designing lighting for sign panels.

56-2.11 Navigation and Obstruction Lighting

Highway structures over navigable waterways require waterway obstruction warning luminaires in accordance with US Coast Guard requirements. The district or Electrical and Mechanical Unit in the Central Office will coordinate with the Coast Guard. Design navigable waterway obstruction lighting in accordance with the US Coast Guard Bridge Administration Manual COMDTINST M16590.5C, *Bridge Lighting and Other Signals* and the *Code of Federal Regulations,* 33 CFR 118.

Any need for aviation obstruction warning luminaires on highway structures will be coordinated with the Federal Aviation Administration (FAA) by the district or Electrical and Mechanical Unit in the Central Office. For information on lighting for navigable airspace obstructions, consult the FAA Advisory Circular AC 70/74602-1L Obstruction Marking and Lighting.

56-2.12 Transition Lighting

Consider transition lighting, to allow sufficient time for eye adaptation, for traffic lanes emerging from a lighted area with very high lighting levels. For additional information, consult the ANSI/IES RP-8.

56-2.13 Roadway Reconstruction

Existing highway lighting shall be evaluated for upgrade to meet current Department highway lighting criteria on roadway reconstruction projects. Contact the Electrical and Mechanical Unit in the Central Office for additional information.

56-2.14 Municipal and Residential Street Lighting

IDOT will not participate in highway lighting on facilities located within an incorporated area except as described in Sections 56-2.02, 56-2.03, and Chapter 5.

56-2.15 Ornamental Lighting

At the request of a local agency, ornamental lighting may be permitted by the Department on a State-maintained facility if the minimum requirements of the Department and ANSI/IES RP-8 are met and the local agency is 100% responsible for construction funding, ownership, electrical energy, and maintenance of such lighting both during and after construction. Special lighting requirements regarding light trespass and glare must also be satisfied. Contact the Electrical and Mechanical Unit in the Central Office for additional information on ornamental lighting requirements.

56-2.16 Lighting for Nighttime Construction

Ensure lighting for nighttime construction activities, either mobile or stationary, is provided and included in all plans. Ensure the lighting design does not impair motorist visibility and meets ANSI/IES RP-8 glare and light trespass requirements. This should be done to help provide for the overall on-site safety of the workers and by making them more visible to motorists where construction is adjacent to traffic. Nighttime lighting also benefits the quality of the construction work. For more information on work zones see Chapter 13.

56-2.17 Temporary Lighting

Consider temporary highway lighting in construction zones requiring complex traffic maneuvers (e.g., crossovers) and where existing lighting will be removed, relocated, or altered by construction operations. Temporary roadway lighting shall meet ANSI/IENSNA RP-8 requirements for lighting, glare, and light trespass. Also, ensure the temporary roadway lighting is designed to meet roadside safety issues (e.g., clear zone setback) in accordance with Chapter 38.

56-2.18 Replacement Lighting

Consider a new roadway lighting design where existing lighting facilities are being replaced on a complete lighting circuit basis or in its entirety. With the exception of spot replacements, large portions of lighting facilities replaced through maintenance or construction operations shall be reevaluated from a lighting design standpoint to ensure lighting facilities are upgraded to meet current Department lighting criteria, including ANSI/IES RP-8 requirements.

This is especially important with older facilities that were installed with a different light source than is currently used, wiring methods, etc. Contact the Electrical and Mechanical Unit in the Central Office for additional information on the replacement of existing lighting facilities.

56-3 MATERIALS AND EQUIPMENT

Because luminaires, electrical devices, and support structures change rapidly with new developments, this section presents an overview rather than an absolute requirement for lighting equipment and materials. The *Standard Specifications, Supplemental Specifications and Recurring Special Provisions, Highway Standards*, and Bureau of Design and Environment (BDE) Special Provisions provide additional details on lighting equipment and materials that are required for IDOT projects. Figure 56-3.A illustrates the various components of a typical highway lighting structure.

56-3.01 Foundations and Mounting

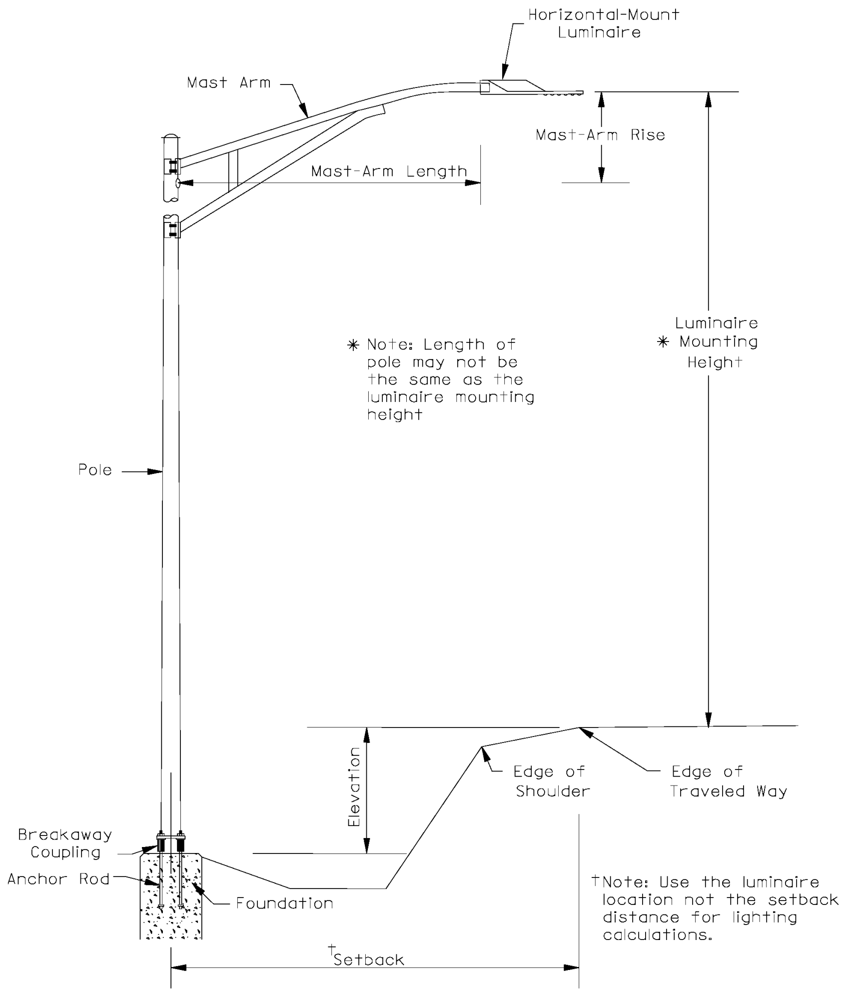
In conventional highway lighting applications, luminaire assemblies generally are attached to davit or mast-arm poles mounted along the roadway either on ground foundations or atop bridge parapets or barriers. Foundations for conventional light poles may be either concrete or steel helix foundations and are constructed from typical designs. However, concrete foundations for light towers in high-mast lighting applications require special designs and soil analyses to determine adequate foundation depth. Depending on factors such as roadside location, most conventional light poles will be mounted on frangible devices (breakaway supports). Attach light poles that are mounted atop parapets and barriers or behind guardrail to foundations with high-strength, non-breakaway bolts. Use special vibration isolating materials to mount light poles on bridges. Where feasible at signalized intersections, a roadway luminaire may be mounted on a combination mast-arm assembly and pole using approved combination structures.

Luminaires installed in underpasses and tunnels are either attached to the wall or suspended from vibration-dampening pendants at the edge of the travel lanes. Light sources that are used to externally illuminate overhead sign panels typically are fastened to the truss or cantilever support structure.

Waterway and aviation obstruction warning luminaires are attached to the structures representing the hazard. Ensure the location and installation of warning luminaires for waterway and aviation also meet the requirements of Section 56-2.11.

56-3.02 Pole Bases

Light poles may be attached to one of several types of bases (e.g., transformer base, breakaway couplings, anchor base). Selection is governed by project need and material suitability. A very important distinguishing characteristic of the pole base is whether it is classified by the Federal Highway Administration (FHWA) as an acceptable breakaway support. If the pole represents a roadside hazard, it shall be mounted on a breakaway support. Section 56-5.05 provides some design guidance on this issue (see Chapter 38 for additional guidance). The following briefly describes a typical pole configuration used by the Department:



Note: Single mast-arm luminaire shown for illustrative purposes. For other luminaire mounting types, see the Highway Standards and Standard Specifications.

TYPICAL HIGHWAY LIGHTING STRUCTURE

Figure 56-3.A

1. Breakaway Coupling. Breakaway couplings are connectors or sleeves that are designed to shear when the pole is hit by an errant vehicle. The bottom of each coupling (device) is threaded onto a foundation anchor rod, and the pole is attached to the top of the coupling. Four couplings are used with each pole. All wiring at the pole base will have simultaneous quick disconnect fuse holders.

2. Frangible Transformer Base. The frangible transformer base consists of a cast aluminum apron between the foundation and the base of the pole. It is designed to deform and break away when hit by an errant vehicle. All wiring inside the base will have quick disconnect fuse holders.

3. Anchor Base. The pole is mounted on leveling nuts and the bolts attach directly to the foundation. The anchor base is not classified by the Department as a breakaway support.

56-3.03 Poles

Light poles for conventional highway lighting applications support luminaire mounting heights ranging from approximately 30 ft to 50 ft (9.1 m to 15.2 m). Light towers for high-mast lighting applications generally range from 80 ft to 160 ft (24.4 m to 48.8 m) and are designed in multiple sections. Ornamental light poles used for local streets generally range in height from 10 ft to 30 ft (3.0 m to 9.1 m).

56-3.04 Arms

Depending on the particular application, luminaires may be mounted on single and/or double mast arms or davit arms at the top of the pole. The use of an arm places the light source closer to the traveled way while allowing the pole to be located further from the edge of the traveled way. Arms longer than 15 ft (4.5 m) require special approval.

56-3.05 Luminaires

Luminaires consist of a light source or optical assembly inside a housing with electrical components to start and regulate the light source. The following sections provide some general information on the basic components of the luminaire.

56-3.05(a) Light Sources

Light emitting diodes (LEDs) shall be used for roadway lighting unless permission is obtained from the Department for a different light source. The local agency shall request this permission from the district in writing and ensures the request demonstrates the ability of the alternative light source to light the roadway to the requirements of this Chapter without additional luminaires and increased cost.

56-3.05(b) Optical System

The following provides a general discussion on the optical system components of LED luminaires:

1. Light Source. LED is the light source used in highway applications and it is defined in Section 56-1.02. The Department uses a correlated color temperature (CCT) for LED roadway lighting of not more than 4,000 degrees Kelvin.

2. LED Package. An assembly of one or more LED dies that includes wire bond or other type of electrical connections, possibly with an optical element and thermal, mechanical, and electrical interfaces. Power source and ANSI standardized base are not incorporated into the device. The device cannot be connected directly to the branch circuit.

3. Lens. The lens is made of a transparent material, usually UV stabilized plastic or glass, which covers and protects the LED package. The lens controls and directs the light emitted.

56-3.05(c) Driver

Luminaires used in highway lighting applications have a built-in driver. The driver is a device comprised of a power source and LED control circuitry designed to operate an LED light source by regulating power to the LED, thereby controlling the brightness or intensity of the LED. However, the driver system converts the supply voltage to a dc voltage and provides a dc output current to the LED while maintaining the current at a constant level/output over variable supply voltage ranges.

56-3.05(d) Housing

The housing integrates the LED optical assembly, driver, and hardware to connect to the power supply, heat management elements, and other associated devices into a self-contained unit. The housing is designed to seal the unit against the entry of dust, moisture, and insects. Housings are generally designed to accommodate access for maintenance, but this access is typically not for field adjustment (i.e., light direction and distribution). The housing is generally cast aluminum or stainless steel.

56-3.06 Other Materials and Equipment

There are numerous other materials and equipment that are used in a highway lighting system (e.g., quick disconnect fuse holders, controllers, photocells, surge arresters, raceways, ground rods, cabling, transformers, conduit, hand holes, pull boxes). The use and specification of these ancillary items will depend on the highway lighting application and may vary on a project-by-project basis.

56-3.07 Electric Service

Electric services shall be a low voltage (0-600V) grounded system delivered to the roadway right-of-way. The service and equipment shall be grounded in accordance with the NEC. The service transformer, typically supplied by the electric utility shall deliver secondary voltages of single-phase 120/240V or 240/480V and, with Department approval, shall be 3-phase voltages of 120/208V or 277/480V.

56-4 LIGHTING PROJECTS

The following provides a general discussion with regard to the preparation of a roadway lighting design in the State (excluding District 1).

1. Responsibilities. Each District is responsible for highway lighting projects installed under contract in their respective jurisdictions. Typically, the District will initiate a lighting project by submitting the project scope, timeframe, warrants, and all supporting information to the Electrical and Mechanical Unit in the Central Office for review. See Section 56-4.02 for a list of required supporting information.

2. Approvals. The Consultant's lighting design criteria must be submitted and approved before lighting plans are prepared. The Consultant's preliminary and final lighting plans shall be submitted to the Electrical and Mechanical Unit for review and approval.

3. Plan Preparation. The District shall provide to the Consultant all information necessary to develop the lighting plan sheets showing the overall project with roadway and area classifications. Base plan information showing roadway geometry shall include: pavement, shoulder, and median widths at frequent intervals; roadway stationing; locations of roadway features; all utilities; the height and location of all overhead conflicts; and the location of existing and proposed utility service points.

4. Final Design Package. The final design package shall include pole locations, luminaire locations with orientation, electrical distribution, wiring diagrams, voltage-drop calculations, luminaire performance tables, lighting calculations with roadway classifications, and special provisions.

Alternatively, and with approval from the Central Office, the District may request the Electrical and Mechanical Unit to prepare the design package.

56-4.01 Determine Classifications and Justify Need

Determine the roadway classification, pedestrian area classification, pavement classification, and environmental conditions. A mutual determination will be made between the district and the Electrical and Mechanical Unit in the Central Office regarding the classification of any interchange or freeways as urban, suburban, or rural. The district will initiate a lighting project by submitting the warrants and all supporting data to the Central Office for review. Highway lighting projects that are justified may be incorporated into the annual improvements program.

56-4.02 Assemble Information

The district assembles all necessary information needed for a lighting project and forwards it to the Electrical and Mechanical Unit in the Central Office or the lighting design consultant. This may include:

- identifying current lighting design policies, preferences, and procedures;

- gathering all necessary roadway and bridge plan and profile sheets and any special detail sheets (e.g., as-built plans for existing lighting, as applicable);
- determining existing and proposed utility locations;
- discussing special considerations with the highway or bridge designer;
- determining existing and proposed roadway cross-sections, plan and profile, construction staging, and right-of-way lines;
- conducting field reviews with photographic inventory;
- establishing the need for temporary lighting, as applicable;
- contacting local officials for local projects;
- contacting and coordinating with the local electrical utility for electric service;
- determining existing and proposed signalized intersections with detailed information on any combination traffic signal and lighting structures;
- noting areas sensitive to light trespass (e.g., soybean fields);
- determining the location of advance warning beacons, changeable message boards, or other devices that may be affected by roadway lighting;
- contacting the FAA for any possible height restrictions on lighting facilities due to airports in the vicinity;
- identifying the need for other lighting needs (e.g., aviation and/or waterway obstruction warning luminaires, overhead sign lighting, bike paths); and
- noting any other special considerations that may affect the lighting design (i.e., location of light poles due to drainage).

56-4.03 Prepare Preliminary Plans

The district will submit to the Electrical and Mechanical Unit in the Central Office or the lighting design consultant the plan sheets showing the overall project with roadway and area classifications including other pertinent information to justify chosen classification and criteria. Ensure that the plans include:

- information gathered in Section 56-4.02 as appropriate;
- stationing at appropriate 100 ft (30 m) intervals and stationing of noses and tangent points of ramps which are formed by the roadway proper and not by the shoulder;

- pavement, shoulder, and median widths at frequent intervals;
- all roadway features which may affect the stationing or setback of poles (e.g., guardrail, barrier median, barrier curb, signs exceeding 50 ft^2 (4.5 m^2), driveways, culverts, railroads, pipelines);
- the approximate height and location of any power and telephone lines along and over the roadway;
- the location of power poles from which service may be obtained;
- if combination signals and lighting are present or proposed, the stationing and offset of the traffic signal poles, the arm length and mounting height of luminaires, the type and wattage of luminaire, and the location of the power pole and control cabinet; and
- lighting calculations in an electronic format with all the supporting data.

Electronic plans are preferred over paper copies. Show existing and proposed roadway geometry and basic plan information as noted above. Also, furnish as-built plans of existing lighting facilities, as applicable. In addition, copies of any available sample calculations, plans, notes, schedules, and pay quantities may provide further clarification for the lighting designer.

56-4.04 Electrical and Mechanical Unit Central Office Design Package and Review

The district will communicate the project scope, configuration details, and timeframe for a lighting design to the Electrical and Mechanical Unit in the Central Office. Upon receipt of the request from the district, the Electrical and Mechanical Unit will design the lighting for the project and send the design package to the district. The design package will include the location of poles and luminaires, the electrical distribution and control system design, and associated special provisions. The Electrical and Mechanical Unit also will furnish wiring diagrams and drawings of equipment, foundations, and electrical details, as applicable. The plans and special provisions will be returned to the district for CADD drafting and completion as final contract documents.

When a consultant is used by the district to complete the design, the preliminary and final plans will be submitted to the Electrical and Mechanical Unit in the Central Office for review and approval.

56-4.05 Field Review

Prior to finalizing plans, the district or the lighting design consultant will conduct a field review to determine if pole and luminaire locations will interfere with existing or proposed underground, at-grade, and aerial utilities and/or roadway structures. The district will notify the Electrical and Mechanical Unit in the Central Office of any conflict that would cause modification to the design. For high-mast lighting designs, ensure that borings are taken for soil analyses to ascertain the correct foundation depth at each tower location.

56-4.06 Final Plan Preparation/Contract Award

The district and/or the lighting design consultant will prepare the final plans, specifications, and estimates and submit them to the BDE for processing and contract award. See Chapter 63 for information on plan preparation and Chapter 66 for information on contract processing.

56-5 LIGHTING DESIGN

When designing a highway lighting system, there are numerous factors to consider. This Section presents design considerations commonly encountered in highway lighting designs and presents IDOT's criteria, policies, and procedures on these issues. Figure 56-5.A presents typical highway lighting design parameters used by the Department.

TYPICAL IDOT HIGHWAY LIGHTING DESIGN PARAMETERS[1, 3]	
LLF (i.e., EF • LLD • LDD)	0.70
Percent of Voltage Drop Allowed	20% maximum [2]
Typical Parameters for Conventional Lighting (Interstate, Expressway, or Rural State Routes)	Aluminum or Steel Pole; Davit or Mast-Arm; Single or Twin-Arm Mounting; 45 ft (13.7 m) Mounting Height; LED Horizontal Mount Luminaire; Breakaway Supports where Justified.
Typical Pavement Classification	Class R3
Typical IES Luminaire Classification for Conventional Highway Lighting	Full Cutoff (FC).
Typical Luminaire Pole Arrangement	Staggered, Opposite, or Median Mounted.

1. Values or equipment other than what is shown in the table must be approved by the Electrical and Mechanical Unit.
2. For high mast towers with motorized lowering devices shall not exceed 5%.
3. Ensure all lighting designs conform to current recommended values in ANSI/IES/RP-8 for the selected roadway and pedestrian activity areas.

TYPICAL IDOT HIGHWAY LIGHTING DESIGN PARAMETERS

Figure 56-5.A

56-5.01 Methodologies

The Illuminating Engineering Society (IES) has been a leader in developing illuminance and luminance methodologies for the design of roadway lighting. These methodologies have been documented and acceptable results are provided in the ANSI/IES RP-8. The levels defined in ANSI/IES RP-8 are minimum acceptable levels and the design approach shall achieve, but not significantly exceed these levels. Ensure calculated lighting levels do not exceed the levels for the next higher roadway and pedestrian classification.

In most cases it is a good practice, and will be required in consultant submittals, to consider both illuminance and luminance design. Luminance shall56 be used for design and illuminance will be used for field verification. Illuminance shall be used where luminance calculations are not applicable (see ANSI/IES RP-8 for applicability of each method). Both of these methodologies require the designer to consider veiling luminance and limit the ratio to the values listed in Figures 56-5.B and 56-5.C. The following sections briefly describe each of the available design methodologies.

56-5.01(a) Illuminance

The illuminance methodology is the oldest and simplest to employ. The illuminance methodology is used to determine the combined amount of luminous flux reaching critical pavement locations from contributing luminaires (i.e., a measure of light quantity) and to calculate how uniformly the luminaires' combined luminous flux is horizontally distributed over the pavement surface (i.e., a measure of light quality).

An inherent disadvantage of the illuminance methodology was that it only accounts for incident light and does not assess the effect on visibility due to reflected light from an object or surface. This sensation is known as "brightness". Objects are distinguished by contrast from their difference in brightness. To address some visibility concerns, "Veiling Luminance Ratio" was added to the illuminance methodology. Illuminance designs consider the average maintained horizontal illumination (E_{avg}), or quantity of light, and the uniformity ratio, or quality of light. See Section 56-1.02 for the definition of uniformity ratio (E_{avg}/E_{min}).

56-5.01(b) Luminance

The luminance methodology is used to simulate driver visibility by assessing the quantity and quality of light reflected by the pavement surface to the motorist's eye from contributing luminaires. Assumptions are made regarding the spatial positioning of the driver's eye, and luminance values are calculated at grid points over the pavement surface.

Roadway Facility Classification④	Area Classification	Pedestrian Activity Area ③	Average Maintained① ⑤ Horizontal Illuminance (E_{avg}) Footcandle (Lux) Pavement Classification ④			Uniformity Ratio (E_{avg}/E_{min})	Veiling Luminance Ratio (L_{vmax}/L_{avg})

IDOT LUMINANCE DESIGN CRITERIA

Figure 56-5.C

In theory, luminance is a good measure of visibility; however, the results of using the luminance methodology in highway lighting applications are greatly affected by the reflectance characteristics of the pavement surface, both now and in the future. Factors affecting pavement reflectivity include initial surface type, pavement deterioration, resurfacing material type, assumptions regarding weather conditions, etc. It is difficult to predict or control these factors. Luminance design parameters include average maintained luminance (L_{avg}), minimum luminance (L_{min}), maximum luminance (L_{max}), maximum veiling luminance (L_{Vmax}), and ratios of L_{avg} to L_{min}, L_{max} to L_{min}, and L_v to L_{avg}.

56-5.02 Computerized Design

The highway lighting design process is an iterative process that is quite effectively implemented by computer. If criteria are not initially satisfied, it will be necessary to change design parameters (e.g., pole spacing, mounting height, luminaire wattage, luminaire distribution) until an acceptable alternative is found. This process will be repeated until the design is optimized to meet the selected criteria.

For computerized designs prepared by outside consultants, the consultant will provide a complete lighting design file in electronic format. The level of precision for calculations shall be in accordance with ANSI/IES TM-34. All lighting calculations shall be performed in Lighting Analysts, AGi32 lighting design software.

56-5.03 Design Process

The following briefly describes the processes used in any highway lighting design:

1. Select Lighting Equipment. Select the lighting equipment and associated design parameters that will be used for the project. This will include items such as luminaire mounting height, pole setback, light source, lamp wattage, etc. It will be necessary to make some initial assumptions during preliminary design. Design parameters then may be iteratively changed to meet the highway lighting criteria.

2. Select Luminaire Arrangement. Select an appropriate luminaire arrangement for the project. This will depend on local site conditions and engineering judgment. Alternative arrangements may need to be considered. The lighting design software will create the required output based on the input criteria.

3. Luminaire Spacing. Typically, luminaire spacing required to satisfy the project specific design criteria will be determined by the lighting design software.

4. Check Uniformity. Once luminaire spacing has been determined, check the uniformity of light distribution and compare this value to the lighting criteria selected in Step #1. Adjust design parameters and recalculate as necessary to meet criteria.

5. Select Optimum Design. Because computerized design is relatively quick and easy, modify key design parameters (e.g., luminaire photometry, location, mounting height) to develop and test several alternative designs. It generally is not good engineering practice to consider only one design, even if found to satisfy the lighting criteria. There often are several alternatives that will work. Optimize and select the most cost-effective and if possible, minimum maintenance design.

Typically, do not terminate a lighting project just before an intersection. Consider motorist decision points and potential pedestrian interaction when evaluating how far to extend the limits of lighting.

56-5.04 Design Considerations

When selecting design criteria for a lighting project, it is necessary to determine classifications for the roadway facility, the area the roadway traverses, and the pavement type that best fit the descriptions contained in ANSI/IES RP-8 and the AASHTO *Roadway Lighting Design Guide*. Do not use the classifications of other publications. The following sections discuss these classifications for the purpose of highway lighting design only.

56-5.04(a) Roadway Classification

Use the following definitions to classify roadway facilities for IDOT highway lighting projects:

1. Freeway. A divided major highway with full control of access and with no crossings at grade.
2. Expressway. A divided major arterial highway for through traffic with full or partial control of access and generally with interchanges at major crossroads. Expressways for non-commercial traffic within parks and park-like areas generally are known as parkways.
3. Major. The part of the roadway system that serves as the principle network for through traffic flow. The routes connect areas of principle traffic generation and important rural highways entering the city.
4. Collector. The distributor and collector roadways serving traffic between major and local roadways. These are roadways used mainly for traffic movements within residential, commercial, and industrial areas.
5. Local. Roadways used primarily for direct access to residential, commercial, industrial, or other abutting property. They do not include roadways carrying through traffic. Long local roadways generally will be divided into short sections by the collector roadway system.
6. Alley. A narrow public way within a block, generally used for vehicular access to the rear of abutting properties.
7. Sidewalk. Paved or otherwise improved areas for pedestrian use, located within public street right-of-way, which also contains roadways for vehicular traffic.
8. Pedestrian Way. Public sidewalks for pedestrian traffic generally not within rights-of-way for vehicular traffic roadways. Included are skywalks (pedestrian overpasses), subwalks (pedestrian tunnels), walkways giving access to park or block interiors, and crossings near centers of long blocks.
9. Bicycle Lane. Any facility that explicitly provides for bicycle travel.

56-5.04(b) Area Classification

For IDOT lighting projects, use the following definitions to classify the area in which the roadway traverses. These definitions match the AASHTO *Roadway Lighting Design Guide*. These definitions do not match the ANSI/IES RP-8 classifications, which are based on pedestrian activity areas.

1. Commercial. That portion of a municipality in a business development where ordinarily there are large numbers of pedestrians and a heavy demand for parking space during periods of peak traffic or a sustained high pedestrian volume and a continuously heavy demand for off-street parking space during business hours. This definition applies to densely developed business areas outside of, as well as those that are within, the central part of a municipality.

2. Intermediate. That portion of a municipality that is outside of a downtown area but generally within the zone of influence of a business or industrial development, often characterized by a moderately heavy nighttime pedestrian volume and a somewhat lower parking turnover than is found in a commercial area. This definition includes densely developed apartment areas, hospitals, public libraries, and neighborhood recreational centers.

3. Residential. A residential development or mixture of residential and commercial establishments, characterized by few pedestrians and a low parking demand or turnover at night. This definition includes areas with single-family homes, townhouses, and/or small apartments. Regional parks, cemeteries, and vacant lands are also included.

56-5.04(c) Pedestrian Activity Classification

The magnitude of pedestrian volume is nearly always related to the abutting land use. Three classifications of pedestrian activity areas during nighttime hours and the types of land use with which they are typically associated are given below. These definitions match the ANSI/IES RP-8 classifications, which are based on pedestrian activity, not the AASHTO *Roadway Lighting Design Guide*:

1. High Pedestrian Activity Areas. Commercial areas in urban environments can have high nighttime pedestrian activity. It is important to provide lighting systems that will increase the visibility of pedestrians. Since the visual environment is much more cluttered, and a high probability for detection of pedestrians is required, the use of both horizontal and vertical illuminances is recommended for design.

2. Medium Pedestrian Activity Areas. Intermediate areas have moderate nighttime pedestrian activities. These areas might typically be those near community facilities such as libraries and recreation centers. Safety for the pedestrian and providing guidance to primary travel ways are key elements in the design of a lighting system in these areas.

3. Low Pedestrian Activity Areas. The lighting system in residential areas can allow both driver and pedestrian to visually orient in the environment, detect obstacles, identify other pedestrians, read street signs, and recognize landmarks.

Consult ANSI/IES RP-8 for the method used in taking pedestrian counts and the associated pedestrian count that corresponds with these conflict areas.

56-5.04(d) Pavement Classification

The following definitions classify the pavement type of the roadway facility. These pavement classifications have mean luminance coefficient Q_0. For IDOT lighting projects, the designer should use a reflectance value for slightly specular asphalt (R3) to be conservative and account for a current or future asphalt overlay of the roadway.

1. Class R1 and (Q_0 = 0.10). Class R1 pavement has a mostly diffuse mode of reflectance. R1 pavements include portland cement concrete road surfaces and asphalt road surfaces with a minimum of 12% of the aggregates composed of artificial brightener (e.g., Synopal) aggregates (e.g., labradorite, quartzite).

2. Class R2 and (Q_0 = 0.07). Class R2 pavement has a mixed diffuse and specular mode of reflectance. R2 pavements include asphalt road surfaces with an aggregate composed of a minimum of 60% gravel with a size greater than 0.40 in. (12 mm).

3. Class R3 and (Q_0 = 0.07). Class R3 has a slightly specular mode of reflectance. R3 pavements include asphalt road surfaces, both regular and carpet seal coats, with dark aggregates (e.g., trap rock, blast furnace slag) and exhibit a rough texture after some months of use. Class R3 pavement represents typical asphalt highways and is used on most highway lighting projects.

4. Class R4 and (Q_0 = 0.08). Class R4 pavement has a mostly specular mode of reflectance. R4 includes asphalt road surfaces with a very smooth texture.

56-5.04(e) Illuminance and Luminance Design Levels

Design criteria for highway lighting projects vary according to the roadway, area, and pavement classification. Figures 56-5.B and 56-5.C present the illuminance and luminance design criteria used by the Department. In addition to these figures, consider the following:

1. Crossroads at Interchanges. Lighting levels on crossroad approaches should not be reduced through an interchange area. If existing crossroad lighting currently is deemed inadequate, consider upgrading the lighting to current criteria to ensure safe and efficient traffic operation.

2. Partial Interchange Lighting. Where partial interchange lighting is provided, luminaires should be located to best light the through lanes and speed change lanes at diverging and

merging locations. The design controls of basic level of lighting and uniformity should be subordinated to overall lighting of the roadway area at these locations.

3. Bridge Structures and Underpasses. Underpass lighting level and uniformity ratios should duplicate, to the extent practical, the lighting levels on the adjacent facility. On continuously lighted freeways and lighted interchanges, the lighting of bridges and overpasses should be at the same level as the adjacent roadway.

4. Transition Lighting. Transition lighting is a technique intended to provide the driver with a gradual reduction in lighting levels and glare when leaving an illuminated area. The designer should consider transition lighting if a study of the specific conditions at a location indicates a need. The designer may also want to consider extending delineation beyond the last luminaire for traffic lanes emerging from a lighted area. This will provide an additional measure of effectiveness. Visual adaptation occurs more quickly when approaching a lighted area and therefore no transition lighting is typically required.

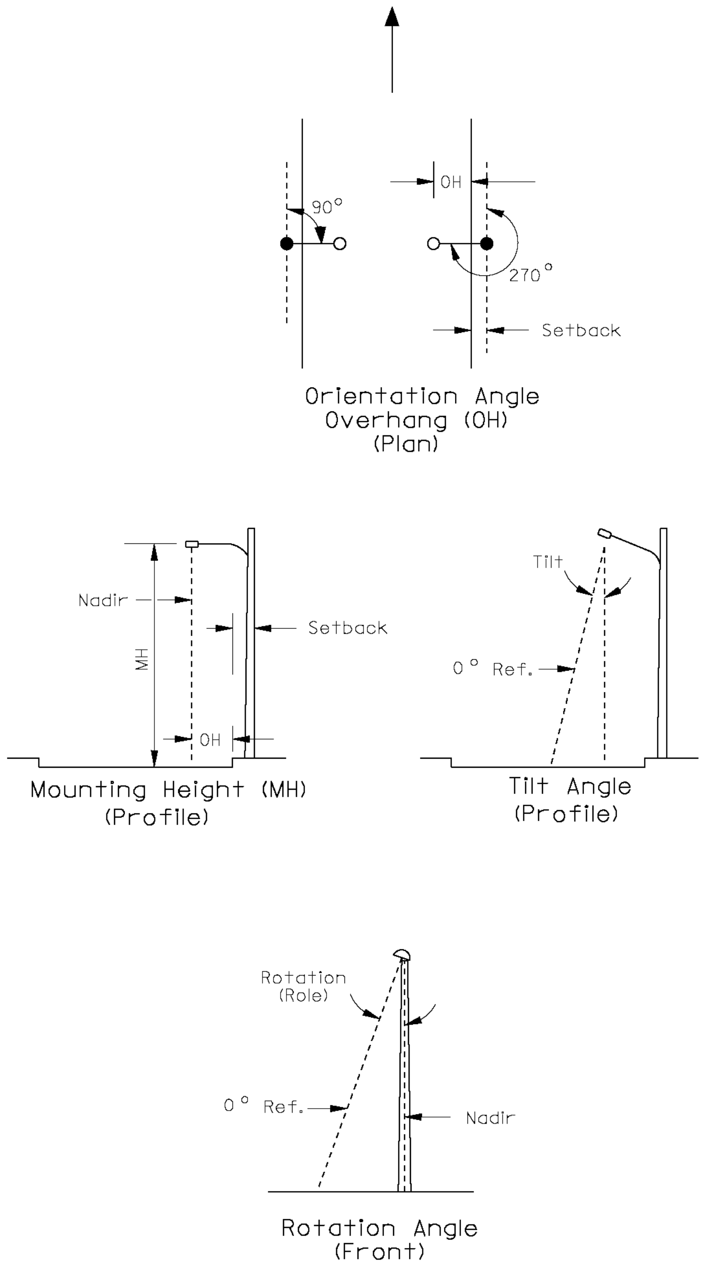
5. Temporary Lighting. The temporary lighting generally shall be designed to the levels and uniformities of the proposed permanent lighting system except where existing lighting is used as temporary lighting.

6. Navigation and Obstruction Lighting. The lighting criteria and locations for waterway and aviation obstruction luminaires will be based on the requirements of the US Coast Guard and the Federal Aviation Administration, respectively.

7. Other Locations. Where lighting is justified for other facilities not covered under this section, consult the references in 56-6 and for additional information on lighting criteria, contact the Electrical and Mechanical Unit in the Central Office.

56-5.04(f) Luminaire Characteristics

Figure 56-5.D illustrates the common terms used in defining and mounting luminaires (e.g., mounting height, overhang). The following sections discuss design issues related to luminaires.



LUMINAIRE GEOMETRY

Figure 56-5.D

56-5.04(f)1 *Light Distribution*

Light distribution is a major factor in highway lighting design. It affects the selection of luminaire mounting height, placement, and arrangement. Specific photometric data and light distribution sheets are available from each luminaire manufacturer. Manufacturers typically classify their luminaire products based on the IES luminaire classification system. This system uses a three part approach to define luminaire distribution — the lateral beam width, vertical angle of maximum candlepower, and the degree of glare control.

The following briefly describes this classification system:

1. Lateral Light Distribution. There are various classifications of lateral light distribution. The selection of a particular lateral light distribution is dependent upon the luminaire mounting height and application. The following defines each type:

    a. Short Distribution (S). The maximum candlepower strikes the roadway surface between 1 and 2.25 mounting heights from the luminaire. The theoretical maximum luminaire spacing, using the short distribution, is 4.5 mounting heights.

    b. Medium Distribution (M). The maximum candlepower is between 2.25 and 3.75 mounting heights from the luminaire. The theoretical maximum luminaire spacing is 7.5 mounting heights. Medium distribution is commonly used in highway applications.

    c. Long Distribution (L). The maximum candlepower is between 3.75 and 6.0 mounting heights from the luminaire. The theoretical maximum luminaire spacing is 12 mounting heights.

    From a practical standpoint, the medium distribution is predominantly used in highway practice, and the spacing of luminaires normally does not exceed five to six mounting heights. Short distributions are not used extensively for reasons of economy, because extremely short spacing is required. At the other extreme, the long distribution is not used to any great extent because the high beam angle of maximum candlepower often produces excessive glare.

2. Transverse Light Distribution. There are seven classifications for transverse light distribution. The following provides application guidelines for each luminaire type:

    a. Type I. The Type I luminaire is placed in the center of the roadway or area where lighting is required. It produces a long, narrow, oval-shaped lighted area. Some types of high-mast lighting are considered a modified form of Type I.

    b. Type I - 4-Way. This luminaire type is located over the center of the intersection and distributes the lighting along the four legs of the intersection.

    c. Type II. The Type II luminaire is placed on the side of the roadway or edge of the area to be lighted. It produces a long, narrow, oval-shaped lighted area, which is usually applicable to narrower roadways.

d. Type II - 4-Way. This luminaire type is placed at one corner of the intersection and distributes the light along the four legs of the intersection.

e. Type III. The Type III luminaire is placed on the side of the roadway or edge of the area to be lighted. It produces an oval-shaped lighted area and is usually applicable to medium width roadways.

A Type III distribution is where the street side segment of the half-maximum-intensity isointensity trace within the longitudinal range where the point of maximum intensity falls (S, M, or L), lies partly or entirely beyond the 1.75 MH street side LRL, but does not cross the 2.75 MH street side LRL; see Figure 56- 5.E.

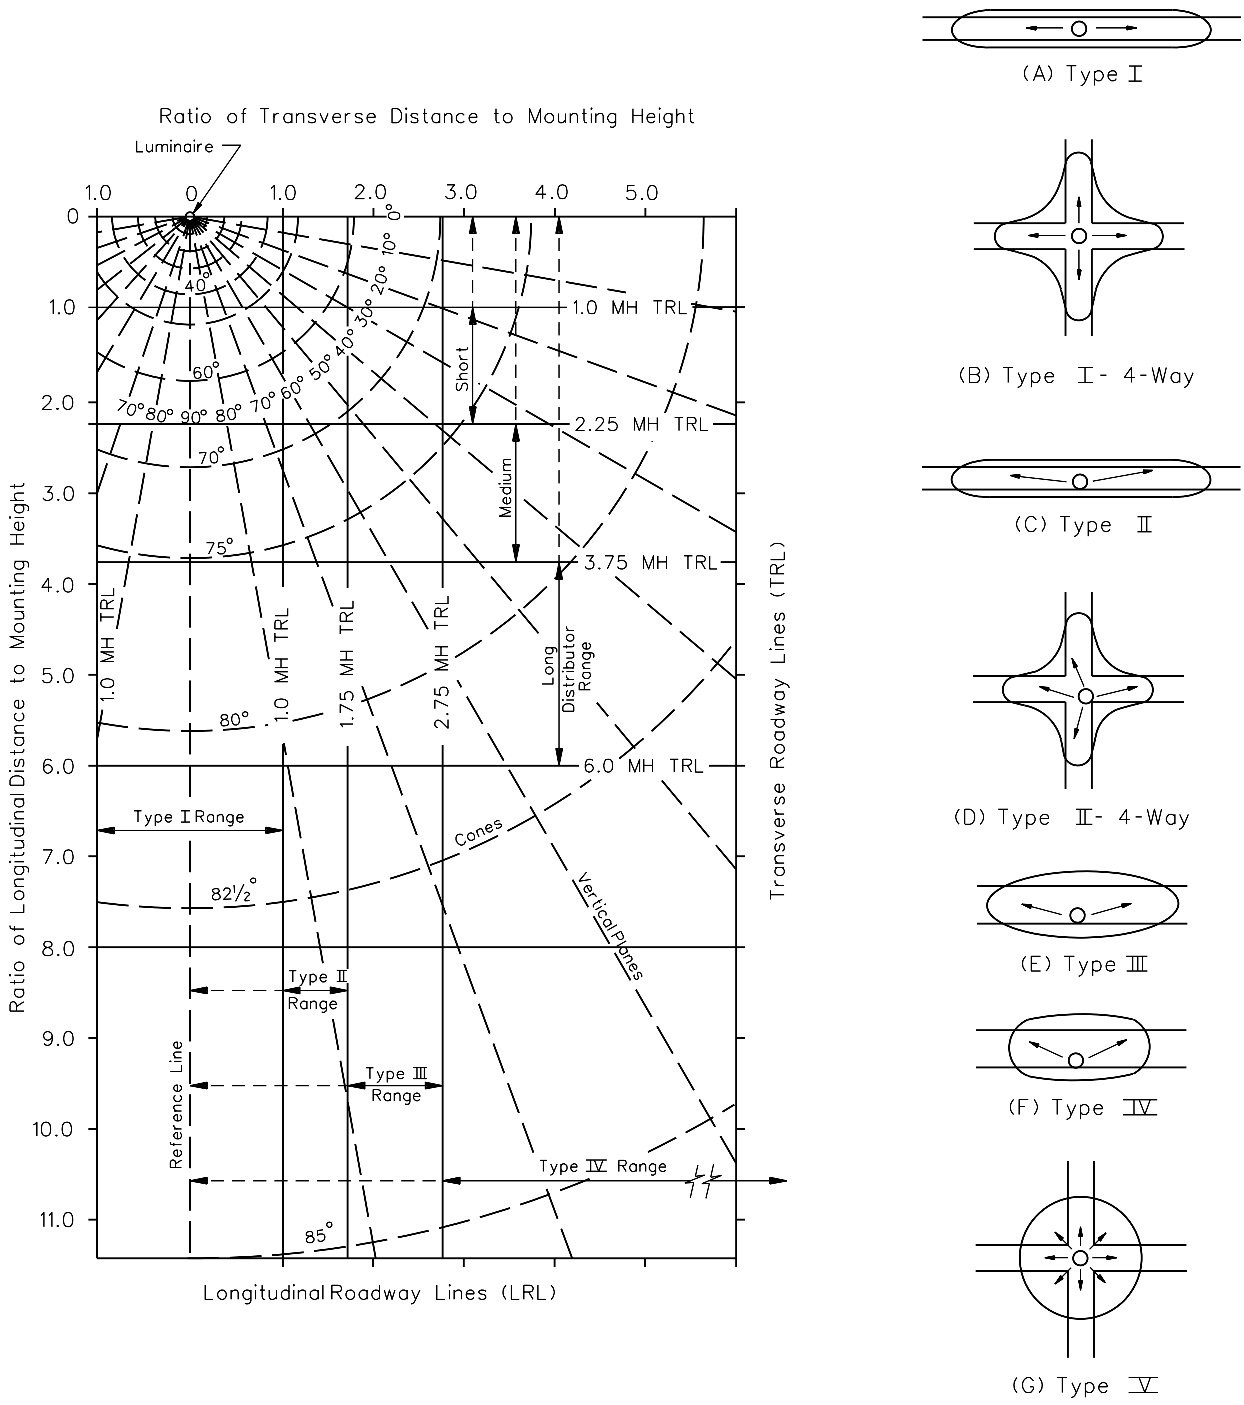
f. Type IV. The Type IV luminaire is placed on the side of the roadway or the edge of area to be lighted. It produces a wider, oval-shaped lighted area and is usually applicable to wide roadways.

g. Type V. The Type V luminaire is located over the center of the roadway, intersection, or area to be lighted. It produces a circular, lighted area. Type V often is used in high-mast lighting applications.

3. Control of Distribution. IES has developed a Luminaire Classification System for Outdoor Luminaires (LCS). This system provides information regarding the lumen distribution within solid angles of specific interest. These are identified as primary solid angles identified as: Forward Light, Back Light, and Uplight. Each of these primary solid angles are further divided into 10 secondary solid angles.

Based on the luminaire lumen output in the various Back light, Uplight, and Glare zones, the luminaire is assigned a BUG rating. This rating can be used as a means of evaluating and comparing luminaires for inclusion in a lighting design. A BUG rating may be used to evaluate luminaire optical performance related to the potential for light trespass, sky-glow, and high-angle brightness control.

A plan view of the theoretical light distribution (i.e., theoretical roadway coverage) and schematics of the intended application of each type of IES luminaire are illustrated in Figure 56-5.E.



PLAN VIEW OF ROADWAY COVERAGE FROM LUMINAIRES

Figure 56-5.E

A system of backlight, uplight, and glare (BUG) ratings has been derived from the IES Luminaire Classification System (LCS). For additional information on the LCS and BUG ratings, consult the *Luminaire Classification System for Outdoor Ligh*ting, IESNA TM-15.

Use only the photometric data with the proper shield, if the project requires luminaire shielding. Do not use the photometric data without the appropriate shield for projects with shields.

56-5.04(f)2 *Mounting Heights*

Higher mounting heights used in conjunction with higher wattage luminaires enhances lighting uniformity and typically reduces the number of light poles needed to produce the same illumination level. In general, higher mounting heights tend to produce a more cost-effective design. For practical and aesthetic reasons, the mounting height should remain constant throughout the system. The manufacturer's photometric data is required to determine an appropriate mounting height. Typical mounting heights used by the Department for conventional highway lighting purposes range from 30 ft to 50 ft (9.1 m to 15.2 m). Mounting heights for light towers are typically 80 ft (24 m) or greater.

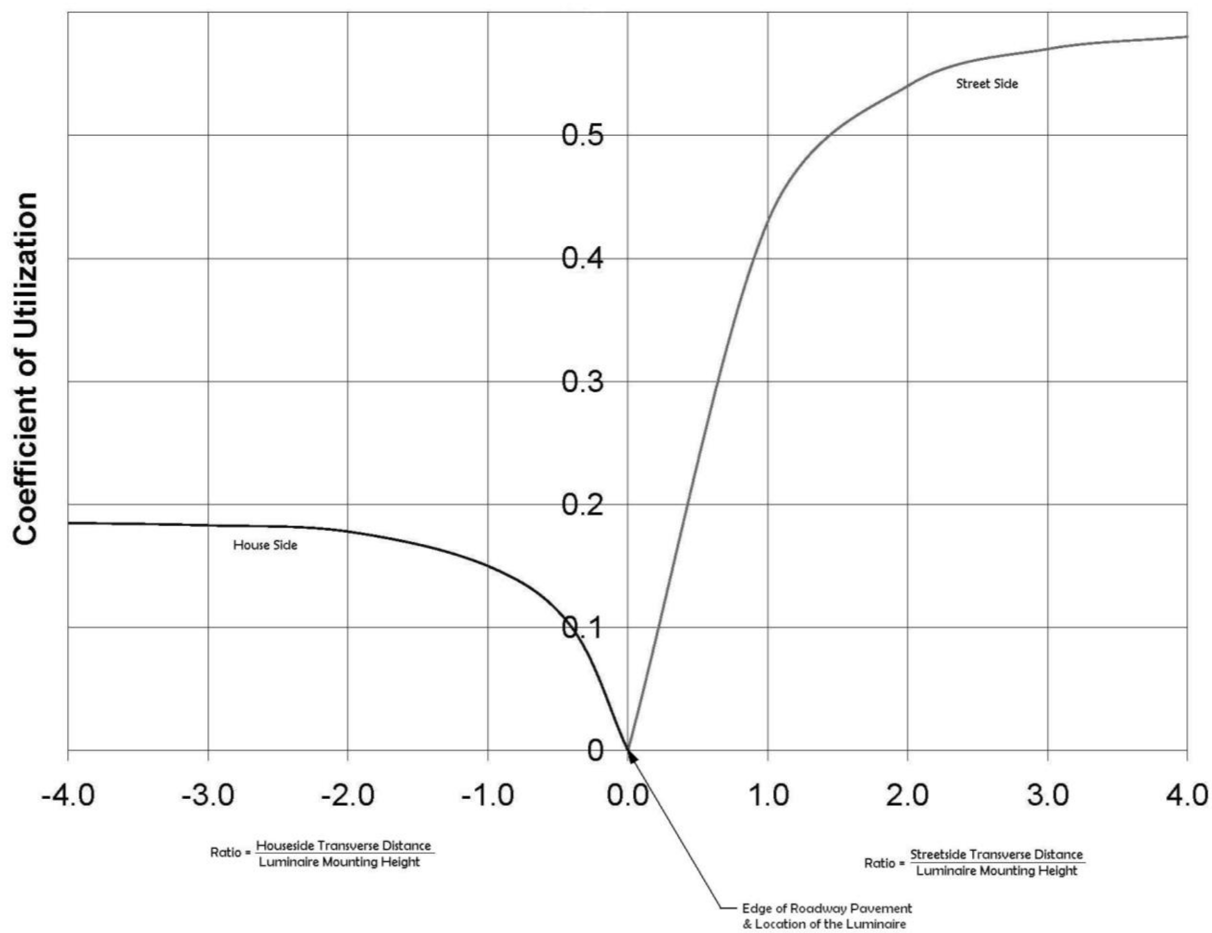
56-5.04 (f)3 *Coefficient of Utilization*

The coefficient of utilization is the ratio of the luminous flux (lm) from a luminaire received on the pavement surface to the rated lumens emitted by the luminaire. A utilization curve is used to obtain a luminaire's coefficient of utilization (CU). Manufacturers typically provide utilization curves and isolux diagrams with each of their respective luminaire products. Figure 56-5.F illustrates a sample utilization curve. The utilization curve relates to the luminaire rather than to the light source. The ratio of transverse distance over luminaire mounting height provides the percentage of bare lamp lumens that are utilized. If the luminaire is placed over the traveled way (i.e., over the pavement), the total lumen utilization is determined by adding the percentages from the street side and curbside (i.e., house-side) light from the coefficient of utilization curve (furnished by the luminaire manufacturer). In essence, the utilization curve defines how much of the total lumen output reaches the area being lighted.

56-5.04(f)4 *Light Loss Factors*

The efficiency of a luminaire decreases over time. The designer must estimate this decrease to properly estimate the light available at the end of the luminaire's serviceable life. The following briefly discusses these factors:

1. <u>Luminaire Lumen Depreciation Factor (LLD)</u>. As the luminaire progresses through its serviceable life, the lumen output decreases. This is an inherent characteristic of all light sources. The initial lumen value is adjusted by a lumen depreciation factor to compensate for the anticipated lumen reduction. This assures that a minimum level of illumination will be available at the end of the assumed life (i.e., after lumen depreciation has occurred). The depreciation factor varies, but for all luminaire calculations, a value of 90% shall be used.



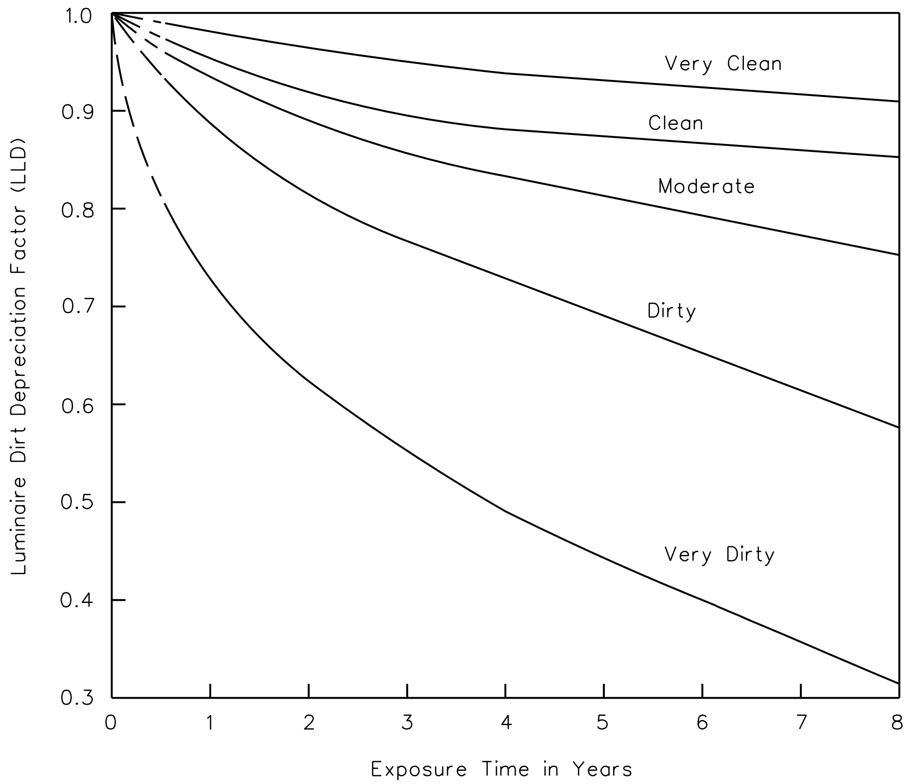
Note: The utilization curve will vary with each manufacturer and luminaire type.

SAMPLE UTILIZATION CURVE

Figure 56-5.F

2. Luminaire Dirt Depreciation Factor (LDD). Dirt on the exterior and interior of the luminaire, and to some extent on the light source itself, reduces the amount of light reaching the pavement. Various degrees of dirt accumulation may occur depending upon the area where the luminaire is located. Industrial areas, automobile exhaust, diesel trucks, dust and other environments all affect the dirt accumulation on the luminaire. Higher mounting heights, however, tend to reduce the vehicle-related dirt accumulation. The relationship between the ambient environment and the expected

level of dirt depreciation over time is shown in Figure 56-5.G. The depreciation factor used in calculations shall be 80%.



Notes:

1. *VERY CLEAN - No nearby smoke or dust-generating activities and a low ambient contaminant level. Light traffic. Generally limited to residential or rural areas. The ambient particulate level is not more than 150 micrograms per cubic meter.*

2. *CLEAN - No nearby smoke or dust-generating activities. Moderate to heavy traffic. The ambient particulate level is not more than 300 micrograms per cubic meter.*

3. *MODERATE - Moderate smoke or dust-generating activities nearby. The ambient particulate level is not more than 600 micrograms per cubic meter.*

4. *DIRTY - Smoke or dust plumes generated by nearby activities may occasionally envelope the luminaires.*

5. *VERY DIRTY - As above, but the luminaires are commonly enveloped by smoke or dust plumes.*

ROADWAY LUMINAIRE DIRT DEPRECIATION CURVE

Figure 56-5.G

3. Equipment Factor (EF). Allows for variations inherent in the manufacture and operation of the equipment (i.e., luminaire, system voltage, voltage drop). It is generally assumed to be 95%.

4. Light Loss Factor (LLF). The light loss factor is the combination of factors used to denote the reduction of the illumination for a given area after a period of time compared to the initial illumination on the same area. It is the product of the luminaire lumen depreciation factor (LLD), the luminaire dirt depreciation (LDD) factor, and the equipment factor (EF) (i.e., LLF = LLD • LDD • EF).

56-5.04(f.5) Luminaire Arrangement

Figure 56-5.H illustrates typical luminaire arrangements for conventional highway lighting designs. Use the calculation points provided in ANSI/IES RP-8, Figure A4.

56-5.04(g) Voltage Drop Determination

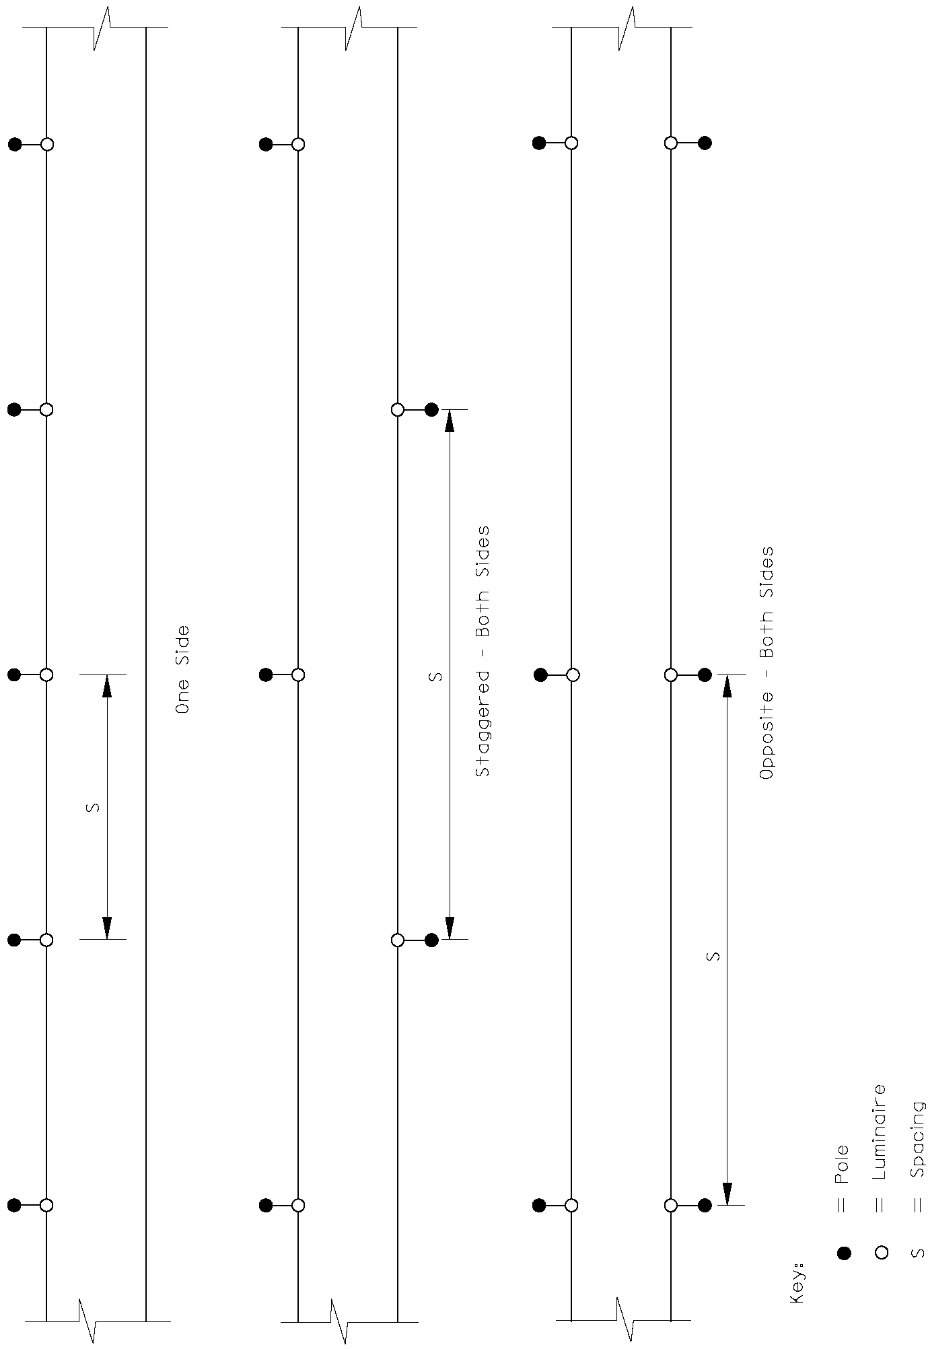
The typical power supply circuit to the highway lighting controller is 120/240 V or 240/480 V, single-phase, three-wire, 60-cycle alternating current. The branch lighting circuit consists of two conductors and an insulated (green) equipment grounding conductor. The luminaires are connected on both sides of the circuit to obtain 240V or 480V across the driver. Use Figure 56-5.I to determine the voltage drop between two adjacent luminaires.

56-5.05 Other Design Considerations

56-5.05(a) Roadside Safety Considerations

Light poles should be installed so that they will not present a roadside hazard to the motoring public. However, the physical roadside conditions often dictate their placement. It is important to recognize this limitation. Overpasses, sign structures, guardrail, roadway curvature, right-of-way, gore clearances, proximity to roadside obstacles, and lighting equipment limitations are all physical factors that can limit the placement of light poles. The designer also must consider factors such as roadway and area classification, design speed, posted speed, safety, aesthetics, economics, and environmental impacts. In addition, there should be adequate right-of-way, driveway control, and utility clearance. Consider the following when determining the location of light poles:

1. Clear Zone. Where practical, place light poles outside the roadside clear zone, and as far from the traveled way as consistent with good lighting design. See Chapter 38 for additional information on roadside clear zone.



TYPICAL LUMINAIRE ARRANGEMENTS FOR CONVENTIONAL HIGHWAY LIGHTING DESIGN

Figure 56-5.H

AMPS①		
Watts	**240 Volts**	**480 Volts**
Obtain from manufacturer	Value	Value/2

Wire Size AWG	Circuit Resistance ohms/100 ft (ohms/100 m)	Wire Size AWG	Circuit Resistance ohms/100 ft (ohms/100 m)

12	0.205 (0.673)	1	0.0160 (0.0524)
10	0.129 (0.4226)	1/0	0.0127 (0.0415)
8	0.0809 (0.2653)	2/0	0.0101 (0.0329)
6	0.0510 (0.1671)	3/0	0.00797 (0.02610)
4	0.0321 (0.1053)	4/0	0.00626 (0.02050)

Notes:

1. *Consult manufacturer's data for specific characteristics of the luminaire and driver.*

2. *Voltage drop is determined using the following equation:*

   $V_d = 2 \cdot D \cdot I \cdot R$ *(For single-phase circuits with minimal impedance.)*

   where:

   V_d = *voltage drop (volts)*

   D = *distance in hundreds of ft (m). See Note 3.*

   I = *current (amperes). Use nominal, full-load current – published by the luminaire manufacturer*

   R = *resistance in ohms/100 ft (ohms/100 m). See Note 4.*

3. *Distance is the circuit length from controller-to-pole or from pole-to-pole for the segment of circuit being analyzed, measured in hundreds of feet (meters).*

4. *DC resistances listed in table above are based upon stranded copper conductor at 167°F (75°C) operating temperature with an insulated covering and located in conduit. Reference source: Table 8 "Conductor Properties," Chapter 9 of the National Electrical Code.*

5. *Total voltage drop at end of a conductor run shall not exceed 20%. See 56-5.06 for voltage drop requirements for HIGH-MAST TOWERS.*

VOLTAGE DROP BETWEEN LUMINAIRES

Figure 56-5.I

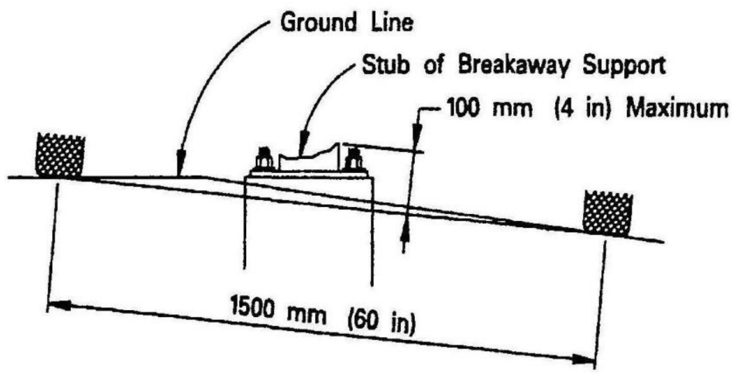
2. Breakaway Supports. Unless located behind or on top of a roadside barrier, wall, guardrail or crash cushion, which are necessary for other safety-related reasons, conventional light poles placed within the roadside clear zone will be mounted on FHWA-approved breakaway supports. Poles outside the clear zone also should be mounted on breakaway supports where there is a possibility of them being struck by errant vehicles. Be aware that falling poles and mast arms may endanger bystanders (e.g., pedestrians, bicyclist, motorists). Consider the following during design:

   a. When to use Non-Breakaway Supports. In areas where pedestrians, bicyclists, or building structures and windows may be struck by falling poles or mast arms after a crash, evaluate the relative risks of mounting the light pole on a breakaway support. Examples of locations where the hazard potential to pedestrian traffic would be greater include:

      - transportation terminals,
      - sports stadiums and associated parking areas,
      - tourist attractions,
      - school zones, or
      - central business districts and local residential neighborhoods where the posted speed limit is 30 mph (50 km/hr) or less.

      In these locations, use non-breakaway supports. Other locations that require the use of non-breakaway supports, regardless of the pedestrian traffic volume, are rest areas and weigh station parking lots and combination traffic signal/light poles.

   b. Breakaway Support Stub. Substantial remains of breakaway supports shall not project more than 4 in. (100 mm) above a line between the straddling wheels of a vehicle on 60 in. (1.5 m) centers. The line connects any point on the ground surface on one side of the support to a point on the ground surface on the other side, and it is aligned radially or perpendicular to the centerline of the roadway. Breakaway supports, including those placed on roadside slopes, must not allow impacting vehicles to snag on either the foundation or any substantial remains of the support. Surrounding terrain may need to be graded in order to permit vehicles to pass over any non-breakaway portion of the installation that remains in the ground or rigidly attached to the foundation. The specified limit on the maximum stub height lessens the possibility of snagging the undercarriage of a vehicle after a support has broken away from its base and minimizes vehicle instability if a wheel hits the stub. The necessity of this requirement is based on field observations. Application of the clearance requirement is illustrated in Figure 56-5.J.



STUB HEIGHT REQUIREMENTS

Figure 56-5.J

c. Wiring. All light poles that require breakaway supports will be served by underground wiring and designed with simultaneous quick disconnect fuse holders.

d. Light Towers. Light Towers used in high-mast lighting applications will be mounted on non-breakaway supports. Also, towers shall be located outside the roadside clear zone as far as consistent with good lighting design unless protected by guardrail, barriers, or crash cushions; see Chapter 38.

e. Bridge Parapets and Concrete Barriers. Where poles are mounted atop bridge parapets and concrete barriers, they will be mounted on non-breakaway supports.

3. Gore Areas. Where practical, locate light poles outside the gore areas of exit and entrance ramps. Generally, lighting support should not be placed within the clear zone of the gore area.

4. Horizontal Curves. Place light poles on the inside of sharp curves and loops. Where poles are located on the inside radius of superelevated roadways, provide sufficient lateral clearance to avoid being struck by trucks.

5. Maintenance. When determining pole and luminaire locations, consider the hazards that will be encountered while performing maintenance on the lighting equipment. Use the criteria provided in Chapter 38 to design and place light poles in conjunction with roadside barriers. Consider the following additional guidelines:

a. Placement. Where a roadside barrier is provided, place all light poles behind the barrier.

b. Deflection. Light poles placed behind a roadside barrier should be offset by at least the deflection distance of the barrier; see Chapter 38. This will allow the barrier rail to deflect without hitting the pole.

c. Concrete Barriers. Light poles that are protected by a rigid or non-yielding barrier do not require a breakaway support.

d. Impact Attenuators. Do not locate light poles within the functional operation of any impact attenuator or other safety device.

6. Protection Features. In most cases protection features (e.g., barriers) should not be added for the primary purpose of protecting a light pole.

56-5.05(b) Foundation, Pole Mounting, and Structural Considerations

The *Standard Specifications*, *Highway Standards* and the electrical detail sheets provide pole mounting details and details for foundation materials, depth, width, reinforcing, etc. When designing lighting systems, also consider the following:

1. Foundation Height Relative to Final Grade. For other than light towers, ensure pole foundations are no more than 0.5 in. (13 mm) higher than the high edge of the surrounding final grade and in compliance with Figure 56-5.J. This permits proper drainage around the foundation and reduces the likelihood of the foundation intensifying a collision. The foundation also is less likely to be destroyed during a collision. When located within the clear zone, ensure that the foundation and fractured breakaway support does not protrude more than 4 in. (100 mm) above the finished grade within a 5 ft (1.5 m) chord as noted in 56-5.05(a)2(c) above. See Chapter 38 for additional information on clear zones.

2. Metal Foundations. The steel (i.e., helix screw-in type) foundation is one that is commonly used by the Department for conventional light poles. This foundation is placed in undisturbed earth using a clockwise rotation similar to a common screw. The metal tube is typically 8-5/8 in. (220 mm) in diameter and 6 ft to 8 ft (1.8 m to 2.4 m) long. Shorter lengths may be appropriate for foundations in areas with shallow bedrock. The metal foundation will accommodate poles with 11.5 in. and 15 in. (292 mm and 381 mm) bolt circles for luminaire mounting heights up to 50 ft (15.2 m).

3. Light Tower Foundations. Foundations for light towers used in high-mast lighting applications typically require specialized designs and soil surveys to ensure adequate support. A 4-ft (1.2-m) diameter reinforced concrete foundation, to a depth as required by the soils analysis, usually is adequate for towers accommodating 80 ft to 110 ft (24.4 m to 33.5 m) luminaire mounting heights. The top 18 in. (450 mm) of the foundation is formed. Below this depth, ensure that the foundation is poured monolithically against the undisturbed earth of the bored hole. Specify the foundation depth on the lighting plans. Additionally, include a level concrete work pad at the base of the tower.

4. Foundations for Temporary Lighting. Foundations for temporary lighting will be determined on a case-by-case basis. This may include direct embedment of wood poles to a depth of from 5.5 ft (1.7 m) for 30 ft (9.1 m) poles, to 12 ft (3.6 m) for 65 ft (19.8 m) poles. The use of butt base anchors also may be considered. However, locate these supports outside the clear zone; see Section 56-5.05(b) for more details.

5. Pole Mounting on Parapets. Poles for bridge lighting typically are mounted on specially designed concrete parapet sections. Mounting design includes the necessary non-breakaway, high-strength bolts, leveling plate, and vibration isolation pad and washers.

6. Structural Design. Poles will be designed and fabricated to meet or exceed AASHTO requirements as documented in *Standard Specifications for Structural Supports for Highway Signs, Luminaires, and Traffic Signals* and NCHRP Report 411. See the *IDOT Standard Specifications, and the Highway Standards* for the appropriate design criteria (e.g., wind loading, luminaire weight, and effective projected area).

56-5.05(c) Other Considerations

In addition to the items discussed in the previous sections, consider the following when designing the highway lighting system:

1. Signs. Place light poles to minimize interference with the driver's view of the roadway and any highway signs. Luminaire locations should not seriously detract from the legibility of signs at night.

2. Structures. Place light poles sufficiently away, generally at least one mounting height, from overhead bridges and sign structures to minimize glare and distracting shadows on the roadway surface.

3. Trees. Insufficiently pruned trees can cause shadows on the roadway surface and reduce the luminaire's effectiveness. Design the pole/luminaire with a height and mast-arm length to negate such adverse effects.

4. Criteria. Consult the authority having jurisdiction of the lighting for design criteria and standards prior to design.

5. Navigable Airspace. Where lighting projects are being considered in close proximity to an active airfield or airport, consider the impact the height of the light pole has on navigable airspace during and after construction. For additional information, consult the FAA Advisory Circular AC 70/7460-2J *Proposed Construction or Alteration of Objects that May Affect the Navigable Airspace*.

6. Luminaire Shielding. Avoid external shielding of luminaires. If external shielding is used, ensure the shields have been tested to achieve the necessary light control and designed to prevent rotation and misalignment. The lighting design must incorporate the correct photometry that accurately depicts the luminaire with the shields in place.

7. Combination Traffic Signal/Light Pole. The use of combination traffic signal structures that have a roadway luminaire top attachment generally improve roadside safety. They should be used, where practical, to eliminate a light pole adjacent to a traffic signal structure. Place combination poles beyond the pedestrian crosswalk to allow pedestrian visibility in silhouette.

8. Light Trespass. Lighting can have considerable impact on crops and must be considered when lighting is installed in rural areas.

9. Environmental. Roadway lighting shall be designed to the extent possible to protect the environment including night skies, fauna, and flora from the potentially undesirable effects from stray light. See ANSI/IES LP-11, *Environmental Considerations for Outdoor Lighting.*

56-5.06 HIGH-MAST LIGHTING DESIGN

In general, the design of high-mast lighting systems follows the same design procedures as discussed elsewhere in Section 56-5. In addition, consider the following:

1. Light Source. IDOT-owned and maintained lighting systems typically use a high lumen output LED luminaire. The number of luminaires required will be determined by the area to be lighted. As a general starting point, it can be assumed that six luminaires will be used per pole.

2. Mounting Heights. Mounting heights in high-mast lighting applications range from 80 ft to 160 ft (24.3 m to 48.8 m). Greater mounting heights require more luminaires to maintain illumination levels. However, greater heights allow for fewer poles and provide better light uniformity. As a general starting point, it can be assumed that mounting heights of 80 ft to 100 ft (24.3 m to 30.5 m) will be used.

3. Location. In determining the location of light towers, review the plan and profile view of the area to determine the critical areas requiring lighting. In selecting tower locations, consider the following:

    a. Critical Areas. Locate light towers so that the highest localized levels of illumination fall within the critical traffic areas (e.g., freeway/ramp junctions, ramp terminals, merge points).

    b. Roadside Safety. Locate light towers outside the roadside clear zone and a sufficient distance from the roadway so that the probability of a collision is virtually eliminated; see Chapter 38.

    c. Signs. Locate light towers so that they are not within the driver's direct line of sight to highway signs.

4. Design. Use point-by-point calculations to evaluate luminance, illuminance, and veiling luminance levels. Calculation grids must be placed at appropriate locations to analyze these levels. Consult the Electrical and Mechanical Unit in the Central Office for assistance to make these determinations.

    Adjust luminaires, pole locations, and other variables, as needed, to ensure that the minimum-maintained illumination is provided, and the uniformity ratio has been satisfied. Give consideration to adjacent land use during the analysis. Ensure the design minimizes glare and maintains light control away from adjoining property.

5. <u>Navigable Airspace</u>. Where lighting projects are being considered in close proximity to an active airfield or airport, consider the impact the height of the light tower has on navigable airspace during and after construction.

6. <u>Voltage Drop</u>. The voltage drop at any high-mast tower shall not exceed 5%.

Chapter Fifty-Seven
TRAFFIC CONTROL DEVICES

57-1 GENERAL

57-1.01 Context

57-1.01(a) Illinois Manual on Uniform Traffic Control Devices (ILMUTCD)

The *ILMUTCD* consists of the national *MUTCD* and the Illinois supplement to the *MUTCD*. The *ILMUTCD* information is divided into four categories — standard, guidance, option, and support. Use these categories to determine the appropriate application for the various traffic control devices. The *ILMUTCD* defines these categories as follows:

1. Standard. These are mandatory actions that are required without exception or with exceptions so noted under the standard heading. Typical phrases include shall, shall mean, shall be satisfied, shall consist, etc.

2. Guidance. This category is considered to be advisory usage, recommended but not mandatory. Deviations are allowed where engineering judgment indicates the need. Typical phrases include should, should be, should be considered, should be given, etc.

3. Option. This category includes procedures and devices that are allowed but carry no recommendations or mandate. The designer is free to use or refrain from their use. Typical phrases include may, may be used, may be considered, etc.

4. Support. This category includes all introductory or explanatory language. It may occur before, within, or after any of the above categories. Typical phrases include is, are, warrants, considered, required, etc.

57-1.01(b) IDOT Application

In reference to the *ILMUTCD* categories, the Department has adopted the following positions:

1. Standard. The designer must meet the conditions of the *ILMUTCD*.

2. Guidance. The designer will follow the *ILMUTCD* with very few exceptions. For situations where it is impractical to follow "guidance" criteria, the designer must obtain Departmental approval.

3. Option. The designer should make every reasonable effort to follow the *ILMUTCD* criteria. For situations where it is impractical to follow "option" criteria, Departmental approval is necessary.

57-2 HIGHWAY SIGNING

57-2.01 Responsibilities

The responsibilities for elements of highway signing projects are as follows:

1. Structural Design. The Bureau of Operations and the Bureau of Bridges and Structures are jointly responsible for establishing Department criteria for the design of structural supports for traffic control devices (e.g., breakaway bases for large signs).

2. Location and Legend. The district Bureau of Operations is responsible for the legends and the initial placement of highway signs, based on proper conveyance of information to the motorist. The roadway designer will review the location of highway signing to ensure that it is compatible with the roadway design. Final design, location, legends, and any changes should be approved and coordinated with the Bureau of Operations.

3. Soil Borings. Projects with large or overhead signs typically will require soil borings. The district is responsible for taking the soil borings.

4. Plan Preparation. The district Bureau of Operations is responsible for preparing or reviewing the highway signing detail sheets to be included in the plans. See Chapter 63 for additional information on plan preparation.

57-2.02 References

For additional information on highway signing material specifications, design, and application criteria, review the applicable publications listed in Section 57-1.02.

57-2.03 Sign Placement

57-2.03(a) General

Placement criteria for highway signs next to and/or over the roadway is documented in the *Bureau of Operations Traffic Policies and Procedures Manual* and the *ILMUTCD*. Additional guidance can be found in the publications listed in Section 57-1.02 and Chapter 38. Uniform placement of highway signing, although desirable, is not always practical because highway alignment and other factors often dictate a more advantageous location. When determining sign locations, consider the following guidelines:

1. Special Locations. Normally, signs should be placed on the right side of the roadway. Under certain circumstances, however, signs may be placed on channelizing islands, overhead structures, or on the left side of the roadway along sharp, right-hand curves, or on the left side of multi-lane highways.

2. Dual Signing. Consider dual signing on one-way or divided roadways (i.e., on both sides of the traveled way) for additional emphasis where a single sign may not provide adequate

warning and where roadway geometry or other factors (e.g., multiple lanes, trucks, parked vehicles) may cause a single sign to be obscured.

3. Geometric Design. Coordinate sign placement and geometric design as early as practical during project planning and design. A geometric design may need to be revised if it does not accommodate adequate sign placement.

4. Overhead Lane Control. Where lane control is desired, place signs directly over the affected lane. For additional information, see the *Bureau of Operations Traffic Policies and Procedures Manual*, *ILMUTCD*, and the publications listed in Section 57-1.02.

5. Nighttime Visibility. Locate signs to optimize their nighttime visibility.

6. Field Conditions. Adherence to desired placement is not always practical. Adjust sign locations to accommodate actual field conditions and try to avoid the following problem areas:

    - at short sags in the roadway,
    - beyond the crest of a vertical curve,
    - where a sign would be obscured by parked cars,
    - where a sign would create an obstruction for pedestrians or bicyclists,
    - where a sign would obscure visibility of hazardous locations,
    - where the visibility of a sign would be impaired by overhead illumination,
    - where a sign would be vulnerable to roadside splatter or snow from plowing operations, and/or
    - at locations close to foliage where the sign face may be covered or the foliage should be removed.

7. Longitudinal Placement. In some cases, signs can be shifted longitudinally without compromising their intended purpose. This may improve their visibility and enhance safety. However, it is vital to stay within the guidelines of the *ILMUTCD*.

8. Sign Groups. In general, signs are mounted individually on supports. However, it may be necessary to erect a sign grouping (e.g., route markings). Consider wind loading, driver ability to read and comprehend information, and breakaway criteria when designing sign groups.

9. Lateral Clearance. The *Bureau of Operations Traffic Policies and Procedures Manual*, *ILMUTCD*, and the publications in Section 57-1.02 provide the criteria for the lateral clearance of signs. In addition, see Section 57-2.04.

57-2.03(b) Placement of Advance Warning Signs

Warning signs are used to warn drivers of potentially hazardous conditions on or adjacent to the roadway. They are placed in advance of the conditions to which they apply. Warning signs should be used sparingly. Use of warning signs at non-hazardous locations tends to cause non-compliance of all signing. If the distances in Chapter 2C of the *ILMUTCD* cannot be met, then consider other measures to attract the motorist's attention to the sign (e.g., flashing beacons, distance plates).

57-2.04 Roadside Safety

For roadside safety applications, the following will apply to highway signs:

1. Design. The *Illinois Highway Standards* and *Sign Structures Manual* contain the Department's details for structural supports for traffic control devices.

2. Ground-Mounted Sign Supports. Supports for ground-mounted signs shall be made breakaway or yielding. All signs must have breakaway supports, whether within or outside the clear zone. Where practical, locate signs behind a roadside barrier that is warranted for other reasons. Provide adequate clearance to the back of the guardrail post to accommodate the barrier's dynamic deflection (see Section 38-6). In addition, do not place breakaway sign supports in drainage ditches where erosion and freezing might affect the proper operation of the support. It is also possible that an errant vehicle entering the ditch will be inadvertently guided into the support. If placed on a back slope, offset these supports at least 5 ft (1.5 m) from the toe of the back slope of the ditch.

57-2.05 Overhead Signs

In addition to the requirements covered in the *ILMUTCD,* consider the following guidelines for overhead signing applications:

1. Lane Control. Consider using overhead signs where the message is applicable to a specific lane. If the sign is placed over the lane, lane use can be made significantly more effective, especially in areas where channelization does not meet the driver's expectations and where additional guidance is required for unfamiliar drivers. Locate overhead signing in advance of the intersection. Lane control signing may be located on the signal mast arm where justified by sight conditions.

2. Driver Unfamiliarity. Consider overhead signing in areas where there is a high volume of unfamiliar drivers.

3. Visibility. Use overhead signs where traffic or roadway conditions are such that an overhead mounting is necessary for adequate visibility (e.g., vertical or horizontal curves, closely spaced interchanges, two or more through lanes in one direction). In addition, consider the visual acuity of elderly drivers.

4. Divergent Roadways. Place overhead signs in advance of and/or at a divergence from a heavily traveled roadway (e.g., at a ramp exit where the roadway becomes wider).

5. Exits. Consider the application of overhead signing where non-uniform exit maneuvers exist (e.g., left-hand or multi-lane exit ramps).

6. Interchanges/Intersections. Use overhead signs at complex interchanges where driver confusion is exhibited, where interchanges are closely spaced, at Interstate-to-Interstate interchanges and/or where there are lane drops on the exit ramp or mainline within the interchange. Consider overhead signing also on the approach to intersections of two major arterial streets.

7. Trucks. Signs may be mounted overhead where there is a significant number of large trucks.

8. Limited Right-of-Way. Use overhead signs where there is limited space for signs on the roadside (e.g., narrow right-of-way).

9. Roadside Development. Consider overhead signs at locations where roadside development seriously detracts from the effectiveness of roadside signs.

10. Uniformity. Signs should be mounted overhead for consistency with other signs on a given section of highway.

11. Overhead Sign Supports. All overhead signs will use non-breakaway supports. Within the clear zone, these structures should be protected with a roadside barrier or, where applicable, with an impact attenuator. In addition, consider placing overhead signs on bridges to eliminate the need for supports. Consult the Bureau of Operations and the Bureau of Bridges and Structures for guidance.

57-2.06 Vertical Clearance

New installations of overhead signs will require a minimum vertical clearance of 17 ft 3 in. (5.25 m) above the roadway and shoulders. Existing overhead signs may have a vertical clearance of 16 ft 9 in. (5.10 m).

57-3 PERMANENT PAVEMENT MARKINGS

57-3.01 Responsibilities

The designer is responsible to provide for the initial placement of pavement markings (e.g., striping, symbols) and the development of the pavement marking detail sheets for insertion into the plans. The district Bureau of Operations will review the pavement marking details and should provide any specific district striping details. The designer will incorporate the pavement marking details into the final highway plans.

57-3.02 References

For additional information on permanent pavement marking material specifications, design, and application criteria, review the applicable publications listed in Section 57-1.02.

57-3.03 Line Types

Line types vary depending on their application. See the *Bureau of Operations Traffic Policies and Procedures Manual*, *ILMUTCD,* and the publications listed in Section 57-1.02 for specific application criteria. Consider the following when developing pavement marking details for permanent roadway application:

1. Reflectorization. Pavement markings must be retroreflective.
2. Color. Pavement markings will be either white or yellow conforming to the standard highway color specifications. For example, word and symbol markings, crosswalk lines, most channelization lines, stop lines, parking space lines, and all lane lines will be white in color. Center lines, no-passing barrier lines, and medians will be yellow.
3. Material. See Department Policy TRA-14, "Guidelines for the Use of a Pavement Marking Materials on State Highways." The material used will be determined by the district Bureau of Operations.
4. Orientation and Style. Line types will vary in thickness and width; will be oriented in a longitudinal, transverse, or diagonal configuration; and will be striped as either single or double lines in a solid, broken, or dotted pattern.

57-3.04 Traveled Way Markings

The following sections present typical traveled way marking applications. Guidelines for line size, color, and placement can be found in the *ILMUTCD* and the *Bureau of Operations Traffic Policies and Procedures Manual*.

57-3.04(a) Center Lines

Center lines are used to separate vehicles traveling in opposite directions. Locate center lines on either side of a longitudinal pavement joint as required by the *IDOT Standard Specifications*. This will minimize the need for remarking after a joint-sealing operation.

57-3.04(b) Lane Lines

Lane lines are used to separate lanes of traffic traveling in the same direction. Use a broken white line for two or more lanes in the same direction. A solid white line may be used to discourage lane changes (e.g., approaches to signalized intersections). To facilitate future maintenance operations, offset all lane lines from longitudinal construction joints as required by the *IDOT Standard Specifications*.

57-3.04(c) Edge Lines

Edge lines are used to delineate the edge of traveled way. Left-hand edge lines are median lines, except on one-way streets, and are discussed further in Section 57-3.04(d). Where the application of a right-hand edge line is justified, use a solid white line.

57-3.04(d) Median Lines

Median lines are required on all multilane divided highways. Provide gaps at all intersections and median crossovers.

57-3.04(e) Channelizing Lines

Channelizing lines are used to separate traffic movement into definitive paths to facilitate safe and orderly movement. Channelizing lines may be used to separate traffic traveling in the same direction (e.g., gore areas). Channelizing lines also may be used to emphasize a flush or raised-curb median.

57-3.04(f) Transitions

Where transitions are necessary, pavement markings are used to guide the motorist through the transition area. See the *Bureau of Operations Traffic Policies and Procedures Manual* and the *ILMUTCD* for the applicable taper rate and length criteria at transitions (e.g., auxiliary lane tapers, beginning taper for left- and right-turn lanes, Interstate exits).

57-3.04(g) No-Passing Lines

A no-passing line is a special type of center line; see Section 57-3.04(a). Place a solid yellow line adjacent to the lanes that warrant the no-passing restriction. Provide no-passing lines along vertical and horizontal curves and elsewhere on two-lane facilities where the driver's line-of-sight is less than the minimum passing sight distance criteria presented in the *ILMUTCD*. The values presented in the *ILMUTCD* should not be confused with the passing sight distances presented in the AASHTO publication *A Policy on Geometric Design of Highways and Streets* which are geometric design criteria based on an assumption that a passing vehicle will be able to complete its passing maneuver. The minimum passing sight distance criteria presented in the *ILMUTCD* are sufficient to allow a passing vehicle to abort its passing maneuver. See Chapter 32 and Chapter 33, respectively, for horizontal and vertical curve design criteria. Conduct a review of successive no-passing zones to ensure that the roadway section will be properly striped (e.g., eliminating less than minimum gaps).

57-3.04(h) Raised Reflective Pavement Markers

Raised reflective pavement markers are used to supplement standard pavement markings. Guidelines are provided in Department Policy TRA-14, "Guidelines for the Use of Pavement Marking Materials on State Highways" where minimum ADT's and other conditions suggest appropriate placement. They should not be used in locations where lighting causes them to be ineffective.

57-3.05 <u>Intersections</u>

Chapter 36 discusses intersection design. The following sections present typical intersection pavement marking applications. See the *ILMUTCD* and the *Bureau of Operations Traffic Policies and Procedures Manual* for line size, color, and placement guidelines.

57-3.05(a) Stop Lines

The stop line is a transverse line that is used to indicate where the desired vehicular stopping point is located. Under certain circumstances, the location of the stop line may be adjusted to fit field conditions. For example, where turning trucks are known to encroach into the opposing lane, place the stop line outside the area of frequent encroachment. On multilane facilities that intersect the crossroad at an angle, it may be appropriate to stagger the stop line for each lane. This consideration is especially important at signalized intersections, which may have substantial clearance times. Consult the Bureau of Operations and the district Geometrics Engineer for additional guidance.

57-3.05(b) Channelizing Markings

Channelizing markings are used to emphasize the appropriate direction of travel. Depending on their use, they may be either white or yellow solid lines.

57-3.05(c) Crosswalks

An engineering study should be used to determine the need for proper location of crosswalks. Typical locations where marked crosswalks are used include:

- points of significant pedestrian concentration,
- signalized or unsignalized intersection approaches, and
- traffic stops that channelize pedestrians into identified corridors.

The crosswalk must encompass all curb ramps to satisfy the accessibility criteria; see Chapter 58.

57-3.05(d) Lane-Use Control Markings

At multilane approaches to intersections, it is often necessary to mark the intersection approach to designate the permitted movements through the intersection. This is especially important at intersections that have complex geometrics and multi-phase signal operations (e.g., exclusive turn lanes, drop lanes, dual left-turn lanes). Consider using lane-use control markings at the following locations:

- where the number of lanes approaching an intersection do not continue through to the opposite side of the intersection (e.g., auxiliary turn lanes);

- at major signalized intersections;

- where there exists an abnormal traffic pattern for an intersection approach; or

- where there is a possibility of confusion at an intersection or unusual conditions prevail.

57-3.05(e) Multiple Turn Lanes

At intersections that have multiple turn lanes (e.g., dual left-turn lanes), a series of single dotted lines may be used to guide the turning traffic through the intersection. The radius of the dotted line as extended through the intersection should be sufficient to accommodate the turning radius of the design vehicle and should be installed in accordance with the *ILMUTCD*.

57-3.06 <u>Interchanges</u>

Use pavement markings at interchanges to properly guide the motorist on and off of the high-speed facility (e.g., exit and entrance ramps, gore areas). See the *Bureau of Operations Traffic Policies and Procedures Manual, ILMUTCD,* and the specific application criteria for pavement markings at interchanges. Chapter 37 provides the criteria for interchange design.

57-3.07 Miscellaneous Marking Applications

57-3.07(a) Special Markings

Special markings (e.g., words, symbols, arrows) are used to guide, warn, and regulate traffic. Where used in a regulatory setting, these special markings are used to supplement the appropriate regulatory signing. Typical applications of special markings include:

- lane-use control at multilane intersections;
- highway-railroad grade crossings;
- school crossings;
- stop-controlled intersections;
- two-way, left-turn lanes;
- interchange ramps;
- one-way roadways;
- word markings; and
- directional arrow markings.

See the references in Section 57-1.02 for design and application criteria for special markings.

57-3.07(b) Truck-Climbing Lanes

For facilities with truck-climbing lanes, provide a broken white lane line between the normal travel lane and the climbing lane. Transition the edge line to the outside edge of the climbing lane. See the *Bureau of Operations Traffic Policy and Procedures Manual* for additional pavement marking application criteria for truck-climbing lanes.

57-3.07(c) Two-Way, Left-Turn Lanes (TWLTL)

On TWLTL's, the center lane is reserved for the exclusive use of a bi-directional, left-turn movement. The TWLTL is designed to harbor left-turning vehicles in the median area until a gap in the opposing traffic stream becomes available. The *Bureau of Operations Traffic Policies and Procedures Manual* and the *ILMUTCD* provide the pavement marking application criteria for two-way, left-turn lane facilities.

57-3.07(d) School Crossings

Mark school crossings according to the criteria presented in the *ILMUTCD*. See the publications in Section 57-1.02 for additional criteria. Pavement markings for school crossings should be used only with the appropriate signing. The proper signing should be in place, if practical, at the time the pavement markings are placed.

57-3.07(e) Highway-Railroad Grade Crossings

Place pavement markings in advance of railroad-highway grade crossings according to the criteria in the *ILMUTCD*. See the publications in Section 57-1.02 for specific design and application criteria.

57-3.07(f) Bicycle Facilities

Broken lines for bicycle paths should have a 1 to 3 ratio (e.g., 3 ft (1 m) segment with a 9 ft (2.7 m) gap). A solid yellow centerline may be appropriate on path approaches to an intersection to discourage passing and help increase bicyclist awareness of the intersection. Use solid white lines to separate bicycles from traffic if they share a common facility. Use the bike symbol, as defined in the *ILMUTCD*, where a separate bike lane is provided on a roadway. See the references in Section 57-1.02 for specific design and application criteria for bicycle facilities. Chapter 17 provides additional information on pavement markings for bicycle facilities. Green pavement markings may be used as a traffic control device to clarify for all users the locations where bicyclists are expected to operate. These markings are supplemental to the other pavement markings that are required for the designation of a bicycle lane. When used, green pavement marking can be installed under a MUTCD Interim Approval, and therefore locations are tracked, and performance reported. Green pavement markings should be limited primarily to within intersections and on intersection approaches where bicyclists and other roadway traffic would have potentially conflicting weaving or crossing movements. Refer to Section 17-2. for further discussion.

57-3.07(g) Rest Areas/Weigh Stations

For the design, marking, and striping criteria for rest areas and weigh stations, see Chapter 16, the Bureau of Operations *Traffic Policies and Procedures Manual* and the *ILMUTCD.*

57-3.07(h) On-Street Parking

Where used, on-street parking should be marked a sufficient distance back from an intersection so as not to obscure, or otherwise diminish, sight distance at the intersection and to minimize interference with the flow of vehicles and pedestrians. The publications in Section 57-1.02 provide additional guidance on on-street parking.

57-4 TRAFFIC SIGNALS

57-4.01 Responsibilities

57-4.01(a) State Projects

The following will apply to traffic signals on State projects:

1. Signal Design. The district will be responsible for the design of the traffic signal and for preparing the traffic signal detail sheets to be included in the plans. The district also will coordinate with any involved local agency to ensure that the selected traffic signal equipment can be maintained by that agency.

2. Structure Design. The central office Bureau of Operations and the Bureau of Bridges and Structures are jointly responsible for establishing the Department criteria for the design of traffic signal structural supports.

3. Review. The central office Bureau of Operations is available to assist and review the traffic signal plans.

4. Road Designer. The road designer will be responsible for reviewing the location of the traffic signal equipment (e.g., controller cabinet, signal supports) to ensure that they are compatible with the roadway design.

5. Signal Phasing and Timing. The district will be responsible for preparing the signal phasing and timing designs for the traffic signal.

6. Agreements. The district will be responsible for preparing any necessary agreements between the State and the local agency for the operation and maintenance of the traffic signal; see Chapter 5.

57-4.01(b) Local Projects

Where a local agency places a traffic signal on a State or Federal route or where an exit or entrance ramp intersects with a local facility, the Department will be responsible for reviewing the plans to ensure that they are in conformance with Department criteria. The local agency will be responsible for design of the traffic signal and for preparing the traffic signal detail sheets. Ensure there is an agreement with the local agency regarding the installation, maintenance, and other aspects of the proposed improvement.

57-4.02 References

For additional information on traffic signal equipment and material specifications, design, and application criteria, review the applicable publications listed in Section 57-1.02.

57-4.03 Definitions

The following list of definitions supplements those found in the various references of commonly used terms in traffic signal design:

1. Active Grade Crossing Warning System. The flashing signals, with or without warning gates, together with the necessary control equipment used to inform road users of the approach or presence of trains at highway-railroad grade crossings.

2. Approach. All lanes of traffic moving toward an intersection or a mid-block location from one direction, including any adjacent parking lane(s).

3. Call. The result of the actuation of a vehicle or pedestrian detector.

4. Network. A geographical arrangement of intersecting roadways.

5. Platoon. A group of vehicles or pedestrians traveling together as a group either voluntarily or involuntarily because of traffic signal controls, geometrics, or other factors.

6. Ramp Control Signal (Ramp Meter). A traffic control signal installed to control the flow of traffic onto freeways at entrance ramps and freeway-to-freeway connections.

7. Right-of-Way (Assignment). Permitting vehicles and/or pedestrians to proceed in a lawful manner in preference to other vehicles or pedestrians by the display of signal indications.

8. Signal Installation. The traffic signal equipment, signal heads and their supports, and associated electrical circuitry at a particular location.

9. Signal Section. The assembly of a signal housing, lens, and light source with necessary components and supporting hardware to be used for providing one signal indication.

10. Signal System. Two or more traffic control signal installations operating in coordination.

11. Steady (Steady Mode). The continuous illumination of a signal indication for the duration of an interval, phase, or consecutive phases. The steady mode is used when a signalized location is operated in a stop-and-go manner.

12. Visibility-Limited Signal Indication. A type of signal face, signal section, or signal indication designed to restrict the visibility of a signal indication from the side, or to limit the visibility of a signal indication to a certain lane or number of lanes or to a certain distance from the stop line.

57-4.04 Traffic Signal Warrants

57-4.04(a) New Traffic Signals

The investigation of the need for a traffic signal includes an analysis of factors related to the existing operations and safety at the study location and the potential to improve these conditions, and the applicable factors contained in the following traffic signal warrants from Section 4C of the *ILMUTCD*.

- Warrant 1, Eight-Hour Vehicle Volume
- Warrant 2, Four -Hour Vehicle Volume
- Warrant 3, Peak Hour
- Warrant 4, Pedestrian Volume
- Warrant 5, School Crossing
- Warrant 6, Coordinated Signal System
- Warrant 7, Crash Experience
- Warrant 8, Roadway Network
- Warrant 9, Intersection near a Grade Crossing

If none of the warrants are satisfied, then a traffic signal should not be considered at the study location. Furthermore, the satisfaction of one or more of the warrants does not in itself justify the installation of a traffic signal. An engineering and traffic study of the site's physical characteristics and traffic conditions is necessary to determine whether a traffic control signal installation is justified at a particular location.

57-4.04(b) Existing Traffic Signals

If it is obvious that an existing traffic signal meets one or more of the traffic signal warrants, then no special documentation will be required.

The Phase I report should document whether the existing signals should be removed or retained based on the following as well as other supporting information:

- number of warrants met,
- expected development and traffic growth on intersecting streets,
- signal progression with adjacent signals, and
- crash potential due to either retention or removal of the signal.

Include a traffic count data sheet to verify that signal warrant(s) are or are not met in the appendix of the phase I project report.

57-4.04(c) Proposed Volumes

For new intersections or where proposed intersection improvements for large developments will significantly increase traffic volumes, traffic signals may be justified where the 8-hour vehicle volume three years after construction exceeds the values required for Warrant 1. The three-year time frame should be increased in the event of staged development. The 8-hour vehicle volume may be considered as 55% of the projected 30th maximum hour volume. See the *ILMUTCD* for additional guidance.

57-4.05 Traffic Signal Needs Study

Although one or more of the warrants presented in *ILMUTCD* may be satisfied, the results of a thorough engineering and traffic study of the site's physical characteristics and traffic conditions may indicate that the installation of a traffic signal is not the most prudent choice. A traffic signal should not be installed unless an engineering study indicates that installing the device will improve the overall safety and/or operation of the intersection. In addition to the *ILMUTCD* traffic signal warrants, consider the following factors:

1. Crash Experience. Consider alternative solutions to crash-related problems (e.g., removing parking, using advance warning signs or larger signs).

2. Geometrics. The intersection's geometric design can affect the efficiency of the traffic signal. Traffic signal installations at poorly aligned intersections may, in some cases, increase driver confusion and reduce the overall efficiency of the intersection. If practical, properly align the intersection to adequately accommodate turning lanes, through lanes, etc. See Chapter 36 for the geometric design criteria of intersections.

3. Costs. The installation and maintenance of traffic signals can be very expensive. A cost-effectiveness analysis may be necessary to determine if the benefits from the reduction in crashes and delays will actually exceed the costs associated with signalization.

4. Location. Consider the intersection relative to the adjacent land use type and density (e.g., urban, suburban, rural) and the potential for future development in the study area. Also consider the location of the intersection within the context of the overall transportation system (e.g., isolated locations, interrelated operations, functional classification). Normally, isolated locations are intersections where the distance to the nearest signalized intersection or potential future signalized intersection is greater than 0.5 mile (800 m).

5. Approach Geometrics and Volumes. For the purpose of comparing intersection conditions to the warrants, lanes added on major streets within 300 ft (90 m) of the intersection should not be considered as approach lanes unless a significant volume of traffic enters the streets within the added lane (e.g., ramp connection).

6. Temporary Signals. The need for temporary traffic signals will be determined on a case-by-case basis. These installations are typically considered for construction and maintenance projects. Use the warrants for permanent signal installations as guidelines to determine temporary signal needs. As practical, design temporary traffic signals consistent with the design criteria for permanent signal installations.

7. Design Year. Consider the design year during the study and assess the potential for future expansion at the intersection (e.g., construction of additional approach lanes).

8. Removal of Confusing Advertising Lights. Advertising lights, or other similar devices located adjacent to the roadway, that are similar in color to traffic signal indications, often can be mistaken for traffic signal control, interfere with the effectiveness of a traffic signal, and possibly contribute to driver confusion and crashes. Where this appears to be a problem, contact the property owner and local officials to explain the problem and possible solutions.

9. Provisions for Future Installations. Consider the future needs of the study location. Assess the anticipated traffic growth and future operational requirements of the signalized location during planning and design, as practical, so that later modifications can be readily incorporated, and total labor and material costs minimized. Traffic signal equipment should be specified with some degree of operational flexibility to accommodate future needs. This is illustrated by the following examples:

    a. If predicted traffic growth is likely to require a left-turn lane in the future, the design should accommodate this future need (e.g., equipment, phasing, circuitry, pole mounting).

    b. If a street will be widened or an intersection will be reconstructed in the foreseeable future, consider either a temporary signal or, if possible, an installation that conforms to the proposed final layout.

    c. If a need for a signal interconnect or additional phases can be foreseen, then provisions for these situations should be incorporated in the initial design.

57-4.06 Traffic Signal Operation

A traffic signal controller is an electronic device mounted in a cabinet for controlling the sequence and phase duration of the traffic signal. Right-of-way is assigned by either energizing or de-energizing the green indication. See the *Standard Specifications for Road and Bridge Construction*, *Bureau of Operations Traffic Policies and Procedures Manual* and the *ILMUTCD* for specifications, design, and application criteria of traffic signal controllers. The following sections provide general information on the various controller operations.

57-4.06(a) Pretimed Operation

A pretimed operation uses a fixed, consistent predetermined cycle length. There can be several different timing programs based on the time-of-day and/or day-of-week. A pretimed operation is best suited where traffic volumes and patterns are consistent from day-to-day (e.g., downtown areas), where variations in volumes are predictable, and where control timing can be preset to accommodate variations throughout the day.

57-4.06(b) Semi-Actuated Operation

Semi-actuated operation is based on vehicular detection from one or more approaches, but not on all approaches. Typically, vehicular detectors (e.g., loop detectors) are placed only on the minor approaches where traffic is light and sporadic. The major approaches are kept in the green phase until a vehicle on the minor approach is detected. If there is a demand on the minor approach and the minimum green time for the major approach has elapsed, the right-of-way then will be given to the minor approach. To accommodate various fluctuations on the minor approach, the minor approach is given enough time to clear one vehicle with additional time added for each new detection up to the maximum green time. Once the minor approach demand has been satisfied or when the maximum green time has been reached, the right-of-way then is returned to the major approach and the cycle begins again. If there is no minor approach demand, the major approach will remain in the green phase indefinitely.

Typical locations for semi-actuated operation include:

- school crossing intersections,
- on access routes to industrial areas or shopping centers,
- on access routes to recreational areas or sport centers,
- on cross streets with poorly spaced signals along the major route, and
- on cross streets with minimal traffic volumes.

57-4.06(c) Fully Actuated Operation

A fully actuated operation has detection devices on all approaches to the signalized intersection. The green interval for each street or phase is determined on the basis of volume demand. Continuous traffic on one street is not interrupted by a detector actuation from the side street until a gap in the traffic appears or when the preset maximum green time has elapsed. Once the minor street demand has been satisfied, right-of-way typically is returned to the major street whether or not a major street detection has been registered. Under heavy demand on all approaches, the intersection tends to operate as a pretimed signal.

A fully actuated operation is an appropriate design choice:

- at isolated locations where volumes on intersection legs are approximately equal with sporadic and varying traffic distribution,

- at locations where traffic signal control is warranted for only brief periods of the day,

- at locations where turning movements are heavy during specific time periods but are light at other times, and

- at high-speed locations where there is a need to avoid “dilemma zone” problems; see Section 57-4.11(c).

57-4.06(d) Pedestrian Control

The traffic signal controller is equipped to safely assign intersection right-of-way to various combinations of both vehicular and pedestrian traffic movements. This flexibility allows the designer to accommodate a pedestrian demand at the intersection by phasing and timing pedestrian WALK and DON'T WALK intervals. These intervals can be either pretimed or actuated by a pedestrian push button; see Section 57-4.07(e). Depending on the intersection design, bicyclists may negotiate the intersection either as a pedestrian or as part of the rolling traffic flow. See Section 57-4.07(f) for additional information on bicycle detection.

57-4.06(e) Special Operation

There are several specialty operations that may be used in a traffic signal design (e.g., flashing mode, signal preemption for emergency and non-emergency priority vehicles, and at highway-railroad grade crossings). These operations should be determined on a case-by-case basis.

57-4.07 <u>Traffic Detectors</u>

The efficient operation of a traffic-actuated signal installation depends greatly upon the proper design and placement of traffic detectors. See the applicable references in Section 57-1.02 for specifications, design, and application criteria for traffic detectors. The following sections provide general information on the various detector types.

57-4.07(a) Detector Operation

The primary purpose of a traffic detector is to detect the presence of a motor vehicle, bicyclist, or pedestrian or to detect the passage of a moving vehicle. The detector actuation is transmitted to the controller which adjusts the signal indications accordingly. There are many types of detector devices available. The inductive loop detector generally is accurate and is preferred because it can be used for passage or presence detection, vehicular counts, and vehicular speed determination.

57-4.07(b) Inductive Loop Detector

An inductive loop detector design consists of two or more turns of wire embedded below the pavement surface. As a vehicle passes over the loop, it disrupts the magnetic field associated with the current running through the wire. This disruption is recorded by a detector amplifier and is transmitted to the controller as a vehicular detection. The advantages of loop detectors are that they can:

- detect vehicles in both presence and passage modes,
- be used for vehicular counts and speed determinations, and
- be easily designed to meet various site conditions.

A major disadvantage of the loop detector is that it is very vulnerable to pavement surface irregularities (e.g., potholes and cracks), which can cause breaks in the loops.

57-4.07(c) Preformed Loop Detector

The preformed loop detector consists of a detector wire sealed with asphalt rubber or waterproof flexible sealant inside a conduit made of heavy-duty reinforced rubber hose or rigid plastic. This detector may be placed on a base course and covered by a bituminous or concrete surface course. This detector may also be placed within a concrete slab by attaching it to the reinforcing steel and pouring the concrete slab, encasing the detector. The preformed loop detector works the same way as the inductive loop detector.

Preformed loop detectors should be considered in situations where saw-cutting of pavement is impractical or impossible, such as in bridge decks or gravel road approaches to signalized intersections. This detector should be considered for use in concrete pavement because of pavement cracking associated with sawed loops.

57-4.07(d) Video Image Detector

The video image detector consists of one or more video cameras and an automatic control unit. The control unit detects a vehicle by comparing the images from the camera(s) to those stored in memory. The detector can work in both the presence and passage modes. This detector also allows the images to be used for counting and vehicular classification. Special housings are required to protect the camera from environmental elements. This detector should be considered for use with concrete pavement because of pavement cracking associated with sawed loops. Early models experienced problems during adverse weather conditions (e.g., wind, fog, rain, snow); however, recent versions have eliminated many of these problems.

57-4.07(e) Pedestrian Detectors

The most common pedestrian detector is the pedestrian push or call button. The push buttons, as “operable parts”, shall meet the requirements of Section R403 of the Draft *Public Right-of-Way Accessibility Guidelines* (PROWAG) and Part 4 of the ILMUTCD. Locate pedestrian call buttons so that they comply with *Americans with Disabilities Act* (*ADA*) requirements.

57-4.07(f) Bicycle Detectors

The two most common devices for bicycle detection include:

1. <u>Pedestrian Push-Button Detector</u>. With the push-button detector, the bicyclist must stop and push the detector button for the controller to record the call. This may require the bicyclist to leave the roadway and proceed on the sidewalk to push the detector button.

2. Inductive-Loop Detector. The inductive-loop detector (e.g., quadrupole) can detect the bicycle without the bicyclist's interaction. To ensure detection, the bicyclist should be guided directly over the loop wire. A problem with using inductive loop(s) for bicycle detection is that they require a significant amount of metal to be activated. Today's bicycle designs tend to use a substantial amount of non-metallic, man-made materials to increase their strength and reduce their weight. This substantially has reduced the amount of material that can be detected in bicycles.

57-4.08 Traffic Signal Mounting

Under most circumstances, traffic signals typically are mounted on mast arms that are placed on the far side of the intersection. This allows better location and alignment of signal heads for various lane configurations. In addition, the rigid mounting also allows for better control of the signal heads under wind-loading conditions. On mast arm mounted signals, provide one signal head per lane of traffic.

Under certain circumstances, pedestal- or post-mounted signals may be used (e.g., left-turn signal in median). See the IDOT publications in Section 57-1.02 for application and placement criteria on post-mounted signals in medians.

Under some temporary situations (e.g., temporary traffic signals in construction zones), signal heads may be mounted on span wires. Some problems with using span wire designs include:

- they do not provide enough rigidity under wind-loading conditions,
- the signal faces are difficult to see on narrow streets,
- pedestrians have difficulty seeing the signal faces, and
- installations are often considered to be aesthetically displeasing.

Consequently, span wire designs typically are not used for permanent installations. See the applicable references in Section 57-1.02 for specifications on mounting materials and for design and application criteria for typical traffic signal mounting.

57-4.09 Placement of Traffic Signal Equipment

In general, the designer has limited options available in determining acceptable locations for the placement of signal pedestals, signal poles, pedestrian detectors, and controllers. Considering roadside safety, place these elements as far from the roadway as practical. However, due to visibility requirements, limited mast-arm lengths, limited right-of-way, restrictive geometrics, or pedestrian requirements, traffic signal equipment often must be placed relatively close to the traveled way. Consider the following when determining the placement of traffic signal equipment:

1. Clear Zones. If practical, the placement of traffic signals on new construction and reconstruction projects should meet the clear zone criteria presented in Section 38-3.

2. Controller. In determining the location of the controller cabinet, consider the following:

a. The controller cabinet should be placed in a position so that it is unlikely to be struck by an errant vehicle. It should be placed outside of the clear zone, if practical.

b. The controller cabinet should be located where it can be easily accessed by maintenance personnel.

c. The controller cabinet should be placed so that a technician working in the cabinet can see the signal indications in at least one direction.

d. The controller cabinet should be located where the potential for water damage is minimized.

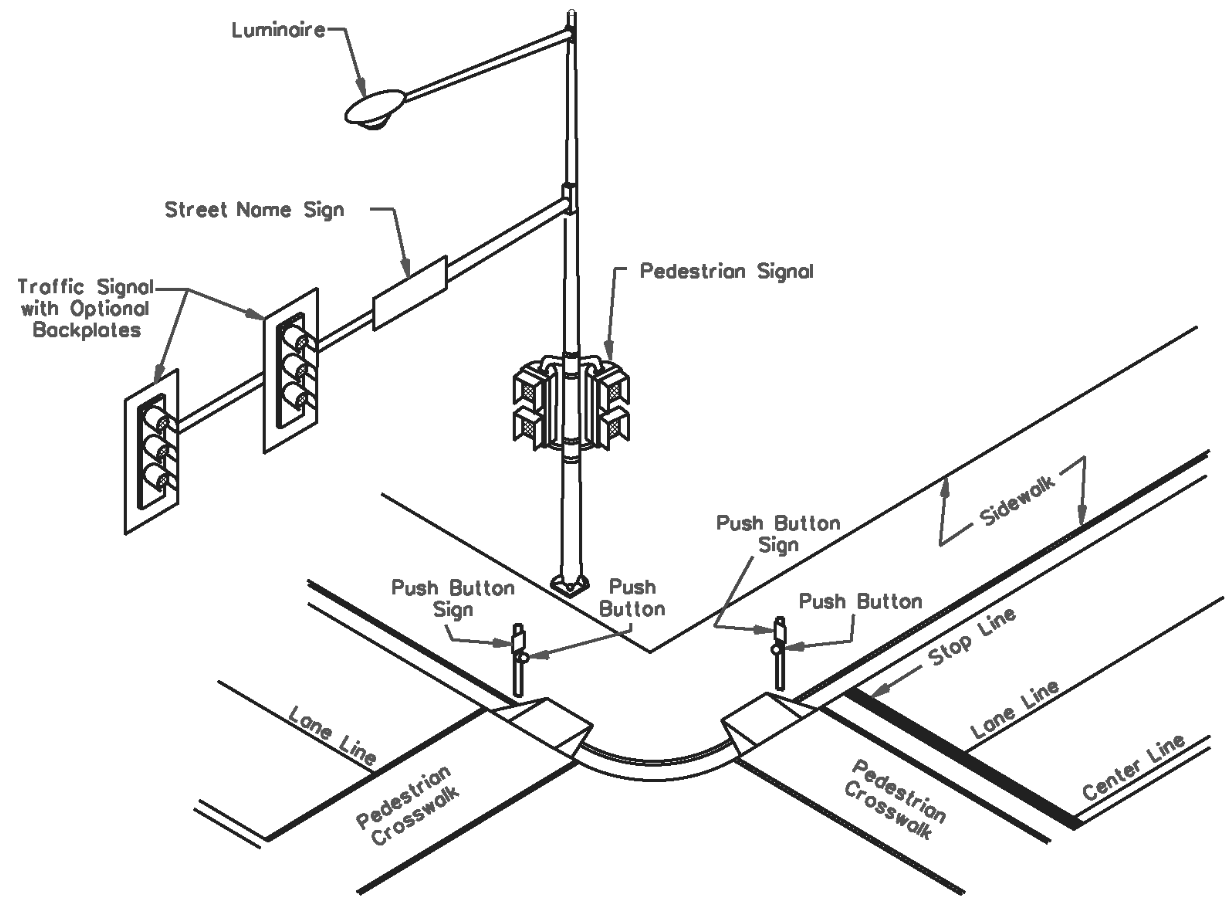
e. The controller cabinet should not obstruct intersection sight distance.

f. The power service connection should be reasonably close to the controller cabinet.

3. Pedestrians. All new and altered pedestrian signals including those used in conjunction with pedestrian hybrid beacons (PHB) shall include accessible pedestrian signals (APS) with push buttons. If the signal pole must be located in the sidewalk, it shall be placed in a location that minimizes pedestrian conflict. In addition, the signal pole shall not restrict access to curb ramps or reduce the sidewalk width below minimum; see Chapter 58.

4. Layout. Figure 57-4.A illustrates a typical urban traffic signal pole installation.

See the *Bureau of Operations Traffic Policies and Procedures Manual, ILMUTCD,* and the applicable references in Section 57-1.02 for specific IDOT criteria for the placement of traffic signal equipment (e.g., placement of signals in medians, use of near-right signals).



TYPICAL TRAFFIC SIGNAL POLE INSTALLATION

Figure 57-4.A

57-4.10 Traffic Signal Phasing

The district Bureau of Operations is responsible for determining the signal phasing plan. The selected phase designation diagram must be included in the traffic signal details and should identify the roadway preferentially. The following sections provide information on signal phasing.

57-4.10(a) Phasing Types

A traffic phase is defined as the part of the signal cycle allocated to any combination of traffic movements receiving the right-of-way simultaneously during one or more intervals. A phase includes the green, yellow change, and red clearance intervals. Each cycle can have two or more phases. As the number of non-overlapping phases increases, the total vehicular delay at the intersection will increase due to the lost time of starting and clearing each phase. Strive to use the minimum number of phases practical that will accommodate the existing and anticipated traffic demands. As necessary, conduct a capacity analysis to determine if the proposed phasing is appropriate. The following presents typical applications of various phase operations:

1. Eight-Phase Operation. An eight-phase operation provides the maximum efficiency and minimum conflict for high-volume intersections with heavy turning movements. Left-turn lanes should be provided on all approaches. It is most appropriate for actuated control with detection on all approaches. The eight-phase operation allows for the skipping of phases or selection of alternate phases depending upon traffic demand. The *Highway Standards* illustrate a typical eight-phase operation. An eight-phase operation uses the NEMA dual-ring controller.

2. Other Phases. For other phase operations (e.g., six-phase operations), the eight-phase operation can be used by eliminating the non-applicable phases from the sequence.

Highway Standard 857001 illustrates the movements that typically should be assigned to the various numbered phases. As a general rule, on four- and eight-phase operations, the through movements are assigned to the even-numbered phases, and the left turns are assigned to the odd-numbered phases.

The signal controller permits control of each individual phase. Each phase is programmed as a single-entry operation in which a single phase can be selected and timed alone if there is no demand for service in a non-conflicting phase. Dual entry programming may be used to allow timing of concurrent phasing when a demand for a conflicting phase does not exist.

There are several computer programs available that can assist the designer in determining the appropriate phasing requirements; see Section 57-4.12.

57-4.10(b) Left-Turn Phases

The most commonly added phases are for left turns (i.e., left-turning vehicles are given a green arrow without any conflicting movements). Left-turn phases can be either a leading left, where the protected left turn precedes the opposing through movements, or a lagging left, where the left-turn phase follows the opposing through movements. The decision on when to use either a leading-left or a lagging-left turn will be determined on a case-by-case basis. In most situations, the preferred practice is to use the leading left. Leading pedestrian intervals may necessitate the use of lagging lefts which in turn may require further modifications to left turn phasing such as protected-only or flashing yellow arrows. The district Bureau of Operations should be contacted for further information and guidance. Figure 57-4.B provides a comparison for each left-turn phase alternative.

Not all signalized intersections will require a separate left-turn phase. The decision on when to provide an exclusive left-turn phase is dependent upon such factors as traffic volumes, delays, and crash history. Its use will be determined on a site-by-site basis. For intersections with exclusive left-turn lanes, consider the following guidelines when determining the need for a left-turn phase:

1. Capacity. Consider a left-turn phase where the demand for left turns exceeds the left-turn capacity of the approach lane.

2. Delay. Consider a left-turn phase where the delay time for left-turning vehicles is excessive for four hours during an average day. Delay is considered excessive when left-turning vehicles are delayed for more than two complete signal cycles.

3. Miscellaneous. In addition to capacity and delay guidelines, consider intersection geometrics, total volume demand, crash history, posted speeds, etc.

57-4.11 Traffic Signal Timing

57-4.11(a) Pretimed Control

Consider the following guidelines when developing signal timing for pretimed signals:

1. Phases. Keep the number of phases to a minimum. Each additional phase reduces the effective green time available for the movement of traffic flows (i.e., increased lost time due to starting delays and clearance intervals). Adding concurrent phases, if feasible, will normally enhance capacity.

2. Cycle Lengths. Short cycle lengths yield the best performance by providing the lowest average delay, provided the capacity of the cycle to serve the vehicles is not exceeded. In general, consider the following relative to cycle lengths:

    a. Delay. For two-phase operations, shorter cycle lengths generally produce the shortest delays.

    b. Capacity. Longer cycle lengths will accommodate more vehicles per hour if there is a constant demand during the entire green period on each approach. Longer cycle lengths have higher capacity because, over a given time period, there are fewer starting delays and clearance intervals.

Leading-Left-Turn Phase	
Advantages	**Disadvantages**
• Minimizes conflicts between left-turn and opposing straight through vehicles by clearing the left-turn vehicles through the intersection first. • Drivers tend to react quicker than with lagging-left operations.	• Left-turning vehicles completing their movement may delay the beginning of the opposing through movement when the green is exhibited to the stopped opposing movement. • Opposing movements may make a false start in response to the movement of the vehicles given the leading green.
Lagging-Left-Turn Phase	
Advantages	**Disadvantages**
• Both directions of straight through traffic start at the same time. • Approximates the normal driving behavior of vehicular operators. • Provides for vehicle/pedestrian separation as pedestrians usually cross at the beginning of straight through green or several seconds ahead of straight through green where a leading pedestrian interval (LPI) is used. • Where pedestrian signals are used, pedestrians have cleared the intersection by the beginning of the lag- green interval. • Cuts off only the platoon stragglers from adjacent interconnected intersections.	• Left-turning vehicles can be trapped during the left-turn yellow change interval as opposing through traffic is not stopping as expected which can lead to crashes.

COMPARISON OF LEFT-TURN PHASE ALTERNATIVES

Figure 57-4.B

3. Green Intervals. The division of the cycle into green intervals will be approximately correct if made proportional to the critical lane volumes for the signal phases. The critical lane volumes can be determined quickly by using the Planning Methodology from the *Highway Capacity Manual*. In addition, check the green interval against the following:

    a. Pedestrians. If pedestrians will be accommodated, check each green interval to ensure that it is not less than the minimum green time required for pedestrians to cross the respective intersection approaches plus the initial walk interval time.

    b. Minimum Lengths. In general, relative to driver expectations, major movements should not have green intervals that are less than 15 seconds. Exceptions to this may be appropriate for turn phases.

4. Capacity. For intersection approaches with heavy left turns, the capacity of an intersection should be checked to determine the need for a separate left-turn lane; see Section 57- 4.10.

5. Phase Change Interval. Check each phase change and clearance interval (yellow and all-red) to ensure that approaching vehicles can either come to a stop or clear the intersection during the change interval.

6. Coordination. Traffic signals within 0.5 mile (800 m) of each other should be coordinated together in a system. Section 57-4.13 further discusses signal system coordination.

7. Field Adjustments. All signal-timing programs should be checked and adjusted in the field to meet the existing traffic conditions.

When determining appropriate cycle and interval lengths, consider the following:

1. General. Cycle lengths generally should fall within the following ranges:

    - Two-Phase Operations — 50 - 80 seconds.
    - Three-Phase Operations — 60 - 100 seconds.
    - Four-Phase Operations — Minimum 80 seconds.

2. Phase Change Interval. The yellow change interval advises drivers that their phase has expired, and that they should stop prior to the stop line or allows them to enter the intersection if they are too close to stop. The yellow change interval should be followed by a red-clearance interval (all-red phase) of sufficient duration to permit traffic to clear the intersection before conflicting traffic movements are released. The equation for calculating phase change intervals is found in the *Bureau of Operations Traffic Policies and Procedures Manual*.

There are several software programs available to assist in determining the most efficient design. Section 57-4.12 discusses several of these programs.

57-4.11(b) Basic-Actuated Control

Actuated-control designs are somewhat different than that of pretimed control. The design of actuated control is basically a trade-off process to optimize the location of vehicular detection to provide safe operation, but yet provide controller settings that will minimize the intersection delay. The compromises that must be made among these conflicting criteria become increasingly difficult to resolve as approach speeds increase. The following discusses some of the design considerations for actuated controls.

Basic-actuated control with passage detection is limited in application to isolated intersections with fluctuating or unpredictable traffic demands and low approach speeds. Basic-actuated control can be employed using either semi-actuated or full-actuated operation.

Because of the small area covered by the small-loop detector and its location from the stop line, this type of detection typically is used with controllers that have a locking memory feature for detector calls (i.e., the controller retains the detector actuation made during yellow and red intervals and when an arriving vehicle did not receive enough green time to reach the intersection).

When developing the signal timing plan and establishing detector locations for basic-actuated control, consider the following:

1. Minimum Assured Green (MAG). Although there is no timing adjustment labeled MAG on the controller, the designer still must calculate the MAG. The minimum green time is composed of the initial green interval plus one vehicle extension. Long minimum greens should be avoided. For snappy operation, the minimum assured green normally should be between 10 and 20 seconds for any major movement. Base the actual value selected on the time it takes to clear all possible stored vehicles between the stop line and the detector. If the MAG is too short, the stored vehicles may be unable to reach the stop line before the signal changes. Use Equation 57-4.1 to calculate MAG:

   $$MAG = 3.7 + 2.1n$$ *(Greenshield's Formula)* (Equation 57-4.1)

   where: MAG = minimum assured green, s

   n = number of vehicles per lane which can be stored between the stop line and the detector

   Where pedestrians must be accommodated, a pedestrian detector (e.g., APS with push button) should be provided. Ensure that the timing will be sufficient for the pedestrian to cross the intersection. The minimum times for pedestrians, as discussed in Section 57- 4.11(a) for pretimed signals, is also applicable to actuated systems.

2. Initial Green. The initial green setting is simply the MAG, usually minus one vehicular extension. Typically, the initial green should be limited to a maximum of 10 seconds.

3. Detector Placement. Set the detector setback distance equal to the time required for the typical vehicle to stop before entering the intersection. The vehicular passage time

typically is used to determine this placement. Use the posted speed of the approach roadway to determine the appropriate setback.

4. Maximum Green Interval. This is the maximum time the green should be held for the green phase, given detection from the side street. Typically, for light to moderate traffic volumes, the signal should "gap out" before reaching the maximum green time. However, for periods with heavy traffic volumes, the signal rarely may gap out. Therefore, a maximum green interval is set to accommodate the waiting vehicles. The maximum green interval can be determined assuming a pretimed intersection. It may be somewhat longer to allow for peaking.

5. Change and Clearance Interval. Determine these intervals in the same manner as for pretimed signals.

6. Left-Turn Lanes. Left-turn lanes should be treated like side streets with semi-actuated control. Use short allowable gaps and minimum greens times. The designer must be careful of vehicles which may enter the left-turn lane beyond the detector. Presence detectors should be used at the stop line.

7. Intermediate Traffic. Where vehicles can enter the roadway between the detector and intersection (e.g., driveways, side parking) or where a vehicle may be traveling so slow that it does not clear the intersection in the calculated clearance time, the signal controller will not register their presence. A presence detector at the stop line may be required to address these situations; see Section 57-4.11(d).

57-4.11(c) Advanced-Design Actuated Control

Advanced-design actuated control usually is used at isolated intersections with fluctuating or unpredictable traffic demands and high-speed approaches. An advanced-design actuated control is one that has a variable initial interval. It can count waiting vehicles beyond the first and can extend the initial interval to meet the needs of the number of vehicles actually stored between the stop line and the detector. As with basic-actuated control, the small-area detection requires that the controller have a locking memory.

The timing for advanced-design actuated control requires a significant amount of judgment. Therefore, field adjustments often are required after the initial setup. The following discusses several considerations in the signal timing and detector placement:

1. Detector Placement. For high-speed approaches, locate the detector in advance of the dilemma zone as illustrated in Figure 57-4.C. This typically will place the detector about 5 seconds of passage time from the intersection. The speed selected should be the posted speed of the approach roadway. Figure 57-4.D provides the appropriate detector setback distances for various combinations of passage times and approach speeds. Figure 57-4.D also provides the passage times that are appropriate for various other types of actuated controls.

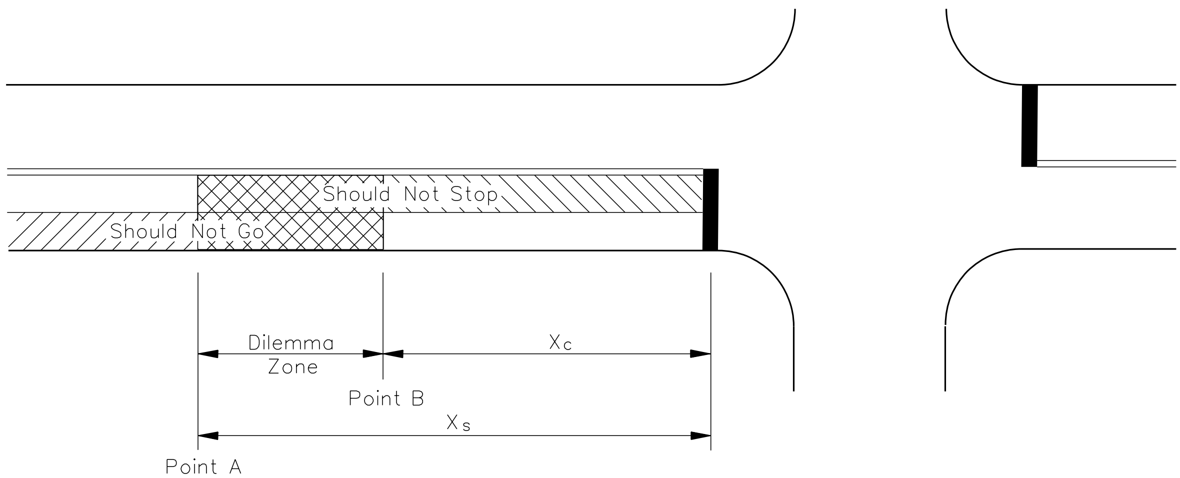
2. Minimum Initial. Because the controller can count the number of vehicular arrivals, the minimum initial time only should be long enough to meet driver expectancy. Typically, the minimum initial interval is set at eight to fifteen seconds for through movements and five to seven seconds for left turns.

3. Variable Initial. The variable initial is the upper limit to which the minimum initial can be extended. It must be long enough to clear all vehicles that have accumulated between the detector and the stop line during the red. The variable initial is determined in the same manner as the minimum assured green for basic-actuated control; see Section 57-4.11(b).

4. Number of Actuations. The number of actuations is the number of vehicles that can be accommodated during the red that will extend the initial green to the variable initial limit. This is a function of the number of approach lanes, average vehicle length, and lane distribution. It should be set based on the worst-case condition (i.e., vehicles are stored back to the detector).

5. Passage Time. The passage time is the time required for a vehicle to pass from the detector to the stop line. This typically is based on the posted speed of approach roadway.

6. Maximum Green. The maximum green should be set the same as for basic-actuated control; see Section 57-4.11(b).



Notes:

1. X_C = *Maximum distance upstream of stop line from which a vehicle can clear the intersection during the yellow change interval.*

2. X_S = *Minimum distance from stop line where the vehicle can stop completely after the beginning of the yellow change interval.*

3. *At "Point A," 90% of the drivers will decide to stop at the onset of the yellow indication while 10% of the drivers will continue through the intersection.*

4. *At "Point B," 10% of the drivers will decide to stop at the onset of the yellow indication while 90% of the drivers will continue through the intersection.*

5. *For further information on dilemma zones, see FHWA* Traffic Detector Handbook*.*

DILEMMA ZONE

Figure 57-4.C

DETECTOR SETBACK DISTANCE — ft (m)							
Approach Posted Speed (mph)	Passage Time in Seconds from Detector to Stop Line						
	1	2	3	4	5	6	7
20	29 (9.0)	58 (17.5)	87 (26.5)	116 (35.5)	145 (44.0)	174 (53.0)	196 (59.5)
25	36 (11.0)	78 (24.0)	108 (33.0)	144 (44.0)	180 (55.0)	216 (66.0)	252 (77.0)
30	44 (13.5)	88 (27.0)	132 (40.0)	176 (53.5)	220 (67.0)	264 (80.5)	308 (94.0)
35	51 (15.5)	102 (31.0)	153 (46.5)	204 (62.0)	255 (77.5)	306 (93.0)	357 (109.0)
40	59 (18.0)	118 (36.0)	177 (54.0)	236 (72.0)	295 (90.0)	354 (108.0)	413 (126.0)
45	66 (20.0)	132 (40.0)	198 (60.5)	264 (80.5)	330 (100.5)	396 (121.0)	462 (141.0)
50	73 (22.5)	146 (44.5)	219 (67.0)	292 (89.0)	365 (111.5)	438 (133.5)	511 (156.0)
55	81 (24.5)	162 (49.5)	243 (74.0)	324 (99.0)	405 (123.5)	486 (148.0)	567 (173.0)
60	88 (27.0)	176 (53.5)	264 (80.5)	352 (107.5)	440 (134.0)	528 (161.0)	616 (188.0)
65	95 (29.0)	190 (58.0)	285 (87.0)	380 (116.0)	475 (145.0)	570 (173.5)	665 (203.0)

Legend: Basic Controllers (thin line); Density (thick line); Variable Initial Only (double line); Dilemma Zone (shaded)

DETECTOR SETBACK DISTANCES

Figure 57-4.D

7. Allowable Gap. The density feature in controllers permit a gradual reduction of the allowable gap to a preset minimum gap based on one or more cross-street traffic parameters — time waiting, cars waiting, and/or density. Generally, time waiting has been found to be the most reliable and usable. As time passes after a conflicting call, the allowable gap time is gradually reduced. The appropriate minimum gap setting will depend on the number of approach lanes, the volume of traffic, and the various times of day. Fine-tuned adjustments will need to be made in the field.

8. Change and Clearance Interval. Determine these intervals in the same manner as for pretimed signals.

57-4.11(d) Actuated Control with Large Detection Areas

Large area detectors are used in basic-actuated control in the "non-locking" memory mode and with the initial interval and vehicular extension set at or near zero. This is referred to as the loop occupancy control (LOC). Large area detectors are used in the presence mode, which holds the vehicle call for as long as the vehicle remains over the loop. One advantage of large area detectors is that they generally reduce the number of false calls due to right-turn-on-red vehicles. With large area detectors, the length of the green time is determined by the time the area is occupied. However, a minimum green time of eight to fifteen seconds should be provided for driver expectancy. The following discusses several applications for LOC:

1. Left-Turn Lanes. An LOC arrangement is appropriate for left-turn lanes where left turns can be serviced on a permitted green or yellow change or where vehicles can enter the left-turn lane beyond the initial detector. Consider the following when using the LOC for left turns:

    - To ensure that the driver is fully committed to making the left turn, the initial loop detector may need to be installed beyond the stop line to hold the call.

2. Through Lanes (Low-Speed Approaches). On low-speed approaches, the dilemma zone protection generally is not considered a significant problem. The length of detection area and controller settings are determined based on the desired allowable gap. For example, assuming a 30 mph (48 km/hr) approach speed and three-second desired allowable gap, the length of LOC area is calculated to be as follows:

$$\frac{30\text{ mi}}{\text{h}} \times \frac{5280\text{ ft}}{\text{mi}} \times \frac{\text{h}}{3600\text{ s}} \times 3\text{s} = 132\text{ ft} \qquad \text{(US Customary) Equation 57-4.2}$$

$$\frac{48\text{ km}}{\text{h}} \times \frac{1000\text{ m}}{\text{km}} \times \frac{\text{h}}{3600\text{ s}} \times 3\text{s} = 40\text{ m} \qquad \text{(Metric) Equation 57-4.2}$$

By subtracting the vehicular length 20 ft (6 m) from the length of LOC area, the required length of detection area then is 112 ft (34 m). If a typical loop layout is 45 ft (13.7 m) long; then, for a 30 mph (48 km/hr) approach speed, the vehicular extension setting should be set at 1.5 seconds to provide the three-second gap. The vehicular extension setting of 1.5 seconds for a 30 mph approach speed was calculated as follows:

$$\frac{112\text{ ft} - 45\text{ ft}}{\frac{30\text{ mi}}{\text{h}} \times \frac{5280\text{ ft}}{\text{mi}} \times \frac{\text{h}}{3600\text{ s}}} = 1.5\text{ s}$$

If the initial interval is set at zero and the vehicular extension is between zero and one second then, under light traffic conditions, a green as short as two or four seconds may occur. Check to determine if there are pedestrians or bicyclists present; if so, provide the minimum green times for their crossings. Also consider driver expectancy. Generally, drivers for major through movements expect a minimum green interval of eight to fifteen seconds.

3. Through Lanes (High-Speed Approaches). For high-speed approaches, it generally is not practical to extend the LOC beyond the dilemma zone (five seconds of passage time back from the stop line). To cover the dilemma zone problem, an extended-call detector is placed beyond the dilemma zone. This detector is used in a non-locking mode. The time extension is based on the time for the vehicle to reach the LOC area. Intermediate detectors may be used to better discriminate the gaps.

   There are several concerns with using the LOC concept for high-speed approaches. Some of these concerns include the following:

   - The allowable gap generally is higher than the normally desired 1.5 to 3 seconds. The controller's ability to detect gaps in traffic is impaired substantially. As a result, moderate traffic routinely will extend the green to the maximum setting — an undesirable condition.

   - For high-speed approaches, LOC designs only should be used if the route is lightly traveled (e.g., 8,000 to 10,000 ADT). High-speed approaches with heavy volumes are served better with density control. The intersection of a high-speed artery with a low-speed crossroad might be served better by using density control on the artery and LOC for the crossroad.

57-4.12 Computer Software

There are numerous software programs available to assist the designer in preparing traffic signal designs and timing plans. New programs, as well as updates to existing programs, are being continuously developed. The current Highway Capacity Manual and the following website, http://ops.fhwa.dot.gov/trafficanalysistools/index.htm, are recommended for aid in selecting the appropriate analysis tool. The following programs are the most widely used for signal timing and optimization:

1. Highway Capacity Software. The Highway Capacity Software (HCS) replicates the procedures described in the *Highway Capacity Manual*. It is a tool that greatly increases productivity and accuracy, but it should be used only in conjunction with the *Highway Capacity Manual* and not as a replacement for it. HCS is the software required by IDOT for intersection and interchange capacity analyses.

2. Synchro. Synchro provides interactive time-space diagrams for arterials. It can be used to optimize signal splits, cycle lengths, phase orders, and offsets. Outputs include vehicle delay, level of service, queue length, queuing penalty, stops, fuel usage, and dilemma vehicles.

3. SIDRA. IDOT requires the current version of **S**ignalized (and unsignalized) **I**ntersection **D**esign and **R**esearch **A**id (SIDRA) for capacity analyses of roundabouts. SIDRA closely follows the methods used in the *Highway Capacity Manual* (HCM), which IDOT requires for computing highway capacity analyses. SIDRA software also includes alternative tools for applications beyond the ability of the HCM.

Most of these software programs can be purchased from McTrans Center, Trafficware LTD., or from Strong Concepts. SIDRA can be purchased directly from the software manufacturer. Many of these software programs can be used for either the network operating systems or stand-alone operating systems.

57-4.13 Signal System Design

As traffic volumes continue to grow, installing coordinated signal systems is an important consideration for improving traffic flow. By coordinating two or more traffic signals together, the overall capacity of the facility can be increased significantly. As compared to constructing additional lanes, coordinating traffic signals is a relatively inexpensive method of improving capacity because it reduces vehicular delay with minimal disruption to the highway system. Although not a capacity panacea, the use of a coordinated traffic signal system could satisfy the needs of highway users for many years. Generally, traffic signals that are within 0.5 mile (800 m) of each other are good coordination candidates. The following sections present application guidelines for traffic signal systems.

57-4.13(a) System-Timing Parameters

The basic system-timing parameters used in a coordinated system include:

1. Cycle. The period of time in which pretimed control (or actuated control, with demand on all phases) displays a complete sequence of signal indications. In most systems, the cycle length is common to all intersections operating together and is called the background cycle.
2. Split. The proportioning of the cycle length among the various phases of the local controller.
3. Offset. The time relationship determined by the difference between a specific point in the local signal sequence (typically the beginning of the major street green interval) and a system-wide reference point.
4. Time-of-Day/Day-of-Week. The time-of-day/day-of-week system selects system timing plans based on a predefined schedule. The timing plan selection may be based not only on the time-of-day but also on the day-of-week and week-of-year. Some systems permit the selection of plans based upon a specific day of the year.
5. Traffic Responsive. Traffic-responsive systems implement timing patterns based on varying traffic conditions in the street. Most traffic-responsive systems select from a number of predeveloped timing plans.

57-4.13(b) Advantages of Traffic Signal Systems

A primary objective of installing a traffic signal system is to develop a good progression of traffic. Some advantages of providing good traffic progression are as follows:

1. Operational and Environmental Benefits. Traffic signal systems reduce fuel consumption, pollutant emissions, and vehicle operating costs.

2. Increase In Capacity. A higher level of traffic service is provided in terms of higher overall speed and reduced number of stops. Traffic will flow more smoothly and an improvement in level of service often results.

3. Speed Uniformity. The speed of vehicles will be more uniform because there will be no incentive to travel at excessively higher speeds to make a green signal indication that is not in step. On the other hand, the slow driver is encouraged to speed up to avoid having to stop for a red-signal indication.

4. Crash Reduction. Fewer crashes will result because platoons of vehicles will arrive at each traffic signal at a green signal indication, thereby reducing the possibility of red-signal violations and rear-end collisions. Naturally, if there are fewer occasions when a red-signal indication is displayed to a majority of motorists, there is less likely to be crashes than can be attributed to due to driver inattention, brake failure, slippery pavement conditions, and other similar factors.

5. Greater Traffic Control Obedience. Greater obedience to signal indications will be obtained from both motorists and pedestrians. This results because motorists will aggregate in platoons of closely-spaced vehicles due to their desire to ride the “green wave” produced by the coordinated signals. Pedestrians will remain at curbside during the passage of each platoon and realize a sufficient gap between platoons to safely cross.

6. Greater Use of Arterial Streets. Through traffic will tend to remain on arterial streets rather than shifting their route over to parallel minor streets.

57-4.13(c) System Types

There are several different methodologies available to coordinate traffic signals. Most of these take advantage of computer technology. As new signal controllers, computers, and software are developed, the design of coordinated traffic signal systems will continue to improve. These systems should match existing systems and/or be coordinated with nearby systems as practical. The following briefly describes several types of traffic signal coordination systems:

1. Interconnected Time-of-Day System. The interconnected time-of-day system is applicable to both pretimed and actuated control, in either a grid system or along an arterial system. The typical configuration for this type of system includes a field-located, time clock-based master controller generating pattern selection and synchronization commands for transmission along a cable interconnect. Local intersection coordination equipment interprets these commands and implements the desired timing.

2. Time-Base-Coordinated Time-of-Day System. Time-base coordination often is used as a backup for computerized signal systems. Operationally equivalent to the interconnected time-of-day system, this type of system uses accurate time-keeping techniques to

maintain a common time of day at each intersection without physical interconnection. Time-base coordination is tied to the 60 Hz AC power supply, with a battery backup in case of a power failure.

Time-base coordination allows for the inexpensive implementation of a coordinated signal system because the need for a cable interconnect is eliminated. However, time-base systems require periodic checking by maintenance personnel, because the 60 Hz reference from the power company sometimes is inconsistent. In addition, power outages sometimes affect only portions of a system, resulting in drift between intersections that continue to operate on power company lines and those that maintain time on a battery backup.

3. Adaptive or Traffic-Responsive Arterial Systems. The traffic-responsive arterial system normally is used with semi-actuated controllers along an arterial. The field located system master selects predetermined cycle lengths, splits, and offsets based upon current traffic flow measurements. These selections are transmitted along a cable interconnect to the slave controllers at the local intersections.

   Cycle lengths are typically selected based on volume (and sometimes occupancy) level thresholds on the arterial; the higher the volumes, the longer the cycle length. Splits frequently are selected based on the side-street volume demands, and offsets are selected by determining the predominant direction of flow along the arterial.

   System sampling detectors, located along the arterial, transmit data back to the master controller along the interconnect cable. Most current systems have the capability to implement plans on a time-of-day basis as well as through the use of traffic-responsive techniques.

4. Distributed-Master (Closed-Loop) Systems. The distributed-master (frequently called closed-loop) system advances the traffic-responsive arterial system one step further by adding a communications link between the field-located master controller and an office-based microcomputer. Most systems are designed to interface with a standard personal computer over dial-up telephone lines or fiber optic lines. This connection is established only when the field master is generating a report or when the operator is interrogating or monitoring the system. With proper equipment, several systems can share a single office-based microcomputer.

   The system permits the maintenance of the complete controller database from the office. The controller's configuration data, phase and timing parameters, and coordination patterns can be downloaded directly from the office.

   The distributed-master system provides substantial remote monitoring and timing plan updating capabilities for only a minor increase in cost — typically, only the expense of the personal computer and the monthly costs of a standard business telephone line. Graphics displays usually are provided to assist in monitoring the system.

57-4.13(d) Communications Techniques

Systems other than time-base-coordinated systems require some type of communications medium to maintain synchronized operation between intersections. Two primary communications options are available. One is to employ hardwired communications through leased telephone lines, fiber optics, or direct wiring. A second option, which has been unreliable in some cases, is to utilize the through-the-air frequencies of radio communications and cellular telephone equipment. The requirements for the communications network depend on the needs of the system. Therefore, decisions on an appropriate communications technique will be made on a case-by-case basis.

58-1 ACCESSIBILITY STANDARDS

58-1.01 General

58-1.01(a) Referenced Accessibility Standards

Section 504 (49 CFR 27) of the Rehabilitation Act of 1973 (29 U.S.C. 794), the Illinois Environmental Barriers Act, 410 ILCS 25/1, and Title II (28 CFR 35) of the Americans with Disabilities Act (ADA) of 1990 (42 U.S.C. 12131) prohibit discrimination on the basis of disability by public entities. To that end, the following sections present guidance which is intended to ensure the Department's newly constructed facilities, and existing facilities being altered, are accessible to individuals with disabilities. The guidance is generally based on information presented in the *2010 ADA Standards for Accessible Design* and the *Illinois Accessibility Code*. However, for situations in the public right of way that are not specifically or adequately addressed by either of the above standards, the guidance is taken from information presented in the *Draft Public Rights-of-Way Accessibility Guidelines (Draft PROWAG)*.

Where other agencies or local codes require criteria which exceed the above referenced standards, then the stricter criteria may be required. This will be determined on a case-by-case basis.

58-1.01(b) Scoping Requirements - New Construction, Added Elements, and Alterations

When determining the scope of an improvement, the following categories of action must be considered.

1. New Construction. Newly constructed facilities shall fully comply with the applicable accessibility requirements.

2. Added Elements. Elements added to existing facilities shall fully comply with the applicable accessibility requirements. However, where elements are added to existing facilities but the pedestrian circulation path serving the added elements is not altered, the pedestrian circulation path is not required to be altered if out of compliance. For example, if a new bench is installed on an existing sidewalk that has a cross slope exceeding 2 %, the sidewalk is not required to be altered to reduce the cross slope because the bench is installed on the sidewalk.

3. Alterations. Alterations are changes to an existing facility that affect or could affect pedestrian access, circulation, or use. Alterations include: resurfacing, rehabilitation, reconstruction, historic restoration, or changes or rearrangement of structural parts or elements of a facility as well as the various roadway surface treatments listed as such in

Figure 58-1.A. Note: The surface treatments listed under the heading "Maintenance" in Figure 58-1.A are not considered alterations and thus do not trigger the need to address ADA.

Altered elements, spaces, or facilities shall comply with the applicable accessibility requirements to the maximum extent practicable within the scope of the project. This typically means that alterations must be fully compliant; however, there are exceptions.

- Existing Physical Constraints. Where existing physical constraints make it impracticable for altered elements, spaces, or facilities to fully comply with the applicable accessibility requirements, compliance is required to the extent practicable within the scope of the project. Existing physical constraints include, but are not limited to, underlying terrain, right-of-way availability, underground structures, adjacent developed facilities, drainage, or the presence of a notable natural or historic feature.

- Alterations to Qualified Historic Facilities. Where the State Historic Preservation Officer or Advisory Council on Historic Preservation determines that compliance with a requirement would threaten or destroy historically significant features of a qualified historic facility, compliance shall be required to the extent that it does not threaten or destroy historically significant features of the facility.

- Transitional Segments. Transitional segments used to connect new, added, or altered elements to existing unaltered elements shall comply to the extent practicable.

One other requirement for alterations is they shall not decrease or have the effect of decreasing the accessibility of a facility or an accessible connection to an adjacent building or site.

The issue of whether resurfacing constitutes an alteration within the scope of Section 504 of the Americans with Disabilities Act (ADA) was at the heart of a court case in Philadelphia, PA (*Kinney v. Yerusalim*, 9 F.3d 1067 (3d Cir. 1993), cert. denied, 511 U.S.C. 1033 (1994)). The plaintiffs argued that the City of Philadelphia violated the ADA when the City only installed curb cuts when work on the City streets otherwise affected the curb or sidewalk and not during resurfacing projects. The City did not dispute the requirement that the regulations mandate the installation of curb cuts when the City "alters" a street. The City protested the notion that resurfacing of a street constituted an alteration. The judgment determined an alteration occurs when the usability of a facility is affected, and, if affected, the alteration should apply to all users. Further an interpretation of the guidelines determined interdependency between the street and its curbs. If a street is to be altered to make it more usable for the general public, it also must be made more usable for those with ambulatory disabilities thus requiring installation or upgrading of curb ramps.

The basis for the various roadway surface treatments listed in Figure 58-1.A to be classified as either alterations or maintenance is discussed in joint technical assistance issued by the U.S. Department of Justice and the U.S. Department of Transportation. A copy of the joint technical assistance can be found on the FHWA's website: http://www.fhwa.dot.gov/civilrights/programs/doj_fhwa_ta.cfm .

ALTERATIONS	
• Addition of New Layer of Asphalt • Cape Seals • Hot In-Place Recycling • Microsurfacing / Thin-Lift Overlay	• Mill & Fill / Mill & Overlay • New Construction • Open-graded Surface Course • Rehabilitation and Reconstruction
MAINTENANCE (i.e. not alterations)	
• Chip Seals • Crack Filling and Sealing • Diamond Grinding • Dowel Bar Retrofit • Scrub Sealing • Slurry Seals	• Fog Seals • Joint Crack Seals • Joint Repairs • Pavement Patching • Spot High-Friction Treatments • Surface Sealing

ALTERATIONS VS MAINTENANCE

Figure 58-1.A

Where accessibility requirements cannot be fully met within the scope of an alteration project, the barriers to full compliance must be documented as well as the measures taken to meet compliance to the maximum extent practicable; see Chapter 31. The non-compliant element must be added to the transition plan inventory. If too many ADA elements cannot be made compliant within the scope of the project, the scope of the project must be increased to achieve a higher level of compliance.

58-1.01(c) Maintaining Accessibility During Construction

During construction, accessibility must be maintained consistent with the features present in the existing facility. If a project is being constructed in stages, the designer may need to provide for the reconstruction of certain curb ramps at different times to maintain accessibility. In other cases, temporary facilities may need to be developed and included in the construction plans. See Section 55-2.01(d) for additional discussion on accommodating pedestrians/bicyclists in a traffic control plan.

58-1.02 Buildings and Facility Sites

For accessibility criteria in buildings, airport terminals, rest areas, weigh stations, and transit stations; and the sites on which they are located, use the accessibility criteria set forth in the *2010 ADA Standards for Accessible Design* and/or the *Illinois Accessibility Code.* These documents contain the accessibility requirements for interior building features including rest rooms, drinking fountains, elevators, telephones, etc.; as well as exterior features including parking, stairs, ramps, and walkways.

58-1.03 Bus Stops

Bus stops and shelters shall comply with Section R308 of the Public Rights-of-Way Access guidelines (PROWAG). If benches are provided, they shall comply with Section R212.6 of PROWAG. Detectable warning surfaces are required at the boarding platform for bus stops; however, since a boarding platform is defined as having a height greater than 6 in. (150mm), detectable warnings are not required at bus stops with curb heights of 6 in. (150mm) or less.

58-1.04 Parking

58-1.04(a) Off-Street Parking

The following criteria apply to off-street parking:

1. Minimum Number. Figure 58-1.B provides the criteria for the minimum number of accessible spaces.

2. Location. Accessible parking spaces and accessible passenger loading zones that serve a particular building shall be the spaces or zones closest to the nearest accessible entrance on an accessible route. In separate parking structures or lots that do not serve a particular building, locate the accessible parking spaces on the shortest possible circulation route to an accessible pedestrian entrance of the parking facility. In buildings with multiple access entrances with adjacent parking, accessible parking spaces may be dispersed and located closest to the accessible entrances.

3. Signing. Designate the accessible parking spaces with ground-mounted signs as shown in the *ILMUTCD* as sign number R7-8 with sign number R7-I101 (“Fine” placard) below. The signs shall not be obscured by a vehicle parked in the space.

4. Dimensions. Accessible parking spaces shall be a minimum 16 ft (4.9 m) wide including an 8 ft (2.4 m) access aisle; see Figure 58-1.C. Two accessible parking spaces shall not share a common access aisle. Parking access aisles shall blend to common level with an accessible route and should be diagonally striped pursuant to the Illinois Vehicle Code, 625 ILCS 5/11-1301.8. Parked vehicular overhangs shall not reduce the clear width of an accessible circulation route.

5. Passenger Loading Zones. Passenger loading zones shall provide an access aisle at least 60 in. (1.5 m) wide and 20 ft (6.1 m) long adjacent and parallel to the vehicular pull-up space. If there are curbs between the access aisle and the vehicular pull-up space, provide a curb ramp that complies with Section 58-1.09. Vehicular standing spaces and access aisles shall be essentially level. Surface slopes shall preferably be 1.5% but shall not exceed 2% in both directions.

58-1.04(b) On-Street Parking

Where on-street paid or time-limited parking is provided and designated in areas zoned for business uses, the on-street parking design should meet the following accessibility criteria:

1. Number of Spaces. Figure 58-1.B provides the criteria for the required number of on-street accessible spaces.
2. Location. On-street accessible parking spaces should be located where the street has the least crown and grade and close to key destinations. Spaces should also be located nearest the point of sidewalk access (see access aisles below).
3. Access Aisles. For a parallel parking space and where the width of the adjacent sidewalk or available right-of-way exceeds 14.0 ft (4.3 m), a 60 in. (1.5 m) wide access aisle shall be provided at street level the full length of the parking space and shall connect to a pedestrian access route. This is illustrated in Figure 58-1.D. The access aisle shall not encroach into the vehicular travel lane. An access aisle is not required where the width of the adjacent sidewalk or the available right-of-way is less than or equal to 14.0 ft (4.3 m). When an access aisle is not provided, the parking spaces shall be located at the end of the block.
4. Signing. Designate the accessible parking spaces with ground-mounted signs as shown in the ILMUTCD as sign number R7-8 and include the appropriate “Fine” placard below. Locate these signs so they are visible from a driver’s seat.
5. Curb Ramps. If there are curbs next to an on-street accessible parking space, provide a curb ramp complying with Section 58-1.09. Accessible parking spaces adjacent to intersections may be served by the sidewalk curb ramp at the intersection, provided that the path of travel from the access aisle to the curb ramp is within the pedestrian crossing area.

Total No. of Parking Spaces	Minimum Number of Accessible Spaces
1 to 25	1
26 to 50	2
51 to 75	3
76 to 100	4
101 to 150	5
151 to 200	6
201 to 300	7
301 to 400	8
401 to 500	9
501 to 1000	2% of total
1001 and over	20 plus 1 for each 100 over 1000

Notes:

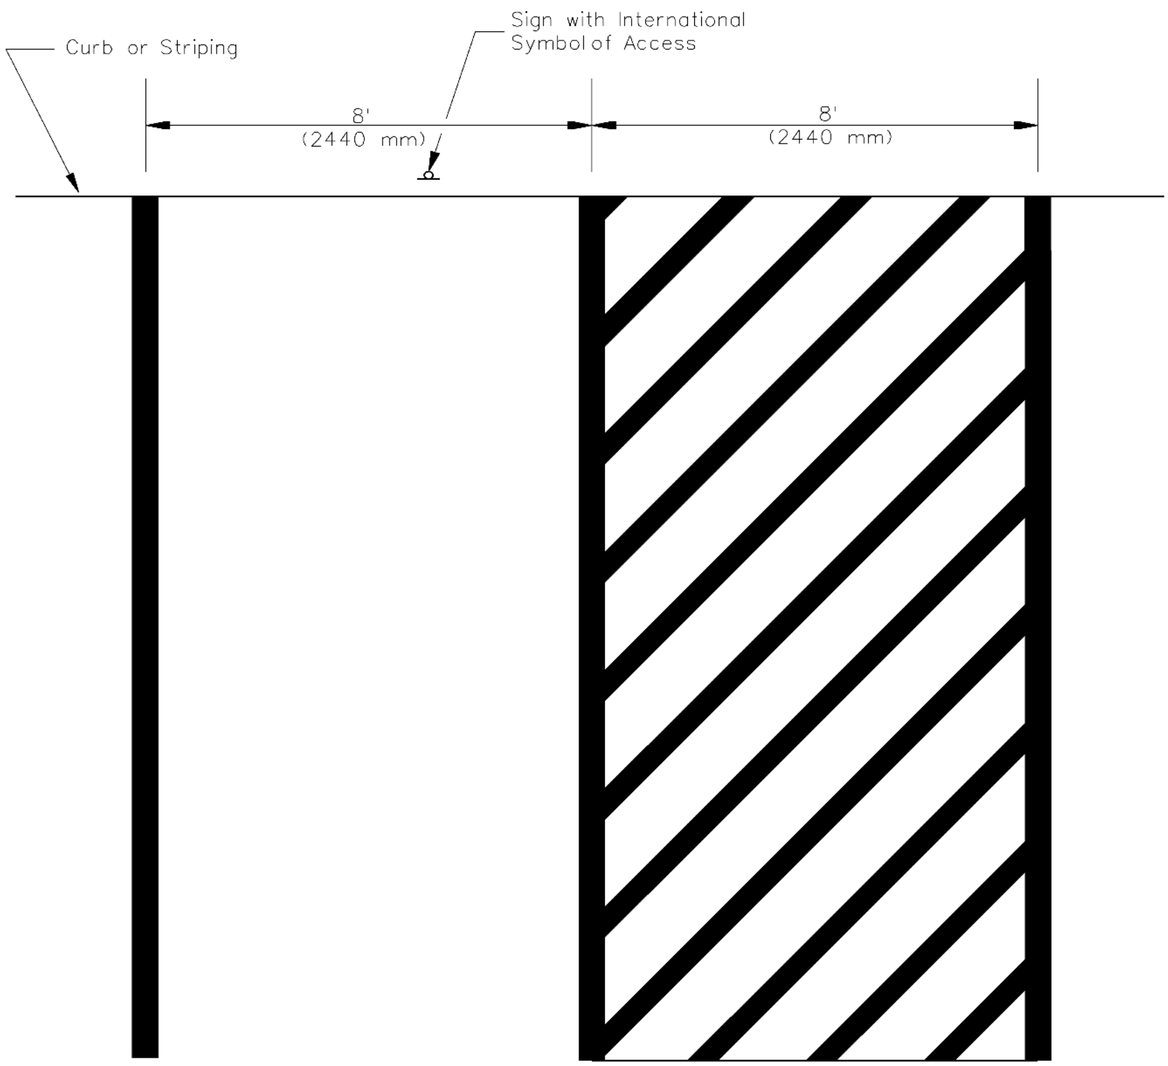
a. *If one or more passenger loading zones are provided, then at least one passenger loading zone shall comply with Item # 5 in Section 58-1.04(a).*

b. *Parking spaces for side-lift vans are accessible parking spaces and may be used to meet the requirements of this Section.*

c. *The total number of accessible parking spaces may be distributed among closely spaced parking lots, if greater accessibility is achieved.*

MINIMUM NUMBER OF ACCESSIBLE PARKING SPACES

Figure 58-1.B



ACCESSIBLE PARKING SPACE DIMENSIONS
(Off-Street Parking)

Figure 58-1.C

58-1.05 Accessible Route

58-1.05(a) Definition

An accessible route is a continuous, unobstructed path connecting all accessible elements and spaces. Interior accessible routes may include corridors, floors, ramps, elevators, lifts, and clear floor space at fixtures. Exterior accessible routes may include sidewalks, parking access aisles, curb ramps, crosswalks at vehicular ways, pedestrian overpasses and underpasses, ramps, and lifts.

58-1.05(b) Selecting Accessible Routes

At buildings and facility sites (airport terminals, rest areas, weigh stations, transit stations, etc.), at least one accessible route shall be provided within the boundary of the site from public transportation stops, accessible parking, accessible passenger loading zones, and public streets or sidewalks to the accessible route for the building they serve. The accessible route shall, to the maximum extent feasible, coincide with the route for the general public.

Within the public right-of-way, all routes are held to the accessible standard.

58-1.06 Sidewalks

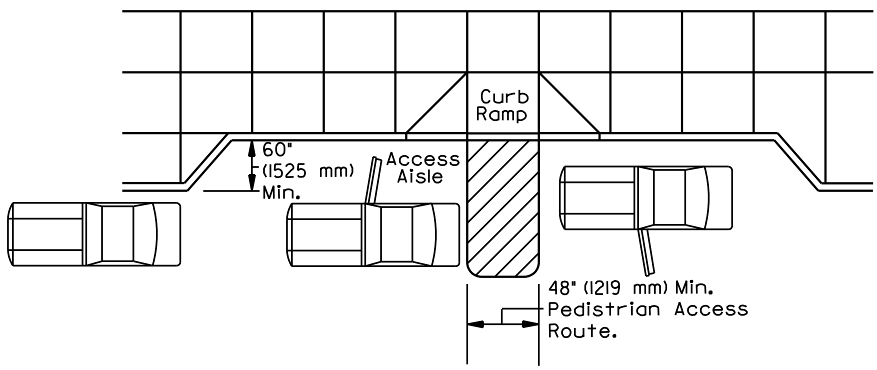
Section 48-2.04 presents the Department's warrants and design criteria for sidewalks. The following represents the accessibility criteria:

1. Width. The typical sidewalk width is 60 in. (1.5 m). The minimum width is 48 in. (1.2 m).

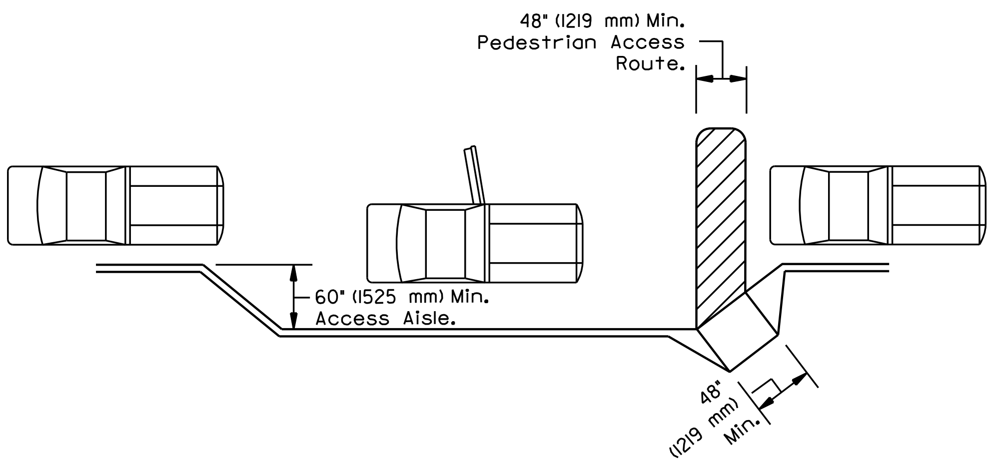
2. Passing Spaces. If the sidewalk has less than 60 in. (1.5 m) clear width, then passing spaces at least 60 in. by 60 in. (1.5 m by 1.5 m) shall be located at reasonable intervals not to exceed 200 ft (60 m). A T-intersection between two walks is an acceptable passing space such that the T-intersection consists of a 60 in. by 60 in. (1.5 m by 1.5 m) passing space. Paved driveways may also provide acceptable passing space in residential areas such that the area of the driveway used for passing does not have a cross slope perpendicular to the direction of travel greater than 2%.

3. Surface. All sidewalk surfaces shall be stable, firm, and slip resistant. The vertical alignment of the surface should be flush and free of abrupt changes. However, changes in level up to ¼ in. (6 mm) are allowed without treatment. Changes in level between ¼ in. and ½ in. (6 mm and 13 mm) shall be beveled with a slope no greater than 1:2. Changes greater than ½ in. (13 mm) are not allowed.

4. Horizontal Openings. Horizontal openings in gratings and joints shall not exceed ½ in. (13 mm) in the dominant direction of travel. Elongated openings in gratings shall be placed so the long dimension is perpendicular to the dominant direction of travel. Where possible, gratings should be located outside the pedestrian path of travel.



(a) Double Accessible Parking Space
with Curb Ramp.



(b) Single Accessible Parking Space
with Curb Ramp.

ACCESSIBLE PARKING
(On-Street Parking)

FIGURE 58-1.D

5. Running Slope. For sidewalks located within the street or highway right-of-way, the running slope shall not exceed the general grade established for the adjacent street or highway. For sidewalks located outside of such right-of-way, the running slope shall be 5% maximum.

6. Cross Slope. The sidewalk cross slope shall not exceed 2%. However, to allow for some variation during construction and maximize the accessibility of the sidewalk, a cross slope in the range of 1.0% to 1.5% should be used. Where driveways or alleys intersect with sidewalks, give design priority to the sidewalk cross slope rather than to the grade of the driveway or alley. This may require regrading the driveway or realigning the sidewalk. Figure 58-1.E shows one example.

7. Protruding Objects. Objects projecting from walls (e.g., signs, telephones, canopies) with their leading edges between 27 in. (685 mm) and 80 in. (2.0 m) above the finished sidewalk shall not protrude more than 4 in. (100 mm) into any portion of the sidewalk. Freestanding objects mounted on posts or pylons may overhang their mountings up to a maximum of 12 in. (305 mm) when located between 27 in. (685 mm) and 80 in. (2.0 m) above the sidewalk or ground surface. Protruding objects less than 27 in. (685 mm) or greater than 80 in. (2.0 m) may protrude any amount provided that the effective clear width of the sidewalk is maintained. Where the vertical clearance is less than 80 in. (2.0 m), provide a barrier to warn persons with visual impairments.

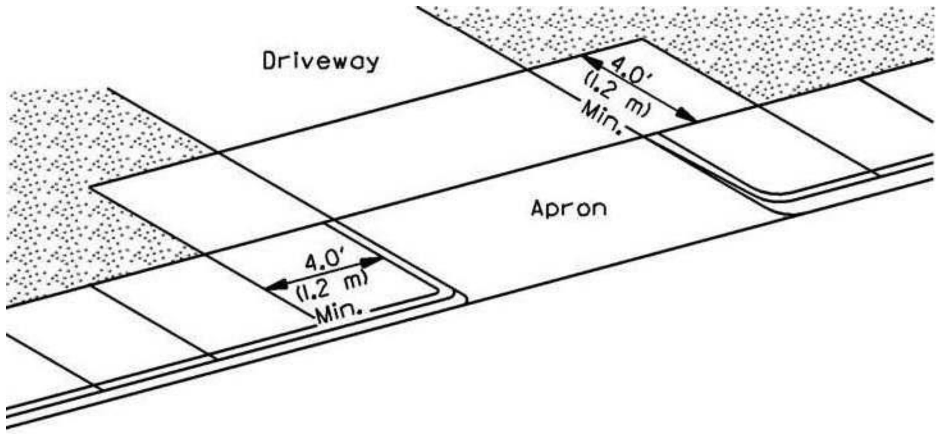
8. Separation. Sidewalks will be separated from roadways by curbs, planted parkways, or other barriers, which will be continuous except where interrupted by driveways, alleys, or connections to accessible elements.

9. Curb Ramps/Crosswalks. Curb ramps and crosswalks must comply with the criteria in Section 58-1.09.

10. Bridges. Bridges can present special problems for meeting the above sidewalk criteria. Due to geometric restraints of the facility being crossed, special treatments may be required; consult with BDE and the Bureau of Bridges and Structures.

58-1.07 Stairs

Stairs shall not be part of an exterior accessible route because they cannot be safely negotiated by individuals with mobility impairments. Where stairs are located within the public right-of-way in conjunction with an accessible route, they must comply with Section 504 of the *2010 ADA Standards for Accessible Design,* which includes the provision of handrails.



SIDEWALKS AT DRIVEWAY APRONS

Figure 58-1.E

58-1.08 Ramps

Portions of sidewalks whose running slope exceed 5% and are not following the general grade of an adjacent street or highway are typically considered ramps (Note: These ramps are different from curb ramps; see Section 58-1.09 for curb ramps. The following represents the accessible criteria for ramps:

1. Running Slope and Rise. Ramps shall have a running slope greater than 5% up to an 8.3% maximum. The maximum rise for any single ramp run shall be 30 in. (760 mm). For elevation differences greater than 30 in. (760 mm), a series of ramps and landings must be used. Ramps to be constructed on existing building/facility sites or inside existing buildings/facilities may have a running slope which exceeds 8.3% within the rise limitations shown in Figure 58-1.F, if space limitations dictate.

2. Width. The minimum clear width of a ramp in the public right-of-way shall be 48 in. (1.2 m). The minimum clear width of a ramp for a building/facility site shall be 36 in. (915 mm). Where handrails are provided, the clear width is measured between inside edge of the rails.

3. Landings. Ramps shall have level landings (preferably sloped 1.5% and no greater than 2% in both directions) at the bottom and top of each run and shall have the following features:

   - The landing shall be at least as wide as the widest ramp run leading to the landing.
   - The landing length shall be a minimum of 60 in. (1.5 m).

- If ramps change direction at landings, the minimum landing size shall be 60 in. by 60 in. (1.5 m by 1.5 m).

4. Handrails. If a ramp run has a rise greater than 6 in. (150 mm) or a length greater than 72 in. (1.8 m), it shall have handrails on both sides. See the applicable accessible guidelines for additional handrail criteria.

5. Cross Slope and Surfaces. The cross slope of ramp surfaces shall not exceed 2%; however to allow for some variation during construction and maximize the accessibility, a cross slope in the range of 1.0% to 1.5% should be used. Ramp surfaces shall comply with the criteria for “Surface” of sidewalks; see Section 58-1.06.

6. Edge Protection. Each side of ramp runs and ramp landings shall have edge protection. Edge protection may be either an extended ramp surface or a curb/barrier. An extended ramp surface shall extend 1 ft (300 mm) beyond the inside face of the handrail. A curb/barrier shall prevent a 4 in. (100 mm) sphere from passing under the handrail.

7. Outdoor Conditions. Outdoor ramps and their approaches shall be designed so that water will not accumulate on walking surfaces.

Running Slope	Maximum Rise
> 8.3% but ≤ 10% (> 1:12 but ≤ 1:10)	6 in. (150 mm)
> 10% but ≤ 12.5% (> 1:10 but ≤ 1:8)	3 in. (75 mm)

Note 1: These dimensions may only be used when space limitations will not fit a standard ramp.
Note 2: Running slopes steeper than 12.5% (1:8) are not allowed.

ALLOWABLE EXCEPTIONS TO STANDARD RAMP DIMENSIONS
(Existing Sites, Buildings, and Facilities)

Figure 58-1.F

58-1.09 Curb Ramps and Crosswalks

A curb ramp shall connect sidewalks at each pedestrian street crossing or crosswalk. For the purpose of this section, a pedestrian crosswalk is defined as that portion of a highway or street ordinarily included within the prolongation or connections of lateral lines of sidewalks at intersections. It also includes any portion of a highway or street distinctly indicated as a crossing for pedestrians by lines or other markings on the surface. It does not include such prolonged or connecting lines from an alley across a street.

58-1.09(a) Responsibility for Construction of Curb Ramps

The determination by the Department whether to construct or modify curbs and/or curb ramps is dependent upon two issues: scope of the project and jurisdiction.

1. Scope. If curbs or crosswalks will be altered as part of the State project and there is sidewalk leading up to the crosswalk, the Department will construct/reconstruct curb ramps within the scope of the project. If the curb ramps cannot be made fully compliant within the scope of the project, they must be made compliant to the maximum extent practicable and such decision documented/approved on the ADA Statement of Maximum Extent Practicable form (BDE 3101). Section 58-1.01(b) and Figure 58-1.A further discuss the types of projects that are considered alterations. See Section 31-7 for guidance on requesting approval for compliance to the maximum extent practicable and the processing of BDE 3101.

2. Jurisdiction. If curbs or crosswalks will not be altered as part of a project and the Department does not have jurisdiction over the curbs, provisions for curb ramps will be the responsibility of local governments. Where curbs and crosswalks will not be altered but the Department does have jurisdiction over the curbs, curbs and inaccessible curb ramps will be reconstructed as part of the project to the maximum extent practicable.

   Jurisdiction will be determined by the existence and provisions of maintenance agreements. Where written maintenance agreements do not exist, contact the Bureau of Local Roads and Streets (BLRS) or use the BLRS publication *Jurisdictional Transfer Guidelines* as the initial basis to determine the applicable jurisdictional responsibility of the highway and its elements.

58-1.09(b) Design and Construction of Curb Ramps

Curb ramps shall meet the following criteria:

1. Crosswalks. Curb ramps at marked crossings shall be wholly contained within the markings, except when flared sides are provided. The flared sides of a curb ramp may be outside of the crosswalk. At unmarked crosswalks, place the curb ramp within the area that would reasonably be expected to be used as a crosswalk.

2. Diagonal Curb Ramps. Avoid using a diagonal curb ramp whenever practical due to its effect on the crosswalk width and the indirect path of travel it induces. It is preferable to use two perpendicular curb ramps or a depressed corner rather than a diagonal curb ramp.

3. Raised-Curb Medians. Where a raised-curb median exists within a crosswalk, depress the median to the level of the crosswalk. Provide detectable warning surfaces behind the back of each curb if the median opening is greater than 6 ft measured between the back

of curbs (See the *Highway Standards*). Another option is to provide curb ramps on both sides of the median and a minimum level landing area 60 in. (1.8 m) by 60 in. (1.8 m) between the ramps. A level landing area shall be provided at the upper end of each ramp if the median curb ramps are not in-line.

4. Pedestrian Signals. The location of the curb ramp must be consistent with the operation of pedestrian-actuated traffic signals, if present.

5. Cross Slope. The maximum cross slope of curb ramps shall be 2%. However at pedestrian street crossings without yield or stop control, and at midblock pedestrian street crossings, the cross slope of curb ramps shall be permitted to equal the street or highway grade; see Section 58-1.09(e) for the U.S. Access Board's interpretation of what constitutes yield or stop control. This means there may be some twist in the cross slope of the curb ramp itself or in the portion of sidewalk between the bottom of the curb ramp and the back of curb (i.e. a lower landing) if it exists. Best practices are to: 1) provide a lower landing and limit the twist to the landing or 2) limit the twist to the lower part of the curb ramp; while in either case keeping the rate of change gradual enough to ensure the stability of a person in a wheelchair.

6. Running Slope. The running slope of a curb ramp within the public right-of-way shall be 8.3% maximum. However, in situations where applying this maximum grade would cause the length of the curb ramp to become excessive (e.g. longer than 25-30 ft), the length of the curb ramp can be fixed at 15 ft (4.6 m) and a grade steeper than 8.3% can be used. This exception is commonly known as the "15 ft Rule" and is intended to mitigate the problem of "chasing" a steep sidewalk grade.

   The running slope of a curb ramp within a building or facility site shall not exceed 8.3% (1:12). However in existing buildings/sites with space limitations, the running slope may exceed 8.3% (1:12) and comply with Figure 58-1.F.

7. Flared Sides. Where a pedestrian circulation path crosses the curb ramp (that is where pedestrians can approach the curb ramp from the side), flared sides shall be provided. The flared sides shall be sloped a maximum of 10% measured parallel to the curb line. The flared sides are not considered part of the ramp width or the pedestrian access route.

8. Width. The clear width of curb ramps within the public right-of-way shall be 48 in. (1.2 m) minimum (excluding any flared sides). The clear width of a curb ramp within a building or facility site shall be 36 in. (0.915 m) minimum.

9. Grade Breaks. Grade breaks at the top and bottom of curb ramp runs shall be perpendicular to the direction of the ramp run. Grade breaks are not permitted on the surface of ramp runs or their turning spaces. Surface slopes that meet at grade breaks shall be flush.

10. Turning Spaces. The requirements for turning spaces vary depending upon the type of curb ramp as follows:

a. Perpendicular Curb Ramps. A turning space shall be provided at the top of a perpendicular curb ramp and shall be permitted to overlap other turning spaces and clear spaces. The slope of the turning space shall be 2% maximum in both directions. The size of the turning space shall be 48 in. x 48 in. (1.2 m x 1.2 m) minimum unless the space is constrained at the back of the sidewalk. When constrained the size shall be 48 in. x 60 in. (1.2 m x 1.5 m) minimum with the 60 in. (1.5 m) dimension provided in the direction of the ramp run.

b. Parallel Curb Ramps. A turning space shall be provided at the bottom of a parallel curb ramp and shall be permitted to overlap other turning spaces and clear spaces. The slope of the turning space shall be 2% maximum in both directions. The size of the turning space shall be 48 in. x 48 in. (1.2 m x 1.2 m) minimum unless the space is constrained on two or more sides. When constrained the size shall be 48 in. x 60 in. (1.2 m x 1.5 m) minimum with the 60 in. (1.5 m) dimension provided in the direction of the pedestrian street crossing.

c. Blended Transitions. If the running slope of either of the curb ramp types listed above is 5% or less, they are then technically classified as a blended transition. Turning spaces are not required for blended transitions.

11. Surface. The surface of a curb ramp shall be stable, firm, and slip resistant.

12. Detectable Warnings. Detectable warnings shall be according to Section 58-1.09(c)

13. Clear Spaces. Beyond the bottom grade break of curb ramps and blended transitions, a clear space 48 in. x 48 in. (1.2 m x 1.2 m) minimum shall be provided within the width of the pedestrian street crossing and wholly outside the parallel vehicle travel lane. These spaces are provided by default with parallel curb ramps and perpendicular curb ramps that align with the crosswalk. For skewed/diagonal perpendicular curb ramps, care must be exercised to ensure this space is provided.

58-1.09(c) Detectable Warning Surfaces

Detectable warning surfaces are required at curb ramps, blended transitions, medians and pedestrian refuge islands, at-grade railroad crossings, transit platform edges, and other locations where pedestrians are required to cross a hazardous vehicular way. Where pedestrian access routes cross alleys and commercial entrances, detectable warnings are only required if traffic control devices (e.g., yield signs, stop signs, or signals) are present at the alley/entrance.

Detectable warnings surfaces consist of truncated domes aligned in a square or radial pattern. The size and spacing of the truncated domes is shown in the various accessibility standards. The color of the detectable warning surface shall contrast visually with adjacent walking surfaces either light-on-dark or dark-on-light. Detectable warning surfaces shall extend 2 ft (610 mm) minimum in the direction of pedestrian travel and for the full width of the walking surface (excluding any flared sides). Other requirements for detectable warnings vary with the application as follows.

1. <u>Curb Ramps, Blended Transitions, and Pedestrian Refuge Islands/Medians</u>. Locate the detectable warning surface as shown in the *Highway Standards*. Note the following tolerances for placement of detectable warning surfaces:

   Side Border: Detectable warnings should extend the full width of the walking surface (excluding flared sides) but a border along each side up to 2 in. (50 mm) in width is allowed.

   Curb Set-Back: Detectable warnings located at the back of curb should closely align with the curb but a gap up to 6 in. (150 mm) behind the curb is allowed.

2. <u>Rail Crossings</u>. Locate the detectable warning surface on each side of the rail crossing and the edge of the detectable warning nearest the rail crossing shall be 6 ft (1.8 m) minimum and 15 ft (4.6 m) maximum from the centerline of the nearest rail. Where pedestrian gates are provided, place the detectable warning surfaces on the side of the gate opposite the rail.

3. <u>Boarding Platforms and Transit Stops</u>. Detectable warning surfaces at boarding platforms and transit stops for buses and rail vehicles where the edges of the boarding platform are not protected by screens or guards shall be placed at the edge of the platform and extend the full length of the public use areas of the platform. Note: Detectable warning surfaces are not required at bus stops with curb heights of 6 in. (150mm) or less; see Section 58-1.03.

4. <u>Stairs at Building and Facility Sites</u>. Stairs, except those enclosed in stair towers or set to the side of the path of travel, shall have detectable warnings placed at the top of the stairs and for their full width (inside of handrails).

58-1.09(d) Accessible Pedestrian Signals/Pushbuttons

Accessible pedestrian signals (APS) are a special category of pushbuttons which communicate information about pedestrian signal timing in a non-visual format, such as audible tones, speech messages, and/or vibrating surfaces. Without these devices, people of low vision or who are hard of hearing find it difficult to utilize the pedestrian signal system/pedestrian crossing. To ensure the transportation services provided by the Department are accessible to all users, all new and altered pedestrian signals shall be of the accessible type. Furthermore, since pedestrian push buttons are considered an “operable part,” they must be located in accessible locations and within allowable reach ranges of a pedestrian access route. Refer to the Central Bureau of Operations’ document entitled, *OPS-T-13: Policy on Accessible Pedestrian Signals and Pushbuttons for Traffic Signals and Pedestrian Hybrid Beacons,* Section 4E.08 of the *Manual on Uniform Traffic Control Devices,* and *Section R403 of the Draft PROWAG for detailed information*.

58-1.09(e) Crosswalks

Pedestrian street crossings or crosswalks are an integral component of a pedestrian access route and may either be marked or unmarked. The U.S. Access Board guidance allows for varying maximum crosswalk cross-slopes depending upon whether or not there is “yield or stop control” for approaching vehicular traffic. For the purposes of accessibility requirements, the U.S. Access Board has provided the interpretation that the presence of a yield sign or stop sign constitutes “yield or stop control” on that approach since each and every approaching vehicle must stop or slow considerably. Conversely, a signalized approach to an intersection is not considered to have “yield or stop control” since vehicles may proceed through the intersection at running speed when approaching on a green signal indication. This is an important determination in the design of crosswalk cross slopes. Per current ADA criteria, the maximum cross slope of a crosswalk at an intersection with yield or stop control shall be 2%. The maximum cross slope of a crosswalk at an intersection without yield or stop control shall be 5%. Where the pedestrian access route is contained within a midblock pedestrian street crossing, the cross slope of the pedestrian access route shall be permitted to equal the mainline roadway grade. Where crosswalk cross slopes greater than 2% are allowed by policy it is still important to consider ways to achieve cross slopes as close to 2% as practicable.

For information regarding the placement of parking relative to an existing or proposed crosswalk see Section 48-2.05.

58-1.10 Roadway Approach Grades

Section 58-1.09(e) sets maximum values for the cross slope of pedestrian street crossings (i.e., crosswalks) for locations both with and without yield or stop control. The cross slope of the pedestrian street crossing, where present, is also the approach gradient of the roadway through that crossing and must be designed accordingly. When marked or unmarked crosswalks exist or are proposed, roadway approach grade values in compliance with, or more restrictive than, those shown in Section 36-1.06 may be necessary to achieve accessibility standards.

58-1.11 Pedestrian Overpasses and Underpasses

When deciding where to locate a pedestrian crossing, highway and structural designers must coordinate their efforts to properly address the accessibility considerations. The following are applicable:

1. Warrants. Threshold warrants for considering a pedestrian overpass are dependent on pedestrian volumes, vehicular volumes, and distance to the nearest “safe” alternative crossing. These warrants are determined on a case-by-case basis.

2. Accessible Route. All current and future accessible routes must be identified. If existing routes are inaccessible, the designer must evaluate the likelihood that the routes will be made accessible in the future. This evaluation may lead to the decision to relocate the pedestrian overpass or underpass to another site where accessibility can be more easily provided.

3. Design. The proposed design must meet the *accessible* criteria for stairs, ramps, curb ramps, and sidewalks. Refer to Chapter 17 for additional over- and underpass information.

58-1.12 Rest Areas

The accessibility guidelines referenced in Section 58-1.02 address the features present at rest areas. However, certain features need further clarification:

1. Picnic Areas. Where picnic areas/tables are provided in accessible or common use areas, at least 5%, but not less than one, of the picnic areas/tables shall be accessible. An accessible route shall lead to and through such picnic areas or tables. Signs displaying the international symbol of accessibility should be erected at those locations which include accessible facilities.

2. Separator Islands. Many rest areas include islands to separate passenger vehicle parking areas from truck parking areas. In many cases, individuals with disabilities travel in vehicles that may have to park in the truck parking area. In addition, many tour buses use these areas. Accordingly, provide an opening in the island as discussed for "Raised Curb Medians" in Section 58-1.09(c) to provide accessibility for persons with disabilities. Also, consider special markings or signing to indicate the location of this opening.

3. Parking. Provide the minimum number of accessible parking spaces per Figure 58-1.B in both automobile and truck parking areas. See Chapter 16 for additional design criteria.

58-2 OFF-STREET PARKING

A proposed highway project may incorporate some form of off-street parking. Typical applications may include:

- providing off-street parking to replace on-street parking which will be removed as part of a proposed project;
- the construction of a park-and-ride lot for commuters; or
- the construction of a new rest area or improvement to an existing rest area.

58-2.01 Park-and-Ride Lots

58-2.01(a) Location

Park-and-ride lots may be located in either rural or urban areas to accommodate car-pooling or to provide access to transit terminals. By locating these lots outside of the downtown area, congestion is reduced, parking lot property costs are lowered, and accessibility is improved. The general location and size of park-and-ride lots is normally determined during Phase I. Guidance for site selections can be found in the AASHTO *Guide for the Design of Park-and-Ride Facilities*. Some of the factors that will affect the location of the parking facility include:

1. Site Availability. Park-and-ride lots may consist of publicly owned property, excess State right-of-way, or property used with the permission of private owners. When reviewing sites, consider the long-term availability of the lot.
2. Accessibility. The lot should be convenient to residential areas, bus and rail transit routes, and major highways used by commuters.
3. Visibility. The park-and-ride lot should be visible from the access road.
4. Demand. The lot must be large enough to accommodate the anticipated demand for parking spaces. In addition, sufficient transit service must be available to accommodate the anticipated demand.
5. Congestion. The location should precede any points of congestion on the major commuting highway to maximize its benefits.
6. Capacity. There should be sufficient capacity on connections between the lot and the major commuting highway.
7. Design. The site location must be compatible with the design and construction of the lot. Considerations will include property costs, terrain, drainage, subgrade soil conditions, and available space in relation to the required lot size, visibility, and access.
8. Land Use. The location of the lot should be consistent with the present and future adjacent land use. Consider the lot's visual and other impacts on surrounding areas. Where

necessary, site sizing and design should allow for buffer landscaping to minimize the visual impact.

58-2.01(b) Layout

Consider the following when laying out a park-and-ride facility:

1. Entrances and Exits. Locate entrances and exits so that they have the least disruption to existing traffic on the street, allow easy access to and from the lot, and provide the maximum storage space within the lot. In addition, consider the following:

   a. Location. Provide separated entrances and exits whenever practical, preferably on two or more streets. The entrance should be on the "upstream" side of the traffic flow nearest the lot and the exit on the "downstream" side. If separation is not reasonable, the combined entry-exit point should be as close to mid-block as practical.

   b. Spacing. Separate entrances and exits should be at least 150 ft (45 m) apart and 150 ft (45 m) from a public road intersection. Desirably, these distances should be 300 ft (100 m). For lots with less than 150 spaces, these dimensions may be reduced to 100 ft (30 m).

   c. Traffic Signals. If a traffic signal is warranted or is expected in the future, the entrance should be more than 1200 ft (400 m) from an adjacent signal. Ensure that the traffic signal can be interconnected and/or coordinated with the other traffic signals to allow vehicular progression along the route.

   d. Storage. Ensure that there is sufficient storage on the mainline for entering the lot. This may require providing separate left- and/or right-turn lanes. Also, check the exiting traffic to ensure that the exiting queue will not adversely affect the traffic circulation in the lot itself.

   e. Design. Design all entrances and exits for capacity, sight distance, turning radii, acceleration and deceleration lanes, turn lanes, etc., according to the criteria in Chapter 36. The typical design vehicle will be a BUS.

2. Drop-off/Pick-up Zones. Drop-off and pick-up zones for buses and autos should be clearly separated from each other and from parking areas to avoid as many internal traffic conflicts as possible. Circulation for drop-off and pick-up facilities should be one-way and adjacent to the terminal loading/unloading area. Angle the parking at 45° towards the loading terminal to allow vehicles to pull through.

3. Traffic Circulation. Arrange the traffic circulation to provide maximum visibility and minimum conflict between small vehicles (e.g., autos, taxis) and large vehicles (e.g., large vans, buses). Locate major circulation routes at the periphery of the lot to minimize vehicular-pedestrian conflicts. A counter-clockwise circulation of one-way traffic is preferred. This allows vehicles to unload from the right side.

4. Pedestrian and Bicyclist Considerations. Consider pedestrian and bicycle routes when laying out the commuter lot. Avoid entrance and exit points in areas with high-pedestrian volumes, if practical. Provide sidewalks between the parking areas and the modal transfer points. Locate passenger waiting areas in a central location or near the end of the facility. Maximum walking distances to any loading area should not exceed 1000 ft (300 m). Longer walking distances may require more than one loading area.

   Crosswalks should be provided where necessary and be clearly marked and signed. Include signing and pavement markings for all pedestrian and bicycle paths to eliminate indiscriminate movements. In high-volume lots, fencing, barriers, or landscaping may be warranted to channel pedestrians and bicyclists to appropriate crossing points. Crossings at major two-way traffic circulation lanes should have a refuge island separating the travel directions.

   Include a bicycle parking area relatively close to the loading area. If a large volume of bicycle traffic is expected, provide a designated bicycle lane to and from the bicycle parking area.

5. Accessibility. Section 58-1 discusses accessibility criteria, which also apply to park-and-ride lots.

58-2.02 Replacement Parking Guidelines

In general, on-street parking should be discouraged due to their inherent hazards and capacity problems. Review the following when considering removing on-street parking:

1. Implementation. Ensure that early involvement coordination is conducted with the affected municipality to determine any significant social, economic, and environmental effects from both parking removal and replacement. Discuss existing parking patterns to determine replacement requirements based on actual needs rather than the existing number of available spaces. This information should be included in the Phase I report, combined with estimated costs for parking replacement. Replacement off-street parking may be let as part of the roadway improvement or as a separate municipal contract.

2. Participation. The Department will provide 100% of all engineering, right-of-way (except where replacement parking is constructed on municipally owned property), and construction costs required to construct alternative (off the State system) parking on a maximum ratio of 1 to 1. Alternative parking can consist of improving adjacent local streets to provide some parallel parking, the construction of off-street parking facilities, or combinations thereof. Construction costs will include those items the Department deems reasonable to provide parking facilities including a paved surface, drainage, lighting, pedestrian walkways, and fencing. The construction and installation of guard and toll collection facilities, metering devices, and parking capacity beyond the maximum replacement ratio will be the municipality's responsibility.

3. Maintenance. Provide an agreement with the municipality which allows them to accept jurisdiction of the parking facility including but not limited to its maintenance, operation, repair, reconstruction, provision of electrical energy for lighting systems, and striping. See Chapter 5 for information on local agreements. The municipality will hold the State harmless from any suits arising from construction, operation, and maintenance of these parking facilities.

4. Right-of-Way. The municipality will be responsible for acquiring all necessary rights-of-way and easements in its own name and will provide the Department with certification that it holds good and sufficient title to these properties. This will include the following:

   a. Hazardous Waste Survey. The Department will, at its own expense, conduct a survey for potential hazardous wastes and notify the municipality of its acceptance or rejection of the site.

   b. Site Purchase. The municipality will follow the procedures contained in IDOT's *Land Acquisition Manual* and provide the Department with an estimate of right-of-way costs, including its purchase price plus fees associated with negotiators, appraisals, title evidence, and legal services for each potential parcel. The Department will be allowed to either accept or reject the parcel(s).

   c. Municipally Owned Site. If the municipality owns the site selected for replacement parking, it will provide the property at no expense to the Department. The cost of clearing the municipally owned property will be the Department's responsibility and will be included in the construction contract.

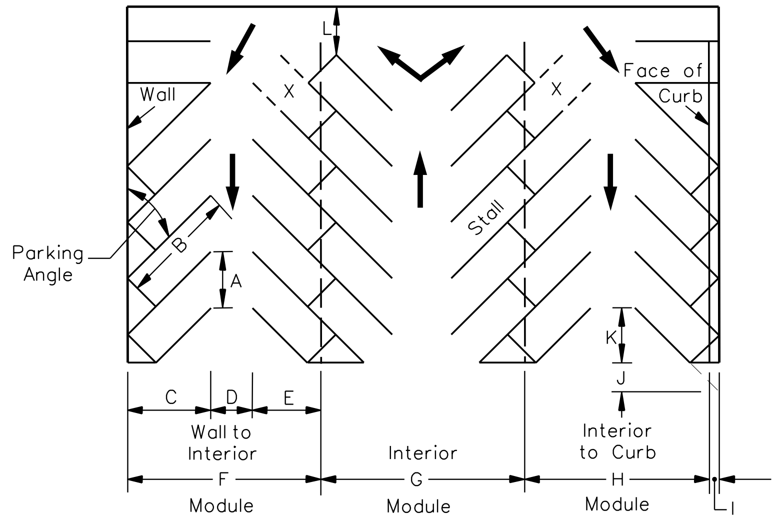
5. Enforcement. The municipality will be responsible for enacting and enforcing ordinances prohibiting parking at all locations where on-street parking is removed.

6. Ownership. The municipality will, unless otherwise approved by the Department in writing, retain in public trust for a period of at least 20 years, all parking facilities constructed at State expense. If the municipality wishes to remove itself from this agreement, the Department will not unreasonably withhold such approval but will require pro rata compensation for its initial expense in constructing the parking facilities as a condition of its approval.

58-2.03 Design Elements

Consider the following elements in the design of off-street parking lots:

1. Parking Lot Dimensions. Parking stall dimensions vary with the angle at which the parking space is arranged relative to the aisle. Figure 58-2.A provides the design dimensions for 9 ft x 18.5 ft (2.7 m x 5.6 m) parking stalls and shows how stalls may be combined into a parking lot. From a traffic operations standpoint, one-way aisles are desirable and should be designed to provide counterclockwise circulation. When determining parking stall widths, consider the following:



X = Stall not accessible in certain layouts

Parking Layout Dimension for 9 ft x 18.5 ft (2.7 m x 5.6 m) Stalls at Various Lengths

		Parking Angle							
Design Feature	**Notation**	**45° (ft)**	**45° (m)**	**60°(ft)**	**60° (m)**	**75° (ft)**	**75° (m)**	**90° (ft)**	**90° (m)**
Stall width, parallel to aisle	A	12.7	3.9	10.4	3.2	9.3	2.8	9.0	2.7
Stall length of line	B	25.0	7.6	22.0	6.7	20.0	6.1	18.5	5.6
Stall depth to wall	C	17.5	5.3	19.0	5.8	19.5	5.9	18.5	5.6
Minimum aisle width between stall lines	D	12.0	3.7	16.0	4.9	23.0	7.0	26.0	7.9
Stall depth, interior	E	15.3	4.7	17.5	5.3	18.8	5.7	18.5	5.6
Module, wall to interior	F	44.8	13.7	52.5	16.0	61.3	18.7	63.0	19.
Module, interior	G	42.6	13.0	51.0	15.5	61.0	18.6	63.0	2
Module, interior to curb face	H	42.8	13.1	50.2	15.3	58.8	17.9	60.5	19.
Bumper overhang (typical)	I	2.0	0.6	2.3	0.7	2.5	0.8	2.5	2
Offset	J	6.3	1.9	2.7	0.8	0.5	0.2	0.0	18.
Setback	K	11.0	3.4	8.3	2.5	5.0	1.5	0.0	4
Cross aisle, one-way	L	14.0	4.3	14.0	4.3	14.0	4.3	14.0	0.8
Cross aisle, two-way	—	24.0	7.3	24.0	7.3	24.0	7.3	24.0	0.0
									0.0
									4.3
									7.3

Notes:

1. *See Section 58-1 for criteria on the number and dimensions of accessible parking spaces.*

2. *If a special section is designated for subcompact vehicles, these stalls can be 8 ft x 15 ft (2.5 m x 4.6 m) for a 90° angle.*

3. *Stalls should be wider for commercial parking.*

4. *The designer should consider bumper overhang when placing lighting, railing, etc. Therefore, these appurtenances should be placed beyond dimension "I" in the figure.*

5. *Two-way traffic in aisles may only be used with a 90° parking angle. Use an aisle width of 26 ft (7.9 m).*

PARKING LOT LAYOUT DIMENSIONS
(9 ft x 18.5 ft (2.7 m x 5.6 m) Stalls)

Figure 58-2.A

- Typical stall widths (measured perpendicular to the vehicle when parked) range from 8.5 ft to 9.5 ft (2.6 m to 2.9 m).

- The recommended minimum stall width for self-parking of long-term duration is 9.5 ft (2.6 m).

- For higher turnover self-parking, a stall width of 9 ft (2.7 m) is recommended.

- Stall widths at supermarkets and other similar parking facilities, where large packages are prevalent, should desirably be 9.5 ft (2.9 m) or even 10 ft (3.0 m) in width.

2. Bus Loading Areas. Bus loading and unloading areas located adjacent to park-and-ride lots should be designed to provide for continuous counterclockwise circulation and for curb parking without backing maneuvers. The through traffic lanes and the curb loading area should each be 12 ft (3.6 m) wide. Figure 58-2.B provides criteria for the recommended lengths of bus loading areas.

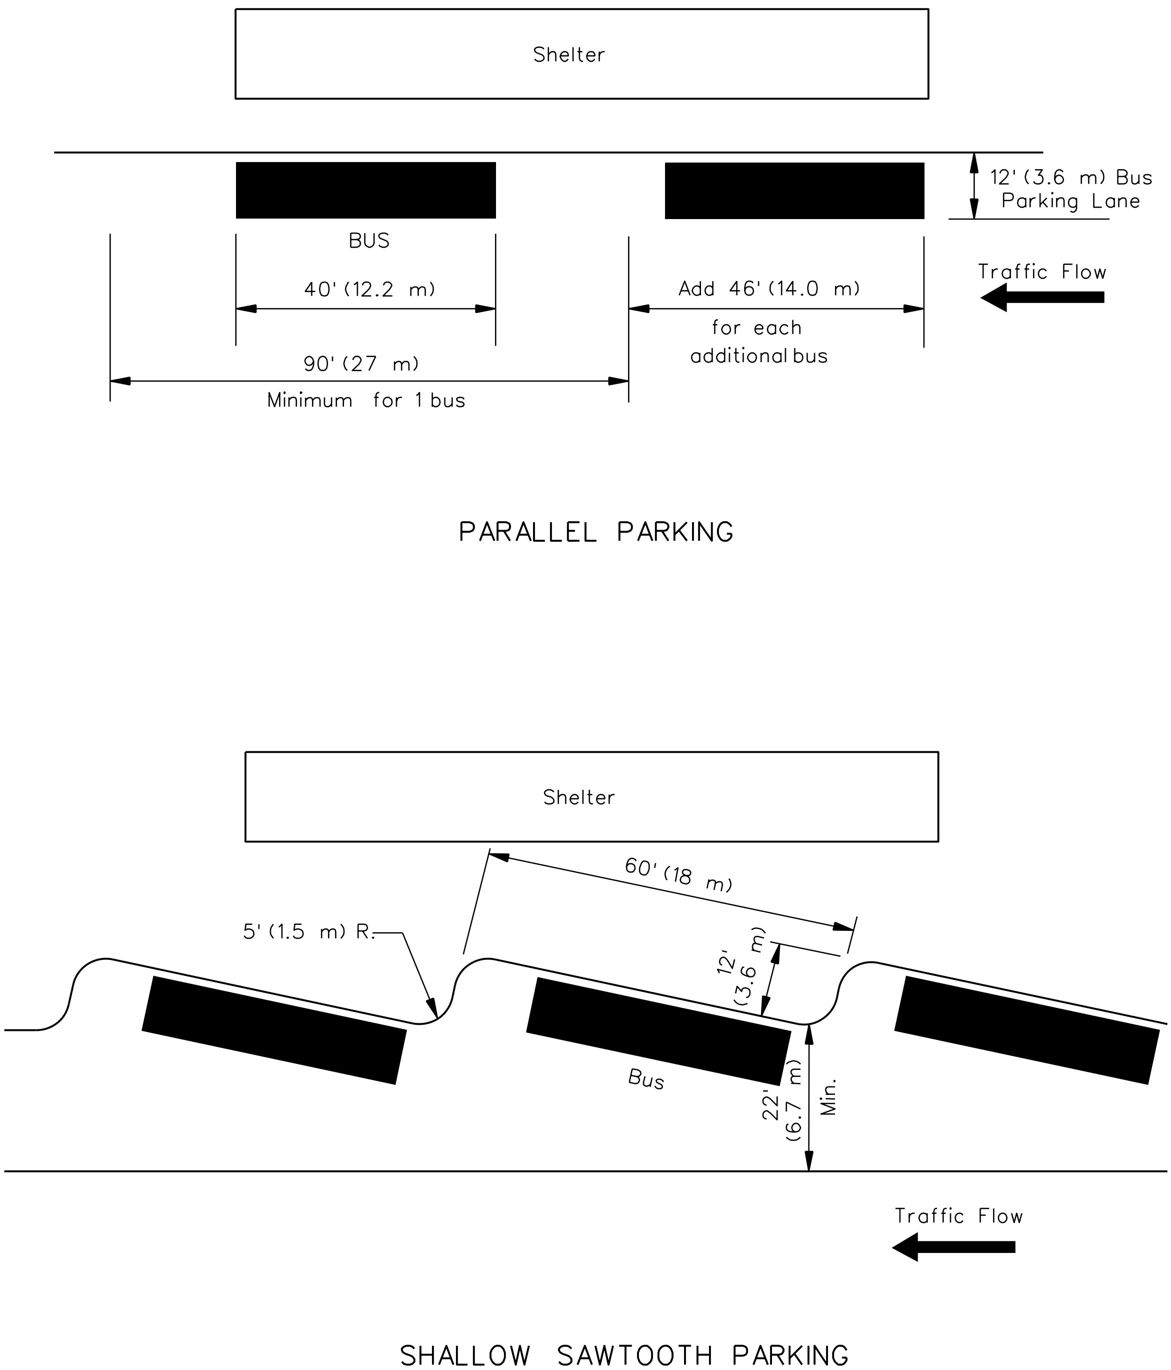
3. Sidewalk Dimensions. All sidewalks should be at least 5 ft (1.5 m) wide. In loading areas, the width should be 12 ft (3.6 m) or the adjacent sidewalk width plus 7 ft (2.1 m), whichever is greater. The accessibility criteria must be met for all new lots; see Section 58-1.

4. Cross Slope. To provide proper drainage, the minimum cross slope on a parking lot should be 1%. As a maximum, the cross slope should not exceed 5%. Desirably, design the lot to direct the drainage runoff into existing drainage systems. If water impoundment cannot be avoided along pedestrian routes, bicycle routes, and standing areas, provide drop inlets and underground drainage. In parking areas, design the drainage to avoid standing water. The detailed drainage design for the lot should be prepared using the Department's *Drainage Manual* to determine design frequency, pavement discharge, and capacity of drainage inlets.

5. Pavements. Minimum pavement design for parking areas in a park-and-ride lot is 3 in. (75 mm) of bituminous concrete on 8 in. (200 mm) of aggregate base. For bus routes, the minimum pavement design should be 5 in. (125 mm) of bituminous concrete on 10 in. (250 mm) of aggregate base. For additional information on pavement designs; see Chapter 54.

6. Lighting. Desirably, the lot should be lighted for pedestrian safety and lot security. Ensure provisions are considered for lighting supports and power lines. Chapter 56 provides information on the design of lighting.

7. Shelters. Pedestrian shelters are desirable when loading areas for buses and trains are provided. Their inclusion will be determined on a case-by-case basis. The shelter should provide approximately 5 ft^2 (0.5 m^2) of covered area per person. As a minimum, the shelter should provide lighting, benches, and trash receptacles. Routing information signs and a telephone should also be considered.



RECOMMENDED LENGTHS FOR BUS-LOADING AREAS
(Park-and-Ride Lots)

Figure 58-2.B

8. <u>Bicycle and Motorcycle Storage</u>. Provide bicycle stalls that allow the use of locking devices. Bicycle stalls are typically 2 ft by 6 ft (600 mm by 1.8 m). Motorcycle stalls are 3 ft by 6 ft (1.0 m by 1.8 m).

9. <u>Traffic Control Devices</u>. Provide signs and pavement markings to direct drivers and pedestrians to appropriate loading zones, bicycle facilities, parking areas, including accessible parking, and entrances and exits. Coordinate the use of traffic control devices with the district Bureau of Operations.

10. <u>Fencing</u>. The need for fencing around a parking lot will be determined on a case-by-case basis.

11. <u>Landscaping</u>. In some locations, consider landscaping to minimize the visual impact of the parking lot. This may include providing a buffer zone around the perimeter of the lot or improving the aesthetics of the lot itself. Desirably, include a 10 ft to 20 ft (3.0 m to 6.0 m) buffer zone around the lot to accommodate vegetation screens. Also, raised-curb islands and parking lot separators provide suitable locations for shrubs and trees. Landscaping should include low maintenance vegetation that does not cause visibility or security problems. See Chapter 59 for guidance on landscaping.

12. <u>Snow Removal</u>. To assist with snow removal and storage, the design should include a 10 ft to 20 ft (3.0 m to 6.0 m) snow shelf around the perimeter of the lot on at least two sides. This area can coincide with the buffer zone around the lot, provided that the entire area is not filled with shrubs or trees. Place any fencing outside the area of the snow shelf. Providing painted islands rather than raised-curb islands can also make it easier to plow snow from the parking lot.

58-3 BUS STOPS AND TURNOUTS

58-3.01 Location

58-3.01(a) Bus Stops

If local bus routes are located on an urban or suburban highway, the designer should consider their impact on normal traffic operations. The stop-and-go pattern of local buses will disrupt traffic flow, but certain measures can minimize the disruption. The location of bus stops is particularly important. These are determined not only by convenience to patrons, but also by the design and operational characteristics of the highway and the roadside environment. If the bus must make a left-turn, for example, do not locate a bus stop in the block preceding the left turn.

There are three basic bus stop designs — far-side or near-side of an intersection, and mid-block. Advantages and disadvantages for each of these bus-stop locations are listed in Figure 58-3.A. In addition, consider the following:

1. Far-Side Stops. For capacity and other reasons, far-side stops are generally preferred to near-side or mid-block bus stops.

2. Near-Side Stops. Near-side stops must be used where the bus will make a right turn at the intersection.

3. Mid-Block Stops. Mid-block bus stops may be considered where right turns at an intersection are high (250 vph in peak hour) and far-side stops are not practical.

58-3.01(b) Bus Turnouts

Interference between buses and other traffic can be reduced significantly by providing bus turnouts. Turnouts remove stopped buses from the through lanes and provide a well-defined user area for bus stops. Consider bus turnouts where the following conditions exist:

- The street provides arterial service with higher speeds (e.g., posted speeds of 35 mph or greater).
- Bus volumes are 10 or more during the peak-hour.
- Passenger volumes exceed 20 to 40 boardings an hour.
- The average bus dwell time generally exceeds 30 seconds per stop.
- During peak-hour traffic, there are at least 250 vehicles per hour in the curb lane.
- Buses are expected to layover at the end of the trip.
- Potential vehicular/bus conflicts warrant the separation of transit and other vehicles.

	Advantages	Disadvantages
Far-Side Stop	• Minimizes conflicts between right-turning vehicles and buses. • Provides additional right-turn capacity by making the curb lane available for traffic. • Minimizes sight distance problems on approaches to the intersection. • Encourages pedestrians to cross behind the bus. • Creates shorter deceleration distances for buses because the bus can use the intersection to decelerate. • Results in bus drivers being able to take advantage of the gaps in traffic flow that are created at signalized intersections.	• Multiple stopped buses may block the intersection during peak periods. • May obscure sight distance for crossing vehicles. • May increase sight distance problems for crossing pedestrians. • Can cause a bus to stop twice, first for the traffic signal and then for the far-side stop, which interferes with both bus operations and all other traffic. • May increase number of rear-end accidents because drivers do not expect buses to stop again after stopping at a red signal. • Could result in traffic queued into intersection when a bus is stopped in travel lane.
Near-Side Stop	• Minimizes interference when traffic is heavy on the far side of the intersection. • Allows passengers to access buses closest to crosswalk. • The width of the intersection allows easier re-entry into the traffic stream where curb parking is allowed. • Eliminates the potential of double stopping. • Allows passengers to board and alight while the bus is stopped at a red signal. • Provides driver with the opportunity to look for oncoming traffic, including other buses with potential passengers.	• Increases conflicts with right-turning vehicles. • May result in stopped buses obscuring curbside traffic control devices and crossing pedestrians. • May cause sight distance to be obscured for cross vehicles stopped to the right of the bus. • May block the through lane during peak period with queuing buses. • Increases sight distance problems for crossing pedestrians.
Mid-Block Stop	• Minimizes sight distance problems for vehicles and pedestrians. • May result in passenger waiting areas experiencing less pedestrian congestion. • Desirable if a large generator is located mid-block. • Less walking for passengers where the distance between intersections is large. • May be appropriate where there is a fairly heavy and continuous transit demand throughout the block.	• Requires additional distance for no-parking restrictions. • Encourages patrons to cross street at mid-block (jaywalking). • Increases walking distance for patrons crossing at intersections.

COMPARISON OF BUS STOP LOCATIONS

Figure 58-3.A

- There is a history of traffic and/or pedestrian crashes that can be resolved by a bus turnout.
- Right-of-way width is sufficient to prevent adverse impact on sidewalk pedestrian movements.
- Curb parking is prohibited, at least during peak hours.
- Sight distances prevent traffic from stopping safely behind the bus.
- Appropriate bus signal priority treatment exists at the intersection.
- Other improvements (e.g., widening) are planned for the major roadway.

58-3.01(c) Selection

In general, the municipality or local transit authority will determine the location of the bus stop or bus turnout. However, the designer usually has some control over the best placement of a bus stop or turnout location when considering layout details, intersection design, and traffic flow patterns.

58-3.02 Design

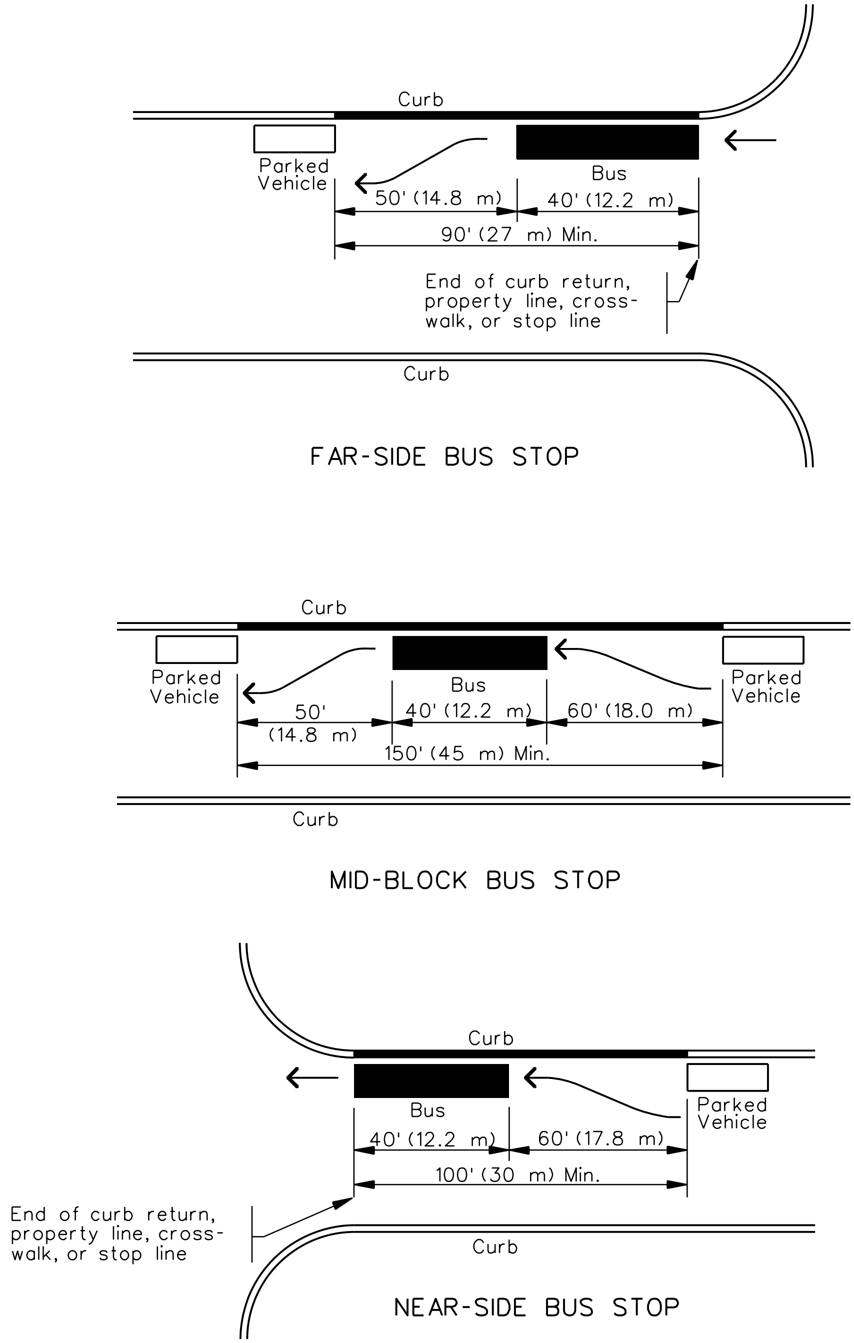
58-3.02(a) Bus Stops

Figure 58-3.B provides the recommended distances for the prohibition of on-street parking near bus stops.

58-3.02(b) Bus Turnouts

Desirably, the total length of a bus turnout will allow for an entrance taper, a deceleration length, a stopping area, an acceleration length, and an exit taper. Figure 58-3.C illustrates the design details for bus turnouts. Providing separate deceleration and acceleration lengths are desirable in open suburban area and on rural arterials and may be provided, wherever feasible. However, common practice is to accept deceleration and acceleration in the through lanes and only build the tapers and stopping area. In addition, consider the following:

1. Far-Side Turnouts. Typically, far-side intersection placement is desirable. Placing turnouts after signal-controlled intersections allows the signal to create gaps in traffic.
2. Near-Side Turnouts. Avoid using near-side turnouts because of conflicts with right-turning vehicles, delays to transit services as buses try to re-enter the traveled way, and obstructions to traffic control devices and pedestrian activities.



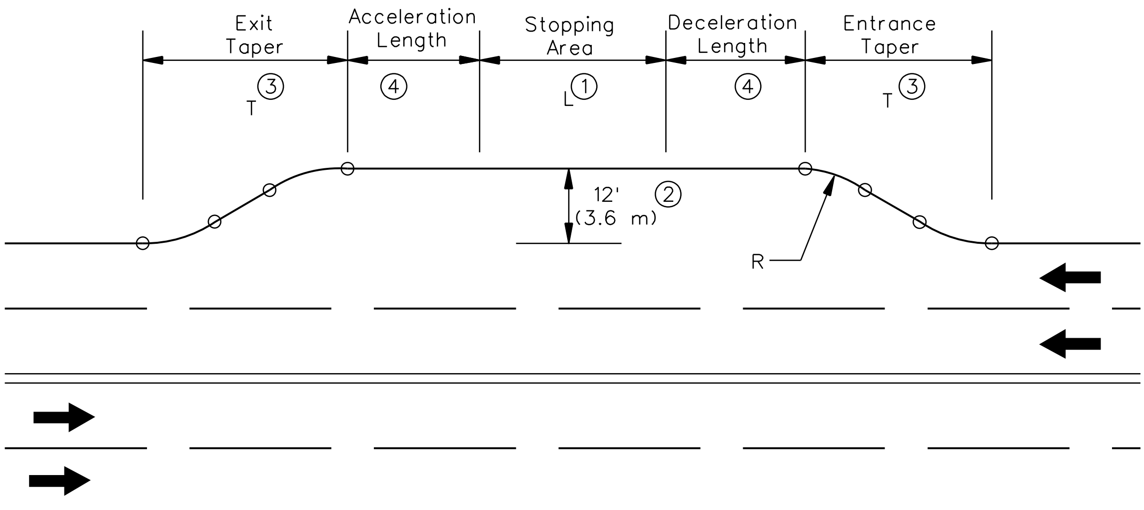
Notes:

1. *Where articulated buses are expected to use these stops, add an additional 20 ft (6.0 m) to the bus distances.*

2. *Provide an additional 50 ft (15 m) of length for each additional bus expected to stop simultaneously at any given bus stop area. This allows for the length of the extra bus (40 ft (12.2 m)) plus 10 ft (2.8 m) between buses.*

ON-STREET BUS STOPS

Figure 58-3.B



Notes:

① *Stopping area length consists of 50 ft (15 m) for each standard 40 ft (12.2 m) bus and 70 ft (21 m) for each 60 ft (18.3 m) articulated bus expected to be at the stop simultaneously.*

② *Bus turnout width is desirably 12 ft (3.6 m). For posted speeds under 30 mph, a 10 ft (3.0 m) minimum bay width is acceptable. These dimensions do not include gutter width.*

③ *Suggested taper lengths are listed below. A minimum taper of 5:1 may be used for an entrance taper from an arterial street for a bus turnout while the merging or re-entry taper should not be sharper than 3:1.*

④ *The minimum design for a bus turnout does not include acceleration or deceleration lengths. Recommended acceleration and deceleration lengths are listed below.*

Design Speed	Entering Speed*	Acceleration Lengths	Deceleration Lengths **	Suggested Taper Lengths
US CUSTOMARY				
35 mph	25 mph	250 ft	185 ft	170 ft
40 mph	30 mph	400 ft	265 ft	190 ft
45 mph	35 mph	700 ft	360 ft	210 ft
50 mph	40 mph	975 ft	470 ft	230 ft
METRIC				
50 km/hr	35 km/hr	60 m	45 m	45 m
60 km/hr	45 km/hr	105 m	70 m	50 m
70 km/hr	55 km/hr	200 m	105 m	60 m
80 km/hr	65 km/hr	310 m	145 m	70 m

* *Desirably, the bus speed at the end of taper should be within 10 mph (15 km/hr) of the design speed of the traveled way.*

** *Based on a 2.5 mph/sec (4.0 km/hr/s) deceleration rate.*

TYPICAL BUS TURNOUT DIMENSIONS

Figure 58-3.C

3. Mid-Block Turnouts. Only use mid-block turnouts in conjunction with major traffic generators.

4. Tapers. Figure 58-3.C provides information on taper lengths that may be used for entrance and exit tapers. To improve traffic operations, use short horizontal curves (100 ft (30 m) radius) on the entry end and 50 ft to 100 ft (15 m to 30 m) curves on the re-entry end. Where a turnout is located at a far-side or near-side location, the cross street area can be assumed to fulfill the need for the exit or entry area, whichever applies.

58-3.02(c) Bus Stop Pads

All new bus stops which are constructed for use with lifts or ramps must meet the accessibility criteria in Section 58-1.

58-3.02(d) Bus Shelters

In general, the municipality or the local transit authority will determine the need for and location of bus shelters. The local transit authority will determine the design of the bus shelter. The designer should ensure that the shelter is accessible, and does not restrict vehicular sight distance, or pedestrian flow.

58-4 FENCING

Fencing is desirable along high-speed highways to protect the driver from unexpected intrusions from outside of the right-of-way line. Fencing deters unauthorized and unsafe entry to the highway by vehicles, pedestrians, or animals. It also reduces the occurrence of objects being dropped or thrown from highway overpasses.

Except where warranted for highway applications, fencing is normally the responsibility of the abutting property owner. Fences may be necessary for retaining livestock, discouraging trespassing, defining property boundaries, or otherwise to keep land use activities within bounds. If private fences are impacted by a highway project, their relocation or disposition is reconciled as part of the right-of-way negotiations and settlement.

58-4.01 General

58-4.01(a) Location

Fencing is typically provided along all segments of fully access controlled facilities; along certain segments of expressways; near schools, playgrounds, and parks; near livestock areas; on some bridges; and between frontage roads and access controlled highways. Fencing is usually erected parallel to the highway centerline. Where right-of-way lines are irregular, the fencing should still be basically parallel to the highway, provided the fencing is within the highway right-of-way. In general, the fence line should coincide with the right-of-way line; however, deviations are acceptable if justified and documented in a Phase I report. Avoid sharp jogs in the fence line to prevent the need for hand mowing. See Section 34-5 and Chapters 35, 44, and 45 for additional guidance on setting right-of-way limits and for the location of access control lines.

58-4.01(b) Fence Types

The following fence types are used by the Department:

1. Woven Wire. This fence type consists of a woven wire mesh and two strands of barbed wire at the top for a total height of 4 ft (1.2 m). It can be placed on either wood or metal posts.

2. Chain Link. Chain link fence consists of an interlocking wire mesh on metal posts. It is typically 4 ft (1.2 m) or 6 ft (1.8 m) high.

3. Existing. Where a portion of an existing fence, which differs from the standard type or height, is to be replaced, the new fence should match the portion of the fence that will remain in place.

All materials and installations must conform to the requirements in the *Illinois Standard Specifications* and the *Highway Standards*.

58-4.02 Freeways (Fully Access Controlled)

The following will apply to fencing along freeways:

1. Warrants. Chain link or woven wire fencing is required along all fully access controlled facilities. Provide continuous fencing along either the right-of-way or access control lines. Also, provide fencing for the entire limits of access control along the crossroad and along the first access connection. However, engineering judgment may dictate exceptions. In addition, where retaining walls, concrete barriers, sound barriers, sight screens, etc., are used, fencing usually is not required to preserve access control. With the appropriate fence inserts, the access-control fencing also may be used as a glare screen between frontage roads and the mainline highway.

2. Location. Fences generally will be located to coincide with the right-of-way line, except for the following:

   a. Frontage Roads and Service Drives. Where frontage roads or service drives exist or will be constructed, place the fencing between the adjacent roadway and the freeway or ramps. Fencing is normally located outside the clear zone of a freeway; see Figures 44-2.J and 44-2.K. Where access control fencing is located between a frontage road or service drive and the freeway, it is not necessary to provide fencing outside the right-of-way line of the frontage road.

   b. Structures. Wherever streams, railroads, or grade separations are encountered that prevent the fence from being continued on a straight line, tie the fence to the structure, abutment, or wingwall to ensure that full access control is maintained. See the figures in Section 44-3 for locations of access control lines adjacent to these features. See the *Highway Standards* for the correct application of fencing across stream crossings with culverts.

   c. Outside Ditches. In relatively flat areas (e.g., across floodplains), it may be desirable to place the access control fence on the front slope of the highway embankment rather than at the right-of-way line. Placing the fence on the front slope eliminates the potential problem of obstructing sheet flow if the fence is placed along the right-of-way line. The obstruction of sheet flow is usually caused by vegetation build-up along the fence and due to field plowing adjacent to the fence.

3. Type of Area. The following will apply:

   a. Built-Up Areas. Chain link fencing is generally used in urban, suburban, and other similar built-up areas. Use 6 ft (1.8 m) high chain link fence in areas having a high concentration of children (e.g., schools, churches, playgrounds, housing developments). Use 4 ft (1.2 m) high chain link fence in areas adjacent to single-family homes, parks, reservoirs, commercial and industrial properties, etc. The designer must consider the type of impending development adjacent to the highway to determine the appropriate height. This may require a higher fence to be installed initially to preclude replacement a short time later.

b. Rural Areas. In rural areas where little development is existing or planned, woven wire fencing is typically used.

c. Deer Crossings. Where known deer crossings exist, use a woven wire fence with a minimum height of 10 ft (3.0 m). Also, the limits of this fence must be long enough to deter deer from going around the fence. Connect the fence directly to the wingwalls of structures to minimize deer intrusions onto the highway.

4. Construction. Construct access control fencing on the State right-of-way line with the face of the fencing toward the abutting property. Delineate this location on the contract plans. The fence will be maintained by the State.

5. Gates. Where they are considered necessary for maintenance and operational purposes, gates may be required in the access-control fencing. Limit the number of these gates to an absolute minimum. Only provide gates to allow access for:

- maintenance to otherwise inaccessible portions of the highway right-of-way, and
- public utility installations where no other access is available or can be reasonably provided.

All gates must have adequate locking devices to ensure that they are only used by authorized personnel. The district is responsible for maintaining a record of all personnel that possess keys to the locked gates.

58-4.03 Expressways (Partial Access Control)

The following will apply to fencing along expressways:

1. Warrants. Fencing is highly desirable along expressways similar to freeways. At a minimum, existing fencing should be replaced in rural areas and should be considered in built-up residential areas in rural locations. Where it is decided that fencing may be omitted in rural areas, provide informational signs at approximately ¼ mile (400 m) intervals on the right-of-way lines to notify the public that the highway is access controlled. The signs should indicate that the Illinois Department of Transportation may be contacted for any requests for new access points. Also, to minimize future access problems along crossroads, provide fencing along the entire access control limits of each crossroad.

2. Location. The criteria in Section 58-4.02 for freeways also apply to expressways.

3. Type of Area. The criteria in Section 58-4.02 for freeways also apply to expressways with the exceptions noted above in Item 1.

4. Construction. The criteria in Section 58-4.02 for freeways also apply to expressways.

58-4.04 Protective Fencing on Highway Overpasses

58-4.04(a) General

Protective fencing is generally provided wherever there is a potential hazard to highway users resulting from objects being dropped or thrown from overhead crossings, where there is a need to protect pedestrians who cross on the overpass, or where a bikeway is carried across the structure. This fencing is categorized as vertical pedestrian railing, curved bridge fence railing for pedestrians, and bicycle railings. The protective fencing should satisfy the aesthetic consideration of the structure and should be designed in conformance with the latest Department standards. See 92 Ill. Admin. Code 510 for additional guidance. See the *Bridge Manual* for detailed drawings on the different types of protective fencing located on structures and to the typical sections shown in Figures 39-5.L and 39-5.M.

58-4.04(b) Evaluation of Need

The districts will be responsible for determining the need of vertical pedestrian railings or curved bridge fence railings. The vertical railing is desirable in urban areas where there is considerable pedestrian traffic on the bridge. The curved bridge fence railing may also be used in urban areas with considerable pedestrian traffic and where there are reported incidents of objects being thrown or dropped from an overpass or there is the high potential of such events occurring. If fencing is required, the cost apportionment and maintenance requirement will be as discussed in Section 5- 5.02(j).

58-4.04(c) Pedestrian Bridges

Provide protective fencing on all new pedestrian bridges. The cost apportionment will be the same as for the pedestrian crossing itself. The need for protective fencing on existing pedestrian bridges will be determined on case-by-case basis using the guidance discussed in Section 58- 4.04(b).

58-4.05 Fencing or Safety Devices on Top of Retaining Walls

The purpose of a fence or safety device is to alert pedestrians, bicyclists, and/or motorists of a difference in elevation to prevent injury from a fall or vehicular crash. Consider installing a fence or safety device at the top of any wall that is over 1 ft (300 mm) tall if the top of the wall is closer than 2 ft (600 mm) to a sidewalk, trail, parking lot, public common area, or stairway landing. Walls located further away from human or vehicular activity may be higher before a fence is considered necessary. Regardless of the height of the wall, provide a fence or safety device if any activity (e.g., driving, walking, riding a bike, running, or other playground type activities) could result in harm or damage by someone inadvertently going over the wall. A fence or safety device is required when the difference in grade level on either side of the wall is in excess of 4 ft (1.2 m) tall. Consider aesthetics of any fence, especially in urban areas, where the wall and barrier are located adjacent to private property.

58-5 MAILBOX TURNOUTS

Mailboxes and newspaper tubes served by carriers in vehicles may constitute a safety hazard, depending upon the placement of the mailbox and the width of the turnout. Therefore, the designer should make every reasonable effort to replace all non-conforming mailboxes and turnouts with designs that meet the criteria in the IDOT Maintenance Policy 3-100 “Placement of Newspaper Boxes,” IDOT Maintenance Policy 3-200 “Construction and Maintenance of Mailbox Turnouts,” and Chapter 11 of the AASHTO *Roadside Design Guide*. Mailbox turnouts must be addressed on reconstruction and 3R projects. Where shoulder widths permit on 3P and SMART projects, the designer should address mailbox turnouts. Coordination with the local postmaster and property owner is required for all changes of mailbox locations.

58-5.01 Location

Mailbox turnouts should be placed for maximum convenience to the patron, consistent with safety considerations for highway traffic, the carrier, and the patron. When determining the location of mailboxes, consider the following:

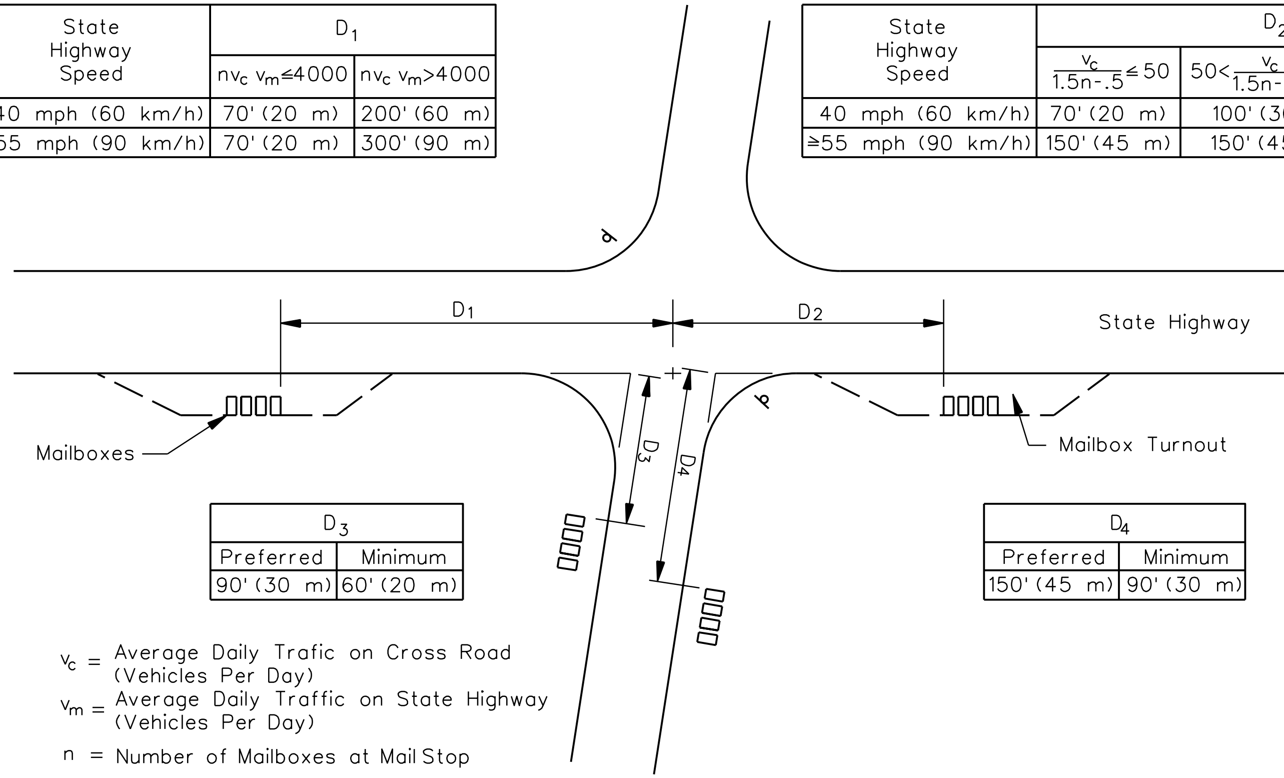
1. Intersections. Placing a mail stop near an intersection will have an effect on the operation of the intersection (e.g., reduction of intersection sight distance, blocked lanes). The nature and magnitude of this impact depends on traffic speeds, volumes on each of the intersecting roadways, the number of mailboxes at the stop, type of traffic control, how the stop is located relative to the traffic control, and the distance the stop is located from the intersection. Figure 58-5.A provides the recommended minimum clearance distances to mailbox stops near intersections. On State highways, many of the above potential problems are alleviated by the use of mailbox turnouts. Where feasible, locate all new turnout installations on the far-right side of an intersection with a public road. However, in some cases the designer may determine that it is preferable to locate the turnout on the near-side of an intersection.

2. Near-Side/Far-Side at Driveways. On rural two-lane highways where a single mailbox installation is required, the near side turnout is preferable because this design allows the postal patron to pull up to the mailbox and then to turn into the driveway without backing up. If there is a need for multiple mailbox installations at one location, the far-side turnout is preferable because all postal patrons except for one can pull into the turnout and then drive out and proceed to their homes; see Figure 58-5.B.

3. Newspaper Boxes. Newspaper boxes are only permitted at mailbox turnouts. Where practical, the newspaper box should be erected on the same post as the mailbox.

State Highway Speed	D_1	
	$nv_c\ v_m \le 4000$	$nv_c\ v_m > 4000$
40 mph (60 km/h)	70' (20 m)	200' (60 m)
≥55 mph (90 km/h)	70' (20 m)	300' (90 m)

State Highway Speed	D_2		
	$\frac{v_c}{1.5n-.5} \le 50$	$50 < \frac{v_c}{1.5n-.5} < 400$	$\frac{v_c}{1.5n-.5} > 400$
40 mph (60 km/h)	70' (20 m)	100' (30 m)	100' (30 m)
≥55 mph (90 km/h)	150' (45 m)	150' (45 m)	200' (60 m)



D_3	
Preferred	Minimum
90' (30 m)	60' (20 m)

D_4	
Preferred	Minimum
150' (45 m)	90' (30 m)

v_c = Average Daily Trafic on Cross Road (Vehicles Per Day)

v_m = Average Daily Traffic on State Highway (Vehicles Per Day)

n = Number of Mailboxes at Mail Stop

RECOMMENDED MINIMUM CLEARANCE DISTANCES TO MAILBOX STOPS NEAR INTERSECTIONS

Figure 58-5.A

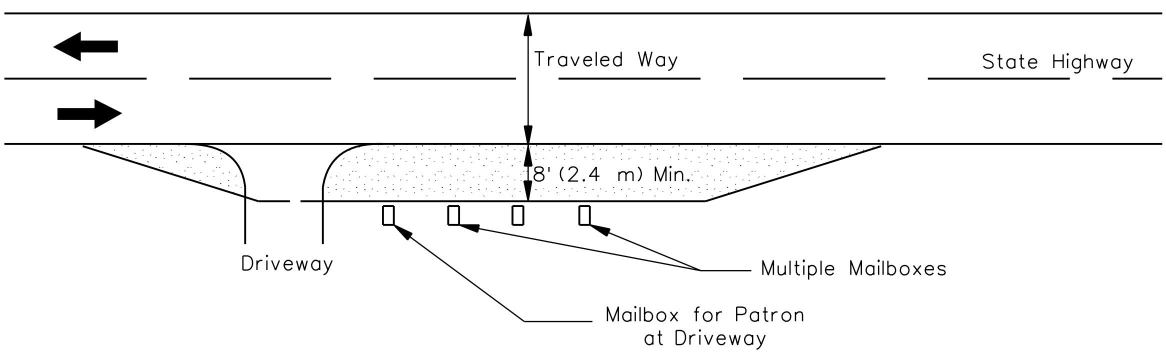
TURNOUT ON NEARSIDE OF DRIVEWAY
WITH SINGLE MAILBOX



TURNOUT ON FARSIDE OF DRIVEWAY
WITH MULTIPLE MAILBOXES

MAILBOX TURNOUTS AND DRIVEWAYS

Figure 58-5.B

4. Postal Patrons. When determining the location of mailboxes, try to minimize the walking distance to the mailbox site for the patron. It is undesirable to require pedestrians to travel along the shoulder. However, this may be the preferred solution for distances up to 200 ft (60 m) when compared to other alternatives (e.g., constructing a turnout in a deep cut, placing a mailbox turnout just beyond a sharp crest vertical curve (poor sight distance), constructing two or more closely spaced turnouts).

5. Right or Left Side. Only place boxes on the right-hand side of the highway in the direction of travel of the carrier, except on one-way streets where they may be placed on the left-hand side; see Figure 58-5.B.

6. Guardrail. Where a mailbox is installed in the vicinity of an existing guardrail and where practical, place the mailbox support behind the guardrail.

7. High-Speed/High-Volume Facilities. On expressways or other high-speed multilane highways in rural areas, mail delivery usually is accomplished by the mail carrier using the 10 ft (3.0 m) wide paved shoulders for deceleration and as a mailbox turnout area. Where the local postmaster only will agree to deliver mail in one direction and a postal patron is located on the opposite side of the median, it may be necessary to provide a walkway through the median. This is highly undesirable and only should be used as a last resort. Instead, encourage the postal patron to pick up his/her mail at the post office.

   As an option to shoulder mail delivery along the route, it may be possible to set up post office box delivery only. However, this change in mail delivery must be agreed to by the postal patrons and the local postmaster.

   In some situations, a number of closely spaced houses may have access to a frontage road or service drive rather than direct access to the expressway. In this case, locate the mailboxes on the frontage road or service drive.

8. Suburban/Urban Areas. A potential problem frequently occurs on State highways where a roadway section with shoulder originally existed and where the roadway is reconstructed to a curb and gutter cross section. Previously, the mail carrier would have delivered mail from a vehicle by driving along the shoulder. With the reconstruction to a curb and gutter section, the mail would now have to be delivered by driving on the pavement adjacent to the curb and gutter. Under certain conditions, some mail carriers feel that mail delivery along a curb and gutter roadway has the potential to be hazardous. The factors which could contribute to a potential problem along the street are high-operating speeds, the number of through and turning lanes, and the amount of congestion due to traffic volumes. To alleviate the potential for mail delivery problems where a curb and gutter cross section is proposed, the district should work closely with local postmaster during the development of the project. In many cases, after coordination with a postmaster is completed, Department personnel will determine that the potential for mail delivery problems is minor and no special design features are needed. However, where the potential for mail delivery problems is determined to be significant, it may be possible to modify rural type delivery on streets with curb and gutter by considering the following:

a. Grouping. Where there are a number of closely spaced houses located along a State highway, it may be desirable to group two, four, or six mailboxes at one location. Due to the possibility of spearing of windshields by the horizontal support, it is desirable to individually mount each mailbox on a separate support. However, it may be acceptable to mount multiple mailboxes on one support if it meets the criteria in Chapter 11 of the AASHTO *Roadside Design*. Figures 58-5.C and 58- 5.D illustrate possible placement for groups of mailboxes along urban routes.

b. Neighborhood Delivery and Collection Box Unit (NDCBU). Relocate all mailboxes along the block around the corner on a side street by using a NDCBU. However, it should be noted that postal patrons usually do not like this solution in older established neighborhoods.

c. Park and Loop Routes. Request the mail carrier to park his/her vehicle on a side street, walk the block, and return to the vehicle.

d. Paved Shoulder. Provide a continuous 6 ft (1.8 m) paved shoulder with curb and gutter located behind the shoulder. This alternative is expensive and right-of-way may not be available in many cases. However, this design allows for mail carriers, garbage trucks, and delivery trucks.

9. Problems. Where a satisfactory mail delivery solution cannot be reached between all parties involved, contact the Delivery Programs Support Analysts at one of the U.S. Postal Services' district offices at the following locations:

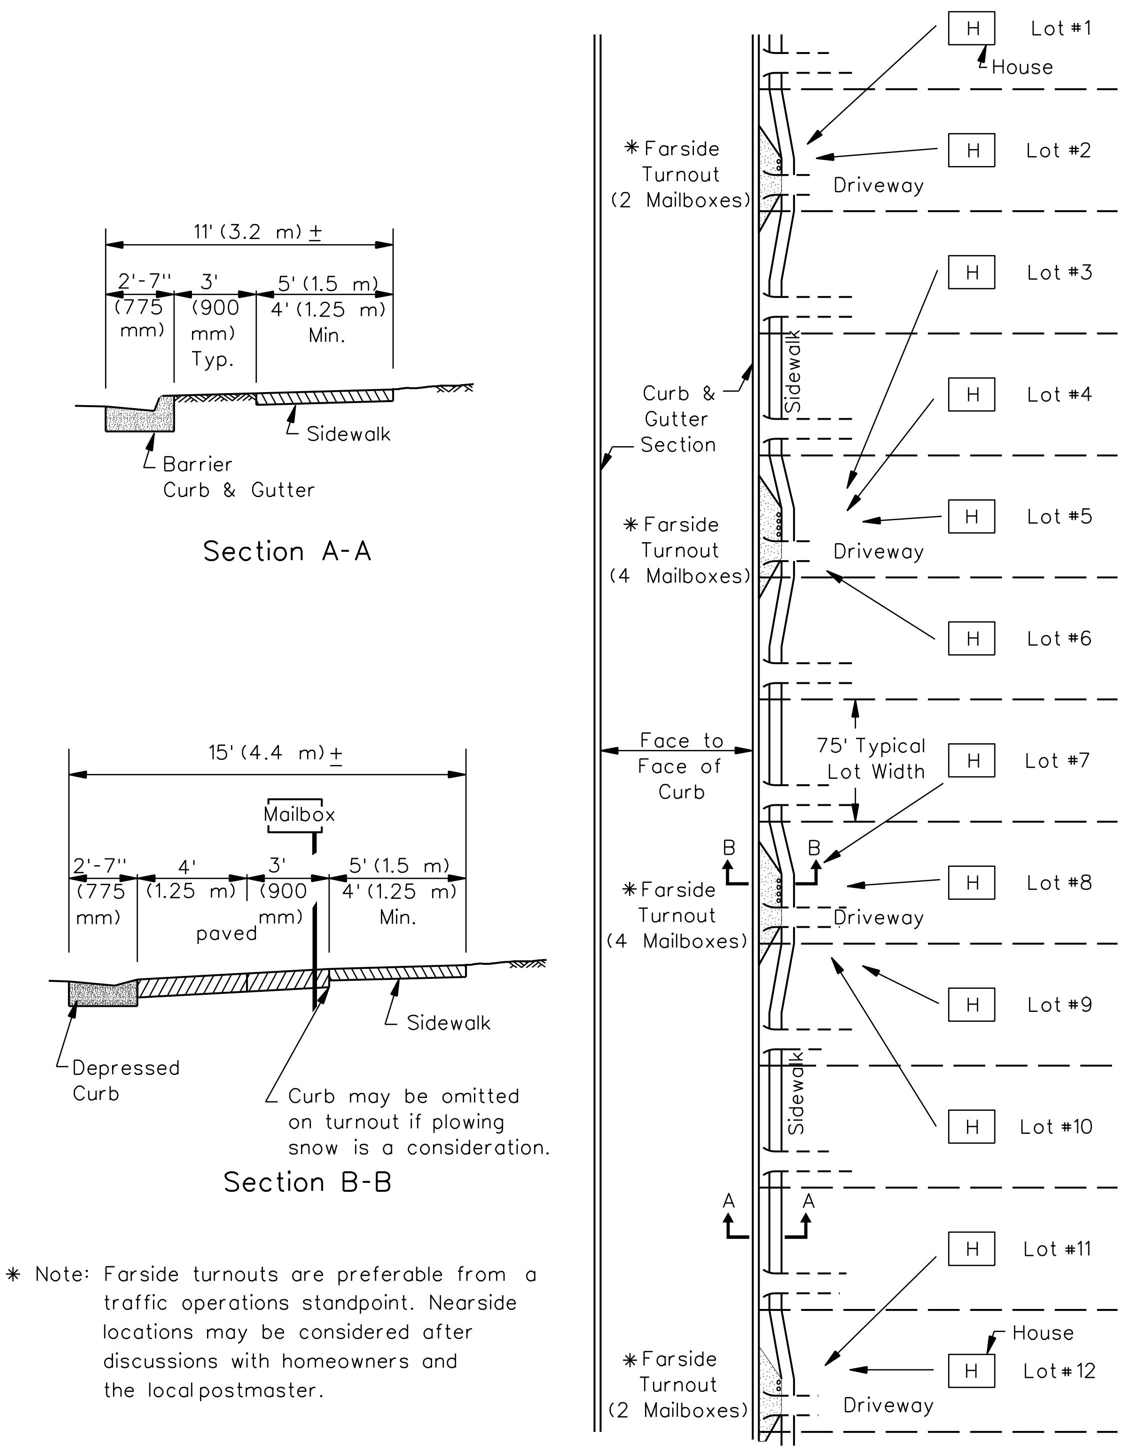
- For northern Illinois, contact the postal official at (630) 260-5260.
- For central Illinois, contact the postal official at (708) 563-7360.
- For southern Illinois, contact the Midwest Area Office in St. Louis at (314) 692-5426.

58-5.02 Design Features

58-5.02(a) Typical Designs

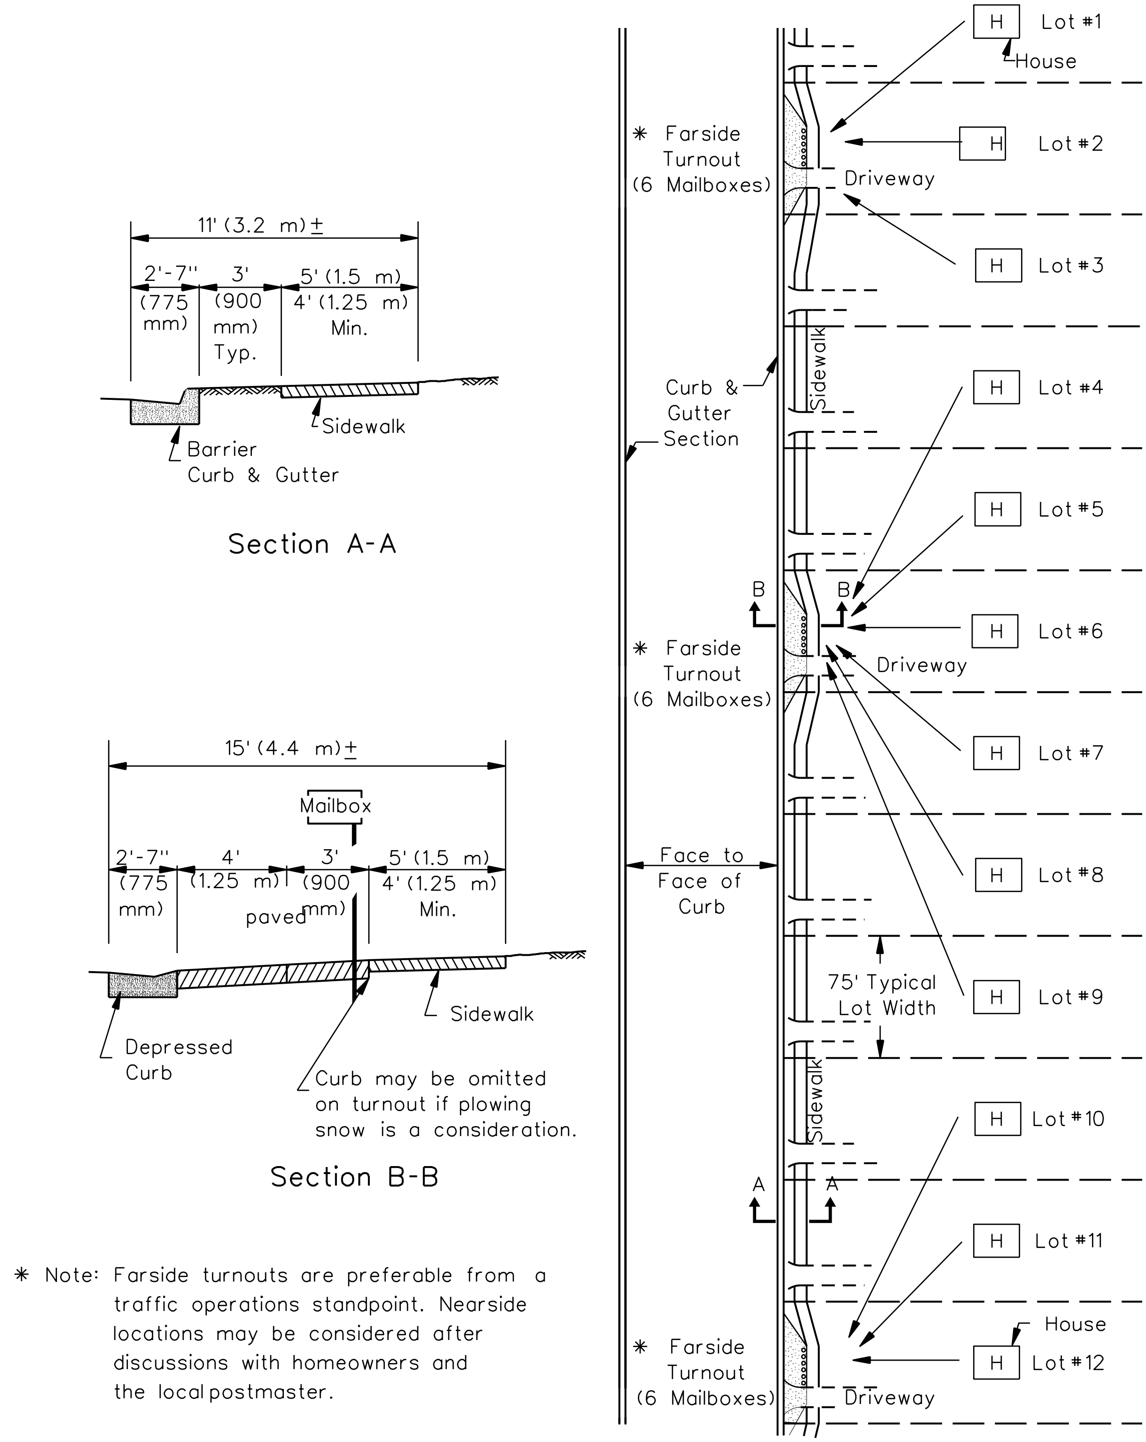
The *Highway Standards* provide the geometric design criteria for rural mailbox turnouts. The designer should also consider the following:

1. Stopping Sight Distance. Ensure that there is sufficient stopping sight distance in advance of the mailbox turnout.



URBAN MAILBOX TURNOUTS
(Two or Four Mailboxes Grouped Together)

Figure 58-5.C



URBAN MAILBOX TURNOUTS
(Six Mailboxes Grouped Together)

Figure 58-5.D

2. Width. To ensure stopped vehicles are outside of the traveled way, mailbox turnouts should be at least 8 ft (2.4 m) wide.

3. Narrow Shoulders. Widening and/or resurfacing of highways with limited right-of-way may result in shoulder widths which are too narrow for mailbox turnouts (i.e., less than 8 ft (2.4 m)). In these cases, it will be necessary to widen out the shoulder at the mailbox location to provide the minimum width and, in some cases, installing a sufficient length of pipe culvert to provide for roadside drainage.

4. Surface. Provide an all-weather surface at the turnout. The minimum design should be 6 in. (150 mm) of aggregate or a combination of aggregate and a bituminous surface.

5. Heights. Mailbox heights are usually located so that the bottom of the box is 3 ft (1.0 m) to 4 ft (1.2 m) above the mail stop surface.

6. Mailbox Supports and Attachment Design. For guidance on mailbox posts, supports, and attachments, see the AASHTO *Roadside Design Guide*.

7. Multiple Mailboxes. To reduce the possibility of ramping, multiple mailboxes supports should be separated by a distance at least equal to three-fourths of their height above ground. Due to the number of vehicles using the turnout, desirably the surface should be bituminous. See 58-5.01 for restrictions on multiple mailboxes in a turnout.

8. Neighborhood Delivery and Collection Box Units (NDCBU). NDCBU is a cluster of 8 to 16 locked boxes mounted on a pedestal or within a framework. These clusters can weigh between 100 lbs to 200 lbs (45 kg to 90 kg) and may be a roadside hazard. Consequently, they should be located outside the clear zone in rural areas and preferably on a side street in urban areas. Normally, NDCBU are located in trailer parks, apartment complexes, and new residential subdivisions.

58-5.02(b) Special Designs

Due to the multitude of different conditions, the standard mailbox turnout designs may not always be practical. This is especially true in urban and suburban areas. Therefore, where special agreements have been reached with a local postmaster and where special designs will be needed, provide these details in the Phase I report. These commitments are then carried forward into the contract plans, plan notes, and special provisions.

If during the preparation of the plans it is determined that temporary locations will be required for mail delivery during construction, provide the necessary details in the plans and special provisions. Also, if it is determined that an existing mailbox support which has temporarily been moved is potentially hazardous to traffic, it should be replaced with a suitable support.

58-5.03 Mailbox Supports

During the preparation of the Phase I report, the district is required to address the problem of hazardous mailbox supports. Removal and replacement of mailboxes can be a sensitive issue and should be reviewed with the local postal authorities and the postal patron. The process to determine and achieve compliance on this issue consists of the following:

1. Survey. Conduct an on-site survey to determine whether there are any hazardous mailbox supports within the clear zone of the project. Document these locations in the Phase I report. If there are no hazardous supports on the project, note this in the Phase I report.

2. Notification by Department. If a mailbox box support is determined to be hazardous, the person conducting the field check is required to notify the postal patron. This can be accomplished either through the normal mail service or by placing a postage stamped envelope with a completed form letter enclosed into the patron's mailbox. A sample form letter is shown in Figure 58-5.E and discusses the following issues:

    - potential adverse safety effects,
    - appropriate safety design,
    - potential personal liability, and
    - IDOT's request to change the support to an acceptable design.

    Note that the Department contacts postal patrons to remove or replace the support only when a highway is proposed for improvements.

3. Documentation. If an answer is received from the postal patrol, document the following in the project files for Phase II design:

    - the owner's decision to change to a safe mailbox support; or
    - if the owner is undecided, urge the owner to strongly consider a safe support and document all phone conversations or meetings and the results.

4. Notification by Postmaster. If no response is received from a postal patron who has a hazardous mailbox support or if the owner indicates that he/she does not wish to change the support, the district may contact the local postmaster and ask for the postmaster's help in getting the mailbox support removed. If the local postmaster is agreeable, he/she has the authority to notify the patron in writing of the safety hazard of an existing support. Postal regulations require that box supports must bend or break away when struck by a vehicle and that such supports are now readily available for purchase. The local postmaster can give the owner 30 day notice, and if compliance is not achieved, the postmaster has the authority to suspend mail delivery to the box.

5. Phase II Field Reviews. If a hazardous mailbox support is constructed or discovered after design approval, use the above procedures and add the appropriate documentation to the files and reports.

6. Documentation for Construction Personnel. Provide the resident engineer with the correct information on each property owner who has a hazardous mailbox support and what the owner has decided concerning the mailbox support. Also, see Section 58-5.02.

Description of Mailbox Support _________________________________
____

TO: ___________________________________
____
____

Dear ___________________________________:

It is the intent of the Illinois Department of Transportation to make improvements on the above-described route in the near future. A part of these improvements includes protecting the driving public from roadside hazards. A recent survey of mailbox supports within this project indicates that your mailbox support as described above is a potential hazard to the traveling public and should be changed to meet certain safety requirements.

Each year during Mailbox Improvement Week, the United States Postal Services provides you a pamphlet describing ways to aid the Postal Service in the delivery of your mail. The following is a paragraph, taken from a recent pamphlet, describing the kinds of supports that should be avoided because they can cause serious vehicular damage and personal injury.

> "Reports have been received that some mailbox supports are so massive that they are damaging the vehicles and causing serious injuries to people who accidentally strike them. The use of heavy metal posts, concrete posts, and miscellaneous items of farm equipment, such as milk cans filled with concrete, should be avoided. The ideal support is an assembly which, if struck, will bend or fall away from the striking vehicle instead of severely damaging the vehicle and injuring its occupants."

SAMPLE HAZARDOUS MAILBOX SUPPORT LETTER

Figure 58-5.E

Because your mailbox support is private property, we do not intend to remove or change it to a safer type. However, in the interest of public safety, and to avoid any potential liability if struck by a vehicle, we are requesting that you consider changing the support to a safer type.

Because there are a number of different, safe designs from which to choose, we will be glad to help you select one that you would prefer. At the bottom of this letter, there is a name and telephone number which you can call (collect if you wish) to receive more information about the installation of a safety mailbox support.

If you prefer, you may also ask that someone visit your residence at an agreeable time, during Department working hours, to further explain the safety problems and assist you in selecting an appropriate, safe support. You may arrange this by means of the previously mentioned telephone number or by placing your name and telephone number in the space provided at the bottom on this letter and returning it in the pre-addressed, stamped envelope enclosed for your convenience.

Thank you for your cooperation. We are looking forward to hearing from you so that, together, we can improve highway safety.

Very truly yours,

____
Regional Engineer

Figure 58-5.E
(continued)

58-6 RECREATIONAL ROADS

Design criteria for recreational roads are applicable to roads in State parks, recreational areas, national forests, and scenic drives. The objective for this type of facility is to provide a safe highway and still retain the aesthetic, ecological, environmental, and cultural amenities of the area.

In the design of recreational roads, consider the following:

1. Design Criteria. For design guidance, see the "Recreational Roads" section in the AASHTO *A Policy on Geometric Design of Highways and Streets*. Strict adherence to highway criteria for these types of roads may be inappropriate and unwarranted. Design speeds are usually low and driver expectancy is such that the reduction of criteria does not produce serious safety concerns. Therefore, the designer must use engineering judgment to ensure that the criteria fit the terrain and expected usage of the highway.

2. Design Vehicle. Depending on the nature of the recreational areas, the most common design vehicle will be a motor home with a boat trailer. Where garbage pickup or other maintenance vehicles are required, an SU may be the appropriate design vehicle. In some situations, only a passenger car may be appropriate. The designer must use engineering judgment to determine the appropriate design vehicle. Use the selected design vehicle to determine lane widths, vertical clearances, intersection designs, etc.

58-7 SEALING OF ABANDONED WATER WELLS

Abandoned water wells located on highway project right-of-way must be properly sealed by a licensed well driller in accordance with the requirements of the *Illinois Water Well Construction Code,* 415 ILCS 30/1 et seq. and *Water Well Construction Code*, 77 Ill. Adm. Code 920.120. When abandoned water wells are identified on proposed project right-of-way during Phase I or Phase II, appropriate provisions shall be included in the contract plans to ensure compliance with the applicable well sealing and notification requirements of the Water Well Construction Code. In addition, any information that the district has available concerning the abandoned well (e.g., location, depth, diameter, type, liner material, etc.) also shall be included in the plans.

58-8 SURVEY MARKERS AND MONUMENTS

58-8.01 Right-of-way Markers

Right-of-way markers are used to delineate the extent of State highway right-of-way. Construction details for right-of-way markers are illustrated in the *Highway Standards*.

Place right-of-way markers at the following locations:

- opposite points of curvature and tangency and opposite the midpoint of curves;
- along tangents so that two markers are always intervisible;
- at each corner of all offsets; and
- at all intersecting roads, except for streets in subdivisions outside of corporate limits.

Indicate the location of all right-of-way markers on the plans. Set the back of the marker flush with the right-of-way line.

Right-of-way markers may be omitted along freeways or controlled access highways where access control fencing is constructed on the right-of-way line. The fence line should be coincident with the right-of-way line (i.e., the back of the posts should be tangent to the right-of-way line). However, use markers for areas where the right-of-way line deviates from the fencing (e.g., grade separations, frontage roads) in compliance with the above requirements.

Do not place markers at the intersections of the right-of-way line with property lines in rural areas except for compliance with the above requirements. The intention of the markers is to delineate right-of-way lines and not to be construed as indicating the dividing line between adjacent property owners.

58-8.02 Permanent Survey Markers

Permanent survey markers are used to delineate the highway centerline. Construction details for permanent survey markers are illustrated in the *Highway Standards*.

Place markers at the PT's and PC's of all horizontal curves and space them along tangents so that two markers are always intervisible. Indicate the location of all markers on the plans.

For two-lane highways, place the Type I markers on the centerline in the pavement. When these highways are resurfaced, the marker should be raised to be flush with the new surface or referenced by means of permanent ties as discussed in Section 58-8.03.

On divided highways, place Type II markers, either precast or site constructed, in the median so that the plaque is flush with the median surface. If the horizontal alignment of the opposing roadways is not concentric, reference the respective roadway centerlines to the survey centerline. The Type II marker may also be used as a permanent benchmark.

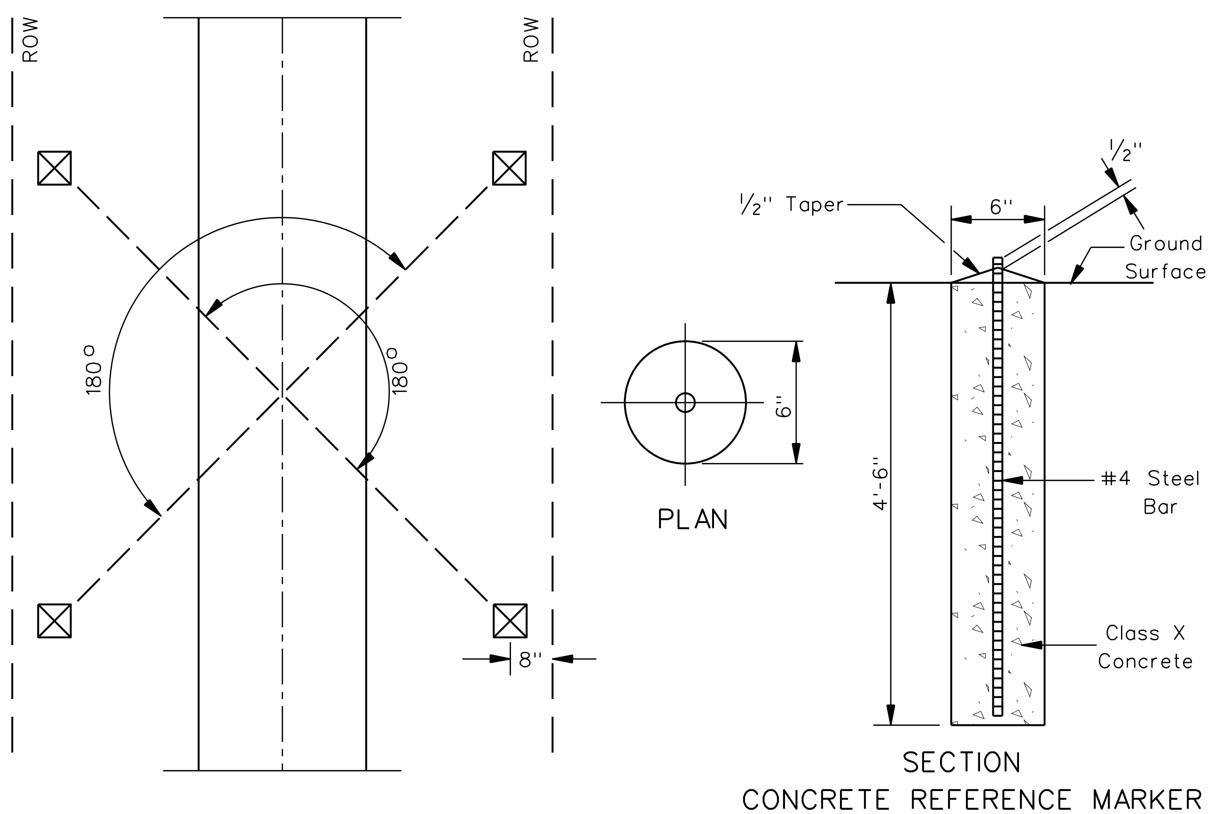
58-8.03 Permanent Survey Ties

Permanent survey ties should be used in place of survey markers on highways having bituminous surface treatments and may be used at the option of the Regional Engineer on highways having bituminous concrete surface courses.

The permanent ties must consist of a metal rod or pin embedded in concrete within the highway right-of-way. At least four permanent ties must be provided for each survey point and must be located so that arcs struck from the ties will result in a precise point of intersection. Construction details for permanent survey ties are illustrated in Figure 58-8.A.

58-8.04 Land Survey Monuments

Public Act 79-649 requires that monument records of United States public land survey monuments used as control corners of a survey be filed with the Recorder of Deeds or Registrar of Titles in the county of the survey. Procedures and instructions for the implementation of this *Act* are contained in the *Land Acquisition Policies and Procedures Manual*.



PERMANENT SURVEY TIES

Figure 58-8.A

The provisions of this *Act* require to preserve the U. S. public monuments that are subject to disturbance by the construction of a highway (605 ILCS 5/9-104).

If it is determined during the design stage of a project that a U.S. public land survey monument will be affected by the construction operations, the designer will prepare a Special Provision for inclusion into the contract providing for the preservation of the monument. Clearly indicate in the Special Provision the placement of reference monuments for the location of land survey monuments lowered below the finished grade. The Special Provision should clearly state that the setting of reference monuments, lowering of U.S. public land survey monuments, measuring of distances and angles, and the preparation of the monument record document must be done by or under the supervision of either a contractor-provided or district-provided Illinois Professional Land Surveyor. It is also required that the monument records be filed in accordance with Section 220/7 of the Land Survey Monuments Act, 765 ILCS 220/7.

Proper methods of referencing U.S. public land survey monuments are discussed in the *Land Acquisition Manual*. Monuments referenced as indicated in the *Land Acquisition Manual* need not be placed or marked in the surface of the pavement but must be covered after the monument has been lowered to a level of a minimum of 12 in. (300 mm) below the finished grade. Direct access to monuments under the pavement is not necessary and the installation of monument boxes is not required.

Chapter Fifty-nine
LANDSCAPE DESIGN

59-1 OBJECTIVES

59-1.01 General

The Department is responsible for transportation facilities that occupy considerable land area throughout the State. These facilities are developed to be operationally sensitive and a positive economic asset to the State of Illinois through a balanced blend of environmental, economic, aesthetic, and engineering values. This Chapter provides guidance on the implementation of visual and environmentally based aesthetic components of transportation. It also includes procedures for the establishment of components of the physical landscape.

59-1.02 Effective Design Objectives

All design elements and components must be compatible with each other and with the environment into which they are to be introduced. This objective often necessitates the use of materials native to the surroundings. Give consideration to the wide range vegetation zones in Illinois and to the various vegetation types present in the project area when selecting materials.

The objectives of effective landscape design include the following:

- identify social, economic, aesthetic, and environmental effects early enough to permit analysis and consideration while alternatives are being formulated; see Part III, Environmental Procedures;
- involve other agencies and the public in the planning and design decision process early enough to allow their ideas to influence technical studies and final decisions; see Chapter 19;
- use all practical means to restore and enhance the quality of the environment, e.g., consider using native plantings when feasible;
- minimize required maintenance activities after construction; see the *Bureau of Operations Maintenance Policy Manual*; and
- bring together all aspects of the project, including planning, design, construction, and maintenance.

59-2 AUTHORATIVE BASIS FOR LANDSCAPE DESIGN

59-2.01 Federal Statutes, Regulations, and Policies

Numerous Federal regulations establish the basis for this chapter including:

- 23 U.S.C. 319 "Landscaping and Scenic Enhancement,"
- 23 CFR 752 "Landscape and Roadside Development,"
- *National Environmental Policy Act*,
- *Highway Beautification Act of 1965*,
- *1973 Policy on Operation Wildflower*, and
- SAFETEA-LU – National Scenic Byways Program.

59-2.02 Illinois Statutes and Directives

A number of Illinois statutes and directives also establish basis including:

- Departmental Policy D&E-18 "Preservation and Replacement of Trees,"
- *Illinois Endangered Species Act*,
- *Illinois Interagency Wetlands Policy Act*,
- *Illinois Exotic Weed Act*.

59-3 LANDSCAPE DESIGN PRINCIPLES

59-3.01 General

The establishment of design principles for environmentally based planning, design, construction, and management of the roadside landscape in Illinois is essential.

59-3.02 Principles

The following controlling principles are based upon the conservation of natural resources; creating a facility that is compatible with its surroundings; minimizing future management efforts and expenditures; and producing a high quality, environmentally responsible finished product:

1. Environmental Impact. Where practical, avoid adverse or disruptive impacts to landscape and environmental features on or adjacent to the right-of-way. Where total avoidance of adverse or disruptive impacts is not practical, undertake all reasonable measures to reduce and minimize impacts to these features. If damage or disruption is unavoidable, undertake all reasonable measures to offset damages through mitigation in the project area or other designated areas. Note that the designer cannot recreate or restore natural systems but can utilize native plant materials to represent some of the appearances and functions of the impacted feature; see Part III, Environmental Procedures.

2. Environmentally Sensitive Areas. Consider environmentally sensitive areas and those harboring threatened or endangered species to be a controlling factor in all designs.

3. Use of Native Plants. Emphasize the use of plants native to and grown in Illinois which are appropriate to the site, its planned use, and its future management.

4. Site Compatibility. Design a specific landscape effect that is compatible with the site.

5. Future Management Considerations. Consider the future management plan for the roadside area to be a controlling factor in the planning and design of that area.

6. Sustainable Roadside Environment. Strive to produce a sustainable roadside environment.

7. Visual Quality. Visual appearance and visual unity of the facilities are important components. Recognize that visual quality must be a component in almost all design development and that numerous factors influence the final appearance of the finished project. Durability and appearance are the two items most noticed and commented upon by the traveling public.

59-3.03 Application of Principles

Apply landscape and environmentally based design principles to the full range of highway types, from multi-lane freeways to the rehabilitation and improvement of existing local arterials and rural collector roads. They also apply to all highway components and features including:

- the roadway, i.e., the travel surface itself;
- the roadside, i.e., the remainder of the right of way including any existing natural vegetation and/or plantings;
- ancillary structures, e.g., bridges, culverts, retaining walls; and
- highway appurtenances, e.g., fences, signs, lights, roadside barriers, guardrail, cable barrier (High Tension Cable Barrier), Road Weather Information System (RWIS), traffic controller boxes, and continuous count sites.

The principles also apply to other types of transportation facilities constructed by the Department including public transit, railroad terminals, airports, ferry terminals, and port facilities.

The extent of the application of these principles will depend on the type of project, the environmental resources affected, and the public entities involved.

59-4 LANDSCAPE DESIGN PROCESS

59-4.01 Determine Management Level

Landscape and environmentally based design solutions are initiated in the planning and location phase. It is important, however, that the planned level of management extend into the design, construction, operation, and maintenance of transportation facilities. This is underscored by the likelihood that a large share of future transportation demands will have to be accommodated by upgrading existing facilities while recognizing their management will continue to be limited.

59-4.02 Phase I (Planning)

During the planning and location phase, apply the landscape and environmentally based design principles to assess environmental effects and identify measures to mitigate adverse impacts. Use the principles to help identify landscape features that can be incorporated into project planning and to influence development of alternatives to the proposed action and any environmental commitment.

59-4.03 Phase II (Design)

In the design phase, focus on how each of the principles apply to a particular project, what commitments have been made, and how to incorporate the principles into design plans for such project features as landscaping, environmental impact mitigation measures, support facilities, and associated structures.

59-4.04 Phase III (Construction)

The construction phase ensures that mitigation measures committed to in the design and planning phases are carried out and conditions discovered in the field receive consideration.

59-4.05 Phase IV (Operation and Maintenance)

Finally, the incorporation of landscape and environmentally based design principles into the operation and maintenance of transportation facilities can help to ensure the continued effectiveness of project mitigation measures. Consideration shall be given to the cost of and frequency of maintenance for all design practices.

59-5 RESPONSIBILITY FOR PREPARATION OF DESIGN

59-5.01 General

It is the designer's responsibility to be aware of any aspect of the design which would adversely affect the roadside and to modify such design elements, where necessary, to achieve a harmonious design that meets the criteria for the project. The designer also is responsible for notifying other Bureaus of potential impacts on their respective operations.

59-5.02 District Landscape Architects/Roadside Manager

The Landscape Architect/Roadside Manager in the Bureau of Operations provides the required expertise in landscaping aesthetics, material selection, and visual quality. The Landscape Architect/Roadside Manager advises the designer and reviews design criteria and proposals.

59-5.03 District Environmental Unit

The district Environmental Unit identifies those aspects requiring the input of the Landscape Architect/Roadside Manager in Phase I of the project including commitments regarding wetland mitigation, erosion control, endangered species habitat protection and restoration, and tree replacement or removal. This Unit also identifies the impact of the visual component of noise mitigation structures and notes critical areas adjacent to the project needing protection.

59-5.04 BDE Location and Environment Section

The Location and Environment Section provides expertise and policy directives in environmentally based landscape matters. The Location and Environment Section also reviews design criteria and proposals to ensure conformance with environmental regulations and commitments.

59-6 DESIGN FACTORS

59-6.01 General

Design factors are intended as a guide for the designer to use in developing a solution for a particular project condition. Determine the appropriateness of the design as it applies to given features of the highway environment. Not all factors will apply to most projects, nor will all project situations be covered by those described in this Section.

59-6.02 Coordination of the Design Process

Use the following guidelines to coordinate the design process:

1. Coordination within the Department. During the design process, coordination of many disciplines (e.g., engineering, landscape architecture, roadside maintenance, biology, hydrology) is needed to achieve the proper environmentally based design. This is true not only for large and complex projects but also for small and simple projects. Obtain all available inputs to ensure a coordinated environmentally based design.

2. Coordination with Outside Regulatory Agencies. Where transportation projects involve wetlands, endangered species, Illinois natural areas, nature preserves, historic sites, and culturally sensitive areas or where the planned facility is adjacent to public resources such as streams or forests, the design aspects of the improvement will be coordinated by the central office or the district depending upon the project phase.

3. Coordination with Local Jurisdictions and the General Public. Coordination is best accomplished through the environmental review, public involvement process and/or the Context Sensitive Solutions (CSS) process. The designer is responsible for coordinating with local jurisdictions and abutting landowners adjacent to or affected by the project. Consider the potential impacts to any local management or long range plans. Ensure that aspects of the project are not adverse to broad public values. Early coordination with local jurisdictions and with the general public may provide valuable input to ensure the success of an acceptable design. Coordination at local level includes municipalities, park and forest preserve districts, counties, chambers of commerce, residential and commercial developments, fire and other special districts. Coordination at the general public level may include garden clubs, beautification agencies, and other general public groups with valuable input.

59-6.03 Protection of Existing Features

Certain existing landscape features, whether manmade or natural, should be protected through a process of identification; enhancement, restoration, or preservation; and avoidance or incorporation into the design of the highway improvement. Consider the following when determining the need for protecting existing features:

1. Review Previous Commitments. Review commitments in environmental documents, tree surveys, wetland reports, public hearing records, project reports, and other project documents for those requiring protection during project development and implementation.

2. Statute Protection. Determine which features of the project area are protected by statute. These may include wetlands, endangered species, nature preserves, natural areas, and cultural sites.

3. Cultural Environment. Determine the project's setting or cultural environment, e.g., rural, urban, or in a transitional area. The design should be influenced by the cultural and physical environment adjacent to it and existing features should be protected where practical.

4. Existing vegetation and restoration areas. If native plantings exist in addition to protected areas listed in number 2. above, these areas shall be protected and impacted areas restored to pre-construction conditions.

A variety of techniques may be employed to protect identified resources, including both temporary and permanent measures as appropriate. Consider the following guidelines:

1. Temporary Fencing. Use temporary fencing to protect special waste areas, trees that are not to be disturbed, existing vegetation to remain in critical erosion prone areas (e.g., steep slopes, concentrated flow areas) and areas where it is necessary to prevent stockpiling or construction traffic access. Natural resources (e.g., prairies, woodlands, wetlands) should be protected. Where drainage is flowing from the construction area to these valuable resources, it is usually better to specify perimeter erosion barrier and temporary fencing. The designer should clearly label on the plans the limits of construction and what is to be protected by the temporary fencing.

2. Tree Trunk Protection. Specify tree trunk protection to prevent damage by construction equipment to existing trees located within or along the limits of the construction area.

3. Pruning for Safety and Equipment Clearance. Show pruning of overhanging branches for safety and equipment clearance purposes on the plans.

   Note: Trees that require more than 20% of the crown to be pruned should be considered for removal instead of pruning. Pruning in urban areas shall only be conducted by an International Society of Arborculture (ISA) certified arborist.

59-6.04 Grading and Alignment

That portion of the design process concerning alignment and grading offers the best opportunity to fit the highway into the landscape, thereby avoiding unnecessary environmental impacts and yielding a functional and aesthetically pleasing form. The basic guideline for grading and alignment is the AASHTO *Guide for Transportation Landscape and Environmental Design* and Chapter 33. In addition, consider the following guidelines:

1. Environmental Commitments. During Phase I engineering, ensure that all environmental commitments are reviewed to appropriately influence alignment and grading decisions. These commitments also will serve as controls during Phase II plan preparation.

2. Surrounding Landscape. Give consideration to the surrounding landscape. Blend the alignment and grading to fit the existing topography with minimal visual or physical disruption.

3. Clearing and Construction Limits. Carefully plan the establishment of clearing and construction limits. Consider both existing landscape features and critical areas. No volunteer trees or brush shall be left on ROW or in fence rows when designing landscaping or habitat reconstruction projects. Clearing and tree removal must be specified in accordance with Departmental Policy D&E-18.

4. Plant Survival. Consider the survival potential of existing plantings to be preserved and proposed plantings at the time that grading decisions are made. This is especially critical in confined areas where landscape features, e.g., screening, are proposed. Plant material to remain within the project limits should be properly cared for so that it is alive and in good condition when the project is complete. Consider the following guidelines:

   a. Root Pruning. Specify root pruning where trenching or excavation is within the root zone of adjacent trees or shrubs to remain in place to prevent ripping up roots.

   b. Fertilizer Nutrients. Specify fertilizer nutrients for trees and shrubs that will be disturbed by construction but will remain-in-place.

   c. Supplemental Watering. Specify supplemental watering for trees and shrubs that will be disturbed by construction but will remain-in-place. Watering should begin immediately after root pruning, top pruning, or other construction disturbance.

   d. Tree Pruning. Specify tree pruning where an entire tree needs to be pruned, to correct structural problems, or improve the overall appearance.

   e. Temporary Fencing. Specify temporary fencing where protection of existing trees is necessary. At a minimum, place fencing around the drip line of each tree to be protected. However, if space allows, place fencing 5 ft (1.5 m) out from the drip line of each tree to be protected.

   f. Tree Trunk Protection. Specify tree trunk protection to prevent damage by construction equipment to existing trees located within or along the construction area.

   g. Reduction in competition. Use a Best Management Practice to reduce the presence of unwanted species and reduce competition with desired species.

59-6.05 Erosion Control

See Chapter 41 for information on Department policy and procedures for erosion and sediment control.

59-6.06 Drainage

Design the drainage of the highway system as part of, and not separate from, the natural hydrology of the environment; see *Drainage Manual* for more information. Consider the following factors during design:

- the environmental impacts of drainage;
- storm sewer management;
- detention/retention basin design;
- how the drainage way is to be designed or altered from its original pattern;
- the affect that the channel lining will have on values such as wildlife, aquatic life, sediment filtration, and water quality; and
- the impact that water retention and/or soil saturation will have on existing or proposed plant material;
- maintenance requirements of drainage features;
- Colonization by invasive species, e.g. Common Reed (*Phragmites australis*).

59-6.07 Visual Quality

A project's visual quality is ensured by encouraging a positive visual change that will improve or enhance the surrounding landscape. Define the visual environment by identifying key views, analyzing resources, depicting the project's proposed appearance, and assessing its visual impacts. Manmade features have been integrated successfully into a large portion of Illinois natural landscape. To better provide for visual quality in a project, evaluate the project's relationship with the following:

- natural landscape elements;
- topographical and physical characteristics;
- ecological influences;
- recreational sites;
- residential areas and their character;
- historical features;
- visual values;
- existing land uses, e.g., industrial, junkyards; and
- existing and proposed project profile.

Review these elements to ensure that visual quality is adequately integrated into the project.

59-6.08 Safety

Safety should be the highest functional goal of every design, and all landscape and environmentally based design principles must be compatible with this criteria. During design, consider the following:

- the location, size, and height of plantings in relation to sight distance, drainage, and clear zones; and
- traffic-calming designs in urban areas; and
- pedestrian safety in areas such as rest areas, transit stations, and bikeways.

59-6.09 Scenic Byways, Rest Areas, Special Projects, and Settings

Existing scenic conditions, auxiliary facilities, special roadway designations, roadway destinations, and historical values of the project area are examples of special conditions which may be present and which may impact the design of a project. Many of these conditions are held in high regard by the public, and their sensitive treatment is essential to a successful project. Ensure that design decisions are compatible with such special conditions. It may be necessary to provide a higher type of design than is normally required.

Designs for special conditions shall be coordinated with the Landscape Architect/Roadside Manager to reduce conflict of Operational activities.

59-6.09(a) Scenic Quality Preservation

The project area may be a designated scenic byway or may possess an outstanding scenic quality that must be preserved as part of the project. This may require special limited grading, aesthetic treatments of highway appurtenances, preservation or enhancement of adjacent features, or other actions to preserve unique aspects of the area. These cases normally require special attention and unique designs to improve the quality and safety of the roadway.

59-6.09(b) Auxiliary Facilities

Auxiliary facilities may be required or desirable as a part of the project, e.g., rest areas, scenic overlooks, roadside tables, scenic vistas. The planning and design of these facilities should be an integral part of the roadway design. Give special attention to site amenities, aesthetics, and environmental values as well as safety and future maintenance.

59-6.09(c) Special Designations

A project area may carry a special designation that sets the route apart as a special experience for the traveler. Examples of these are the Great River Road, Historic US 66, the Lake Michigan Circle Tour, and many similar corridors. It is important to become familiar with the meaning and the special features associated with such designations so that any necessary supportive enhancements can be developed, e.g., opening vistas of the Mississippi River along the Great River Road, providing informational signing along Historic US 66.

59-6.09(d) Roadway Destinations

Certain roadway segments may serve primarily as access to a destination, e.g., state park or historic site. Designers of such segments must be aware of the significance of the site and its surroundings and ensure that the project design is compatible with its destination.

59-6.09(e) Historical Influences

Historical influences may affect the project as a nearby destination, as an adjacent feature, or, in some cases, as a part of the roadway or its appurtenances. Pay particular attention to these influences and prepare the project design to be compatible or harmonize with them. Historical markers, structures, districts, and bridges all may influence the design of a project. Required avoidance of or mitigation of impacts to historical resources usually is identified in early project coordination, but the designer should be alert for any unidentified items. Special consideration may need to be given to landscaping within designated National Register Historic Districts.

59-6.09(f) Special Designs

Various elements of the design may need to be modified from the standard treatment or designed to a higher visual quality standard than the ordinary roadway elements to be compatible with the above special circumstances. Give special consideration to the design of features such as bridges, signing, retaining walls, tree protection, colors and textures of appurtenances, and similar items. Design these treatments to be compatible with their surroundings and with the features that make the segment unique. If questions arise regarding a proper design approach, contact in-house specialists, e.g., district Landscape Architect/Roadside Manager.

59-7 DESIGN ELEMENTS

59-7.01 General

Highway landscape plantings are the living component of the highway design and, through the use of native and non-native materials, provide the means to fully integrate the highway with the surrounding environment. Landscape plantings will serve as functional elements, e.g., erosion control, screening, sound abatement, snow control, in the highway environment.

59-7.02 Responsibility

The district Roadside Development Unit (Landscape Architect/Roadside Manager) has the primary responsibility for determining the plant selection on a site-specific basis for a design project. The district Landscape Architect/Roadside Manager keeps a current preferred plant list for his/her respective district. Consider the following guidelines:

1. Native Plants. Native plants are effective in perpetuating a self-sustaining roadside landscape, increasing biodiversity, reducing maintenance costs, and are more adapted to regional environmental conditions.
2. Non-Native Plants. Non-native plants may be selected for certain results if a native plant cannot be found to achieve the same effect, e.g., color, texture, growth habit, for emphasis or survivability, e.g. de-icing activities.
3. Plant Maintenance. Maintenance is a major consideration in landscape plant selection. Strive to choose those plants that once established require a minimum of maintenance.
4. Ash Trees. Due to Emerald Ash Borer (EAB) in Illinois, no varieties of ash trees (e.g., fraxinus spp.) should be planted as this can contribute to the spread of this species.
5. Disease Prevention. The designer should check current guidance on plants susceptible to pests that cause biohazards.

59-7.02(a) When to Plant

Plantings are placed as follows:

- when required by the Phase I report;
- when planting can fulfill one of the “Functions of Planting” as outlined in this chapter;
- when required by law or Department policy;
- when requested by local residents or communities;
- at any location where the local community will assume plant maintenance; and
- where right-of-way agreements indicate that trees will be planted.

59-7.02(b) Site Analysis

The design process begins with the site analysis, which includes the following items:

Determine final contours and cross sections including:

- steep slopes,
- flat areas, and
- drainage features.

Identify adjoining land usage as follows to better blend landscaping with the pre-existing environment:

- urban,
- rural,
- industrial,
- scenic vistas,
- agricultural, and
- natural forested areas.

Consult the USDA Hardiness Zone Maps and analyze native plant communities and climate for the area including:

- local plant types,
- hardiness zone, and
- exposure.

Analyze landscape position as follows:

- upland,
- lowland,
- wetland, and
- floodplain.

This is important because plants are site specific to their environment.

Analyze soil types and structures including the following factors:

- soil types,
- soil textures,
- available moisture,
- drainage,
- fertility, and
- pH.

Ensure plantings are compatible with roadside safety requirements by determining the following:

- clear zones, and
- sight distances.

Because the planned roadside maintenance often dictates the type of planting, determine future maintenance including the following factors:

- scope,
- responsibility,
- future cost,
- mowing requirements,
- burn management requirements,
- chemical weed control, and
- fertilization.

Identify existing features such as the following:

- drainage structures,
- signage and lighting,
- walls,
- roadway and shoulders,
- structures,
- curbs and medians,
- interchanges and intersections,
- alleys,
- driveways,
- fire hydrants,
- utility lines,
- railroad crossings,
- buildings,
- traffic signs and signals, and
- underground utilities.

This is important because these existing features can influence the final design.

59-7.02(c) Function of Plantings

The functions of plantings are as follows:

1. Aesthetics. Planting is one method used to improve the visual quality of the highway system.

2. Screening. Screening undesirable views seen from and toward the highway can be performed with plants.

3. Delineation. Plants may be used to delineate changes in highway alignment. Plants on the outside of curves, at “T” intersections, and at overpasses may aid in directing the motorist. Plants also may be used to frame or form a background for directional signs.

4. Erosion Control. Temporary and permanent plantings may be used to prevent erosion and enhance soil stability.

5. Control of Snow. Living snow fences can reduce maintenance costs, provide increased driver safety, and greatly enhance the appearance of the roadside.

6. Preventing Headlight Glare. Planting can be very effective in screening headlight glare from oncoming vehicles.

7. Environmental Mitigation. Planting may be used for various types of mitigation including various types of buffers, sound barriers, tree replacement requirements, wetland replacement, and providing wildlife habitat.

8. Pollution Control. Planting may be used to attenuate air pollution, dust, and auto emissions.

9. Psychological Considerations. Planting may help to alleviate driver fatigue by changing the driving experience and making it more interesting.

10. Adjacent Landscape Enhancement. Plantings can be used to enhance adjacent landscapes for the better enjoyment of the motorists.

Plant varieties also should be selected for their desirable growth habits, insect and disease resistance, and proven desirable features for highway use.

59-7.02(d) Considerations for Plantings

The functions of plantings are used as the basis for planting shade trees, intermediate trees, shrubs, evergreens, vines, ground covers, and seedlings. Landscape plantings are used to mitigate and replace trees that were removed through highway construction and mitigation for wetland replacement. Installation of landscape plantings are covered in the *Standard Specifications*. Consider the following when designing landscape plans:

1. Hardiness. Select plants for a particular section of roadway based on their climatic and soil requirements. In Illinois, climatic conditions and soil types are favorable to both southern and northern plant groups. Conduct a study of soils, climate, and existing plant growth in the area when planning each planting project. Plant hardiness zones will be as stated in the *Standard Specifications*. Use the USDA Plant Hardiness Zone Map, latest edition, when selecting plant material for any project.

2. Size. The size at which a plant matures will determine the number of plants that will be required in a group planting. The highway speed determines the amount of time a motorist views the planting. Consequently, on higher speed highways, utilize the large group

concept of landscaping in lieu of the individual plant concept. Consider the following guidelines:

- Younger Plants. Younger plants generally establish themselves faster than older plants. As a general practice, specify the smallest size of plants that is consistent with the requirements of the environment.

- "Balled and Burlapped" Planting. Specify all deciduous trees larger than 1.5 in. (40 mm) in diameter or 5 ft (1.5 m) in height as "balled and burlapped" at the time of planting. Also, specify this method of planting for plants that, according to good horticultural practice, require a ball of earth. It is acceptable to specify container-grown material in lieu of "balled or burlapped" plants as an alternative. The relationship of the plant size to the soil ball size or the container size will be as stated in the *Standard Specifications*.

- Perennial Plants. Perennial plants can be planted as bulbs, tubers, or container plants. Bulbs and tubers should be of a size large enough to produce a healthy plant and to flower the first year. Container plants should be well rooted in the container. A quart (liter) sized container is usually the smallest size that should be planted on highway projects.

- Prairie Forbs and Grasses. Prairie forbs and prairie grasses can be planted as root plugs or as seed. The minimum size plug should be 1.25 in. (30 mm) in diameter by 4.25 in. (110 mm) deep.

3. Roadside Safety. Do not locate woody plants with diameters at maturity greater than 4 in. (100 mm) in the clear zone, as defined for new construction. Also, such plants normally should not be planted on the foreslope or in ditches even if outside the clear zone. Curb and gutter is not considered a barrier and clear zone requirements must be applied to these sections of roadway.

4. Sight Distance. When planting in urban areas, consider potential sight distance problems and the potential for obstructing traffic signals, traffic signs, roadway lighting, railroad signals, etc.

5. Impact of Tree Roots. Trees with shallow fibrous systems have the ability to damage nearby sidewalks, storm sewers, and pavement.

6. Fertilizing and Mulching. For survivability and lack of future maintenance, give consideration to fertilizing and mulching all plantings.

7. Existing Soil. Where practical, use the existing soil in the planting operation. In cases where highway construction has made the condition of the existing soil unsuitable, consider the use of soil amendments or new topsoil. Where soil conditions require topsoil placement to ensure adequate growth, specify the following depth of topsoil for the appropriate areas:

- 8 in. (200 mm) where extensive plantings of wood or perennial plants are proposed, and

- 24 in. (600 mm) for plantings in landscaped medians.

8. Impacts of Salt. Due to the adverse effect of salt upon plants, give special consideration to the type and location of plants and their proximity to the roadway in those areas of the State where there is extensive snow and ice control.

9. Agricultural Areas. If planting trees adjacent to agricultural fields, make sure there is enough right-of-way after the tree planting to accommodate any shading from mature trees and minimize impacts to farm machinery, i.e. mobility. Otherwise, do not plant large trees or evergreens on the right-of-way where there is adjacent agricultural land use.

10. Signage. Do not place plants in a location that will block the view of legally placed advertising signs.

11. Growth Balance. Every large-scale planting operation should include a small percentage of relatively fast growing short lived trees that will, in a short period of time, provide the overall landscape with some big trees while the slower growing trees mature. This practice will benefit the current motorist as well as the driver of the future.

12. Blending. Where adjacent land use is wooded, (e.g., parks, forest preserves), use landscape plantings to blend into the existing wooded area and erase the effects of highway construction.

13. Screening. Landscape plantings are used to screen adjacent properties that have undesirable land usage; to reduce highway noise, dust, etc., reaching adjacent properties; and/or to screen the highway from a residential area or park.

14. Snow Drifting. Do not plant dense continuous hedges within 40 ft (12 m) of the edge of pavement where they may cause snow to drift onto the pavement.

15. Permit Planting. All plants placed by permit should be maintained by the person or agency requesting the permit. Removal and/or replacement will be the responsibility of the person requesting the permit.

16. Harmful Plants. Do not plant poisonous or toxic plants in urban areas. Likewise, plants with thorns are suitable only to rural areas.

17. Messy Plants. Do not plant trees or shrubs that drop fruit (e.g., crabapples) immediately adjacent to sidewalks or driveways.

18. Ease of Maintenance. Trees shall be placed a minimum of 20 feet from trunk to trunk to allow mowing between trees. Large trees will require additional spacing based on crown width at maturity. Shrub plantings in rural areas and those used for living snow fence shall be placed to allow mowing between the planting and the ROW line.

59-7.03 Classification

Consider the following groups for planting:

1. Shade Trees. A single-stem, high-headed, deciduous plant that generally grows to a height in excess of 30 ft (9 m).

2. Intermediate Trees. Generally, a multi-stem, deciduous, low, round-headed plant that matures at 30 ft (9 m) or less in height.

3. Shrubs. Low-growing multiple stemmed plants that are either deciduous or evergreen.

4. Evergreen Trees. Tall-growing evergreen plants.

5. Ground Cover and Vines. A colony forming plant less than 1.5 ft (0.5 m) high that has the ability to spread and root itself.

6. Seedlings. Small shade trees, intermediate trees, shrubs, and evergreens that are usually less than 2 years old.

7. Shelterbelts. Also referred to as "living snow fences," shelterbelts are multiple rows of trees or shrubs planted to provide protection from wind driven snow. There are many advantages to shelterbelts, as compared to snow fences, including roadside beautification, wildlife benefits, little or no maintenance after establishment, and long service life. A disadvantage of shelterbelts is that they may require 5 to 10 years from the time of planting to become effective depending upon their size at the time of planting. Also, use signage to prevent incidental mowing.

59-7.04 Trees

59-7.04(a) General

Departmental Policy D&E-18 provides guidance on the preservation and replacement of trees during the planning, design, and maintenance of facilities on the State highway system.

59-7.04(b) Objective

In determining if the tree replacement is appropriate, consider if the replacement achieves one or more of the following results:

- enhances the scenic quality of the highway,
- provides additional habitat for wildlife,
- results in financial savings from reduced maintenance,
- enhances air quality,
- serves as a deterrent to soil erosion,
- not hinder a driver's visibility or otherwise create a traffic hazard,

- allows for natural forest revegetation,
- properly mitigate for environmental impacts, and/or
- follows through on a commitment to a regulatory agency, e.g., US Fish and Wildlife Service.

59-7.04(c) Planning

Consider the following when making decisions on trees replacement in the project area:

- clear zones are not affected,
- slope planting blends with adjacent forested areas,
- revegetation of riparian zones around bridges and drainage structures,
- provides screening of undesirable views and objects,
- frames vistas,
- achieve commitments to property owner,
- evergreen trees are highly susceptible to damage from salt or salt spray. Distance from pavement and predominant wind direction should be considered.

59-7.04(d) Site Analysis

Investigate and determine the proper mixture of plant materials best suited for the project area. Use the following to determine the proper selections:

- native plant communities; see Figure 59-7.A;
- landscape type - upland, lowland, bottomland, wetland;
- soil conditions - texture, available moisture, drainage, fertility, pH; and
- climate - hardiness zone, exposure.

59-7.04(e) Design, Plans, and Specifications

Use the following, along with previously gathered information, to develop the final design for tree planting:

- plans and special provisions,
- delineating planting locations,
- plant materials,
- soil amendments, and
- plant care.

NATURAL DIVISIONS OF ILLINOIS

Figure 59-7.A

59-7.05 Grasses and Forbs

59-7.05(a) General

Grasses, grains, legumes, and forbs form the backbone of highway vegetation cover. The large number of species and varieties of vegetative cover may be used for many applications.

Native Grasses. There are numerous species of native Illinois grasses. These grasses are commonly referred to as prairie grasses.

Forbs (Wildflowers). Forbs, commonly referred to as wildflowers, should be native flowering plants that collectively will provide blooms throughout the growing season. They are used for either visual effect, such as in urban areas, to reconstruct habitat along Illinois ROW, or to mitigate environmental impact. If the area is highly visible, consider planting plugs and/or annual species.

Consider the following guidelines when selecting the seed class for the project:

1. Temporary Erosion Control. Temporary erosion control mixtures are seeded to prevent soil from being displaced on a construction project that will be exposing soil. The mixture is spread over all exposed earth to provide a quick cover of the turf that will interrupt the force of rain on the soil and prevent soil from moving. The temporary erosion seed mixture may need to be spread on construction sites numerous times during construction activities. The temporary erosion control mixture also can be combined with a permanent erosion control mixture to provide a nurse crop while the permanent seed is establishing. Use temporary vegetative cover for temporary erosion control at locations where the duration of the turf cover is short term and is expected to prevent loss of soil; see Section 41-2.01(b).

2. Permanent Erosion Control. Permanent vegetative cover is used for permanent erosion control in most highway applications. To achieve a cost-effective permanent cover, select an appropriate seed mix for the landscape conditions and planned maintenance; see Section 41-2.01(b).

3. Weed Control. Good vegetation establishment will minimize weed growth, thereby reducing pesticide requirements.

4. Groomed Appearance. In certain areas, a vegetative cover that can be mowed into a park-like appearance might be most appropriate such as urban settings.

5. Wildlife. Provide a vegetative cover that will enhance and encourage wildlife where appropriate.

6. Diversity. Provide a diverse vegetative cover that will add color, texture, and form to the highway environment. This is important because not only does diversity provide a visual experience, but also breaks up the monotony of the driving task.

7. Sodding. Seed mixtures are most commonly used; however, some instances may call for the use of sodding to provide for the rapid establishment of turf.

59-7.05(b) Seed Classes

The seed classes specified in Section 250 of the *Standard Specifications* are used for specific applications as follows:

a. Lawn Mixtures (Class 1, 1A, 1B). Lawn mixtures are used in urban settings to create a park-like appearance. This class also includes salt tolerant and low maintenance mixes. Use this class for:

- all urban reconstruction not covered in Class 2A (below), and/or
- all projects where the entire right-of-way is not torn up and Bluegrass is the primary existing cover.

b. Roadside Mixtures (Class 2 and 2A). Roadside mixtures are a hardy mix used in more rural settings where a tougher lower maintenance turf is desired. This class includes a salt-tolerant mix as well. Use Class 2A seeding for:

- new construction or reconstruction projects of limited access routes in locations intended to be mowed by the Department,
- all rural reconstruction projects where the entire right-of-way is to be seeded or any situation where grasses (other than Bluegrass) are the primary existing cover, and/or
- areas adjacent to roads subject to salt spray and/or disposition.

c. Slope Mixtures (Class 3 and 3A) Slope mixtures are used on slopes usually 3H:1V or greater and are divided in a Northern and Southern mixes.

d. Native Grass (Class 4, 4A, and 4B). Native grass mixtures can be planted to create specific turf conditions. This class includes mixes with lower growth height (low profile) and a mix typically used for wetland mitigation.

e. Forb Mixtures (Class 5, 5A, and 5B). These mixtures predominately feature flowering species with mixes including annual, native forbs, or wetland forbs.

f. Conservation Mixtures (Class 6 and 6A). Conservation mixtures are used for wildlife nesting cover and include salt tolerant mix. These are usually planted at the request of resource agencies. Use caution when considering this class with other seeding classes.

g. Temporary Turf Cover Mixtures (Class 7). This mix is used to provide a quick growing cover over areas disturbed due to construction and is typically used as part of a project's erosion and sediment control plan. Consider the following when using Class 7:

- as a temporary cover for areas to be regraded more than a year from the time of seeding, and/or
- winter shut down.

59-7.05(c) Planning

Because of the splashes of color added to the highway landscape by native wildflowers, place these plantings in areas of high visual impact, e.g., interchanges. Wildflower plantings, although colorful, will still need periodic maintenance. Typical practices might include selective mowing, selective herbicide application, or roadside burning to prevent establishment or undesirable vegetation. Consider future maintenance requirements of the roadside when planning the appropriate planting mixtures.

Wildflower plantings can be placed in stand-alone groupings or combined in a plant community with native grasses to restore part of the native landscape. The advantage of using native species is that they are adapted to the Illinois environment and, therefore, do not require fertilizer nutrients or topsoil.

If native grasses are to be mixed with forb plantings, consult the district Landscape Architect/Roadside Manager for the appropriate mix, because grasses can out-compete forbs. Select grass species that are compatible with forbs. Prairie grasses also may be added to other turf grass mixtures to enhance diversity, erosion control, and aesthetics in the turf area. Consider prairie grasses for use on all new and highway reconstruction projects. These grasses especially can be effective on steep slopes 1V:3H or greater, and where maintenance is limited (e.g., slopes 10 ft (3.0 m) or more in height and 100 ft (30 m) or more in length), due to their deep rooting ability that holds the soil in place. Native grass and forbs mixtures should only be considered in residential areas if a right-of-way fence is present.

Select a location that will maximize the visual impact to the motorist. Examine the highway alignment to determine where to maximize the visual experience with any flowerbeds or grass plantings.

59-7.05(d) Site Analysis

Consider the following guidelines during the analysis:

1. Visual Analysis. Consider the sight line of the motorist when planning any wildflower or native grass establishment. These areas include interchange locations, outsides of curves, gore areas, and back slopes. In urban areas, the view from the surrounding neighborhood as well as the motorist's view must be compatible with existing neighborhood landscapes and coordinated with local municipalities.

2. Landscape Position, Upland, Lowland, Bottomland, and Wetland. Some native grasses and wildflowers are adapted to dry or mesic conditions (prairie) while others require wet or saturated conditions. Consult the district Landscape Architect/Roadside Manager to determine which species are appropriate for a given set of roadside conditions.

3. Soil Conditions. Determine the type of soil and identify the soil's characteristics. Consult soil maps prepared by the Natural Resource Conservation Service for information

regarding project soils. Although native species are adapted to Illinois soil conditions, determining the soil type can dictate the use of a specific species for planting.

59-7.05(e) Considerations for Planting

Consider the following guidelines when planting grasses and forbs (wildflowers):

1. Growth Rate. The native grass and native wildflowers are mostly warm season plants that do not begin their growth until warm weather arrives. Most roadside plantings of native grasses and native wildflowers take 3 to 5 years to show results. The native species spend their initial growth establishing an extensive root system once the seeds germinate, thereby resulting in a longer time frame to show results. Using a temporary seeding might be ideal for high profile areas during this establishment time.

2. Using plugs or container plants of native species can help to accelerate the time between planting and establishment.

3. Applications. Grasses and wildflowers can be used separately or in combination to provide a specific effect or restore a native Illinois landscape. Native roadside plantings offer many benefits to highway managers, motorists, and wildlife. Their thick deep roots anchor the soil and prevent erosion. Native species tolerate a wide range of soil types, climatic conditions, and hydrology making them suitable for most highway conditions. They offer a motorist a rich, aesthetic landscape full of texture and color enhanced by seasonal change. Native-planted roadsides provide habitat for wildlife.

   Where it is desirable to eliminate most future mowing, native grasses and forbs are strongly encouraged for the following applications:

   - inaccessible areas, e.g., when a creek or similar barrier separates an area from the roadway;
   - in wide right-of-way areas;
   - interchanges;
   - bordering slope walls and retaining walls;
   - between the back of guardrail and top of retaining walls in narrow areas; and
   - outside access control fencing on rural freeways, (except those immediately adjacent to agricultural land, residential areas, or frontage roads).

   Discuss the selection and application of native grasses and forbs with the district Landscape Architect/Roadside Manager.

4. Planting Methods. The method of planting these species ranges from complete seed bed preparation to inter-seeding existing turf. Usually, seed mixtures are selected for planting

grasses and forbs; however, plant plugs may be used to achieve faster results. If plugs are selected (also known as perennial plants), consult the *Standard Specifications* for planting times.

59-7.05(f) Site Preparation

Site preparation may consist of:

- tilling or disking the soil to be seeded;
- application of chemical weed control;
- placement of soil amendments (e.g., fertilizer, lime, compost); and/or
- placement of topsoil.

Where soil conditions require topsoil placement to ensure adequate growth, specify the following depth of topsoil for the appropriate areas:

- 4 in. (100 mm) for use with Seeding Classes 1 and 2 or sodding;
- 12 in. (300 mm) in wetland mitigation areas, or what is required by the Corps of Engineers for the specific project; and
- topsoil is not normally required for seeding Classes 4 and 5. Use compost or coarse sand (usually 2 in. (50 mm) depth) to amend the existing soil where necessary.

For those seed mixtures requiring complete seedbed preparation, placement of a fertilizer is usually required. A fertilizer is not required for native grass mixtures (Class 4, 5 and 6) and for temporary turf cover (Class 7). Agricultural ground limestone may be specified to adjust soil pH. Turf requires a pH of 7.0 to germinate.

1. Seeding. Once the site preparation has been completed, the seed mixture (See Section 59-7.04(b) is applied. The type of seed mixture will dictate the seeding method to be utilized. Seeding methods are described in the *Standard Specifications*.

2. Mulch, Erosion Control Blanket, and Turf Reinforcement Mats. Mulch, erosion control blankets, or turf reinforcement mats are placed once the seed mixture has been applied to the site. The purpose of mulch is to hold the soil moisture level at the ground surface, prevent displacement of seed, and protect seed from predation. For guidance on choosing the proper mulch, erosion control blanket, or turf reinforcement mat; see Section 41-2.02.

59-7.05(g) Design, Plans, and Specifications

The design plans and specifications should contain the following information:

- type of seed bed preparation,
- delineation of planting locations including selective mowing stakes and signs,
- plant materials required sizes and rates,

- fertilizer requirements (usually only for non-native species),
- mulch requirements and method.

59-7.06 Selective Mowing Stakes

Consider the following guidelines when specifying selective mowing stakes:

1. Application. Use selective mowing stakes to delineate areas that are not to be mowed, e.g., areas that contain plants or natural features that need to be protected from mower damage, areas of existing vegetation, areas seeded or planted with trees, shrubs, wildflowers, or prairie plants. Another use of staking would be to delineate mowing lines to create an aesthetic or visual effect.

2. Placement. Place selective mowing stakes in a manner as to delineate the mowing boundaries of the feature to be protected or created. Spacing of the stakes will depend upon the size and shape of the area. Use a maximum spacing of 15 ft.

3. When selective mowing stakes are utilized the appropriate habitat sign should be installed at the beginning of each run of mowing stakes and every 200 ft for long straight runs. Increased frequency should be considered for tight curves, e.g., ramps.

59-7.07 Sodding

Appropriate uses of sodding are as follows:

- urban areas with residential or commercial development, e.g., in front of homes, businesses, parks, adjacent to paved shoulders or edges of paved ditches;

- rest areas;

- in front of maintained parks and cemeteries;

- erosion control in ditch bottoms and around culverts; and

- special areas, e.g., channelized medians, around inlets in grassed areas. Small areas which would normally be seeded should be sodded where a large majority of the remainder of the project (± 90%) is to be sodded.

Consider the following guidelines when specifying sodding:

1. Salt Tolerant Sod. Specify salt tolerant sod in those areas where large quantities of deicing salt are used by maintenance forces, e.g., highly urbanized areas.

2. Topsoil. Topsoil is usually required.

3. Fertilizer. Fertilizer should be included and incorporated prior to sod installation. Fertilizer requirements are indicated in the *Standard Specifications*.

4. Watering. Specify the number of supplemental waterings. Field adjustments can be made according to season and time of application. Watering rates and requirements are indicated in the *Standard Specifications*.

5. Staking. Specify staking on all slopes of 1V:2H or steeper. Staking requirements are indicated in the *Standard Specifications*.

6. Lime. Consider lime application after a soil pH analysis is taken.

Design considerations for placing sod in ditches are as follows:

1. In urban areas, except expressways, place sodding in ditches with grades of 0.75% to 2.5%.

2. Place sodding in ditches 50 ft (15 m) upstream and downstream from the ends of culverts, unless grades or volume of water flow require a paved ditch, aggregate ditch, or riprap.

3. Place sodding on moderately steep slopes and ditch flow lines where appearances dictate except in continuously flowing ditches or wet ditches.

59-7.08 Perennial Plants

Perennial plants are hardy flowering bulbs, tubers, and herbaceous plants. Perennial non-native flowering plants are often used in the highest visual impact areas, usually in urban areas. Perennial native species often are used more in rural areas. Only specify perennial plants for use when:

- required by commitments in the Phase I report to resource and regulatory agencies and to comply with Federal requirements for wildflower planting,
- requested by local residents or communities, and /or
- needed on any highway to blend the right-of-way into adjacent land uses.

Planting beds containing non-native perennial plants are designed to give the impression of a highly maintained park-like atmosphere. These can be more expensive to establish than other plantings and require intense maintenance. High maintenance ornamental flower beds should only be planted when a local community agrees to accept maintenance of the flower bed. Consider the following for planting perennial plants:

1. Non-Native. Non-native perennial plants require:
   - complete bed preparation,
   - fertilizer,
   - permanent mulch,
   - watering, and
   - a period of establishment.

2. Native. Native perennial plants require:

- bed preparation or planting in existing turf;
- mulch, unless planted in existing turf;
- watering; and
- a period of establishment.

59-7.09 Wetlands

Use the *Illinois Wetland Restoration and Creation Guide* to assist in the design of wetland mitigation sites and the guidance in the following Sections.

59-7.09(a) Planning

Use the following guidelines when planning wetlands:

1. Project Goals and Objectives. Establish project goals and objectives for wetland compensation in the planning phase of highway development. For compensation that will be provided via wetland restoration or creation, the primary goal is to establish jurisdictional wetlands as defined by current Federal and State criteria. The secondary goal is to restore or create a specific amount (acres (hectares)) and type (emergent, forested) of wetland.

   The amount and type of wetland to be replaced is determined by the agency with jurisdiction over the impacts. Compensation ratios to wetlands where a Section 404 permit has been required will be determined by the US Army Corps of Engineers (US ACOE). Some US ACOE district offices allow for compensation ratios as defined in the IDOT Wetland Action Plan (see Appendix A). Currently, wetlands that are considered isolated fall under the jurisdiction of the IDNR and compensation ratios are defined in the Wetland Action Plan.

   For the Federal and State goal of no net loss of wetlands, the minimum replacement is 1:1 and the greatest is 5.5:1, replacement to loss. Usually, replacement should be in-kind, but out-of-kind may be justified; see Section 26-8 for more information.

2. Site Selection. Select sites that have a majority of poorly drained soils and that are designated as prior converted by the Natural Resources Conservation Service (NRCS). The NRCS field offices and published soil survey reports can provide information to assist in identifying sites that meet these criteria. If either component of the criteria is not met, there are a number of obstacles that may arise that could block approval of the proposed wetland compensation site. If both criteria are satisfied, planning, design, construction, and maintenance of the planned wetland is much simplified.

Site selection also should include sufficient ground to buffer planned wetlands from adjacent land uses that are not compatible with the establishment of native plant communities. There exist no guidelines, regulatory or scientific, for determining the appropriate amount of buffer to provide. The minimal buffer consists of a 10 ft to 20 ft (3 m to 6 m) belt of upland that is planted with native grasses and forbs. Embankments planted to prairie may be sufficient.

3. Site Assessment. Assess every proposed wetland compensation site both off- and on-site for its possibilities and limitations. Evaluate the site using topographic maps, aerial photography, published soil survey reports, and other existing geographic information. Survey the site for existing vegetation cover types and jurisdictional wetlands. Field-check county soil survey mapping and delineate any hydric soils. Field-check the site's geology and hydrology for confining layers (aquacludes) and sources of surface water. Note the presence of drain tile blowouts and outlets.

59-7.09(b) Design

Keep designs for planned wetlands simple. Reliance on sophisticated design features to provide hydrology or other attributes will likely increase the margin for failure. Design for low maintenance and utilization of natural systems. Consider the following additional guidelines:

1. Grading. Even the best sites will require some earthwork, e.g., a shallow 1 ft to 2 ft (300 mm to 600 mm) berm may have to be constructed at property boundaries to contain surface water, or earth may have to be moved to enlarge an existing wetland. Excavation for creation of wetlands should extend no deeper than 1 ft to 2 ft (300 mm to 600 mm). Any deeper and side slopes become too steep and erosion and siltation become a problem. The shape or configuration of a wetland should be curvilinear like an oxbow and not geometric.

   Although sometimes recommended by regulatory agencies, stockpiling and backfilling topsoil generally is unnecessary for creation of wetlands. Because most substrates can be used as a medium for plant growth, it usually is unnecessary to specify their removal and backfilling with topsoil in the plans and specifications. This practice may be warranted only where soils are very shallow or clayey. In Illinois, most if not all, soils are very deep. Salvaged topsoil may contain a bank of weed seed that should not be used in the planned wetland.

2. Emergent Wetlands. Natural revegetation may be proposed for some exceptional sites. This approach to restoration may be acceptable to the regulatory agencies if it can be demonstrated that a viable seed bank exists in the soils or that there is an adequate source of propagules. A cover crop should be planted in areas proposed for natural revegetation. The cover crop stabilizes the soil and helps control weeds. A recommended crop mix consists of red top at 5.0 lb/acre (5.6 kg/ha). Virginia wild rye at 10 lbs/acre (11.2 kg/ha) may be added to the red top. Never specify agricultural grain or perennial rye as a cover crop. They can alter soil characteristics and impair the growth of desirable wetland plants.

At other sites, the revegetation may have to be accelerated. One to five percent of the surface area of the planned wetland should be planted and the rest seeded to a temporary cover. Tubers, corms, rootstock, etc., are usually set on 1 ft (300 mm) centers; however, the faster a species rate of spreading, the more distance there can be between transplants. Planting areas should be protected from predators. Low netting supported 1 ft to 2 ft (300 to 600 mm) above the mature height of the plants works well.

3. Forested Wetlands. Forested wetlands usually are planted with hardmast producing species as favored by the Federal regulatory agencies. The species of choice include swamp white oak (Quercus bicolor), pin oak (Q. palustris), pecan (Carya illinoensis), and shellbark hickory (C. laciniosa). These four species grow naturally throughout Illinois and are commercially available. A cover crop of red top at the rate of 5 lb/acre to 10 lb/acre (5.6 kg/ha to 11.2 kg/ha) should be planted with the trees. Virginia wild rye at the rate of 5 lbs/acres to 10 lb/acres (5.6 kg/ha to 11.2 kg/ha) may be added to the mix. These plants are hydrophytic.

   Various methods of tree installation may be used. If bare root seedlings are specified, install a minimum of 560 trees/acre (225 trees/ha). If 3-gallon (11 L) potted material is specified, install a minimum of 70 trees/acre (28 trees/ha). If 1.75 in (45 mm) balled and burlapped material is specified, install a minimum of 30 trees/acre (12 trees/ha). These numbers are consistent with previous practices, but may have to be increased at the request of the Federal regulatory agencies. A goal of 80% survival of all planted trees is usually required as a project goal for forested wetlands. Vegetation between rows should be mowed out completely during the first two growing seasons and then reduced to one mowing pass in a single direction (i.e., north to south or east to west) between rows for the next three growing seasons.

   Seeds or acorns may also be proposed for establishment of forested wetlands. A common specification is to plant three seeds or acorns per hole 2 in. to 4 in. (50 mm to 100 mm) deep. Plant one seed or acorn deeper than the other two to deter predation by animals, e.g., squirrels. Each hole is 3 ft (900 mm) on center and rows are 10 ft (3 m) apart.

4. Plants. Use the following guidelines for plants:

   a. Selection. The best guideline for plant selection is to observe what is growing in similar wetlands near the planned wetland. Select the dominant or common plants in the model wetland for use in the planned one. Select natural associates and group plants by community type.

   b. Nativity. Plants native to the region always should be specified for use in wetland replacement projects. Where feasible, buy plants from nurseries located within 100 miles (160 km) north or south and 200 miles (320 km) east or west of the compensation site.

   c. Availability. Take care to specify only those species that are commercially available. Keep plant lists short and simple. Select the more common wetland plants and let nature fill-in with the uncommon species.

d. Adaptability. Many of our wetland plants, especially the woody ones, are propagated in uplands. Often these plants die in our planned wetlands because they are not adapted to wet conditions. Vegetation must be grown in conditions similar to those in which they will be planted. If this option is not available at the supplying nursery, dormant stock should be planted during the dormant season so that when the plants break dormancy they will develop the necessary structures for survival.

Young woody plant material should be specified because it is not use to growth under ideal conditions and is better able to adapt to wetlands. The survival rate for transplanted containerized plants and seedling plugs is higher than for seed, bare root, and balled and burlapped material.

5. Planting. Consider the following guidelines when planting:

a. Deconsolidation. Where heavy machinery is used to move earth and create wetland conditions, compacted surface material should be deconsolidated. This is especially true with fine textured (clay) materials or substrates. Site construction plans and specification always should state that before planting, the substrates will be deconsolidated by plowing, discing, rototilling, or ripping. The depth of deconsolidation should be 4 in. to 6 in. (100 mm to 150 mm) for herbaceous material and 12 in. to 18 in. (300 mm to 450 mm) for woody plants.

b. Planting "In-The-Dry". Wherever practical, plant "in the dry" with most of the water drained from the site. Water may have to be drained from a site mechanically (e.g., through pumping) so that planting "in the dry" may be accomplished and so that planting schedules may be met. Do not plant in standing water. Plantings are more likely to be done properly, and costs will be reduced by as much as a factor of 10.

c. Bowls. Do not build bowls around planting holes with excess soils. Bowls divert water from the plants during overland flow.

d. Mulch. Do not mulch plants because mulch will wash or float away.

e. Stakes and Anchors. Trees and shrubs more than 4 ft (1.2 m) in height should be staked using standard landscape specifications. Where surface water may freeze, trees and shrubs should be wired to anchors. The anchors should be sufficiently deep to prevent plant material from being lifted by ice.

59-7.10 Wildlife Habitat

Wildlife has four basic needs for habitat — food, water, shelter, and space. These needs can be provided through both vegetative and structural components in the landscape design. Consider the following guidelines:

1. Vegetative Cover. Vegetative components of wildlife habitat include:

a. Conifers. Conifers provide escape cover, winter shelter, and summer nesting sites. Also, the sap, needles, twigs, buds, and seeds are eaten by wildlife.

b. Grasses and Legumes. Grasses and legumes provide habitat for ground nesting birds; forage for deer, rabbits, woodchucks, meadow voles, and others; hunting areas for foxes, hawks, kestrels, owls, coyotes, weasels, and skunks; winter cover for pheasants and deer; and winter food for seed-eating winter birds.

c. Nectar Plants. Nectar plants typically are provided for hummingbirds, orioles, bees, moths, and butterflies.

d. Other. Other vegetative cover include:

- summer fruit, berry, and cover plants;
- fall fruit, grains, and cover plants;
- winter fruits and cover plants; and
- mast, i.e., plants that produce nuts and acorns.

2. Structural Components. Structural components of wildlife habitat include:

- nest boxes;
- dead trees, fallen trees, and perches;
- brush piles and rock piles;
- cut banks, cliffs, and caves;
- dust and grit;
- salt; and
- water.

The type of vegetative and structural components of wildlife habitat restoration will be dictated by the species involved, degree of impact, and availability of plant material. A number of published guides exist that list habitat requirements for wildlife species. Consult the district Environmental Coordinator and Landscape Architect/Roadside Manager prior to initiating design.

59-7.11 Planting in Urbanized Areas

Use the following criteria for planting in urbanized areas:

1. Minimum Distance from Intersections, Alleys, and Driveways. The following criteria relates to distances as measured from the property line and along the property lines:

a. Intersections. Do not locate trees within 50 ft (15 m) on the near side and 20 ft (6 m) on the far side of the intersection; see Figure 59-7.B. Trees on medians should be located a minimum of 50 ft (15 m) from intersections.

b. Alleys. Do not locate trees within 20 ft (6 m) on the near side and 10 ft (3 m) on the far side.

c. Commercial Driveways. Do not locate trees within 20 ft (6 m) on the near side and 10 ft (3 m) on the far side.

d. Residential Driveways. Do not locate trees within 10 ft (3 m).

2. Minimum Distances from Walks, Curbs, Utilities, and Structures. The following criteria applies from face of curb or center of utility to edge of tree, as measured horizontally:

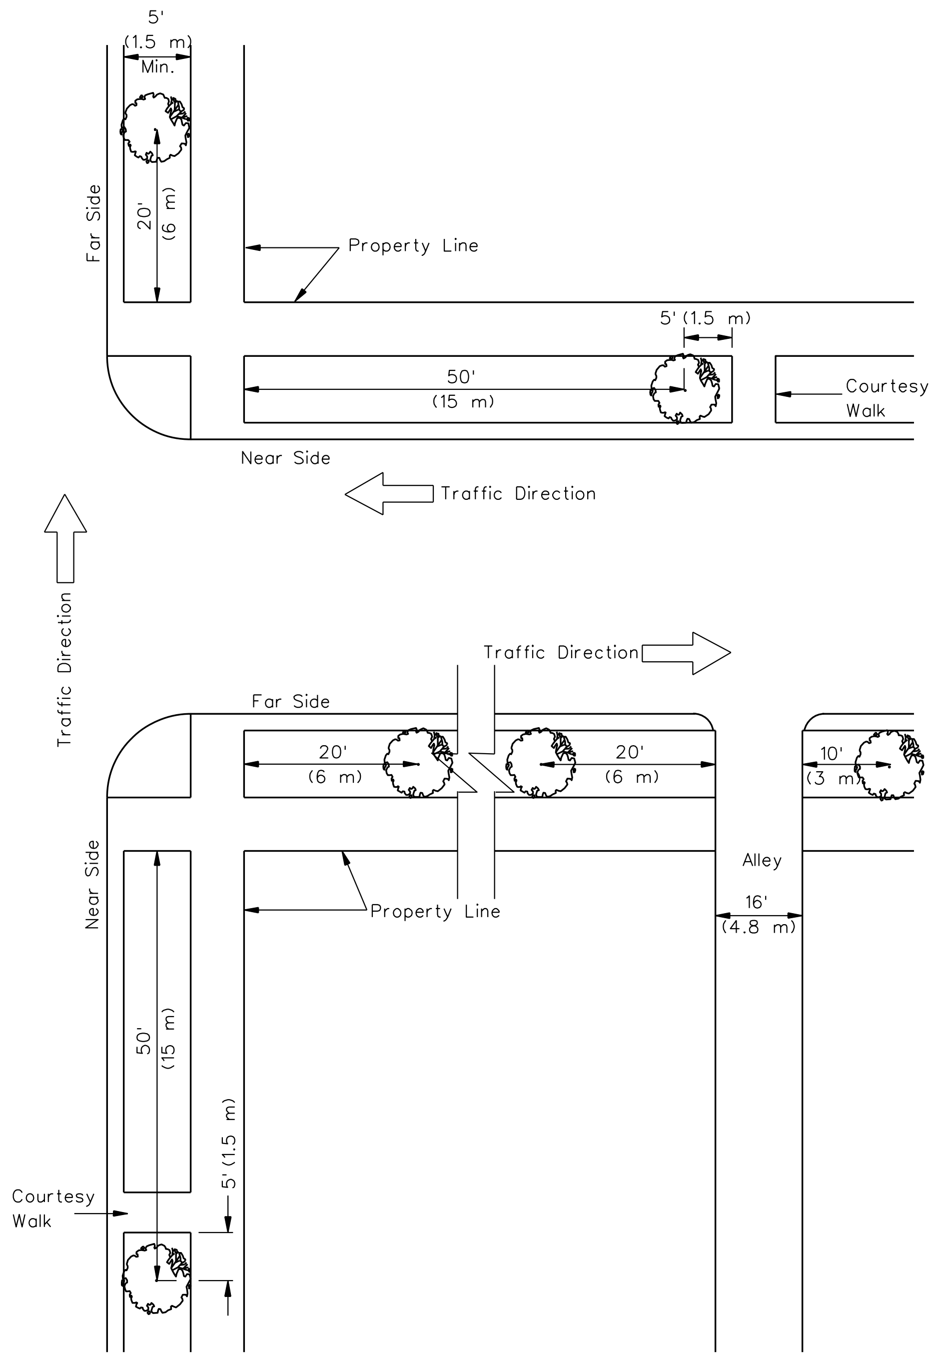
a. sidewalks and carriage walks — 3 ft (900 mm);

b. access of courtesy walks — 5 ft (1.5 m);

c. face of curb — 4 ft (1.2 m);

d. manholes and catchbasins — 10 ft (3 m);

e. fire hydrants — 10 ft (3 m);



MINIMUM PLANTING DISTANCES FROM INTERSECTIONS

Figure 59-7.B

- underground utility mains and services — 5 ft (1.5 m);
- street lights — see Item 3;
- existing trees — see spacing criteria below;
- overhead wires — no ascending shade trees will be planted under overhead wires or where mature width will reach overhead wires;
- railroad crossings — 100 ft (30 m), written approval from railroad is required to plant within 100 ft (30 m); and
- other structures — 30 ft (9 m) or as directed.

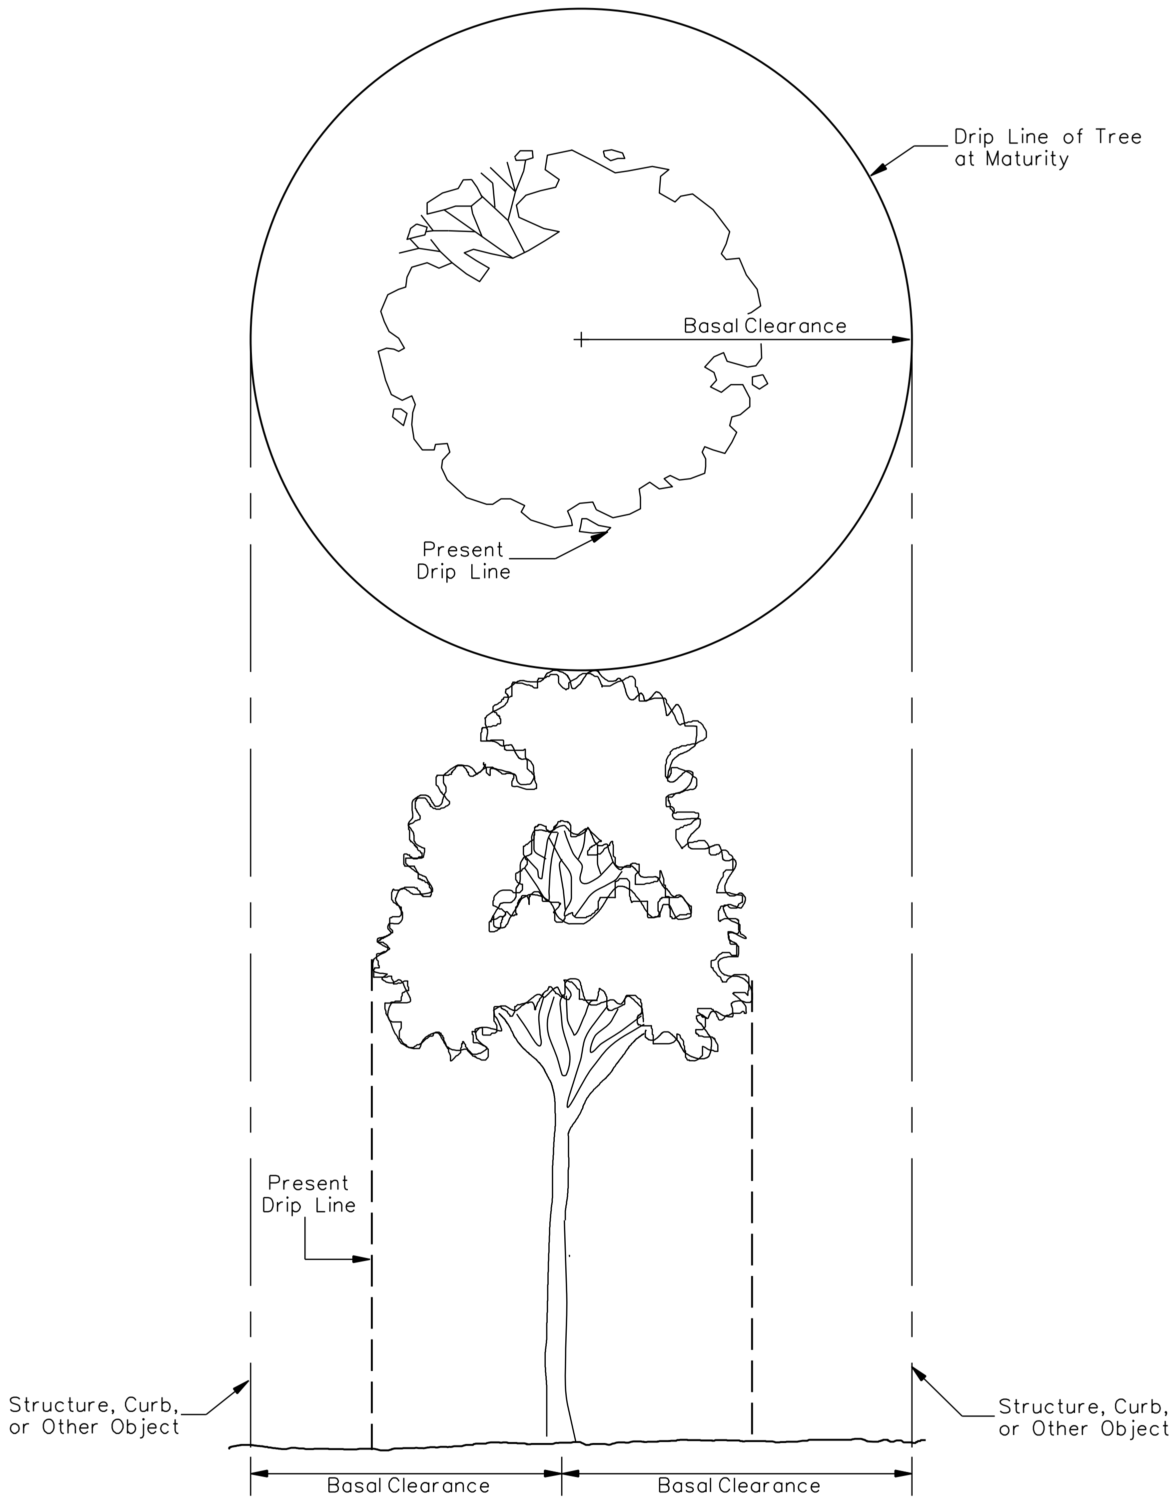
These requirements are for reduced speed urbanized areas and must be adjusted for higher speeds so that clear zone and sight distance requirements are met.

3. <u>Minimum Basal Clearance Between Trees and Structures</u>. Basal clearance is defined as the distance from the center of the tree to the structure or object involved; see Figure 59- 7.C. Minimum basal clearance between trees and between trees and structures located on parkways, medians, or other areas of the right-of-way are as follows:

   - Trees with spreading crowns must have a minimum basal clearance of 15 ft (4.5 m).
   - Trees with global or pyramidal crowns must have a minimum basal clearance of 12 ft (3.6 m).
   - Trees with fastigiate or columnar crowns must have a minimum basal clearance of 10 ft (3 m).
   - Do not plant trees in areas where basal clearance is less than 10 ft (3 m) without written permission from the district Landscape Architect/Roadside Manager.
   - The Department will determine the form classification of a given tree or species of tree; see Figure 59-7.D.
   - Select tree species from the approved tree list of the district Landscape Architect/Roadside Manager or from a municipal tree list if it is applicable to the project site.

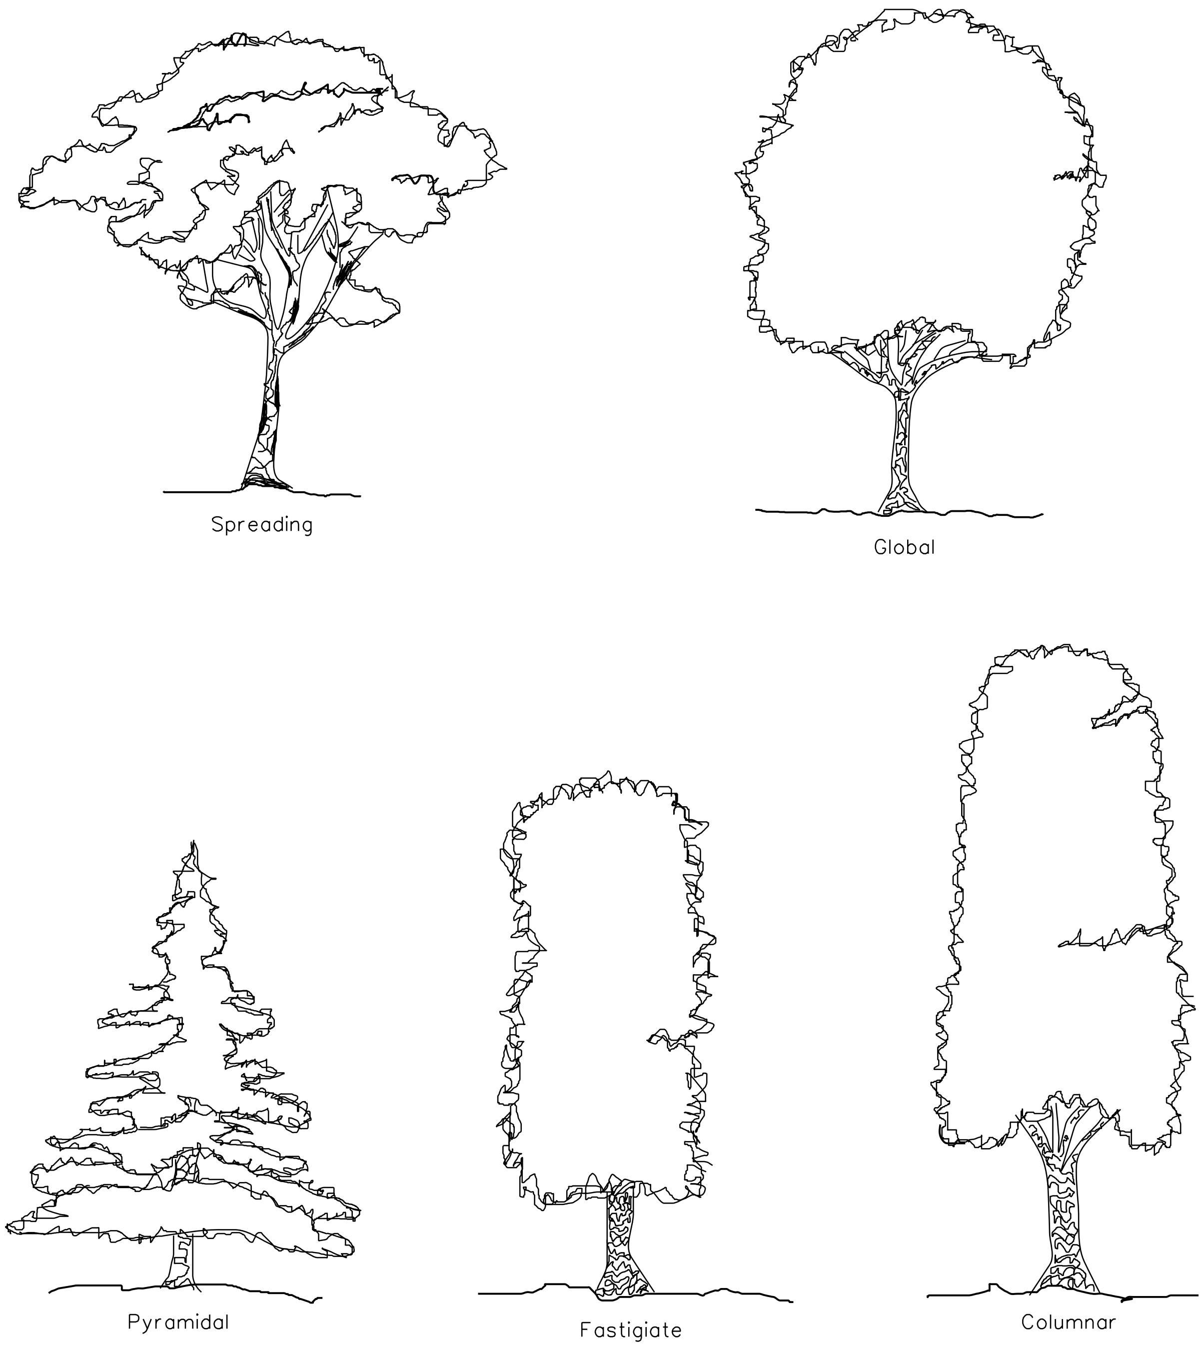
4. <u>Spacing of Trees Within Parkways</u>. Use the following criteria for spacing of trees within parkways:

   - Space trees with spreading crowns at a minimum of 30 ft (9 m).
   - Space trees with global or pyramidal crowns at a minimum of 25 ft (7.5 m).



BASAL CLEARANCE

Figure 59-7.C



REPRESENTATIVE FORM CLASSES

Figure 59-7.D

- Space trees with fastigiate or columnar crowns at a minimum distance of 20 ft (6 m).

5. Spacing Between Trees Within Median or Other Right-of-Way Areas. Spacing will follow the same criteria given for spacing between trees within parkways with the following exception: if the median is concrete paving or other hard surface material, obtain written approval for the specific tree planting proposal. Spacing of trees located on other right-of-way must be approved by the district Landscape Architect/Roadside Manager.

6. Width of Parkway, Medians, and Other Public Ways. Landscape designs must be so arranged to provide a sufficiently wide, clear, and safe pedestrian walkway. The required width will in no case be less than 6 ft (1.8 m) wide, measured from a line 1 ft (300 mm) within the right-of-way. Use the following criteria:

   a. Minimum Width of Parkways. Use the following criteria for minimum width of parkways:

      - Do not plant trees on any parkway that is less than 6 ft (1.8 m) in width except when specific permission is granted by the district Landscape Architect/Roadside Manager.

      - Do not plant trees on any commercial or industrial sidewalk or cut-out in a sidewalk that is less than 16 ft (4.8 m) in width, except when specific permission is granted by the district Landscape Architect/Roadside Manager.

   b. Minimum Width of Medians. Do not plant any trees or shrubs in a median unless a local community agrees to the maintenance of the median. Do not plant trees on any median that is less than 10 ft (3 m) in width, except when specific permission is granted by the district Landscape Architect/Roadside Manager.

   c. Minimum Width of Other Right-of-Way. Do not plant trees on any right-of-way that is less than 26 ft (7.8 m) in width except when specific permission is granted by the district Landscape Architect/Roadside Manager.

7. Lateral Location of Trees Within Parkways, Medians, and Right-of-Way Areas. Use the following lateral location criteria:

   - The lateral location of trees being planted should reflect the ultimate pavement width of arterial streets.

   - Where practical, trees planted in parkways will be planted in the lateral center of the parkway, or as close to it as practicable, unless specifically approved otherwise.

   - Space and locate trees planted according to their crown form, basal clearance, and the recommendations of the district Landscape Architect/Roadside Manager.

- Do not plant trees that will branch lower than 10 ft (3 m) immediately adjacent to sidewalks.
- Do not plant trees that will branch lower than 14 ft (4 m) immediately adjacent to driveways.

In urbanized areas, a maintenance agreement with the local agency is usually required.

59-7.12 Visual Quality

Visual quality is a functional goal that is achieved by conserving existing visual resources and enhancing the built environment through landscape and environmental design. Consider the following factors during design:

- the view from the road and of the road;
- outstanding scenic qualities;
- the color choices for roadside features;
- the location of utilities;
- clear zones, sight lines, and profiles;
- bridge and structure designs;
- number, type, and location of signage; and
- noise mitigation structures.

59-7.13 Erosion Control

See Chapter 41 for information on erosion and sediment control.

59-7.14 Architectural Design Elements

There are a number of architectural design elements that can be incorporated into highway design to make the project compatible with its environment including:

- retaining walls constructed with special finishes, modular block, or stone;
- noise barrier walls;
- sight-screen fences and walls to screen unsightly areas such as junkyards;
- sculptures, graphics, and other special art work;
- guardrails and concrete barriers;
- highway appurtenances including signs, delineators, traffic signals, and control boxes;
- access control fencing;

- bridge designs;
- light poles, historical lighting fixtures, and lighting of tunnels, bridges, and pedestrian sidewalks and trails;
- enhanced light quality and special aesthetic enhancement light for structures, sculptures, flag poles, and other artwork;
- planter boxes;
- bicycle racks;
- bollards and barriers; and
- decorative surface areas including stone surfaces, patterned and/or colored concrete, and precast concrete pavers and natural stone pavers.

59-7.15 Plan Preparation

Provide a copy of the construction plan sheets and cross sections to the district Landscape Architect/Roadside Manager for plant placement/replacement input.

Include the following in the plans:

1. Plant key sheet, including the following information:
    - code numbers with heading of trees, intermediate shrubs, evergreens, seedlings, and wildflowers;
    - scientific name;
    - common name;
    - measured size (include balled and burlapped, container grown, and bare root);
    - key number (optional);
    - each or units;
    - quantity;
    - sheet locations; and
    - general notes, if any;
2. Sheets showing actual location of items on project with key number; and
3. Any standard sheet, e.g., details of hole size, bracing, mulch.

See Chapter 63 for further details.

59-7.16 Highway Related Areas

The transportation system contains supplemental areas and facilities (e.g., bikeways, information centers, weigh stations, rest areas) that are specifically designed for uses other than driving. It is important to understand that these areas and facilities are integral, not separate, features of the highway. Detailed treatment is required to ensure that these areas and facilities provide maximum benefit to the user and blend into or complement the surrounding landscape.

The need for supplemental highway related areas and facilities are evaluated at the inception of the design process. Rest areas, scenic overlooks, and truck weigh stations shall be planned in conjunction with the entire highway system. Other facilities are designed to take advantage of the environment through which the highway passes. Urban streetscape and scenic highways can be either carefully planned and managed or evolve unplanned.

Separate bikeways can exist within the right-of-way. Park-and-ride lots are becoming increasingly important aspects of the highway and must be addressed in evaluating the total highway environment.

As highways and bridges are being reconstructed in response to age, determination, and changes in use, similar attention must be paid to the various highway related areas that have been constructed to support the highway system. Consult the AASHTO publication *A Guide For Transportation Landscape and Environmental Design* for considerations involving highway related areas. See Chapter 16 for information on rest areas and weigh stations.

59-7.17 Roadside Seeding in Areas Disturbed By Construction

Since the early 1980's, the Department's decisions on type of cover and plant material for roadside areas have been largely influenced by consideration of the level of maintenance/management anticipated for the areas involved. This practice has helped the Department to achieve a better fit between available funding and manpower resources and the amount of roadside maintenance needed. When allowable as a project cost, experience has shown that where a low level of maintenance/management is desired, native Illinois grasses and other native selections often are the best choice for planting. Furthermore, Roadside Use of Native Plants published by the FHWA is guidance that encourages the use of native plants to the project locale where practical. The guidance in this topic clarifies requirements on developing plan specifications for roadside seeding/cover and is intended to maximize the benefits of using native plants.

Use the following procedures in developing seeding/cover specifications for 3R, reconstruction, and new construction projects:

1. Mowing Widths. Consult with the district Landscape Architect/Roadside Managers to determine applicable mowing widths for all projects in accordance with current mowing policies of the Bureau of Operations.

2. Seeding For Mowed Areas. In all areas that Operations' policy stipulates must be mowed for safety of the motoring public, specify the appropriate seeding selections from Classes 1 or 2, depending upon the site conditions and geographical location of the project. The designer should consult the district Landscape Architect/Roadside Manager on the specific seeding selections.

3. Seeding For Areas That Will Not Be Mowed. In those areas that Operations policy stipulates are not to be mowed regularly, specify appropriate seeding selections from Class 4 and Class 5 or, for steep inaccessible slopes, from Class 3. As with specifications for mowed areas, the designer should consult with the district Landscape Architect/Roadside Manager on the selections within these classes for specific circumstances. Do not use Class 4 seeding in ditch bottoms or drainage ways where it would impede the flow of water. In areas that are not to be mowed, plantings within 10 ft (3 m) of the shoulder break/face-of-curb should not exceed a height of 3 ft (1 m) at maturity and should not interfere with sight distances.

4. Seeding for Areas Involving Special Environmental Commitments. For project goals or commitments involving wildflower planting, environmental mitigation, aesthetics, or habitat enhancement the designer should consult with the district Landscape Architect/Roadside Manager on the use of Class 5 or Class 6 seeding.

5. Overseeding/Interseeding on 3R or Reconstruction Projects. On 3R or reconstruction projects, existing turf in unmowed areas and all damaged turf should be overseeded or interseeded in accordance with the specifications using an appropriate class as determined by the district Landscape Architect/Roadside Manager to establish turf that will require little or no regular maintenance.

6. Turf Establishment on New Construction Projects. On new construction projects, turf should be established by conventional methods appropriate to the seeding class as determined by the district Landscape Architect/Roadside Manager.

7. Use of Other Grasses and Forbs. Grasses and forbs other than those in seeding Classes 1 through 6 may be specified for use at the discretion of the district Landscape Architect/Roadside Manager. Any such plants must be appropriate to the location and intended management of the project and, generally, should be species native to the project locale.

Chapter Sixty
OTHER DEPARTMENT MANUALS

The *Bureau of Design and Environment Manual* (*BDE Manual*) includes the necessary information on the topics discussed in the *Manual* for the vast majority of roadway projects designed by the districts. However, it does not present all information that may be required by the designer on all projects. For specific projects or for specific project elements, the road designer may need to reference other publications to perform a fully comprehensive analysis of the project. Chapter 60 briefly discusses other publications available within IDOT that are often required by the designer for a roadway project. The designer may also need to review the national highway engineering literature to research a specific problem or to design special elements. Summaries of national publications can be found in the publication catalogs of the various organizations (e.g., AASHTO, ITE, TRB).

60-1 GENERAL

For in-house designers, copies of most documents and publications used in design are available on the Inside IDOT Policy and Research Center Library website or by contacting the IDOT Library. For consultants and other individuals, these documents can be located on the Department’s official website.

60-2 BUREAU OF DESIGN AND ENVIRONMENT

In addition to the *BDE Manual*, the various sections of the Bureau of Design and Environment are responsible for maintaining the following documents:

60-2.01 *IDOT Coded Pay Items*

Every pay item has a unique assigned number for data processing. The *IDOT Coded Pay Items* provides a listing of all pay items and numbers used by the Department for a project. These numbers and titles are tied to the *Standard Specifications for Road and Bridge Construction*. Only use these numbers and descriptions in the plans and estimates. Both US Customary and metric pay items are presented in the *IDOT Coded Pay Items*.

Part VII of the *BDE Manual* provides additional information on how to use the *IDOT Coded Pay Items* during plan development.

60-2.02 *Standard Specifications for Road and Bridge Construction*

The *Standard Specifications for Road and Bridge Construction (Standard Specifications)* are the specifications adopted by the Department for work methods, materials, and basis of payment used in construction. The *Standard Specifications* are intended for general repetitive use. They provide Department criteria for:

- bidding,
- awarding the contract,
- the contractor's duties,
- controlling the material quality,
- the contractor's and the Department's legal requirements,
- executing the contract, and
- measuring and paying for construction.

See Section 66-1.02 for more information on the *Standard Specifications*.

60-2.03 *Computer Aided Design, Drafting, Modeling and Deliverables Manual*

The *Computer Aided Design, Drafting, Modeling and Deliverables Manual* provides the policies on the use of Computer Aided Design and Drafting (CADD) software used on Department roadway and structures projects. It defines the following:

- The requirements for CADD files and 3D models used on Department projects, such as file formats and file naming and referencing conventions,
- The deliverables requirements for both 2D and 3D CADD files at various stages of the project lifecycle,
- MicroStation and GEOPAK configuration information,

- Standard software used by the Department,
- CADD Workspace Configuration used by the Department,
- Drafting guidelines to be used on both roadways and structures projects,
- Links to additional resources, district CADD contacts, CADD subscription services, and example roadway and structures construction plans, and
- Various Frequently Asked Questions (FAQ's) concerning CADD.

60-2.04 ***Highway Standards***

The *Highway Standards* provide details for laying out or constructing various design elements that are consistent from project to project (e.g., guardrail, curb and gutter, signs, fencing, landscaping). The *Highway Standards* contain both US Customary and metric units. The *Highway Standards* are developed by BDE in collaboration with other bureaus. See Section 66-1.05 for more information on the *Highway Standards*.

60-2.05 ***Survey Manual***

The *Survey Manual* provides the Department's survey policies and regulations. It includes:

- a discussion of geodetic surveying covering datums, State-plane coordinates, and geodetic surveying;
- design surveys;
- photogrammetric surveys covering accuracy requirements as well as GPS procedures;
- land surveys, which includes a discussion of the public land surveys;
- construction surveys, which includes staking procedures;
- a chapter on safety designed to eliminate crashes and property damage; and
- several appendices with more in-depth discussion of curves, specifications for different types of surveys, survey point codes, and confined space entry policy.

60-2.06 ***Community Impact Assessment Manual***

The purpose of the *Community Impact Assessment Manual* is to present information to be used in socioeconomic or community impact assessments, identify data sources, and aid in the evaluation of alternatives for transportation improvements. This manual is designed to provide accurate, clear, and consistent information to assist IDOT personnel and consultants in completing community/socioeconomic impact documentation. The manual encompasses the socioeconomic or community impacts of the environmental assessment process from initiation of a highway project through the various stages of project development, to the concluding stages of the preparation of final documentation. In addition, the manual includes suggestions for mitigation and enhancement efforts that may be appropriate for various projects.

60-3 BUREAU OF BRIDGES AND STRUCTURES

The Bureau of Bridges and Structures is responsible for the following documents:

60-3.01 *Bridge Manual*

The *Bridge Manual* is a compilation of design procedures, plan presentation guidelines, specifications interpretation, standard practices, design details, and base sheets for bridges and other structures. It includes:

- a discussion on the organization of the Bureau of Bridges and Structures;
- plan preparation checklists for TS&L and final plans;
- sample plan sheets;
- a discussion on the Department's bridge planning process;
- preliminary bridge investigation techniques;
- bridge geometric criteria;
- structure rehabilitation techniques;
- utility attachments on structures; and
- design criteria for decks, structural steel, expansion devices, bearings, abutments, piers, piles, embankment and slope walls, and other miscellaneous details.

There are both US Customary and metric versions of the *Bridge Manual*.

60-3.02 *Culvert Manual*

The *Culvert Manual* is a compilation of design procedures, design charts and tables, standard details, and base plan sheets which are used to aid in the design and detailing of:

- simple-span, reinforced concrete box culverts;
- precast concrete box culverts;
- horizontal cantilever wingwalls;
- vertical cantilever, L-type wingwalls; and
- vertical cantilever, T-type wingwalls.

There are both US Customary and metric versions of the *Culvert Manual*.

60-3.03 *Prestressed Concrete Manual*

The *Prestressed Concrete Manual* is a compilation of design procedures, design charts and tables, examples, standard details, and base plan sheets that are used to aid in the design and detailing of Illinois standard precast, prestressed concrete bridge beams.

60-3.04 *Sign Structure Manual*

The *Sign Structures Manual* presents guidelines for the selection of sign supports, sign support design details, and CADD criteria for incorporating traffic signs into the plans. The following types of sign structures are discussed in the *Sign Structures Manual*:

- simple-span sign structures,
- cantilever sign structures,
- bridge-mounted sign structures,
- monotube sign structures,
- break-away wide flange steel sign posts, and
- break-away tubular steel sign posts.

60-3.05 *Drainage Manual*

The *Drainage Manual* is a compilation of the Department's policies and criteria on drainage and hydraulics for road and bridge projects. The *Drainage Manual* provides guidance on:

- division of responsibility for drainage,
- legal requirements,
- drainage polices,
- permits,
- preparation of drainage studies and hydraulic reports,
- floodplain encroachments,
- hydrology,
- open channel flow,
- culvert hydraulics,
- bridge hydraulics,
- storm sewers,
- roadside ditches,
- erosion and sediment control,
- scour,
- detention storage,
- pumping stations, and
- rules for construction in rivers, lakes, and streams.

60-3.06 *Structural Services Manual*

The *Structural Services Manual* provides guidance and information on the maintenance and repair of existing structures. It includes information on:

- plan preparation and review responsibilities,
- bridge inspections,

- bridge deck overlays,
- expansion joint replacement,
- longitudinal joint closure,
- bridge rail and parapet repair and replacement,
- deck drains,
- bearing replacements,
- jacking and cribbing,
- pin and link replacement,
- fatigue,
- impact repairs for steel and concrete beams,
- steel and concrete superstructure repairs,
- guidelines for bridge deck repair, and
- substructure repairs.

60-3.07 ***Geotechnical Manual***

The *Geotechnical Manual* addresses the application and treatment of soils and foundations on State projects. It presents guidance and information on:

- geotechnical investigation requirements;
- geotechnical analyses of subgrades, embankments, cut slopes, and foundations;
- recommendations for design problems involving embankments, cut slopes, peat deposits, frost action, drainage, and foundations;
- preparation and submittal of Geotechnical Reports;
- geotechnical engineering aspects for construction;
- the State's geology and pedology;
- laboratory and field testing of soils;
- Illinois' modified testing procedures and methods; and
- geotechnical glossary.

60-3.08 ***Bridge Manual Design Guides***

The *Bridge Manual Design Guides Manual* is a compilation of various design elements on CADD that are commonly found on bridge and other structures projects. The manual provides examples of Type, Size, and Location (TSL) plans that indicate a range of grade separation and stream crossing structures, as well as retaining walls that have been developed to provide planners with a quick reference for bridge planning policy and presentation methods.

60-3.09 ***Bridge Condition Report Procedures and Practices***

This document is a guideline for preparing Bridge Condition Reports for the improvement of roadway structures and was developed to provide the wide range of information necessary to complete reports for various types of bridge projects. The guideline reviews background information, field inspection, and testing (in brief), general analysis procedures and report preparation. Example Bridge Condition Report formats are provided in the document.

60-4 BUREAU OF CONSTRUCTION

The Bureau of Construction is responsible for the *Construction Manual*. The *Construction Manual* expands on the *Standard Specifications for Road and Bridge Construction* and provides guidelines for uniform field inspection and documentation procedures on highway construction. It contains explanatory information on:

- contract administration;
- earthwork;
- landscaping;
- temporary erosion control;
- subgrades, subbases, and base courses;
- surfacing;
- structures including concrete, steel, and timber structures;
- piling;
- reinforcing bars;
- culverts;
- curb and gutter;
- chain link and woven wire fencing;
- traffic control;
- construction memoranda;
- documentation and project procedure guidelines;
- inspection checklists; and
- construction forms and reports.

60-5 BUREAU OF LAND ACQUISITION

The Bureau of Land Acquisition is responsible for the *Land Acquisition Policies and Procedures Manual*. The *Land Acquisition Policies and Procedures Manual* presents information on:

- the organization, functions, and activities of the Bureau of Land Acquisition;
- preparation of right-of-way plans;
- programming of right-of-way projects;
- land surveying criteria;
- development of right-of-way plats;
- legal descriptions for right-of-way;
- guidelines for designing the right-of-way;
- administration of incidental land surveying services;
- policies and procedures for appraisals and appraisal reviews;
- policies and procedures for negotiations;
- policies and procedures for acquisition;
- policies and procedures for property management of State property;
- policies and procedures for relocation assistance and payment program; and
- other miscellaneous Land Acquisition policies and procedures.

60-6 BUREAU OF LOCAL ROADS AND STREETS

The Bureau of Local Roads and Streets is responsible for the following documents:

60-6.01 *Local Roads and Streets Manual*

The *Local Roads and Streets Manual* replaces the *Administrative Policies* and *Federal-Aid Procedures Manuals*, used previously.

The *Local Roads and Streets Manual* provides information on:

- the Bureau of Local Roads and Streets' responsibilities for vouchering the State's motor fuel tax funds and township bridge funds to the local agencies;
- local agency (i.e., municipalities, counties, and road districts) responsibilities for maintaining complete records of disbursements, refunds, transfers, and balances involving all State funds transferred to the local agencies;
- design guidelines for local roads and streets including functional classification, engineering analyses, roadway design, traffic control devices, pavement design, bridges and culverts, and hydraulics;
- guidelines for addressing right-of-way acquisitions, railroads, and utilities;
- policies and procedures for preparing plans, specifications, estimates, proposals, contracts, highway system revisions, resolutions, agreements, and other miscellaneous documents;
- letting, award, and construction procedures;
- maintenance administration and operations for local facilities; and
- guidelines and procedures for projects involving Federal funding, including:
    + environmental analyses and reports;
    + public involvement guidelines; and
    + FHWA coordination, review, and approval.

60-6.02 *Highway Jurisdiction Guidelines for Highway and Street Systems*

The guidelines in the above referenced document summarize highway jurisdiction issues and outline the process required for jurisdictional transfers. The document also addresses vacations and additions to the township and road district system, which may become necessary in the project development process.

.

60-7 BUREAU OF OPERATIONS

The Bureau of Operations is responsible for the following documents:

60-7.01 *Traffic Policies and Procedures Manual*

The *Traffic Policies and Procedures Manual* presents guidelines for the uniform placement of traffic control devices and the application of traffic control policies and procedures. It contains guidance and information on:

- statutory and administrative requirements for traffic control devices;
- information-gathering procedures and data sources;
- traffic engineering studies and investigations including accident studies, speed studies, warrant studies, observance studies, time and delay studies, and school-zone safety;
- plan preparation including agreements, contracts, specifications, etc., for traffic plans;
- the selection, design, and placement of signing, pavement markings, traffic signals, object markers, delineation, rumble strips, traffic control in work zones, bikeways, and highway and sign lighting, and;
- permits including access control, special vehicular movements, road closures for local celebrations, utilities, snowmobiles on State routes, and other miscellaneous permits.

60-7.02 *Illinois Standard Highway Signs*

The *Illinois Standard Highway Signs* illustrates the layout and design details for the highway signs used by the Department. It includes the MUTCD number, allowable sign sizes, and design details for:

- regulatory signs,
- warning signs,
- construction signs,
- guide signs,
- general information signs,
- motorist services signs,
- civil defense signs, and
- school signs.

60-7.03 *Illinois Manual for Uniform Traffic Control Devices*

The *Illinois Manual for Uniform Traffic Control Devices* (ILMUTCD) consists of the *Illinois Supplement to the MUTCD* and the FHWA *Manual on Uniform Traffic Control Devices* (MUTCD). Note that there is not actually a document entitled the *Illinois Manual for Uniform Traffic Control Devices.* Wherever a publication refers to the *Illinois Manual for Uniform Traffic*

Control Devices, the user should first review the *Illinois Supplement to the MUTCD* and, if it does not address the issue, the user should then use the criteria in the FHWA *Manual on Uniform Traffic Control Devices.* These combined documents address the selection, design, and placement of traffic control devices on State facilities.

The *Illinois Supplement to the MUTCD* presents criteria and guidance specific to Illinois which may vary or which are in addition to the FHWA *MUTCD.* It includes:

- reprint of the applicable sections from the *Illinois Vehicle Code* which pertain to traffic control devices;
- revisions and additions to the FHWA *MUTCD* traffic control devices for signing, pavement markings, traffic signals, construction signing, schools, and railroads; and
- a table of Illinois standard signs.

60-7.04 *Handbook for the Policy on Permits for Access Driveways to State Highways*

The *Handbook for the Policy on Permits for Access Driveways to State Highways* provides detailed information regarding requirements for the construction or modification of permitted access to State Highways or the access permit process in general. The information in the *Handbook* is governed by the *Illinois Highway Code sections 605 ILCS 5/4-209, 4-210, 4-211 and 4-212,* and *92 Ill. Admin. Code 550*.

60-7.05 *Accommodation of Utilities on Right-of-Way of the Illinois State Highway System*

The purpose of the above referenced manual is to establish policies and procedures for accommodating utilities on right-of-way of the Illinois State Highway System, which may become necessary for review during project development.

60-7.06 *Policy on Establishing and Posting Speed Limits on the State Highway System*

The above referenced manual, along with the latest revisions/editions to Chapter 11, Article VI of the *Illinois Vehicle Code*, enumerates the procedures for establishing speed limits on highways under the jurisdiction of the Illinois Department of Transportation (IDOT).

60-7.07 Maintenance Policy Manual

The purpose of the *Maintenance Policy Manual* is to provide a written reference that will enable IDOT personnel to more uniformly maintain the State Highway System. This manual contains:

- Guidelines for completing work activities assigned to the central and district Bureaus of Operations (Bureau of Maintenance in District 1).
- References to policies and procedures governing functions of bureaus, offices, or agencies which have a bearing on highway maintenance operations activities, including the planned activities of roadway and structures designers.
- Information regarding necessary local agency agreements and maintenance obligations on state highway projects with side roads or local participation.

60-7.08 *Pavement Marking Selection Installation & Inspection Manual*

The above-referenced manual is authorized by Department Policy TRA-14. It serves as both a guideline for selecting optimum pavement marking materials and as a reference for inspecting the installation of pavement markings. The manual is intended for use in design, maintenance, and inspection.

60-7.09 *Reporting and Signing of Vertical Clearances and Obstructed Turning Movements*

It is necessary to report truck length restrictions for routes where difficulties from load length have occurred due to obstructed turning radii or sag curves with low vertical clearances. Reported truck length restrictions will be utilized, by the central Bureau of Operations, when issuing oversize load permits in order to prevent permitted loads from damaging roadways and becoming entrapped. Additionally, the Illinois Department of Transportation is authorized by the Size, Weight, Load, and Permits law [625 ILCS 5/15-101 *et seq*., Ch. 15] to issue special permits to allow the operation of vehicles or loads that exceed the legal maximum dimension and weights on highways under Department jurisdiction (Federal and State non-local highways maintained by IDOT). Measurements of vertical clearances are used when issuing these permits. It is therefore necessary that IDOT exercise due diligence in the collection, maintenance, security and reporting of all minimum vertical clearances, measured to overhead obstructions, over all state-maintained roadways.

The intent of the above referenced policy document is to provide uniform signing and reporting procedures for vertical clearances and obstructed turning movements in order to reduce instances of vehicles entrapped on roadways.

60-8 BUREAU OF MATERIALS

The Bureau of Materials is responsible for the following documents:

60-8.01 ***Manual of Test Procedures for Materials***

The above referenced manual presents the Department's criteria for sampling and test procedures for evaluating the following materials for road and bridge construction:

- aggregates,
- hot-mix asphalt, and
- Portland cement concrete.

60-8.02 ***Manual for Materials Inspection***

The above-referenced manual is authorized by Department Policy MAT-11.

This manual is a guide for the inspection of metals, plastics, chemicals, admixtures, and other miscellaneous materials. It generally covers materials that are not soils, hot mix, concrete or aggregates.

60-9 BUREAU OF SAFETY PROGRAMS AND ENGINEERING

The Bureau of Safety Programs and Engineering is responsible for the following documents:

60-9.01 ***Traffic Control Field Manual***

The *Traffic Control Field Manual* is issued for the purpose of the proper application of temporary traffic control devices. The manual has been developed to establish the minimum requirements for work site protection, when traffic control is provided by the Department.

60-9.02 ***Systemic Safety Improvements: Analysis, Guidelines and Procedures Manual***

The Systemic Safety Improvements: Analysis, Guidelines and Procedures Manual explains how to collect crucial safety data that is not readily available, analyze safety data, use available resources to implement strategies effectively and make proactive infrastructure improvements, and to target enforcement and education programs. The information presented in this document will assist in better identifying potential safety performance issues on a roadway system and guide efforts to save lives. Specifically, this document includes the tools necessary for conducting safety analyses, network screening and the systemic approach. These guidelines detail the systemic process which includes collecting and organizing data, obtaining critical values, compiling the results, assessing existing field conditions, and selecting appropriate countermeasures.

Section **Page**

Chapter Sixty-three
PLAN PREPARATION

Other parts of the *Bureau of Design and Environment Manual* (*BDE Manual*) provide the designer with uniform criteria and procedures for the design of a highway facility. Incorporate these designs into the roadway plans so that they can be clearly understood by contractors, material suppliers and Department personnel assigned to supervise and inspect the construction of the project. To ensure a consistent interpretation of the plans, individual sheets should have a standard format and content, and the sequence of plan assembly should generally be the same. To provide this consistency, this chapter provides guidelines for the uniform preparation of Phase II plans.

In addition to this chapter, the designer should review:

- Part I of the *BDE Manual* for information on the design process or steps that should be followed in preparing a set of plans,
- Chapter 64 for quantity computations,
- Chapter 65 for cost estimating, and
- Chapter 66 for the contract process.

If problems arise which are not covered in this *Manual*, the designer should consult with the Bureau of Design and Environment personnel as the project progresses to resolve these problems as soon as practical prior to plan completion.

63-1 GENERAL INFORMATION

63-1.01 <u>Responsibilities</u>

The highway designer is responsible for the preparation of Phase II plans. This includes:

- ensuring that the plans are in compliance with the Phase I report, commitments, and agreements;
- ensuring that the survey is properly drafted;
- preparing the plans in the correct format and sequence, and checking for errors and omissions;
- incorporating plan sheets, quantities, and special provisions from other sections/bureaus into the plans;

- calculating the quantities and recording them on the summary of quantities sheet;
- preparing the contract special provisions and supporting documents;
- incorporating appropriate review comments from various other units, bureaus, agencies, etc.;
- requesting the preparation of the construction cost estimate; and
- submitting the plans to the BDE for review, approval, and letting.

63-1.02 Plan Development Stages

The designer is responsible for preparing the plans so that they can be constructed in the field. To ensure the plans are correct and complete, the designer needs to review the Phase I report and the project commitment file. The plans will also be reviewed by others at the preliminary, pre-final, and/or final stages to ensure that they are free from errors and omissions. Chapters 2, 3, and 4 discuss the other activities that are typically involved during the project preparation. The following sections briefly discuss the key stages relative to plan preparation.

63-1.02(a) Phase II Initiation

To properly prepare the plans, the designer must have a well-defined scope of work. The Department's proposed scope of work for a project is defined in the appropriate Phase I report. Part II, Project Development, of the *BDE Manual* discusses how to prepare a Phase I report and what factors should be considered. Part III, Environmental Procedures, discusses the environmental issues that must be addressed.

In addition to the Phase I report, the designer is provided, at the beginning of Phase II, the project commitment file. This file should contain all commitments made to the public and other agencies during the location and environmental study stages of the project. These commitments may include:

- funding arrangements between the Department and local agencies and/or developers, which may include construction costs, signal maintenance, lighting agreements, etc.;
- notification requirements to public agencies, owners, local officials, etc., prior to construction;
- requests for verification of area to be disturbed by the project;
- commitments to owners, public agencies, and/or local officials for plant replacement, removal, or retainage (e.g., trees, shrubs, wetland plants);
- environmental commitments to public agencies, local officials, and/or other groups (e.g., wetland replacement, hazardous material removal);

- relocation, removal, or replacement agreements/requests for existing buildings;
- drainage agreements, including detention areas, culvert locations, ditch construction, etc.;
- relocation, rebuilding, addition, or removal agreements/requests for private and commercial entrances;
- special construction requests (e.g., timing of construction, type of construction, limits of construction);
- existing sign removal and replacement; and/or
- any other special agreements made between the Department and land owners during right-of-way negotiations.

The designer is responsible for maintaining this commitment file and ensuring that these commitments are incorporated into the final plans and agreements. The designer needs to carefully review all minutes of meetings, transcripts of public hearings, and the project study files to ensure all commitments have been listed. If there are any questions, the designer should contact the preparer of the Phase I report. During Phase II, the designer also adds to the file any commitments made to property owners or others affected by the project.

If it is discovered during plan preparation that a change is required to the approved Phase I report or a commitment cannot be met, the designer must immediately notify the Central Office and all appropriate district units so that appropriate action can be taken. Failure to provide the appropriate notification and review may result in project delays.

63-1.02(b) Preliminary Plan Review

This is the best design stage for various other bureaus, sections, agencies, etc., who may have a role in the project to conduct a major review of the plans. This may include a plan-in-hand field review, if deemed necessary. The preliminary plan review will occur after the designer has essentially completed the plans including the cover sheet, plan and profile sheets, detail sheets, cross section sheets, determination of pay items, special provisions, etc. This review may also incorporate the plan sheets from other applicable bureaus. During this stage, the designer should address any utility conflicts and determine if adjustments and/or agreements are necessary. The purpose of the preliminary plan review is to ensure the plans are compatible with the approved Phase I report, are in conformance with the Department's design criteria, and are appropriate for the site. All major content comments must be made during this review period. Incorporation of comments made after this review may require the approval of the Program Development Engineer.

All plan commitments of record should have been incorporated into the preliminary plans. All other bureaus that have made commitments on the project are required to review the preliminary plans to ensure that the plans comply with their commitments.

For complex projects several reviews may be necessary to avoid having to make substantial changes late in the plan preparation process.

63-1.02(c) Pre-Final Plan Review

Pre-final plans are essentially the same as the final plans; i.e., if there are no preliminary review comments, these plans can then be finalized and forwarded to BDE for letting. Prior to this review, the designer should:

- incorporate and/or address all comments made during the preliminary plan review;
- set up a plan-in-hand field review, if necessary; and
- determine the cost participation arrangements (e.g., Federal, State, and local shares).

These cost breakdowns should be noted on the summary of quantities sheet.

Other bureaus and agencies should be given the opportunity to review the pre-final plans to ensure that:

- their comments from the preliminary plan review have been incorporated or addressed in the disposition memorandum,
- the changes to the preliminary draft do not conflict with the bureau's commitments, and
- the plans still conform to the Department's design criteria.

If changes are requested at this point that are desirable, but not mandatory, the Project Engineer determines if they should be incorporated. This will depend on other factors that may preclude them from being added to the plans. If another bureau determines the changes still should be incorporated, an appeal can be made to the Program Development Engineer for their incorporation.

63-1.02(d) Final Plan Review

The purpose of the final plan review is to ensure that reviewer comments from the pre-final plan review have been addressed. Revisions or changes should not be necessary. If changes are deemed necessary, the reviewer should contact the designer directly.

63-1.03 <u>CADD Coordination</u>

63-1.03(a) 3D Modeling Determination

The district Program Development Engineer is ultimately responsible for determining how roadway and structures plans and models are produced. Plans shall be developed using the CADD software and workspace as defined by the IDOT *Computer Aided Design, Drafting, Modeling and Deliverables Manual*.

The district Program Development Engineer shall also define whether three-dimensional (3D) models of road design, structures designs, or both, are required for a project, through discussions with the appropriate district Project Engineer and designer, and with the Structural Design Engineer in the Bureau of Bridges and Structures, respectively. In determining whether or not to develop 3D models for a particular project, the Program Development Engineer considers the following:

- The project's complexity; for small, simple projects it may be more effective to develop two-dimensional (2D) plans only,
- The district designer and/or CADD unit's time availability for the project, and
- The status of district staff's implementation of 3D design and construction practices.

The designer should contact their Project Engineer to discuss overall work and scheduling requirements for each project. If it is determined that 3D modeling will be used for a project, the designer is responsible for contacting the district CADD Manager to discuss the level of detail to be used for 3D models.,

63-1.03(b) Corrections to Plans and Models

The designer is responsible for the information in the plans, CADD files, and the 3D models, and shall insure consistency among all three. Plan review markups received by the designer shall be incorporated to the CADD files in such a way as to preserve the consistency of plans and computer files at all times.

After receiving markups, the designer should check the drawing to ensure that all markups and revisions have been incorporated to the CADD files and models and are reflected in the plan sheets. When checking the revised drawings, the designer should review the new plot against the old plot to ensure that not only the requested revisions were made, but that other changes made using CADD have not adversely affected the drawing and models. The CADD operator may need to adjust features on the sheets and, during this process, mistakes occasionally occur (e.g., accidental deletion of nearby topography, inappropriate movement of dimensions). Designer plan and modeling review is imperative to ensure accuracy and consistency.

63-2 COMPUTERIZED DESIGN

This section briefly discusses the computer hardware and software IDOT uses to prepare contract plans, and where to find additional information regarding the use of CADD on IDOT projects.

63-2.01 *Computer Aided Design, Drafting, Modeling and Deliverables Manual*

The *Computer Aided Design, Drafting, Modeling and Deliverables Manual* provides the policies and regulations on the use of Computer Aided Design and Drafting (CADD) software used on Department roadway and structures projects. It defines the following:

- The requirements for CADD files and 3D models used on Department projects, such as file formats and file naming and referencing conventions,
- The deliverables requirements for both 2D and 3D CADD files at various stages of the project lifecycle,
- MicroStation and GEOPAK configuration information,
- Standard software used by the Department,
- CADD Workspace Configuration used by the Department,
- Drafting guidelines to be used on both roadways and structures projects,
- Links to additional resources, district CADD contacts, CADD subscription services, and example roadway and structures construction plans, and
- Various other Frequently Asked Questions (FAQ's concerning CADD.

63-2.02 Computer Hardware

All Department computer equipment (e.g., PCs, printers, file servers) have been networked or interconnected. This, along with the use of Bentley's ProjectWise, allows designers across the State to access the same information regardless of their location or which machine they are using. To accomplish this, all project files shall be saved on the Central or district office file servers through ProjectWise. The designer is required to export or check-out the project files from the file server to their PC or workstation at the beginning of each work session. At the end of each work session, the designer is required to import or check-in all project files back to the Central or district office file servers. For instructions on how to acquire files, contact the district CADD Manager.

63-2.03 Computer Software

The Department is presently using and requires the use of Bentley Systems, Inc. software (i.e., MicroStation and GEOPAK) as its computer-aided drafting and design (CADD) package.

All users outside of the Department network should consult with the district Project Manager and/or CADD Manager to determine which version(s) of the software programs are acceptable to the Department. This information is also available on the Department's website. All consultants submitting CADD plans to the Department shall use software versions that are compatible with the Department's, and shall meet all CADD requirements presented in the *Computer Aided Design, Drafting, Modeling and Deliverables Manual.* See the *Computer Aided Design, Drafting, Modeling and Deliverables Manual* for more information on computer software and CADD requirements to be used on Department projects.

63-2.04 File Management

Each project is saved in its own project directory in the Department's ProjectWise database. Individual project documents including sheet files are saved within this directory. To allow others to determine the content of files without the need for opening and reviewing them, the designer shall store and name files in accordance with the *Computer Aided Design, Drafting, Modeling and Deliverables Manual*.

63-3 DRAFTING GUIDELINES

See the IDOT *Computer Aided Design, Drafting, Modeling and Deliverables Manual* for plan sheet drafting guidelines.

63-4 PLAN FORMAT AND COMPOSITION

The designer should prepare the plans as simply as practical. The use of duplicated data and unnecessary cross references should be avoided. The following sections provide additional information on what should be included within each sheet. Section 63-3 provides criteria for drafting the information onto each sheet. Section 63-6 provides a checklist the designer may use when preparing a set of plans.

63-4.01 General

The designer should include the following information on every sheet, except for the *IDOT Highway Standards* included in the back of the plans:

1. Sheet Index Block. Title blocks are provided in the lower right corner (upper right for cover sheet) of sheet cells in the IDOT roadway cell library and contains the following information:

    - project route number(s);
    - section number(s);
    - county the project is located in;
    - total number of sheets for the project, including the cover sheet and excluding the highway standards sheets;
    - sheet number;
    - stationing shown on the sheet, if applicable; and
    - contract number

2. Project Numbers. Project numbers will be determined and placed on the plans by the Central Office.

63-4.02 Cover Sheet

A cover sheet is required for all plans. It identifies the project type, project location, and other pertinent project information, and it authenticates the plans by signatures of approval. A pre-drafted cover sheet is available as a cell in the roadway cell library. This pre-drafted sheet provides the State map, blocks for project approvals, design scales, and other related design information.

63-4.02(a) Sheet Content

The designer should include the following information on the cover sheet:

1. Index of Sheets. If the sheet index is not included as a separate sheet in the plans, locate the index of sheets in the upper left-hand corner of the sheet. If the sheet index is not included on the cover sheet, note the location of the index sheet within the plans in the upper left-hand corner of the sheet. Below the sheet index, list the *IDOT Highway Standards* used on the project. See Section 63-4.03 for more information on the format for listing the sheets and *IDOT Highway Standards*.

2. Title Information. Show the project title information in the top center of the sheet in the following order:

    - the title:

      STATE OF ILLINOIS
      DEPARTMENT OF TRANSPORTATION

    - project route number and common name;
    - section number; see Section 63-4.02(b);
    - Federal fund type followed by the Federal project number (if Federally funded);

      Example: HSIP-XXXX

    - location of improvement (optional);
    - type of improvement;
    - county of project location; and
    - construction job number ("C" number).

3. Planning or Design Number. At the district's discretion the planning or design job number (P# or D#) may also be listed on the cover sheet. When used, show the number below the sheet index block.

4. State Map. Locate the Illinois State map along the right side of the border. A location symbol is used to show the general location of the project in the applicable county and the general direction of the project (i.e., north-south, east-west). The location symbol can be found in the roadway cell library. This project location map is not required on those projects using the 8.5 in. x 11 in. plan sheets.

5. Scales. Show the graphic scales used for the plan and profile sheets, cross sections, and detail sheets in the lower left-hand side.

6. Contract Number. Show the contract number in the lower left-hand corner of the cover sheet.

7. Layout Map. The layout map is located at the bottom center of the cover sheet. Show only the area necessary to allow the reader to understand where the project is located. The standard scale for rural layout maps is 1 in. = 1 mile (1:60,000 metric) and should be used wherever practical. Select a scale for urban areas that adequately shows the features of the project. A layout map is not required where construction is taking place at several isolated locations (e.g., district wide patching projects).

The layout map should clearly show the following:

- the location of the project roadway in relation to true north, existing roads, cities, towns, major drainage features, railroads, buildings and, where appropriate, the range, township, and Principal Meridian;
- the beginning and ending stations of the project, any station equations, and omissions to the nearest hundredth of a foot (e.g., 0 + 00.01) (thousandth of a meter (e.g., 0 + 000.001));
- the project numbers and stations of as-built projects onto which the project is tied;
- names of any special features (e.g., McHenry Interchange);
- signed route numbers for US, State, and local highways;
- a brief description for separation structures and bridges on the project over 20 ft (6 m). Use a single station number, based on mainline stationing, at the approximate center of each structure. Indicate the length of each structure, structure number, whether it is an overpass or underpass in relation to the main line, and whether it will be constructed under this contract; and
- scale of layout map.

8. Project Length. Show the project gross and net lengths to the nearest thousandth of a mile (kilometer) immediately below the layout map. Show each length on a separate line unless they are the same. The gross length of the project is the length from beginning to end and is calculated as follows:

   - For paving, widening, or shoulder projects, show the project termini where the full width begins or terminates.
   - For resurfacing projects, show the project termini where the full thickness of resurfacing begins or terminates. However, where two resurfacing projects have overlapping transitions in thickness, the second project should begin at the end station of the first project so that a section will not be shown as unimproved.
   - Show the length of a structural project as the centerline distance between the back-to-back of abutments. This length should be constituted as an omission from a paving project.
   - Grading sections will normally have the same limits as the paving section with the same basic section designation.
   - Measure project lengths for divided highways or one-way facilities along the northbound or eastbound roadway.
   - Only show the length for mainline. Do not include the length of improvement along an intersecting side road or street unless the side road improvement is a separate project. If it is a separate project, show separate gross and net lengths.

   The net length of the project is the gross length minus any omissions.

9. Project Approval Block. Provide a project approval block in the mid to lower right-hand corner of the sheet. The approval box should include:

- the Regional Engineer's signature;
- the Engineer of Design and Environment's signature;
- the Director of the Office of Highways Project Implementation's signature; and
- the date for each of the above signatures.

Note. The above signatures may be hand-written (i.e. "wet"), stamped, scanned or computer-generated.

10. Consultant Projects. For consultant design projects, provide the consultant's company name, professional engineer's signature, date of their license expiration, and their professional stamp/seal in the lower right-hand corner of the sheet to the left of the State approval box. The engineer's signature may be hand-written (i.e. "wet"), stamped, scanned or computer-generated.

11. Authority Note. At the very bottom of the lower right-hand corner, include the following statement, "PRINTED BY THE AUTHORITY OF THE STATE OF ILLINOIS."

12. Utility Information. Information for contacting J.U.L.I.E. is included in the lower left corner of the sheet.

13. Design Designation. For all highway projects involving construction of new pavements, full structural overlays of existing pavements, or structurally designed widenings, the design designation should be shown somewhere on the cover sheet. The design designation is a simple notation to indicate the geometric and structural requirements for the highway. The design designation consists of three basics factors, which is explained with the following example:

Design Designation — 2150(16) Arterial 5.50 (PCC-20)

a. 2150(16). The first four digits represent the design hourly volume (DHV) that is anticipated for 20 years from the proposed date of construction. The last two digits shown in the parentheses represent the design year (2016). For some minor-type highways, the average daily traffic (ADT) for the year of construction may be used in place of the DHV. In this case, show the construction year in parentheses.

b. Arterial. This is the highway functional classification.

c. 5.50 (PCC-20). The first portion (5.50) is the structural design traffic factor (TF). The type of pavement and the structural design period, in years, are indicated in parentheses (PCC-20). The traffic factor represents the summation of equivalent 18 kip single-axle loads, in millions, used to convert mixed traffic to design traffic for the design year. The structural design period also should be included with flexible (HMA) pavement designation. For example, an HMA application would be designated as (FD-20) with the “FD” indicating a full-depth (HMA) pavement and the number 20 indicating a structural design period of 20 years.

14. Structural Pavement Design Information. Structural pavement design information generally should be included on the typical section sheet, but it may be included on the cover sheet. See Section 63-4.05 for information on the structural pavement design information block.

15. Miscellaneous Information. Include the names and phone numbers for the State project engineer, designer, etc., along the left side of the sheet.

63-4.02(b) Section Designation

Each highway improvement is identified by a section number which denotes the type of work being done and a numbering system indicating the continuity of the original work along the route. On Interstate routes, these numbers must proceed from west to east on even-numbered routes or from south to north on odd-numbered routes. Interstate routes are further typified by a number identifying the county in which the work is being done. In counties where the work will be done on the same route by two districts, the Regional Engineers should confer on section designation to avoid duplication. The section designation should always appear on the cover sheet of the plans and in the sheet index block in the lower right-hand corner of all other plan sheets. The section designation should not exceed 30 characters. Figure 63-4.A shows, alphabetically, the counties by code number, and Figure 63-4.B lists the suffixes used to denote the work type.

Where more than one section of a certain work type occurs within the limits of a basic section number, a second numerical suffix should be added to distinguish between the projects (e.g., 60-5HB-1, 60-5HB-2).

County Section	County	County Code		County Section	County	County Code
1	Adams	001		52	Lee	103

WS	Weigh Station
WSP	Weed Spraying
X	Paving Gaps
Y	Widening Shoulders and Ditches
Z	City Pavement

SUFFIXES FOR WORK TYPES

Figure 63-4.B
(3 of 3)

More than one suffix may be used for a single section designation; however, to facilitate the processing of work by the data processing equipment, the section designation must be held to a maximum of 30 characters. For example, where widening and resurfacing are done in one section, indicate it as: "Section (102, 103) (W, RS)." Where widening and resurfacing are separate sections, indicate it as: "Section (102, 103) W, RS."

Within the corporate limits of municipalities, use continuous or consecutive section designations, with the letter "Z" suffix at those locations where the original construction was completed and financed by a municipality or agency other than the State. In addition to the letter "Z" suffix, also add other standard suffix letters indicating the type of improvement.

HMA resurfacing projects by district designation should not contain a reference in the section designation to the type of patching (concrete or HMA) nor should the word "intermittent" be used. Show the section designation as "District *(#)* HMA Resurfacing (*year*) — 1, 2, 3" only if the work involved is located on more than three routes. Other special types of projects such as district-wide guardrail installation, weed spraying, etc., should use similar designations. For bridge repair projects involving multiple locations, use "Bridge Repair — (*year*)" instead of listing each section number.

In the Cook County metropolitan area, the established coordinate system of indicating sections will be acceptable.

63-4.03 Index of Sheets, *Highway Standards*, General Notes, and Commitments

For most projects, Sheet Two will provide a sheet index, list of *IDOT Highway Standards* used, the general notes, and a list of commitments for the project. The information should be clearly labeled "INDEX OF SHEETS, LIST OF ILLINOIS DOT HIGHWAY STANDARDS, GENERAL

NOTES, COMMITMENTS," and placed in order from left to right on the sheet, respectively. For small projects, the sheet index and the *IDOT Highway Standards* list may be included on the cover sheet. The general notes and commitments may be shown elsewhere in the plans.

63-4.03(a) Index of Sheets

The index of sheets indicates the major groups of sheets and those subgroups necessary to facilitate locating each item in the plans. Section 63-3.04 provides the proper order for listing the plan sheets and the appropriate subject breakouts.

63-4.03(b) Highway Standards

The list of Highway Standards for each set of plans is unique and is used to indicate which Standards apply to the project. The designer need only provide the list since the actual Highway Standards will be inserted at the Central Office. The Standards should be listed in numerical order and include the appropriate revision number. The revision number should not be included when referencing the Standard number elsewhere in the plans.

63-4.03(c) General Notes

General notes are used to provide the information necessary for plan users to obtain a complete understanding of the plans. Examples of information that general notes should be used to address include:

- descriptions of work to be performed, or items to be removed, by someone other than the contractor;
- instructions for the contractor on items not to be disturbed, or other such commitments for which the contractor needs to be made aware;
- assumed application rates or unit weights used as the bases for plan quantities of surfacing materials; and
- instructions for interpreting the plans.

General notes should be used with restraint and should not be used to emphasize or otherwise address subjects already covered in the *Standard Specifications, Supplemental Specifications,* or Special Provisions. General notes should also not be used to create or modify a pay item (a special provision is the best way to do this). Further, all general notes used in a set of plans should be of equal importance so it unnecessary to box-out, embolden, or otherwise highlight any note.

Notes that relate to specific details may be shown on the appropriate sheet (e.g., a specific plan and profile sheet, or detail sheet). Section 63-4.03(d) provides a sample listing of notes that are commonly included within a set of plans.

63-4.03(d) Sample General Notes

The following are samples of general notes used by the Department:

1. 10 FOOT TRANSITIONS SHALL BE USED TO MATCH THE PROPOSED CURB & GUTTER TO THE EXISTING.

2. ALL GUTTER OUTLETS SHALL BE EXTENDED TO THE DITCH FLOW LINE.

3. ALL ELEVATIONS IN THE PLANS ARE BASED UPON THE NORTH AMERICAN VERTICAL DATUM OF 1988 (NAVD88).

4. THE EXISTING BUILDING AT STATION 3+00, 125' RT WILL BE REMOVED BY OTHERS.

5. STORM SEWER WATER MAIN IS TO BE USED AT LOCATIONS WHERE LATERAL SEPARATION BETWEEN THE SEWER AND WATER MAIN IS LESS THAN 10 FEET AND THE WATER MAIN INVERT IS LESS THAN 1.5 FEET ABOVE THE TOP OF THE STORM SEWER.

6. AN HISTORIC STONE ARCH STRUCTURE IS LOCATED AT STATION 135+62. DURING RESURFACING OPERATIONS WITHIN 150 FEET OF THIS STRUCTURE, ALL ROLLERS SHALL BE OPERATED IN STATIC MODE. ALL DENSITY REQUIREMENTS SHALL STILL APPLY.

7. THE CONTACT NAME AND TELEPHONE NUMBER OF THE RAILROAD ENGINEER FOR THE XYZ RAILROAD IS _________________________________.

8. THE BITUMINOUS MATERIAL PRIME COAT QUANTITIES HAVE BEEN DETERMINED USING AN APPLICATION RATE OF 0.10 GAL/SQ YD (0.5 L/SQ M).

63-4.03(e) Commitments

A commitment is a documented obligation or promise, made by a properly authorized representative of the Department, for carrying out a specific action or actions affecting the planning, design, land acquisition, construction, or operation of a highway project. A commitment involves special consideration and action(s) beyond what is routinely required for project development/implementation. Section 63-1.02(a) further describes these commitments. When commitments affect construction operations, the designer includes a brief note describing the commitment – e.g., "TREES RIGHT STATION 11 + 25 ARE TO BE LEFT IN PLACE."

63-4.04 Summary of Quantities

63-4.04(a) General Layout

The Summary of Quantities (SOQ) sheets summarize all pay items necessary to construct the improvement. It also includes the applicable construction type codes, pay item code numbers, units of measure, total quantities, and quantity breakdown for each section. One or more SOQ sheets typically will be included in each set of plans. Do not show other data on the SOQ sheets (e.g., general notes).

The designer should arrange the pay items in the SOQ, estimates, and schedule of prices so that those with a straight numerical prefix precede those with an alphabetical prefix. It is often necessary to insert additional items after the plans have been prepared. For this reason, items in the summary of quantities and estimate should be double spaced to allow insertion of any further item without disrupting the numerical sequence.

Chapter 64 presents the guidelines for determining plan quantities. When preparing SOQ sheets, it is important that all quantities be calculated and broken down accordingly prior to completing the SOQ sheets. The designer should prepare the SOQ sheets according to the following guidelines:

1. Construction Type Codes. To properly identify the type of construction, the Department uses a coding system based on several elements. These elements are explained in Section 63-5. The applicable construction code should be shown with the appropriate quantity breakdown.

2. Pay Item Code Number. Every pay item has a unique assigned number for data processing. This code number is located in the *IDOT Coded Pay Items*, which is tied to the *IDOT Standard Specifications*. Section 63-4.04(b) describes the Department's coding procedures and how new items can be added. Do not place "dummy" numbers on the SOQ sheets.

3. Description. A descriptive title is applied to every code item. A complete listing of the appropriate titles can be found in the *IDOT Coded Pay Items*. Only these item descriptions should be used on the plans.

4. Unit. The appropriate pay unit should be placed on the sheet after the item description. The *IDOT Standard Specifications* provide the pay units that may be used for each item. Use abbreviations for the units. (Metric units are shown in lower case except for liter (L) and those derived from proper names, e.g., newton (N)).

5. Total Project Quantities. The first column is the total of all breakdown quantities or, for projects with only one construction type code, it may be the only column. For sheets prepared on the computer, the total column will be automatically calculated by the computer. Place all columns for project breakdowns to the right of the total quantity column.

6. Breakdown Quantities. Develop separate project quantities for each of the breakdowns listed in Section 63-4.04(c). If there is only one condition, then additional breakdown columns will not be necessary.

7. Rounding (Total Quantities). Chapter 64 provides the criteria for rounding quantities prior to their incorporation onto the SOQ sheet.

8. Rounding (Breakdown Quantities). Where quantities are expressed in whole units for the total project quantities, it is permissible to round the breakdown quantities to the nearest tenth of a unit (i.e., 0.1).

9. Specialty Items. Certain items of work require specialized knowledge, skills, or equipment that are typically outside the general contractor's expertise (e.g., electrical work, traffic signals, pavement markings on a paving contract, blasting on a bridge contract, paving work on an electrical contract, etc.). Clearly mark Specialty Items in the Summary of Quantities.

63-4.04(b) Construction Pay Items

To permit utilization of the data processing equipment when preparing the Engineer's and detailed estimates; schedule of price sheet for proposals; unit and weighted average prices; and partial, semi-final, and final payment estimates; the designer should ensure that all pay items are number coded and titled appropriately. The appropriate codes and titles are provided in the *IDOT Standard Specifications* and the *IDOT Coded Pay Item Book*. The Specifications and/or special provisions must address the basis of payment for all contract pay items.

Non-standard pay items in the *IDOT Coded Pay Item Book* are noted with an asterisk (*) after the code number and are not covered by the *IDOT Standard Specifications*. Therefore, a special provision, plan note, or detail will be required for clarification. In most cases, it will be possible by writing a special provision to use an existing pay item and its corresponding code number. However, where it is necessary to include coded pay items for a type of work not related to any item in the coded pay item books, list the item last in the summary of quantities and write up a justification for the new item. The designer should then forward the request to the District Estimating Engineer, who reviews it to determine if another item can be used (e.g., by special provision). If not, the District Estimating Engineer requests a new item (and code number) from the Central Office. The Project Management Unit of the Bureau of Design and Environment will assign a new code number and item description.

The code number consists of eight digits (metric - the letter "M" and seven digits). The first three digits indicate the corresponding section in the *IDOT Standard Specifications*. For example, code number 35101500 (M3511500) corresponds to "Section 351. Aggregate Base Course" in the *IDOT Standard Specifications*. The remaining digits of the code number indicate the numerical sequence the number has in the *IDOT Coded Pay Item Book* section.

A number of pay items, contained in the coded pay item books, are identical except for the numerical codes. For example, "Bituminous Materials (Prime Coat)" has code numbers identifying it according to the type of work being done. The purpose of this is to make possible cost analyses of the various types of work. However, when the quantities are small, the pay items which are identical, except for the numerical code number, should be combined and identified by the code number of the type of work that requires the largest quantity.

63-4.04(c) Quantity Breakdowns

To present the data necessary for cost accounting, the designer must segregate and tabulate the plan quantities for various accounts. Quantity breakdowns will be made on the SOQ sheets in accordance with the following:

1. Construction Type Codes. If a project consists of two or more construction type codes, a breakdown will be required for each code. Section 63-5 describes these codes.

2. Projects. Two or more projects may be combined into one plan set. In this case, separate breakdown columns are required for each project.

3. Funding Appropriations. If the project consists of more than one funding appropriation (e.g., NHI-BRF-320-1( )), the quantities will be segregated according to each appropriate funding type.

4. Urban/Rural. Where a Federal and/or State project crosses an urban boundary, provide separate breakdowns for both the urban and rural portions of the project. Urban boundary locations can be obtained from the district programming section.

5. Counties. Where a Federal and/or State project crosses county lines, provide separate breakdowns for the portions in each county. Project termini coincident with county lines should be shown entirely within one county. If the project is in more than three counties, show it as “various counties.” For projects that involve bridges that are on the county line, show it in the county designated by the structure number.

6. Joint Agreements. Where there is local participation involved (e.g., city, village, county), breakdown the quantities according to the joint agreement and designate them in the SOQ sheet under a separate heading for each local agency.

7. Traffic Signal Improvements. Where there is one Federal-aid route at two or more locations and local participation is involved, it will be necessary to break down each location and the percentage of participation by each locality. In addition, break down the quantities according to the traffic signal work type.

8. Non-participating Work. Where non-Federal-aid work is included in a Federal-aid project, it should be segregated and identified as such. It is Department policy to consider all maintenance type work (e.g., cleaning storm sewers, cleaning drainage structures) as non-participating, and noted as such.

9. Bridge Approaches. Include bridge approach work with the applicable structure construction-type code.

63-4.04(d) Schedule of Quantities

A tabulation of the quantities may be included after the summary of quantities sheets. These tabulations are highly desirable because they simplify the checking of plans, help the contractor and resident engineer to locate quickly the items in the field, and aid in the determination of final quantities used in the improvement. The tabulations should show the location of the item by station and quantity at each location.

All items not included in the typical section should be considered for tabulation. However, judgment should be used in determining which quantities to tabulate based on continuity of the items or their appearance at relatively few locations. Always tabulate items that are scattered throughout the plans or are located at intermittent locations throughout the improvement (e.g., pipe culverts, structural concrete, reinforcement bars, drainage structures). For items in a schedule of quantities that are shown elsewhere in the plans, place a note to this effect in a conspicuous location near the tabulation. A bill of materials, such as is shown on bridge plans or culvert headwall standards, does not include pay items per se and should not be considered as a duplication in the schedule of quantities.

63-4.05 Typical Sections

One or more typical sections are included in the plans to show details and dimensions for roadway surfaces, bases, subbases, subgrade treatments, shoulders, gutters, curb and gutters, medians, sidewalks, ditches, back slopes, and ROW. When preparing the typical sections, the designer should consider the following:

1. Number of Typical Sections. Provide a separate typical section for each of the following conditions:

   - tangent sections;
   - superelevated sections, show the full superelevated section from PC to PT and note the superelevation transition stations;
   - where there are changes to the pavement structure;
   - where there are changes from a curbed section to a non-curbed section or vice versa;
   - changes in pavement widths, including transitions;
   - changes in pavement cross slopes;
   - cross section changes (e.g., shoulder additions, turn lanes, median changes);
   - driveways and side roads which have a significant length of reconstruction; and

- specially constructed detours; show the proposed ultimate development by the use of dashed lines.

2. Orientation. Orient all typical sections horizontally (landscaped) on the sheet.

3. Scale. Draw the typical sections to a suitable scale to show all necessary details. The vertical dimension may use a larger scale for clarity.

4. Order. Show the mainline typical section first, followed by the other sections in the order they appear, in increasing stations, along the mainline.

5. Titles. Show the name of the road or street to which the typical section applies directly below the typical section number or letter. Alphabetize or number sequentially each typical section.

6. Station Limits. Always note the station limits for which the typical section applies directly below each typical section. Also include the station limits for back-to-back of abutments.

7. Cross Section. The typical section cross-section view should show the following elements:

   - the grading template;
   - profile grade line reference, especially where the profile grade line is other than the centerline;
   - surfacing templates for immediate and future development;
   - top widths of surfacing shown to the nearest tenth of a foot (i.e., 0.1 ft) (hundredth of a meter (0.01 m));
   - types of surfacing and thicknesses shown to the nearest ¼ of an inch (millimeter); and
   - pavement cross slopes (% or inches/foot – US Customary, % – metric), dimensions, and slopes necessary to define the typical section.

8. Base Thickness. Show variations in base or subbase thickness due to soil conditions or other reasons in a tabular form and include the station limits for each thickness. In such cases, the typical section only shows the varying thickness.

9. Notes. Include only the design and construction notes that are pertinent to the specific typical section on the typical section sheet. General notes should be shown on the general notes sheet.

10. Notations. Where appropriate for clarity, the various typical section elements (e.g., "P.C.C. SIDEWALK 4 in (100 mm)") may be noted using numbers within circles. If this

approach is used, provide a complete legend on each page. Use the same number for each item throughout the typical section sheets.

11. Quantities. Note the applicable material type on the typical section (e.g., “HMA SURFACE COURSE, MIX “D”, N90.

12. Structural Pavement Design Information. Include the structural pavement design information block on the appropriate typical section sheet to allow checking of the pavement design. For those projects that have two or more roadway segments with different design data, provide separate design information blocks for each segment. The project route design information block always should be shown first. For highway grade separations, provide separate design information blocks for each facility. Figure 63-4.C illustrates the recommended format for a structural pavement design information block.

STRUCTURAL DESIGN TRAFFIC:		Year __________	
	PV = __________	SU = __________	MU = __________
ROAD/STREET CLASSIFICATION:		Class __________	
PERCENT OF STRUCTURAL DESIGN TRAFFIC IN DESIGN LANE:			
	P = __________	S = __________	M = __________
TRAFFIC FACTOR:	Actual TF = ____________	Minimum TF = __________	
PG GRADE:	Top Binder = __________	Lower Binder = ___________	
	Surface = ___________		
SUBGRADE SUPPORT RATING:			
	SSR = __________ (Sta. __________ to __________)		
	SSR = __________ (Sta. __________ to __________)		

Notes: See Chapter 54 for information on how to determine the appropriate pavement values.
For non-mechanistic designs use IBR in place of SSR.

RECOMMENDED STRUCTURAL PAVEMENT DESIGN INFORMATION BLOCK

Figure 63-4.C

63-4.06 Alignment, Ties, and Benchmarks

For new pavement, reconstruction, or realignment of the existing pavement, an alignment, tie, and/or benchmark sheet will be required. These sheets are used to locate the construction control points during all phases of construction. In preparing these sheets, the designer should consider the following:

1. Alignment. On complex projects, a separate alignment sheet may be provided showing the existing and proposed horizontal alignment with the appropriate curve data and other pertinent information. For most projects, this information will typically be provided on the plan view sheet.

2. Reference Ties. Reference ties will generally be required on every project. They generally should be combined on one sheet. However, for simple projects, they may be included on the plan sheets. Figures illustrating the reference tie point locations may be

simple or detailed schematics with the appropriate dimensions and tie points identified, including the stationing and applicable control tie (e.g., POT, PI, PT, PC). Show reference ties having locations tied to the mainline first, by increasing station, followed by ties to other lines in the order they appear along the mainline. Clearly identify the feature to which the ties are referenced (e.g., iron pin 18 in. (0.5 m) deep, corner of wall). Tie figures are generally not drawn to scale. If included within the plan view and if too congested with other topography, transfer the tie figure to an insert directly under the point involved. At least three reference ties are required to each point. Note the tie distances to the nearest 0.01 ft (5 mm). The reference ties should be to features that are not affected by construction.

3. Benchmark Data. Benchmark tabulations should show the station, location, description, and elevation of each benchmark. Show mainline benchmarks first, followed by benchmarks to other facilities in the order they appear along the mainline. Clearly identify the road or line to which a group of benchmarks is referenced. Show elevations in feet to two decimal places (i.e., 0.01 ft); show elevations in meters to three decimal places (i.e., 0.001 m). Provide a detailed description to locate the benchmark used for the level datum source. The description should include the benchmark location, elevation, number, and any other pertinent information.

63-4.07 Plan and Profile Sheets

The plan and profile sheets are the basic design sheets used by the designer to illustrate the horizontal and vertical alignments and to depict the construction items and the topography necessary for construction. Therefore, the designer must ensure that these sheets are drawn with clarity and are as simple as practical, but still provide the necessary information to construct the project.

63-4.07(a) General Guidelines

The following provides general guidelines for the preparation of the plan and profile sheets:

1. Views. For rural and simple urban projects, the Department’s practice is to show the plan and profile views on the same sheet. The plan view is presented in the upper half of the sheet with the corresponding profile view presented directly below it. For most urban projects and complex rural projects (e.g., interchanges), the plan and profile views may be shown on separate sheets. Two or more profiles may be shown on the separate profile sheet. Unless necessary for clarity, the proposed improvement should be superimposed onto the existing topography (i.e., do not provide separate views for the existing and proposed improvement).

2. Sequence of Sheets. Show the plan and profile sheets for the mainline first in increasing stations. Project stationing progresses from South to North and West to East. Do not interrupt the mainline plan and profile sheets with sheets for other facilities (e.g., side roads, detour roads, frontage roads, railroads) or for other detail sheets (e.g., plan

quantities, general notes, drainage details). Insert and cross reference the plan and profile sheets for other facilities after the mainline sheets in the order they appear along the mainline. For those projects using separate sheets for the plan view and the profile view, place the profiles directly after all the plan view sheets. The profile views should appear in the same order as the plan view sheets.

3. Labeling. It is desirable, but optional, to label all plan and profile sheets in the lower right corner so that the plan user can readily determine what plan and/or profile is being shown (e.g., Route 34 — Stations 10 + 25 to 25 + 00).

4. Sheet Overlap. Use matchlines on each sheet (i.e., the plotting should not overlap the beginning and end of successive sheets).

5. Plotting Limits. In general, plot the survey 500 to 1000 ft (150 m to 300 m) beyond the proposed project limits. Where applicable, provide the station equation between the new and old stationing.

6. Note Orientation. Write all notes and dimensions horizontally from left to right, except for the following:

   a. Plan Views. The following apply:

      - Dimensions may be written parallel or perpendicular to the element (e.g., property lines, lane widths).

      - Stationing, at 100 ft (50 m) intervals, is placed parallel with the centerline and noted directly beside the tick mark. Intermediate station callouts (e.g., taper termini) should be written perpendicular to the centerline.

      - Curve data is placed radially on the inside of the curve. However, show all curve control points, stationing equations and angles horizontally.

      - Names for specific items may be written parallel with the feature (e.g., street names, river names).

   b. Profile Views. Elevations for the various features are shown vertically, including the elevation at the stationing intervals.

   c. Special Considerations. Where limited space for notes and dimensions makes horizontal placement detrimental to the readability of the plans, they may be placed vertically.

7. Use of Notes. Keep notes on plan sheets brief, clear, and consistent. Installations and removals should be noted by station with a brief description. Include detailed descriptions on the general note sheet not on the plan and profile sheets.

8. Drafting Details. See the *IDOT Computer Aided Design, Drafting, Modeling and Deliverables Manual for* the location of the roadway cell library that contains the

topography symbols and additional cells that should be used in preparing plan and profile sheets. The *Computer Aided Design, Drafting, Modeling and Deliverables Manual* also provides additional information on plotting details. The *IDOT Highway Standards* provides the recommended abbreviations that should be used on both roadway and structure plans.

9. Key Maps. If the location of the plan section shown is confusing relative to the rest of the project or does not follow in a logical sequence, provide a “Key Map” or a schematic layout as a guide. Because the purpose of any layout or key map is to simplify otherwise confusing aspects of the plans, keep the level of detail to a minimum. One or more key maps may be required.

10. Bridges. On plans for highway grade separation structures, show the plan and profile views of both roadways.

63-4.07(b) Plan View

The following presents the recommended guidelines for preparing the plan view sheets:

1. Centerline. The following should be noted relative to the centerline:

    - Desirably, the survey line should be the centerline of the proposed facility. Where the two do not coincide, indicate their relationship at the beginning and end of the sheet and at all major control points.

    - On divided highways with independent alignments, the centerlines are generally treated as separate roadways. Note the relationship between the centerlines somewhere on each sheet.

    - Use “tick” marks along the centerline at 100 ft (50 m) intervals. Note the station beside the tick mark.

2. Centerline Layout. When laying out the centerline on the plan sheets, the designer should consider the following:

    - Where an alignment is on a tangent, the centerline or survey line should parallel the profile line and be centered vertically in the plan view.

    - Where the alignment is on a curve, angle the tangents to produce a reasonable balance. Desirably, show the entire curve on the same sheet, even if this requires starting a new sheet and leaving part of the preceding sheet blank. If practical, show the PI on the same sheet.

    - The stationing should progress from left to right (i.e., South to North, West to East).

    - Provide separate survey lines for interchange ramps and rest areas.

3. Scales. For rural facilities, typically use a scale of 1 in. = 50 ft (1:500 metric). For urban facilities, depending upon the complexity of the location and work to be accomplished, use a scale of 1 in. = 20 ft (1:250 metric). Other scales may be used to improve the clarity of the plans or for practical purposes.

4. Horizontal Alignment Data. Chapter 32 presents the criteria for horizontal alignment. The horizontal alignment data should be presented in the plans as follows:

   a. Horizontal Curve Data. Place the horizontal curve data, including superelevation, on the plan sheet to which it applies. Figure 63-4.D presents the order and rounding accuracy that should be used to present the curve data.

   b. Superelevation. Show the rate of superelevation on the plan sheets. In the transition portion of superelevated curves, provide superelevation data at 25 ft (10 m) intervals to facilitate construction staking. Elevations of the pavement edges and superelevation rates may be included in a separate table on the plan/profile sheets and/or in special detail sheets. Also, include detailed information and sketches for superelevation transition lengths in the detail sheets.

Simple Curve Data	Accuracy	
	US Customary	Metric
PI	0 + 00.01 (ft)	0 + 000.001 (m)
Δ	00° 00′01″	00° 00′01″
R (existing)	0.01 ft	0.001 m
R (new)	15 ft	5 m
T	0.01 ft	0.001 m
L	0.01 ft	0.001 m
E	0.01 ft	0.001 m
e	0.01%	0.01%
T. R.	1 ft	1 m
S. E. Run	1 ft	1 m
P.C. Sta.	0.01 ft	0.001 m
P.T. Sta.	0.01 ft	0.001 m

HORIZONTAL CURVE DATA
(Plan Sheets)

Figure 63-4.D

   c. Curve Points. For all curve control points, show perpendicular lines from the centerline on the inside of the curve. Indicate these control points with small circles, approximately 0.1 in. (2.5 mm) in diameter. Indicate the curve notation (e.g., PC, PT, PI) and station to the nearest hundredth of a foot (i.e., 00 + 00.01) (thousandth of a kilometer (i.e., 0 + 000.001)) along the perpendicular line. Also show the coordinates of the control point if a coordinate system has been established for the project.

d. Deflection Points. Where deflection points are used in place of a horizontal curve, show the deflection angle to the nearest second (i.e., 00° 00′ 01″). Also include the coordinates, if available.

e. Equations. Equations are used to correct any stationing differences that may occur along the centerline. Show these stationing equations with a small circle on the centerline (0.1 in. (2.5 mm) diameter). Place the station equation at a location on the sheet near the control point and where it can be easily read. Draw a line from the station notation to the point on the centerline.

5. Widths. Note all pavement widths at the beginning and end of each sheet and wherever there is a change in width (e.g., turn lanes, acceleration lanes, truck climbing lane) to the nearest tenth of a foot (meter) (i.e., 0.1 ft (0.1 m)). Individual lane locations are generally not shown on the plan view. They are generally shown on the pavement marking sheets.

6. Topography. The *Computer Aided Design, Drafting, Modeling and Deliverables Manual* presents the topography features that should be shown on the plan sheet. This includes utility and drainage features, buildings, streams, railroads, wells, and other elements affected by the roadway improvement. Trees and other landscaped elements should be shown graphically. In general, show existing elements with light, dashed lines and proposed elements as darker, solid lines.

7. North Arrow. Show the appropriate district North arrow on each plan sheet. The roadway cell library provides cells for each district North arrow.

8. Items to be Removed. Show items within the right-of-way limits that will be removed with cross hatching. Clearly note those items that will be removed by others.

9. Station Call Outs. Provide station call outs at the following locations:

- beginning and ending points of the project;
- match lines with other projects;
- omissions from paving and station equations;
- 100 ft (50 m) station increments;
- horizontal curve points (e.g., PC, PI, PT);
- beginning and ending points of tapers, including the distance and direction from the centerline;

- construction limit locations and right-of-way breaks, including distance and direction from the centerline for right-of-way breaks;
- curb returns for entrances and intersections, including distance and direction from the centerline;
- entrance locations, including the type, width, and surface material of the entrance;
- special or atypical construction applications that cannot be determined by other means (e.g., short sections of curb and gutter replacement, sidewalk replacement, termini for milling, sign removals);
- side street intersections;
- permanent survey and right-of-way markers, including the distance and direction from the centerline;
- section line ties, right-of-way takes, etc., including the distance and direction from the centerline; and
- other locations where appropriate.

Show all distances from the centerline to the nearest one-half foot (i.e., 0.5 ft) (tenth of a meter (i.e., 0.1 m)) unless greater accuracy is required (e.g., horizontal curve data, right-of-way takes).

10. Utilities and Drainage. In general, separate plan and profile sheets should be provided for all proposed drainage and utilities improvements. These sheets are discussed in Section 63-4.09. Where the drainage or utilities features affect construction, these features may be shown on the plan view (e.g., removal of existing culvert, patching for new utility lines). For these situations, note the type and size of the drainage or utility feature (e.g., 1 ft (300 mm) gas line).

11. Right-of-Way. Where right-of-way acquisition is necessary, consider using separate right-of-way sheets to show this information; see Section 63-4.10. Existing and proposed right-of-way limits, however, are always shown on the plan view. Where separate right-of-way plans are not included, note the following on the plan view:

- the dimensions of the property to be acquired;
- station ties to property lines;
- property ownership lines, parcel numbers, and property owners names;
- breaks in the right-of-way alignments, including the station and distance from the centerline;

- all temporary and permanent easements necessary to accommodate intersecting roads and streets, access roads, temporary runarounds, detours, drainage areas, material storage areas, slope widenings, utilities, railroads, or other special uses;

- where the control of access limits do not coincide with the right-of-way limits;

- location of right-of-way markers; and

- any pertinent data affecting the cost of the right-of-way (e.g., structures, businesses, access roads, improvements, fences).

12. Access Lines. On projects where the access rights have been or will be acquired, show all approved points of entry to or exit from the traffic lanes. List each approved point of access, other than those by a ramp at an interchange, by entrance centerline station in a tabular form and by symbol at the appropriate point. Show both the control of access line and the right-of-way line even where such lines are coincident. If control of access is accomplished by constructing a frontage road, it will not be necessary to draw in detail the entrances to the frontage road from the property abutting the highway right-of-way. In these cases, show the control of access line between the frontage road and the mainline facility. Show any access points between the frontage road and the mainline facility in detail. If an approved point of access is a temporary measure under stage development, identify it with an appropriate note as to how it will be eliminated in the future.

13. Guardrail. Show the locations for new and existing guardrail on the plan view.

14. Side Roads and Entrances. When showing side roads and entrances on the plan view, the following apply:

    - Use light, dashed lines to present existing public roads and entrances.

    - For public facilities, note the route number or street name on the side facility. Label private entrances “Private” or “PE,” field entrances “Field” or “FE,” and commercial entrances “Commercial” or “CE.”

    - Outline commercial entrances in detail with dashed lines to show current usage.

    - Note the type of existing surface material.

    - For intersections with public roads, show the angle of intersection from side road centerline to the mainline centerline.

    - Provide the width of the intersecting facility.

    - Indicate the direction of flow in the drainage ditch with an arrow.

15. Special Details. Where special details are required (e.g., steps, retaining walls, pavement joint repair), note the sheet where the detail can be found. In general, do not include the detail on the plan sheet.

16. Miscellaneous. All features, not listed above, should be labeled and, where necessary, the applicable station called. Also, note the distance and direction from the centerline. Some of these elements may include:

- sidewalks (e.g., “6 ft (1.8 m) PCC SW, HANDICAPPED RAMP”);
- curb and gutter (e.g., “COMB. CONC. CURB & GUTTER, TY-B”);
- special paving instructions (e.g., “CLASS B PVMT PATCH”);
- special instructions (e.g., “DO NOT REPLACE EXISTING SIDEWALK”);
- construction done by others (e.g., relocation of utilities); and/or
- fencing (include size and type).

63-4.07(c) Profile View

The profile should present the existing survey gradeline and proposed improvement profile. The following presents the recommended guidelines for the profile view:

1. Location. The profile typically represents the vertical plane intersecting the finished surface of the pavement wearing course or the top of the subgrade along the centerline of the proposed improvement. Add a note on each profile view to indicate whether the profile grade line represents the pavement surface or the top of the subgrade. Where the profile does not represent the centerline, note its actual location on each profile view.

2. Scales. The profile horizontal scale should use the same scale as the plan view. The vertical profile scale is generally 1″ = 5′ (1:60) or 1″ = 10′ (1:120).

3. Existing Ground Line. Plot the existing ground line with a dashed line to the nearest 0.1 ft (0.01 m) and existing pavement surfaces to the nearest 0.01 ft (0.001 m). If the centerline is not on the existing pavement but the existing pavement is nearby, plot the profile of the existing pavement, but do not record the elevations.

4. Vertical Alignment Data. Chapter 33 presents the criteria for vertical alignment. The vertical alignment data should be shown in the plans as follows:

   a. Vertical Curve Notations. Depict the VPC and VPT on the profile grade line with small circles (approximately 0.1 in. (2.5 mm) in diameter). Use a small triangle for the VPI with short segments of the vertical tangents. VPI notes should provide the VPI station (to the nearest hundredth of a foot — 00 + 00.01 (thousandth of a meter — 0 + 00.001)), the elevation (to the nearest hundredth of a foot — 0.01 ft (thousandth of a meter — 0.001 m)), the vertical curve length (see Comment b. below), and “E” distance — the vertical distance (offset) between the VPI and proposed roadway surface (to the nearest hundredth of a foot — 0.01 ft (thousandth of a meter — 0.001m)). Do not include other vertical curve information (e.g., K-values, passing sight distances). Place the VPI notes horizontally above the profile for crest curves and below the profile for sag curves. The VPC and VPT stations and notations are generally not recorded.

b. Vertical Curve Lengths. Round the vertical curve calculations from Chapter 33 to the next highest 50 ft (10 m) increment. The existing vertical curve distance may be shown to the nearest one-half foot (i.e., 0.5 ft) (tenth of a meter (i.e., 0.1 m)).

c. Tangent Grades. Show tangent grades along the profile grade line to the hundredth of a percent (i.e., 0.01%). Positive grades should be shown with the "+" prefix and negative grades with the "-" prefix. A "+" prefix indicates that the grade is ascending from left to right.

5. Benchmarks. Show benchmark identifications and elevations along the top of the profile sheet at the approximate location they appear along the centerline (to the nearest hundredth of a foot — 0.01 ft (thousandth of a meter — 0.001 m)). The benchmark number and location should be fully described so that it can be easily located in the field (e.g., "BM #2 — ON NE BOLT OF FH ON NW CORNER OF 1ST AVE AND MAIN ST").

6. Elevation Labeling. Note the full stationing along the bottom of the profile sheet at 100 ft (50 m) stations. Show the survey elevations and proposed centerline elevations at 100 ft (25 m) intervals for rural projects and at 50 ft (10 m) intervals for urban projects. For vertical curves, use a closer interval. Show the elevations vertically along the station ordinate line to the nearest hundredth of a foot (i.e., 0.01 ft) (thousandth of a meter (i.e., 0.001 m)). The survey line elevation is to the left of the station ordinate line, and the proposed centerline elevation is to the right of the station ordinate line.

7. Pavement Edge Profiles. For drainage purposes and other reasons (e.g., superelevation), it may be desirable to also show the left and right pavement edges. Use a different line type to indicate these profiles (e.g., series of dashes and dots). Clearly label each profile line (e.g., "LEFT AND RIGHT PAVEMENT EDGE").

8. Undercutting. Only show undercutting on the profile where unsuitable material is being removed. Show this area with crosshatching. Note that the undercutting should only be shown to the top of the subgrade and not to the profile grade line. For each undercut location, note the station locations and the depth of excavation.

9. Drainage/Utilities Structures. In general, show the drainage and underground utility locations on the drainage profile sheets. However, for small projects with minimal drainage and underground utilities, these items may be shown on the mainline profile. Section 63-4.09 provides the information that should be incorporated.

10. Ditch Profile Sheets. If no drainage profile sheets are provided, supplemental profile sheets may be provided after the plan and profile sheets to illustrate special ditches and paved ditches. Note the gradient percentage, stationing, beginning and ending elevations, and elevations at all gradient changes. For rural projects, the ditch profiles can be shown on the mainline plan and profile sheets.

11. Bridges. At bridge locations, whether existing or proposed, the profile should include an elevation sketch (to scale) showing the elevations for the abutments, piers, the low vertical clearance point, high water level, and the stream bed.

12. Side Roads. Profiles for side roads may be provided on separate profile sheets or on the cross sections. If separate profile sheets are used, they should be provided after the mainline profile sheets and placed in the order they appear along the mainline. Clearly identify each profile view as to what street or side road the profile view applies. Entrance profiles are typically plotted on the cross sections.

13. Miscellaneous Profiles. Under special circumstances, it may be desirable to provide profiles for tops of curbing, sidewalks, detours, etc. Where these profiles are provided, use a different line type and clearly identify the profile.

63-4.07(d) Surplus Excavation Disposal

The contractor is to dispose of excess waste material, which results from construction operations, off the project right-of-way unless permission is received from the Engineer to place it within the project limits. In many cases it is acceptable to waste this material on the right-of-way when the placement does not adversely affect environmentally sensitive areas, safety, drainage, or aesthetics. When the designer knows that the construction operations will result in excess excavation, find locations within the project limits to place this material.

Consider the following factors when selecting locations:

1. Environmental. The area should not contain wetlands or other environmentally sensitive areas.

2. Drainage. The designer should be certain that drainage will not be adversely affected by any excavation placed on the project.

3. Safety. The wasted material should not create sight distance problems or mounds that could affect a vehicle that has left the roadway.

Areas where it may be permissible to waste this material include flattening front slopes, filling in depressions, interchange infields and in general the area between the top of the back slope and the R.O.W.

The designer should show the areas on the plans and include a schedule showing Station to Station, offset, thickness allowed, and quantity of material that can be wasted. The designer should also include the quantity of material that still needs to be wasted off of the project.

63-4.08 Stages of Construction and Traffic Control Sheets

The strategy for maintaining traffic during the roadway improvement will be described in the Phase I report. For minor projects (e.g., resurfacing, minor widening), the control of traffic can typically be addressed by referencing the applicable *IDOT Highway Standards*. For complex projects (e.g., major widening, extensive replacement of storm sewers), the designer must develop a more detailed set of traffic control plans, often with stage construction. The designer also must develop traffic control plans for projects with detours, runarounds, or other roadways specifically constructed for traffic control.

Where traffic control plans are required, the designer should use the existing topography plans to lay out the staging. A brief description of each construction stage should be provided. The traffic control sheets should include:

- the temporary roadway horizontal alignment;
- the temporary roadway profile gradeline;
- the temporary pavement needed to maintain traffic;
- the proposed area of construction for each stage;
- the temporary traffic lanes;
- signing for the work zone;
- temporary pavement markings;
- temporary roadside safety layouts;
- typical sections for each construction stage;
- a breakdown of work that should be performed during each stage;
- traffic control standards for each stage; and
- general notes for time frames, closures, etc.

63-4.09 Erosion and Sediment Control Details

Projects which disturb the ground have the potential to displace soil by storm events and typically require erosion and sediment control details to be included in the plans. For minor projects (e.g., SMART and 3P), erosion and sediment control, if needed, can typically be addressed by referencing the applicable *IDOT Highway Standards,* Article 107.23 of the *Standard Specifications for Road and Bridge Construction,* and by specifying the items in schedules.

For complex projects (e.g., 3R Projects) the above still applies and, in addition, an ILR10 NPDES permit (i.e. where the project disturbs more than one acre) may be required. This permit requires an Erosion and Sediment Control Plan that is submitted to and reviewed by the Illinois Environmental Protection Agency (IEPA) and is described as a “site plan” in the ILR10 permit. The following is required to be depicted on the plan:

- Project phases
- drainage patterns and approximate slopes anticipated before and after major grading activities,
- locations where vehicles enter or exit the site and controls to prevent offsite sediment tracking,
- areas of soil disturbance,
- the location of major structural and nonstructural controls identified in the plan,
- the location of areas where stabilization practices are expected to occur,

- locations of on-site or off-site soil stockpiling or material storage,
- surface waters (including wetlands), and
- locations where storm water is discharged to a surface water or Municipal Separate Storm Sewer System (MS4).

Note: For sites discharging to an MS4, a separate map identifying the location of the construction site and the location where the MS4 discharges to surface water must be included.

63-4.10 Drainage and Utilities Sheets

Drainage and utilities plan details are generally required for all jobs where drainage and/or utilities are involved. This includes constructing new drainage systems, expanding existing drainage systems, or adjusting existing drainage structures. Where the existing drainage and utilities are not affected by construction, then separate drainage and utility sheets will not be required.

63-4.10(a) Existing Information

If a Phase I report was completed, the existing drainage and utility information should have already been incorporated onto the existing topography plans and plotted using CADD. If the project does not have a Phase I report, then the information must be added to the plans during plan preparation. Information on the existing drainage can be found in the project survey books. Additional information can be obtained from copies of old plans. To determine existing utility locations, the designer must submit existing and proposed plans to the district utility coordinator. The district utility coordinator forwards the plans to the utility companies impacted by the project to obtain information on the utility locations. This submittal should occur as soon as practical during plan preparation because of the lengthy time frame to obtain utility information from the utility companies. Chapter 6 provides information on coordination with utility companies.

To incorporate the existing drainage information using CADD, provide the survey data to the district designer. The plans marked by the utility companies can also be provided to the district designer for plotting. If the project is not being drafted using CADD, then the information must be plotted manually. Typical symbols have been established for showing drainage and utility information and should be met when preparing the plans. These symbols are provided in the roadway cell library.

63-4.10(b) Proposed Design

Information on drainage design is included in Chapter 40 of the *BDE Manual*, the *IDOT Drainage Manual*, and the *IDOT Drainage Tables for Inlet Spacing*.

The designer should also review the information in the Phase I report. This report provides the locations of drainage outfalls for storm water and notes any drainage problems and the need for permits.

Permits may be required from the Metropolitan Water Reclamation District of Greater Chicago (District 1), the Division of Natural Resources, the Environmental Protection Agency, and the Army Corps of Engineers. The need for a permit is usually based on who has jurisdiction for the drainage outfall and the impact of the improvement on possible flooding and the environment. The designer must always assess the need for a permit for a project even though the Phase I report may not have specified a need. Chapter 28 provides additional information on permits.

63-4.10(c) General

Once the mainline plan and profile sheets have been prepared, the designer should use these sheets to plot the drainage and utility information. If the mainline plan and profiles are provided on separate sheets, then the drainage plan and profile sheets should also be provided on separate sheets. Only the information necessary to construct the drainage and utility items should remain on these sheets. The designer should ensure that the levels of all other superfluous information be turned off.

63-4.10(d) Plan View

The following information should be shown on the drainage plan view sheets:

1. Symbols. The roadway cell library provides the symbols that are used to denote the various utility and drainage lines on the plan view. Provide a legend of these symbols on the first drainage sheet. Legends should also be provided on every sheet if it does not hinder the sheet's clarity. Only use the appropriate abbreviations as presented in the *IDOT Highway Standards*.

2. Culverts. For culverts or cross drains, note the following on the plan view:

   - station locations for the ends, including direction and distance from the centerline;
   - culvert type;
   - pipe size and length;
   - flow direction;
   - skew angle;
   - upstream and downstream flow elevations (to the nearest tenth of a foot — 0.1 ft (hundredth of a meter — 0.01 m));

- end section or headwall type and size; and
- for existing culverts, the pipe size, material type, and any instructions to the contractor (e.g., “TO REMAIN IN PLACE,” “EXTEND EXISTING CULVERT”).

3. Structures. Structures are shown on the plan sheet with the general details provided in the profile view. Detailed design information will be provided in the structure plans.

4. Storm Systems. Show storm drainage systems or closed drainage systems on the plan view as follows:

   a. Storm Sewer Pipes. Note each run of pipe between manholes, inlets, catch basins, etc., according to its diameter, length (to the nearest tenth of a foot — 0.1 ft) (hundredth of a meter — 0.01 m), and gradient (to the nearest hundredth of a percent — 0.01%) (e.g., “24 in. SS x 20.5 ft @ +1.52%” (“600 mm SS x 6.28 m @ + 1.52%”)).

   b. Manholes, Catch Basins, Inlets. Provide the following information for these devices:

      - station location and direction and distance from the centerline;
      - the device type;
      - top of grate elevations (to the nearest hundredth of a foot — 0.01 ft (thousandth of a meter — 0.001 m)); and
      - invert elevations for all pipes (to the nearest hundredth of a foot — 0.01 ft (thousandth of a meter — 0.001 m)).

      As an option, the designer may provide a numerical symbol for each of the above devices and list the information in a tabular format on the sheet.

   c. End Sections. Note the type, size, and location offset from centerline for the end section on the plans.

   d. Existing Facilities. Note the proposed disposition of all existing facilities directly next to the facility or as a general note in the plans (e.g., “MANHOLE TO REMAIN”, “REMOVE OR ABANDON ALL EXISTING CATCH BASINS, INLETS AND MANHOLES”).

5. Ditches. Note special ditch locations with invert elevations at 100 ft (25 m) intervals on the earthwork cross sections and not on the drainage plan sheets.

6. Utilities. Note utility locations on the plan view as follows:

   a. Overhead. Where overhead utilities cross the centerline, note the centerline station where the utility crosses and the type of utility (e.g., telephone, electrical).

b. Underground. Where underground utilities are within the right-of-way limits, indicate the applicable centerline station, the type of utility, and the size and depth of the utility. All valve boxes, utilities manholes, etc., constructed by the contractor should be noted similarly as discussed for catch basins, manholes, and inlets in comment 4 above.

63-4.10(e) Profile View

The following provides the procedures for presenting the drainage and utility information on the profile view:

1. Profiles. Use the centerline profile where the plan and profile views are provided on the same page. However, where separate profile sheets are provided, provide separate profile views where two or more systems are located longitudinally along the project.

2. Profile and Elevation Labeling. The criteria for labeling the profile and elevations along the profile as presented in Section 63-4.07(c) also apply to drainage profiles.

3. Storm Systems. Show storm drainage systems or closed drainage systems on the profile view as follows:

    a. Storm Sewer Pipes. Note each run of pipe according to its diameter, type, length (to the nearest tenth of a foot — 0.1 ft (hundredth of a meter — 0.01 m)); and gradient (to the nearest hundredth of a percent — 0.01%) (e.g., “24 in. SS TY-2 85.5 ft @ -0.75%” (“600 mm SS TY-2 26.15 m @ - 0.75%”)). The pipe length is determined where all the above information is the same for the pipe. This pipe length may pass through manholes, catch basins, and inlets. If one of the above pieces of information changes, then provide a separate note for the pipe (e.g., where the gradient changes).

    b. Manholes, Catch Basins, Inlets. The following information should be provided for these devices:

        - station location and direction from the centerline;
        - the device type and size;
        - invert elevations for all pipes leading into and out of the device (to the nearest hundredth of a foot — 0.01 ft (thousandth of a meter — 0.001 m)); and
        - top of casting elevation.

        List this information vertically along the station ordinate.

    c. End Sections. All end sections should be shown with the following information:

- station location and direction from the centerline,
- the device type and size, and
- outflow elevation at the bottom of the pipe.

4. Utilities. The following apply to utilities:

   a. Work Conducted by IDOT. Underground utilities being moved or constructed by the Department's contractor should be noted on plan sheets similarly as discussed for storm drainage systems in Comment 3.

   b. Work Conducted by Others. Show only those utilities that are affected by the improvement. Clearly label the affected utility according to its type and size (e.g., 1 in. (25 mm) water main, 3 in (75 mm) gas line).

5. Ditches. Note the gradient percentage, stationing, beginning and ending elevations, and elevations at all gradient changes.

63-4.11 Right-of-Way Plan Sheets

Where additional right-of-way is required on the project, the designer should consider including the right-of-way plan sheets(or plat of highways sheets) within the plans. These drawings allow the designer to remove the right-of-way dimensioning from the mainline plan and profile sheets, thereby improving their clarity.

63-4.12 Intersection Details

The designer may be required to provide special plan views of large or complex intersections where the general plan and profile sheets cannot adequately illustrate the horizontal alignment details and elevation controls. Only the necessary information for the geometric layout should be provided (e.g., no topography should be shown). Intersection details generally use a 1-in. = 20-ft (1:250 metric) scale. Some of the elements shown on the intersection detail may include:

- pavement elevations to determine cross road profiles, drainage characteristics, etc.;
- lane widths;
- curb or edge of pavement radii;
- accessible curb ramps;
- turning radii for the left-turning design vehicle;
- location of median noses and islands;
- location of traffic signs (e.g., stop, keep right, one-way);
- location of traffic signal poles, mast-arms, loop detectors, etc.;
- pavement markings; and
- construction joint layout.

Clearly show the name of the intersection on the right side of the detail.

63-4.13 Pavement Marking Details

Pavement marking plans are required for all projects where work on the roadway will disrupt the existing pavement markings and where more detail is required than that shown in the *IDOT Highway Standards*.

It is the designer's responsibility to provide the plan view to the appropriate unit as soon as practical during plan development. The Bureau of Operations may or may not develop the pavement marking details depending on the project type, time constraints, and workload. If the Bureau of Operations does not develop the pavement marking details, the designer will be responsible for developing these details. If the designer develops the details, the pavement marking plans still must be reviewed by the Bureau of Operations.

Copies of the general plan sheets will be used to show the pavement markings. However, only show the proposed improvement. The existing topography, right-of-way, drainage information, etc., should not be shown. This allows the pavement markings to clearly stand out. In developing the pavement markings sheet, the designer should consider the following:

1. Labeling. Pavement markings that are not covered by the *IDOT Highway Standards* must be specified and labeled on the pavement marking sheet.

2. Dimensioning. Provide dimensions for lane and median widths. Show stations for all break points in the pavement markings or use dimension lines to locate and show the lengths of pavement marking lines.

3. Raised Reflectors. In addition to pavement markings, raised reflective pavement markers may be specified on a project. They are normally included on all projects where there is no lighting. Contact the Bureau of Operations to determine where they should be used. Raised reflector locations will not be shown on the pavement marking sheets unless they deviate from the *IDOT Highway Standards*.

4. Large Projects. On very large projects with continuous markings, it only may be necessary to show a typical detail of the pavement markings on each sheet.

5. Chicago Projects. District 1 must obtain the details for pavement markings for projects within the City of Chicago. The City of Chicago must review all pavement marking plans within the City.

63-4.14 Special Plans

There are several other bureaus that are responsible for preparing specific details for plans. They are discussed in the following section. The designer will be responsible for providing the plan details to the appropriate bureau. It is important that this information be provided as early as practical to the responsible bureau during plan development to allow time to complete the details and submit them back to the designer for project letting.

63-4.14(a) Landscaping Details

The Phase I report generally includes a statement on landscaping. Whether there is a Phase I report or not, it is the designer's responsibility to ensure landscaping has been considered for a project and that landscaping plans, if required, are included.

Landscaping plans are prepared by the Bureau of Operations. The Bureau provides the designer with landscaping plans, special provisions, pay items, and quantities for incorporation into the final contract. Include schedules of landscaping pay items with other schedules of quantities as discussed in Section 63-4.04(d) along with their botanical and common names clearly shown.

Landscaping details must be coordinated with municipalities, and their input should be considered when preparing the final details. In some cases, local officials may wish to incorporate their own landscaping details into the Department's contract. This can be done by agreement to establish cost participation.

63-4.14(b) Traffic Signal Plans

Traffic signal plans are required on all projects where the project includes new signals, modernization of existing signals, interconnecting signals, or milling the HMA surface at signalized intersections. Milling the HMA surface may damage the existing detector loops in the pavement.

The Bureau of Operations prepares the traffic signal plans and provides the designer with the final plans, special provisions, pay items, and quantities. It is the designer's responsibility to incorporate the traffic signal plans into the final contract.

The designer must provide the Bureau of Operations with the proposed roadway information so the Bureau can prepare its plans in a timely manner. This consist of preparing a 1 in. = 20 ft (1:250 metric) scale intersection plan for all signalized intersections requiring work within the project. The designer should also submit the traffic signal information form to the Bureau of Operations.

63-4.14(c) Lighting Plans

The Phase I report generally includes a statement on lighting. Whether there is a Phase I report or not, it is the designer's responsibility to ensure lighting has been considered for a project and that lighting plans, if required, are included in the final plans. Wherever there is existing lighting on a project, some involvement with proposed lighting work is almost certain.

For all districts except District 1, lighting plans are prepared by the Bureau of Design and Environment Preliminary Engineering Section. In District 1, plans are prepared by the District 1 Bureau of Electrical Operations. The designer will be required to provide the plan view of the project and location of power source as early as practical to the applicable unit to complete its plans, special provisions, pay items, and quantities. The designer incorporates this information into the final contract.

Lighting on a project may be a municipally maintained system. In this case, the municipality must be contacted to determine the disposition of the lighting after completion of the project. There are two possibilities for preparing municipal lighting plans:

- the municipality performs its own lighting improvements coincident with the roadway work or after the project is completed; or
- the municipality may have IDOT perform the lighting design as part of its project. The Department bills the municipality accordingly by agreement.

If a municipality prepares the lighting plans, these must be submitted for review to the appropriate district for review and approval. The district submits the plans to the appropriate lighting unit. After the plans are approved, the municipality will be responsible for providing IDOT with the final lighting plans, special provisions, pay items, and quantities for incorporation into the final contract.

63-4.14(d) Structure Plans

Structure plans are required for all designs with structural elements including new bridges, bridge replacement, bridge repairs, retaining walls, box culverts (new or extensions to existing), junction chambers, and noise abatement walls.

Most major structure plans are prepared by consultants. The Bureau of Bridges and Structures in the Central Office will be responsible for reviewing and/or preparing the structure plans. The designer must provide the proposed roadway information to whomever is preparing the structural design. It is important to include information on the proposed construction staging in this submittal.

The structural engineer's final plan submittal includes the final plans, special provisions, pay items, and quantities for the designer to incorporate into the final contract plans.

For bridge repairs involving nonstructural work (e.g., repairs to such items as the existing deck, parapets, and deck joints), plan details are typically prepared by the district. A "Bridge Condition Report — Deck Repair" is prepared in the district Bureau of Program Development and it includes recommendations for the type of work that should be performed. Plans for bridge repairs must be submitted to the Bureau of Bridges and Structures at least three months prior to the submittal of the plans for letting in order to allow time for their review.

63-4.14(e) Wetland Plans

For projects that involve restoring or creating wetlands as a part of the environmental mitigation commitments, the designer will be responsible for ensuring the plans and special provisions include appropriate details regarding the wetlands work. This information must address the work necessary to provide the elevations, contours, hydrology, soils, and plants for the type, size, and location of wetlands to be provided. The type, size, and location of the wetlands will have been agreed upon through consultation with regulatory and natural resource agencies and documented in a written conceptual mitigation plan prepared and approved during Phase I. The plan information should include the overall schedule for the wetlands work, including the relationship to other aspects of project construction. The information should also include a description of any special measures to be implemented during construction to avoid and minimize unnecessary construction-stage impacts to existing wetlands (e.g., placement of geotextile fabric to prevent permanent compaction of wetlands soils) and to correct temporary impacts (e.g., restoration of preconstruction contours, replanting, or reseeding of areas where wetlands vegetation is disturbed or destroyed).

Show the information concerning any manipulation of soils and hydrology that may be necessary for establishing the wetlands on the plan sheets for grading work. Also, show planting information on plan sheets and in the appropriate specifications. Show the schedule of quantities in the same manner as for other pay items.

63-4.15 Special Details

Detail sheets are used for those items that require more specific information than can be adequately described on either the plan or the profile views of the plan and profile sheets. Detail sheets are used to present:

1. Drainage Drawings. Special details are required for those drainage features not provided in the *IDOT Highway Standards.* This may include all special storm sewer layouts, culverts, inlets, catch basins, manholes, and any other drainage appurtenances. The detail sheets should show lengths, sizes, flow line elevations at ends of drainage structures, changes in flow line grade, and/or any other pertinent drainage details.

2. District Details. These are details that have been developed by each district and are generally only applicable to that district. These sheets are in addition to the *IDOT Highway Standards*. The designer should review these sheets prior to developing any new special details. These details are generally already on CADD.

3. Interchange Details. These are the contour maps around an interchange required for computation of the earthwork quantities. These details are in addition to those provided in the plan and profile sheets. They generally do not include any dimensions. Existing contours are shown as dashed lines, and proposed contours as solid lines.

4. Transitions. Details should be provided showing transitions in surface or base course widths. In addition, show the beginning and ending stations and the distance left or right of the centerline to the controlling points, and any other curve data required to construct the transitions.

5. Signing. Signing plans may or may not be included in roadway contracts. The designer is responsible for preparing the signing plans, special provisions, pay items, and quantities for incorporation into the final contract. To determine sign layout and location,

use the criteria in the Bureau of Operations’ *Traffic Policies and Procedures Manual*. For sign support design, use the criteria in the Bureau of Bridges and Structures’ *Sign Structures Manual*.

6. Special Designs. Additional details may be necessary as plan preparation progresses, which must be developed by the designer (e.g., pavement joint details, superelevation, special guardrail designs, highway/railroad grade crossings). It is important to include sufficient information on these details so that it is clear and understandable for the contractor to accurately bid on the work and for the resident engineer to construct it. However, do not include the code numbers for specific pay items on these sheets.

Clearly label each detail sheet in the sheet description block in the lower right corner of the sheet. The sheet description block should show the name of the detail and the station(s) to which it applies.

63-4.16 Cross Sections

Cross sections provide a graphical representation of the proposed roadway as compared to the existing ground line. Cross sections are generally required on all projects, except those involving resurfacing and/or projects with no earthwork. The following sections present the general guidelines for developing cross section sheets.

63-4.16(a) Procedure

If a Phase I report was prepared, the existing cross sections should have already been developed and may have been plotted using CADD. If the cross sections have not yet been plotted, the designer will be responsible for plotting or having the cross sections plotted. For small projects, the designer may plot the cross sections manually. However, for most projects, the cross sections should be generated using GEOPAK. The designer should review the users’ manual for GEOPAK to determine what information can be plotted with this software package.

63-4.16(b) Layout

When laying out cross sections, the following guidelines should be considered:

1. Orientation. Preferably, draw the cross section horizontally (landscaped) on the sheet. If more practical, the cross sections may be drawn vertically (portrait). Draw the cross sections from the bottom of the page to the top in increasing stations.

2. Spacing. Ensure that the spacing between cross sections is such that there is no overlap of the individual cross section figures, especially in areas of large cuts or fills.

3. Intervals. In rural areas, plot the cross sections at 100 ft (25 m) intervals and in urban areas at 50 ft (10 m) intervals. Plot additional cross sections at major grade breaks, culvert crossings, side streets, entrances, and other locations as necessary. Show the

appropriate station for each cross section directly below or to the right of the cross section. For intermediate sections, the cross section may only need to be drawn to the centerline or the profile grade line.

4. Order. Provide the mainline cross sections first, in increasing stations. Individual cross sections for minor approaches generally will be shown as half sections at the station they occur along the mainline. Where major construction is conducted for a significant distance along sideroads, frontage roads, ramps, etc., place the cross sections for these facilities after the mainline cross section in the order they appear along the mainline. Clearly label each special cross section sheet to allow the user to identify the actual location of the cross section.

5. Scales. The horizontal scale will typically be 1 in. = 5 ft (1:50 metric) or 1 in. = 10 ft (1:100 metric). A larger scale may be used where a greater cross section or height is desired. The vertical scale should always be a 2:1 proportion of the horizontal scale. Show the scales used in the lower right-hand corner of each cross section sheet if not otherwise labeled.

6. Axis Labeling. Along the horizontal axis, "0" is placed at the centerline or profile grade line of the existing facility. Label other horizontal axis points left and right of the "0" in at least 10 ft (3.0 m) increments. For the vertical axis, the axis lines are labeled in 5 ft (1.0 m) increments. Show at least two elevation lines. Note the scaling between the horizontal and vertical (i.e., 2:1 proportion).

63-4.16(c) Plotting Details

Generally, plot the cross section slightly beyond the right-of-way line, or slightly beyond the slope intersection of the proposed improvement with the existing ground line. The distance plotted will be determined based on what is beyond the right-of-way or slope limits. Cross sections should be typically plotted using the following guidelines:

1. Existing Information. Show all appropriate existing information on the cross section including existing pavement structures. Show these elements with a light, dashed line. The existing roadway centerline is typically centered on the sheet. Some of the existing information that should be shown includes:

   - ground line;
   - pavement structure;
   - drainage structures;
   - all below-ground and major above-ground utilities including sanitary sewers, water lines, electrical lines, gas lines, utility poles, etc.;
   - bridges, buildings, retaining walls, or other structures;

- right-of-way and temporary easement lines; and
- bodies of water near the right-of-way limits.

2. Proposed Sections. Overlay the proposed cross section template on top of the existing cross section. Show the proposed improvements as dark, solid lines. Some of the proposed cross section elements shown include:

   - the centerline, or the profile grade line, if different from the centerline;
   - proposed pavement improvements;
   - pavement structures;
   - all side road and entrance approach adjustments;
   - curb and gutter;
   - sidewalk location and depth;
   - proposed sideslope;
   - special fill material location and depth; and/or
   - other special features (e.g., steps, ramps, retaining walls).

3. Drainage Structures. Plot all drainage structures to scale including inlets, catch basins, and manholes. Label each structure with the following information:

   - the station at which the structure is located;
   - the distance from the centerline to the nearest tenth of a foot — 0.1 ft (hundredth of a meter 0.01 m) and direction from the centerline;
   - description and size of the structure; and
   - top and flow line elevations, to the nearest hundredth of a foot — 0.01 ft (thousandth of a meter — 0.001 m).

4. Storm Sewers. Show all storm sewers to the appropriate scale on each cross section. Label the pipe diameter on the first and last cross section of each sheet.

5. Culverts. Where necessary, include culvert profiles at the appropriate station of the cross sections or on separate cross section sheets. Show both the existing ground line and culvert flow lines. Flow line elevations are shown at the ends of the culvert and at changes in grade. Culvert extensions should show the existing culvert flow line in the same line weight as the original ground.

   Show dimensions from the centerline to box culvert or pipe culvert ends to the nearest calculated tenth of a foot (i.e., 0.1 ft) (hundredth of a meter (i.e., 0.01 m)). These distances are measured at right angles from the roadway centerline to the ends of the culvert or to breaks in the flow lines. Round culvert lengths to 2 ft (0.5 m) increments. These dimensions should agree with those shown on the plan sheets.

Culvert profiles are not required for culverts under entrances and minor side roads where the flow line of the culvert is the same as the flow line of the mainline ditch.

6. Ditches. Special ditches should also be noted and the flow line elevation shown to the nearest 0.1 ft (0.01 m) on each cross section. Also, show the direction of flow.

7. Utilities. Plot underground and major overhead utilities on the cross section where the utility is located longitudinally within the construction limits or where the utility crosses the existing or new centerline and is located within the construction limits. Some of the utilities that should be shown include water lines, sanitary sewers, gas lines, and major transmission lines. Label the size and type of each utility (e.g., 2 in. (50 mm) gas line) on each cross section.

8. Grading Notes. Show all undercuts for subgrade and unsuitable material (e.g., topsoil, peat) on the cross section. Porous granular material for backfill is also shown as a shaded area. Note the cut and fill amounts, in square yards (square meters), below or next to each cross section. These areas are based on the end areas. Additional grading notes may be added to the cross sections to provide direction to the contractor (e.g., "GRADE TO DRAIN"). Also, show all earthwork for temporary pavements on the cross section.

9. Approaches. Show all approaches (e.g., side roads, streets, entrances) with a separate cross section at the appropriate station. This cross section may only consist of a half section to the centerline or the profile gradeline. Note the approach type, direction from centerline, and station next to the cross section (e.g., "PROFILE P.E. LT. STA. 101 + 44.32" ("PROFILE STA. 267 + 40.32 SOUTH ST")). Label the approach type according to the entrance type (e.g., residential, private, commercial) or street name. Show the approach slope as a percent.

10. Structures. Show all buildings, bridges, or other structures affected by construction on the cross section sheets.

11. Right-of-Way. In general, incorporate all permanent right-of-way lines onto the cross section. Also show temporary right-of-way and easement lines on the cross sections.

12. Labeling. In addition to the above, the cross sections should provide the following information:

    a. Pavement Elevations. Show the final pavement surface elevation at the profile gradeline to the nearest hundredth of a foot — 0.01 ft (thousandth of a meter, 0.001 m). This elevation should be placed vertically. Other surface elevations as appropriate may be provided (e.g., high and low elevation points for superelevated sections).

    b. Side Slopes. Label side slopes on each cross section of each sheet. Side slopes are labeled vertical to horizontal as a ratio (e.g., 1V:4H).

c. Stations. List the cross section stations shown on the sheet in the lower right corner of each sheet. In addition, if cross sections are provided for more than one facility, note the applicable facility name directly with the station listing (e.g., Route 34, Pine St.). Desirably, place this information outside of the cross section grid.

13. Earthwork. Show the earthwork end areas for cuts and fills, above or beside the cross section. For complex projects involving stage construction, list the end areas by stages.

63-4.17 Highway Standard Drawings

The *IDOT Highway Standards* will be the last sheets added to the project. The Central Office will be responsible for adding these sheets to the plans. The sheets added will be based on the listing provided in the Index of Sheets.

63-5 CONSTRUCTION TYPE CODES

Section 63-4.04 discusses the requirements the designer must follow to break down the quantities on the summary of quantities sheet. One of these breakdowns is based on the type of construction. Figure 63-5.A provides the coding system the Department uses for these construction breakdowns.

Code	Type of Construction
0001	**Roadway, New Construction** Construction of a new roadway that will not replace an existing roadway
0003	**Roadway Reconstruction, Capacity Added (through lanes only)** Reconstruction of existing pavement, work included but not limited to: • Full depth, rubblizing • Small structures and culverts ≤ 20’ • Drainage improvements
0004	**Roadway Reconstruction (No added capacity)** Reconstruction of existing pavement, work included but not limited to: • Full depth, rubblizing • Small structures and culverts ≤ 20’ • Drainage improvements
0005	**Roadway Resurfacing Maintenance** Work to improve serviceability or to provide additional strength to existing roadway, work may include other incidental work in conjunction with resurfacing, work included but not limited to: • Mill and fill • System preservation • Resurfacing • SMART, 3P, surface treatments, crack sealing
0006	**Restoration and Rehabilitation** Work to return existing pavement to a condition of adequate structural support or to a condition adequate for placement of an additional state of construction, work included but not limited to: • 3R • Patching • Reworking or strengthening bases or sub-bases • Substantial pavement stabilization ***prior*** to resurfacing
0007	**Maintenance Relocation** Construction of a roadway at a new location that replaces an existing roadway. The new roadway carries all the through traffic with the previous facility closed or retained as a land-service road only.
0008	**Bridge, New Construction** Construction of a new bridge or culvert that is > 20’, and does not replace or relocate an existing bridge.
0010	**Bridge Replacement (Added capacity/No added capacity)** Total replacement of an existing bridge or culvert that is > 20’, with a new structure on existing or new alignment.

0013	**Bridge Rehabilitation (Added capacity/No added capacity)** Work necessary to restore structural integrity, correct major safety defects, usually resulting in the increase in one or more of the primary condition ratings (deck/super/sub/culverts) bridge must be > 20' with structure number, work includes but not limited to: • Superstructure replacement (full/partial) • Deck replacement (full/partial) + Full depth replacement significantly more that ± 2' (than the normal for replacing expansion joints) • Widening of bridge (adding beams/widening substructure) • Jacking superstructure to improve vertical under clearance • Strengthening + Significant cover plating + FRP wraps/strips (fixing what has been damaged) + Post-tensioning + Multiple in-kind replacements of primary and secondary structure elements such as beam ends, stringers, diaphragms, cross frames, gusset plates, wind bracing, etc. • Substructure repairs • Upgrade bridge railings • Bearing replacements
0020	**Environmental Only** • Erosion control • noise barriers • Rip rap, channel protection (not at bridge) • Wetland mitigation
0021	**Safety** Work that provides features or devices to enhance safety, work included but not limited to : • Traffic signals • Lighting • Sidewalks, ADA improvements • EVPs • Rumble strips • Guardrails • Pavement markings • Shoulder improvements
0028	**Facilities for Bicycle/Pedestrian Trails** Sidewalks (utilizing ITEP funds ONLY)
0030	**Scenic or Historic Highways Programs** • For projects related to scenic or historic highway programs • Construction of turnouts, overlooks, viewing areas • Construction of visitor and welcome centers • Designation signs and markers

0031	**Landscaping & Other Beautification** • Beautification • Tree Removal • Weed Spraying
0042	**Trainees**
0043	**Utilities** • Electrical work, linemen, substations • Storm sewer
0044	**Other** • Building demolition • Overhead sign structures • Pump stations • Retaining wall • Signage • Sweeping • Weigh stations • Work performed on a bridge that carries a railroad over a highway
0047	**Bridge Preservation** Work that prevents, delays, or reduces deterioration of bridge elements, restores the function of existing bridge, keeps bridge in good condition and extends life for bridges > 20’, work includes but not limited to: • Deck sealing • Washing • Painting + Full removal and repaint + Spot painting and zone painting + Over coating of existing paint system • Deck patching (full/partial) • Expansion joint sealing and replacement (including ± 2’ of concrete deck removal) • Eliminating deck joints • Channel debris removal • Lubricating bearings • Retrofit of fatigue prone details • Column jacketing / FRP wrap of substructures (preserving to prevent damage)
0048	**Bridge Protection** Work that adds protection against extreme events and provides security countermeasures, work included but not limited to: • Installing riprap or other scour countermeasures • Seismic retrofits • Impact protection measures + Fenders + Dolphins

	+ Pier protection cells • Security countermeasures + Fencing + Video monitoring + Fire detection/suppression
0049	**Bridge Inspection and Related Training** • Bridge inspections and evaluations • Bridge inspection training • In-depth/special inspections • Load rating
0050	**New Tunnel** Construction of a new tunnel that does not replace or relocate an existing tunnel
0051	**Tunnel Replacement** Total replacement of a tunnel with a new structure constructed with additional lanes in the same general traffic corridor.
0052	**Tunnel Rehabilitation** For the work required to restore structural integrity of a tunnel, as well as, work necessary to correct major safety defects.
0053	**Tunnel Preventative Maintenance** Activities that prevent, delay, or reduce deterioration of tunnels or tunnel elements, restore the function of existing tunnels, keep tunnels in good condition and extend their life.
0054	**Tunnel Protection** Includes impact protection measures, security countermeasures, and protection against extreme events.
0055	**Tunnel Inspection and Tunnel Related Training** Tunnel inspection and evaluation, including in-depth and other special inspections; tunnel inspection related training
0059	**Bridge Resurfacing** • Microsilica overlays with hydrodemolition or scarification • Latex Overlays with hydrodemolition or scarification • Other hard overlay with/without hydrodemolition or scarification • Concrete wearing surfaces • Thin Polymer Overlays (epoxy w/ broadcast aggregate) • Bituminous Overlays with or without waterproofing membrane

CONSTRUCTION TYPE CODES

Figure 63-5.A

63-6 SUGGESTED PLAN PREPARATION CHECKLIST

Date Completed ________________ Route ______________________________

Designer ______________________ Section _____________________________

County/City __________________________

Cross off each item as checked and place this form in the project file.

ALL SHEETS

☐ 1. Complete sheet index block in the lower right-hand corner with the project section number, route number, county, contract number, and sheet numbers.

☐ 2. Use appropriate symbols, cell library, and abbreviations as noted in the *Computer Aided Design, Drafting, Modeling and Deliverables Manual* and *IDOT Highway Standards*.

COVER SHEET

☐ 1. Indicate the location of the index of sheets, if not included on the cover sheet.

☐ 2. Show title information in the top center of the sheet and include:

- ☐ project route number and common name,
- ☐ section designation number,
- ☐ location of improvement,
- ☐ type of improvement,
- ☐ county, and
- ☐ construction job number.

☐ 3. Below the sheet index block, note the design number.

☐ 4. Locate the Illinois State map along the right side of the sheet. Also, indicate the project location on the map.

☐ 5. Show the graphic scales used on plans, profiles, and cross sections in the lower left-hand side of the sheet.

☐ 6. Provide the contract number in the lower left-hand corner of the sheet.

☐ 7. Provide a project layout map at bottom center of the sheet. Include on the map:

- ☐ location of project, and north arrow,
- ☐ beginning and end stations,

- ☐ all important intermediate stations,
- ☐ prominent features,
- ☐ names for special features,
- ☐ route and street names,
- ☐ description of all structures over 20 ft (6 m),
- ☐ scale of location map,
- ☐ township and range numbers, and
- ☐ equation stations.

☐ 8. Provide the project gross and net lengths immediately below the layout map. Only include the mainline distances. Do not include length of intersection improvements.

☐ 9. Include the project approval block in lower right-hand corner of the sheet and check to ensure the signatures and dates for the following are included:

- ☐ Regional Engineer,
- ☐ Engineer of Design and Environment,
- ☐ Director of the Office of Highways Project Implementation,
- ☐ FHWA Division Administrator, where applicable, and
- ☐ local officials, where applicable.

☐ 10. On consultant-designed projects, ensure that the consultant's company name, and the professional engineer's signature, date of their license expiration, and professional stamp are shown beside the State approval box.

☐ 11. Ensure that the note "PRINTED BY THE AUTHORITY OF THE STATE OF ILLINOIS" has been included in the lower right-hand corner.

☐ 12. Show the information for J.U.L.I.E. or C.U.A.N. somewhere on the cover sheet.

☐ 13. Include the design designation notation somewhere on the cover sheet.

☐ 14. Include district project engineer/squad leader name in left margin.

INDEX OF SHEETS, HIGHWAY STANDARDS, PLANS NOTES, COMMITMENT

☐ 1. Completely fill out the sheet index.

☐ 2. Provide a list of all *IDOT Highway Standards* necessary to construct the project. Also, include the revision number.

☐ 3. Include all applicable general plan notes.

☐ 4. Include all applicable commitments.

SUMMARY OF QUANTITIES SHEET

☐ 1. Show the appropriate quantity breakdowns based on the construction and safety work type, project location, funding source, etc.

☐ 2. Provide the correct pay item code number and description; see Section 63-4.04(b).

☐ 3. Use the appropriate pay unit; see *IDOT Standard Specifications* for the appropriate metric pay units.

☐ 4. Fill out the total quantities column.

☐ 5. Round all quantities in accordance with Chapter 64.

☐ 6. Provide separate schedule of quantities sheet for as many pay items as practical.

TYPICAL SECTION SHEET

☐ 1. Ensure that all applicable typical sections are provided.

☐ 2. Provide the mainline typical sections first, followed by other typical sections as they appear along the mainline.

☐ 3. Note the title of the typical section and applicable stations directly below the typical section.

☐ 4. Ensure the following have been included on the typical section:

- ☐ horizontal dimensions rounded to nearest 0.1 ft (0.01 m);
- ☐ vertical dimensions rounded to nearest ¼ in. or ⅛ in. (5 mm or 1 mm) for resurfacing lifts;
- ☐ the profile grade line reference, if different from the centerline;
- ☐ types and depths of surface, base, and subbase courses;
- ☐ side slopes expressed as a ratio of vertical to horizontal distances;
- ☐ cross slopes expressed in inches/foot (US Customary) or percent (metric);
- ☐ percent of superelevation; and
- ☐ all other applicable notations.

☐ 5. Provide a table of base thickness where the base and subbase depths vary and include the applicable station limits.

☐ 6. Include all notes applicable to the typical sections.

☐ 7. Note all applicable pay items on the typical section.

☐ 8. Include the structural pavement design information.

ALIGNMENT, TIE, AND BENCHMARK SHEET

☐ 1. Where necessary for complex projects, include a geometric alignment figure. Also, include a coordinate layout sheet for all alignments, sideroads, radius returns, and parking lots.

☐ 2. Show schematics for reference tie locations that include:

- ☐ the applicable centerline station,
- ☐ the applicable control tie, and
- ☐ the complete description of the features used to determine the tie location.

☐ 3. Show all mainline reference ties first, followed by those for other facilities.

☐ 4. Round all reference tie dimensions to the nearest 0.01 ft (5 mm).

☐ 5. Provide the benchmark data on this sheet and include the following information:

- ☐ centerline station,
- ☐ distance and direction from the centerline,
- ☐ description of location, and
- ☐ benchmark elevation.

PLAN/PROFILE SHEET

PLAN AND PROFILE VIEWS

☐ 1. Provide the mainline plan and profile sheets first, followed by other plan and profile sheets as they appear along the centerline.

☐ 2. Plot existing facilities with a light, dashed line and the proposed facilities with a solid, dark line.

☐ 3. Keep all notes brief, clear, and consistent.

☐ 4. Desirably, label the applicable stations in the lower right corner on each sheet.

PLAN VIEW

☐ 5. Show mainline stationing increasing from left to right. Note where the centerline line is not coincident with the survey line.

☐ 6. Provide tick marks along the centerline at 100 ft (50 m) intervals and note the station.

☐ 7. Use matchlines on sheet.

☐ 8. On projects where a coordinate system has been set up, show the coordinates for all control points.

☐ 9. For rural facilities, use a plan view scale of 1 in. = 50 ft (1:500 metric). For urban facilities, use a plan view scale of 1 in. = 20 ft (1:250 metric).

☐ 10. For all control points along the centerline, provide a 0.1 in. (2.5 mm) diameter circle on the centerline.

☐ 11. Place the horizontal curve data on the inside of the curve to which it applies. Present the curve data in accordance with the format and accuracy presented in Figure 63-4.D.

☐ 12. Include the pavement edge elevations and superelevation rates for superelevated sections.

☐ 13. Show perpendicular lines from the centerline to the inside of the curve at all curve control points. Indicate the curve control point and station.

☐ 14. Where deflection angles are used, show the angle to nearest second of a degree. Include coordinates, if available.

☐ 15. Note all pavement widths at the beginning and end of each sheet and wherever there is a change in pavement width.

☐ 16. Provide the correct district North arrow on each sheet.

☐ 17. Ensure station call outs are provided at:

- ☐ beginning and end points of the project,
- ☐ matchlines with other projects,
- ☐ omissions from paving and station equations,
- ☐ 100 ft (50 m) station increments,
- ☐ horizontal curve points,
- ☐ beginning and ending points of tapers,
- ☐ construction limit locations,
- ☐ right-of-way alignment breaks,
- ☐ curb returns for entrances and intersections,

- ☐ entrance centerlines,
- ☐ special construction applications,
- ☐ side street intersections,
- ☐ permanent survey and right-of-way markers,
- ☐ section lines, and
- ☐ other necessary locations.

☐ 18. In general, do not show utility and drainage information on the plan and profile sheets. Provide this information on the drainage plan and profile sheets.

☐ 19. If separate right-of-way sheets are included with the plans, show the existing and proposed right-of-way limits on the plans. If the right-of-way plans are not included with the plans, also incorporate the following:

- ☐ dimensions of the properties to be acquired,
- ☐ station ties to property lines,
- ☐ property ownership lines,
- ☐ parcel numbers,
- ☐ property owner names,
- ☐ station locations of right-of-way alignment breaks,
- ☐ temporary and permanent easement locations,
- ☐ points where the control of access does not coincide with the right-of-way line,
- ☐ location of right-of-way markers, and
- ☐ any pertinent data that affects right-of-way costs.

☐ 20. Show all approved points of entry or exits across control of access lines.

☐ 21. Show the locations for all new and existing guardrail installations.

☐ 22. For entrances and side road intersections, show the following:

- ☐ the facility with the applicable street name, route number, or entrance type;
- ☐ the existing surface material type;
- ☐ the width of the intersecting facility;
- ☐ for intersections with public roads, the angle of intersection from the side road centerline to the mainline centerline; and
- ☐ direction of ditch drainage.

☐ 23. Properly label all additional constructed improvements.

PROFILE VIEW

☐ 24. Show the profile of the finished surface or top of the subgrade along the centerline for the proposed facility.

☐ 25. Use the same horizontal scale as shown for the plan view. The vertical scale is typically 1 in. = 5 ft (1:50 metric) or 1 in. = 10 ft (1:100 metric).

☐ 26. Show the existing ground line to the nearest 0.1 ft (30 mm) and existing pavement surfaces to the nearest 0.01 ft (5 mm).

☐ 27. Show the vertical curve data above the profile line for crest curves and below the profile line for sag curves. Include the following vertical data for each curve:

- ☐ small triangle at the VPI,
- ☐ small circles (0.1 in (2.5 mm) diameter) at all other vertical curve control points,
- ☐ the VPI station, including short segments of vertical tangents,
- ☐ the vertical curve length,
- ☐ the elevation at the VPI, and
- ☐ the "M" distance between the VPI and roadway surface.

☐ 28. Show tangent grades to the nearest hundredth of a percent (i.e., 0.01%). Use a "+" prefix for positive grades and "-" prefix for negative grades.

☐ 29. If not shown on the benchmark sheet, show the benchmark information on the top portion of the profile view.

☐ 30. Show the elevations for the survey line and proposed centerline vertically every 100 ft (25 m) for rural projects and every 50 ft (10 m) for urban projects. For vertical curves, use a closer interval. The survey elevation is shown to the left of the station ordinate line and proposed centerline elevation to the right.

☐ 31. Provide additional profiles, where necessary, for:

- ☐ pavement edges,
- ☐ drainage structures,
- ☐ special ditches,
- ☐ side roads, and
- ☐ other situations.

☐ 32. Show locations of all undercutting for unsuitable materials with cross hatching and show this excavation to the top of subgrade. Note the applicable stations and depth of excavation on the profile sheet.

☐ 33. For bridges within the project, show elevations for:

- ☐ abutments,

- ☐ piers,
- ☐ low vertical clearance points,
- ☐ the high water level, and
- ☐ stream bed.

STAGES OF CONSTRUCTION AND TRAFFIC CONTROL SHEETS

☐ 1. Determine which *IDOT Highway Standards* are applicable for the traffic control on the project.

☐ 2. Where necessary, provide plan view sheets showing:

- ☐ temporary roadway horizontal alignment,
- ☐ temporary pavement widths,
- ☐ temporary traffic lanes,
- ☐ proposed construction staging,
- ☐ location of signing for work zones,
- ☐ temporary pavement markings,
- ☐ roadside safety layouts, and
- ☐ general notes for construction, closures, time frames, etc.

☐ 3. Where necessary, provide the temporary roadway profile grade line on the profile sheet.

EROSION AND SEDIMENT CONTROL DETAILS

☐ 1. Determine which *IDOT Highway Standards* are applicable for erosion and sediment control on the project.

☐ 2. Where necessary, provide any commitments or General Notes that relate to erosion and sediment control.

☐ 3. Where necessary, provide plan view sheets showing:

- ☐ proposed construction staging,
- ☐ location of environmentally sensitive areas,
- ☐ location of erosion and sediment control items, and
- ☐ general notes for construction, pay items, etc.

DRAINAGE AND UTILITIES SHEETS

☐ 1. For culverts, note the following on the drainage plan view sheet:

- ☐ centerline station for the ends,
- ☐ direction and distance of the ends from the centerline,
- ☐ culvert type,
- ☐ pipe size and length,
- ☐ flow direction,
- ☐ skew angle,
- ☐ upstream and downstream flow elevations,
- ☐ end section or headwall type and size, and
- ☐ all applicable construction notes.

☐ 2. For storm drainage pipes, show the following:

Plan View

- ☐ each run of pipe between manholes, catch basins, and inlets;
- ☐ pipe diameter and length; and
- ☐ gradient.

Profile View

- ☐ diameter of pipe,
- ☐ type of pipe,
- ☐ length, and
- ☐ gradient.

☐ 3. For manholes, catch basins, and inlets, show the following:

Plan View

- ☐ centerline station,
- ☐ direction and distance from centerline,
- ☐ top of grate elevation, and
- ☐ invert elevations for all pipes.

Profile View

- ☐ centerline station,
- ☐ direction from centerline,
- ☐ device type and size,
- ☐ invert elevations for all pipes, and
- ☐ top of casting elevation.

☐ 4. For end sections, show the following:

Plan View

- ☐ centerline station and offset,
- ☐ type, and
- ☐ size.

Profile View

- ☐ centerline station,
- ☐ direction from centerline,
- ☐ device type and size, and
- ☐ outflow elevation at the bottom of pipe.

☐ 5. Note special ditch locations with invert elevations at 100 ft (25 m) intervals on the cross sections. On the profile view note:

- ☐ gradient percentage,
- ☐ centerline station,
- ☐ beginning and ending elevations, and
- ☐ elevations at gradient changes.

☐ 6. Note all overhead utilities where they cross the centerline and the type of utility.

☐ 7. Note all underground utilities within the right-of-way limits affected by the construction with the following:

Plan View

- ☐ centerline station,
- ☐ direction and distance from the centerline, and
- ☐ all applicable elevations.

Profile View

- ☐ type and size.

PLANS FROM OTHER UNITS, SECTIONS, AND BUREAUS

Where necessary, the following plan sheets are provided to the designer from other units, sections, and bureaus to be incorporated into the plans:

☐ 1. Right-of-way plans from the Bureau of Land Acquisition.

☐ 2. Pavement marking details from the Bureau of Operations. If the Bureau of Operations does not prepare the plans, then the designer should develop the pavement marking details.

☐ 3. Landscaping details from the Bureau of Operations.

☐ 4. Traffic signal plans from the Bureau of Operations.

☐ 5. Lighting plans from the BDE Preliminary Engineering Section or, in District 1, the Bureau of Electrical Operations.

☐ 6. Structural plans from the Bureau of Bridges and Structures.

☐ 7. The *IDOT Highway Standards* listed in the sheet index will be incorporated into the plans by the Bureau of Design and Environment for project letting.

DETAIL SHEETS

Where necessary, the following details may be included:

☐ 1. Intersection details which may include:

- ☐ pavement elevations,
- ☐ lane widths,
- ☐ curb or edge of pavement radii,
- ☐ curb ramps,
- ☐ turning radii for left-turning vehicles,
- ☐ location of median noses and islands,
- ☐ location of traffic signal equipment,
- ☐ location of traffic signs,
- ☐ pavement markings, and
- ☐ construction joint layout.

☐ 2. Special drainage details that are not covered in the *IDOT Highway Standards* or on the drainage plan and profile sheets.

☐ 3. District detail sheets.

☐ 4. Earthwork details for interchanges requiring significant earthwork.

☐ 5. Transition details where there is a change in the roadway surface or base course width. These details should include:

- ☐ beginning and end stations,
- ☐ distances and direction from the centerline, and
- ☐ all necessary curve data.

☐ 6. Signing plans, where applicable.

☐ 7. Wetland plans, where required.

☐ 8. Any special designs not covered in the *IDOT Highway Standards* or elsewhere in the plans.

CROSS SECTION SHEETS

☐ 1. Plot rural cross sections at 100 ft (25 m) intervals and urban cross sections at 50 ft (10 m) intervals.

☐ 2. Plot intermediate cross sections at all major grade breaks, pipe crossings, side streets, entrances, and other locations as necessary.

☐ 3. Ensure the spacings between cross sections do not overlap.

☐ 4. The mainline cross sections are placed first, by increasing stations, from the bottom of the sheet to top of the sheet. Provide the cross sections for other facilities after the mainline cross section in the order they appear along the mainline.

☐ 5. Note the stations of the cross section shown on the bottom of the sheet. Also note the name of the facility to which the cross sections apply.

☐ 6. Use a horizontal scale of 1 in. = 5 ft (1:50 metric) or 1 in. = 10 ft (1:100 metric). The vertical scale is a 2:1 proportion of the horizontal scale. Show the scales used in the lower right corner of each sheet.

☐ 7. Plot the existing cross section using a light, dashed line and show the existing:

- ☐ ground line,
- ☐ pavement structure,
- ☐ drainage structures,
- ☐ major utilities,
- ☐ all affected structures,
- ☐ existing and proposed right-of-way and easement lines, and
- ☐ bodies of water near the right-of-way limits.

☐ 8. Plot the proposed cross section using a dark, solid line and show:

- ☐ centerline (and the profile grade line, if different);
- ☐ proposed pavement structure;
- ☐ all side road and entrances;
- ☐ curb and gutter;
- ☐ sidewalk locations and depth;
- ☐ proposed side slopes;
- ☐ special fill materials;

- ☐ all new drainage structures, include the following:
  - ☐ centerline station,
  - ☐ distance and direction from centerline,
  - ☐ description and size of structure,
  - ☐ top and flow line elevations;
- ☐ all underground utilities affected by the construction;
- ☐ special ditch elevations and drainage direction;
- ☐ proposed right-of-way and easement lines; and
- ☐ any other special features.

☐ 9. Provide the proposed centerline pavement surface elevation vertically on each cross section.

☐ 10. Label the side slope on the first and last cross section of each sheet and where there are changes in the slope. Show the side slope using a vertical to horizontal ratio, e.g., 1V:3H.

☐ 11. Show the end area cut and fill amounts, in square feet (square meters), above or beside each cross section.

☐ 12. Show all undercutting for subgrade and unsuitable material.

☐ 13. Show all earthwork for temporary pavements.

☐ 14. Provide separate cross sections for all approaches including side roads and entrances, and note the approach type, direction from centerline, and station next to the cross section.

(Continued)

Chapter Sixty-four
QUANTITY COMPUTATIONS

In addition to preparing clear and concise plans, as described in Chapter 63, the designer needs to compile an accurate summary of the project quantities. This information leads directly to the Engineer's Estimate, which combines the computed quantities of work and the estimated unit bid prices. An accurate summary of quantities is critical to prospective contractors interested in submitting a bid on the project. Chapter 64 presents guidelines on calculating quantities for highway construction projects.

64-1 GENERAL

64-1.01 Guidelines for Preparing Quantity Computations

When preparing quantity computations, the designer should consider the following guidelines:

1. Specifications. Cross check all items against the *IDOT Standard Specifications for Road and Bridge Construction* and the Supplemental Specifications to ensure that the appropriate pay items, methods of measurement, and bases of payment are used. If an item is not covered in the *IDOT Standard Specifications* or Supplemental Specifications (i.e., those having an asterisk in the *IDOT Coded Pay Items*), a special provision, plan note or detail must be included in the contract documents to cover the item.

2. Pay Item Code Number. Every pay item has a unique number assigned to it for data processing. This code number is located in the *IDOT Coded Pay Items.* Section 63-4.04 describes the Department coding procedures, description titles, and units of measurement for pay items. Only the official name and description should be used in the contract documents, special provisions, and summary of quantities. Do not include "dummy" code numbers in the plans.

3. Rounding. The quantity of any item provided in the plans should check exactly with the figure on the computation sheets. Indicate any rounding of the raw estimated figures on the computation sheets. Unless stated otherwise, no rounding of the calculations should be done until the value is incorporated into the summary of quantities sheet.

4. Significant Digits. When calculating quantities, carefully consider the implied correspondence between the accuracy of the data and the given number of digits.

5. Multiple Estimates. Some projects will require two or more estimates for work performed under various funding arrangements, construction and safety work types, and area location. Section 63-4.04 describes the various breakdown categories for quantity computations.

6. Cost Estimate. Only use the total values from the summary of quantities sheets to develop the cost estimate. Show all items described in the plans that will be included in the cost estimate on the plan sheets. Chapter 65 provides Department criteria for preparing construction cost estimates. These quantities are used to determine the final Engineer's Estimate.

7. Estimating Forms/Computation Worksheets. Blank copies of the estimating forms and computation worksheets are available from BDE.

64-1.02 Computer Estimates

For most projects, the computer can be used to develop some of the quantity estimates. For small projects, it may be more efficient to manually calculate the quantities for all elements, including earthwork. Each software package used by the Department (e.g., GEOPAK) uses different procedures for determining how and which quantities can be estimated. The designer should give special consideration to how the plans are prepared on the computer (e.g., cell names, levels, processing procedures) to allow the software to determine the quantities.

64-1.03 Computation Records

In preparing the project quantities, prepare a separate computation sheet for each item used on the project. Combine these sheets and bind them with a cover sheet. The preparer will sign or initial and date each sheet. The checker will also be required to sign or initial and date each sheet. Number the sheets and indicate the total number of pages on each sheet (i.e., sheet x of y). Place the code number and pay item on the top of each sheet. Arrange the sheets in code number order (i.e., numerically and then alphabetically).

Check all values obtained through computations or use of standardized tables, preferably on an independent basis. For those pay items where agreements may be reached to make payment on the basis of planned quantities, an independent check should be performed and noted. Note the resolution of any differences between original and check computations. Where computations are performed by computer, an independent check is not required. However, make spot checks of the input and review the computation output sheet for obvious mistakes. Also, sign and date the computer output similarly to hand computation sheets.

Retain the quantity computations within the project file.

64-1.04 Units of Measurement

Estimate the quantities for all contract bid items using the terms and units of measurement presented in the *IDOT Standard Specifications* and the *IDOT Coded Pay Items*. Show the values determined from the computations on the summary of quantities sheet, and elsewhere in the plans. Figure 64-1.A illustrates typical rounding criteria that should be used on the summary of quantities sheet and in the plans. Note that certain elements are rounded based on standard manufacturer sizes.

64-1.05 Non-Defined Work

64-1.05(a) Lump-Sum Items

Only use lump sum bid items where the scope of work for the item is clearly defined, and the amount of work has a minimal chance of changing during construction. The *IDOT Standard Specifications* defines which quantities may be estimated as lump sum. Wherever practical, list the quantities for the separate items that will be included within the lump sum item. The list should note that the separate "quantities are for estimating purposes only." Where there is a significant chance of quantity changes, the work must be bid by the unit and not lump sum. Where lump sum items are used, the total quantity for the project will always equal one.

64-1.05(b) Items Included in Other Work

No item should be shown as incidental to another pay item or the contract. If any item will be included as part of another item, it must be addressed by the specifications or with a special provision. The designer should only include an item of work in another pay item where the scope of work for both is clearly defined and the probability of the quantity of either item changing is minimal. In general, minimize the use of items included in other pay items. It is impossible for bidders, or the Department, to prepare an estimate for a project that contains incidental items for which quantities or the scope of work are indeterminable.

In general, use the applicable pay item for those items that are normally covered in the *IDOT Standard Specifications*. Where the quantities or scope of work items are indeterminate at the time of bidding, these items should be paid for on a force account basis as described in the *IDOT Standard Specifications*.

64-1.06 Federal Participation in Stockpiling of Salvage Materials

The Federal government participates in the cost of salvaging and stockpiling materials, which cannot be reused in the project. This does not apply to material salvaged from Bituminous Surface Removal or Texturing Existing Pavement, which becomes the property of the contractor for future recycling. Stockpile the material either on the project limits or at a State-owned storage site a reasonable distance off the project limits if necessary to prevent a potential roadside safety problem. The amount of participation will be limited to the following:

- If the material can be used on other Federal-aid routes, participation may be obtained for stockpiling the material.
- If the material is to be retained by the contractor, participation may be obtained for salvaging the material provided the special provisions indicate that the salvage value is to be reflected in the contractor's bid price.
- If the material can be used on non-Federal-aid routes, Federal participation for stockpiling will ordinarily be limited to the dollar amount established by an alternate bid item for contractor disposal.

- If the material has no use, participation will be allowed for the disposal of the material as specified in Article 202.03 of the *Standard Specifications*.

64-2 EARTHWORK COMPUTATIONS

64-2.01 Computer Computations

Earthwork computations for most projects can be determined using the computer and special design software packages (e.g., GEOPAK). Earthwork quantities for small projects, entrances, side roads, ditches, and additional grading features may need to be calculated manually (see Section 64-2.02). For the computer to calculate the mainline earthwork quantities, the following information is typically required:

1. horizontal and vertical roadway alignment;
2. typical sections;
3. terrain data;
4. shrinkage factor;
5. cut and fill slope rates; and
6. identification of sections not to be included (e.g., bridge sections).

The computer provides a listing of the quantities for each station. Include these quantities on the cross sections as described in Section 63-4.16.

64-2.02 Manual Computations

For small projects and to calculate special features on larger projects (e.g., entrances, ditches), it may be necessary to calculate the earthwork quantities manually. Figure 64-2.A provides a sample computation sheet that may be used to develop these quantities. A spreadsheet program may be used in place of these computation sheets. The following steps and examples from Figure 64-2.A illustrate how to use the computation sheet:

1. <u>Station</u>. In rural areas, cross sections are typically plotted and calculated at 100 ft (25 m) intervals and urban areas at 50 ft (10 m) intervals. The intervals shown in Figure 64-2.A are at 50 ft.

2. <u>Grade</u>. Indicate the grade of the profile grade line. Also, indicate if there is a vertical curve and the length of the vertical curve. Figure 64-2.A shows a 500 ft crest vertical curve.

3. <u>Tangent Elevation</u>. This is the grade along the tangent between two VPI's, exclusive of the vertical curve correction. In the example, the tangent elevations are 465.00 ft and 466.00 ft at Stations 4 + 00 and 4 + 50, respectively.

4. <u>Vertical Curve Correction</u>. This is the elevation correction required from the tangent elevation for the vertical curve. Values in this column only will be noted if there is a vertical curve. Chapter 33 illustrates how to calculate the vertical curve corrections. For Station 4 + 00, the correction is 0.12 ft, and for Station 4 + 50, 0.50 ft.

SAMPLE COMPUTATION SHEET

Figure 64-2.A

5. Grade Elevation. This is the actual grade of the profile grade line. For tangent sections, this column is the same elevation as shown in the tangent elevation column. For crest vertical curves, this elevation is determined by subtracting the vertical curve correction from the tangent elevation. For sag vertical curves, this elevation is determined by adding the vertical curve correction to the tangent elevation. For Station 4 + 00, the grade elevation is (465.00 - 0.12 = 464.88 ft) and for Station 4 + 50, (466.00 – 0.50) = 465.50 ft.

6. End Areas. The end areas used to compute the quantities are defined by the ground lines and typical section template (see Figure 64-2.B). After the cross sections have been plotted, determine the areas of cut and fill for each cross section using a planimeter. Include the borrow excavation, waste of unsuitable soils, undercut, rock excavation, trench excavation, and any special excavation or embankment on the section. If topsoil is used on the section, compute the quantity of topsoil. Add the undercut in the cut section to the earth excavation and deduct the topsoil in fill from the embankment quantity. Record the cut and fill areas for each cross section in the "END AREA" columns of the Computation Sheet. Ensure that intermediate cross sections (e.g., culvert location, entrances) are not used for an end section. For the example, the cut end areas for Stations 4 + 00 and 4 + 50 are 1700 ft^2 and 1750 ft ^{2}, respectively. The fill end areas are 10 ft^2 and 0 ft^2, respectively.

7. Sum of End Areas. The "SUM OF END AREAS" columns are the sum of adjacent cross-section areas for the cut and fill columns. Note that the line in the figure is offset between the two end areas. This line indicates the two areas to be added together. For the example, the sum of cut areas is 3450 ft^2 and sum of fill areas is 10 ft^2.

8. Distance. This is the distance between the cross-section interval selected in Comment 1. For the example, this is 50 ft.

9. Section Volumes. Volumes for excavation (cut) and embankment (fill) are determined using the average-end-area formula:

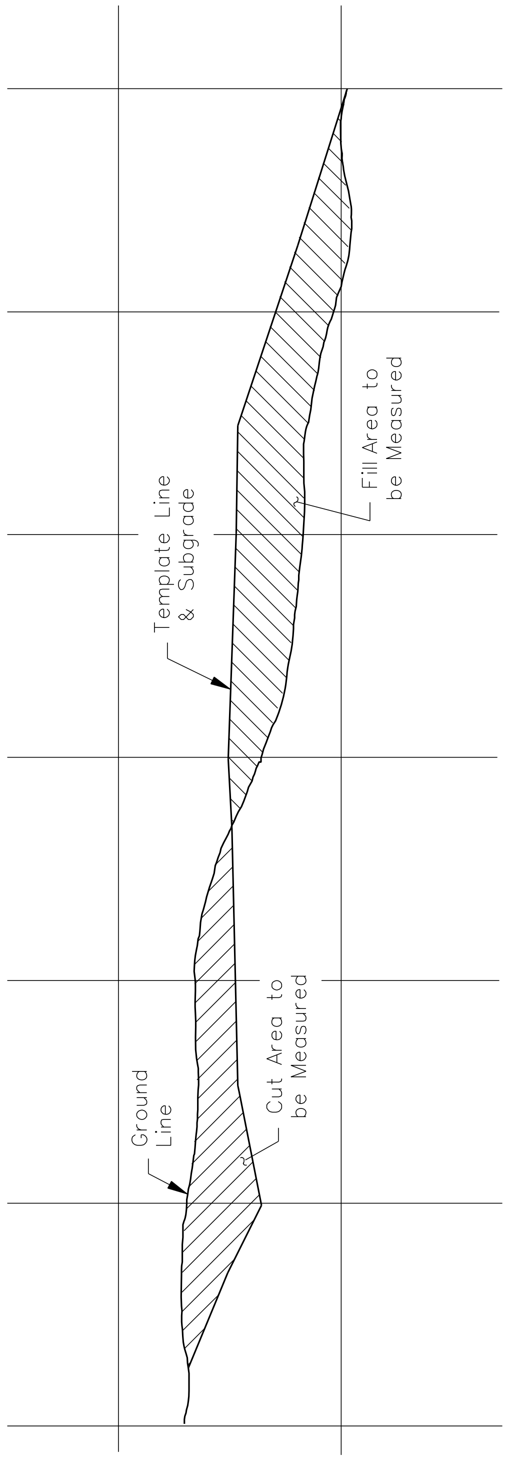
$$V = \left(\frac{A_1 + A_2}{2(27)}\right)(D)$$ (US Customary) Equation 64-2.1

$$V = \left(\frac{A_1 + A_2}{2}\right)(D)$$ (Metric) Equation 64-2.1

where: V = volume, yd^3 (m^3)

$A_1 + A_2$ = sum of cut or fill end areas of adjacent sections (from the "Sum of End Areas"), ft^2 (m^2)

D = distance between sections, ft (m)



END AREA TEMPLATE

Figure 64-2.B

These values are rounded to the nearest yd^3 (m^3) and recorded in the appropriate cut and fill "SEC. VOLUMES" columns on the Computation Sheet.

For the example, the cut and fill volumes are:

Cut: $$V = \left(\frac{1700 + 1750}{2(27)}\right)(50) = 3194\ yd^3$$

Fill: $$V = \left(\frac{10 + 0}{2(27)}\right)(50) = 9\ yd^3$$

10. Total Section Volumes. This is the sum of the section volumes for both the cut and fill columns. For the example, these are 35,508 yd^3 for cut sections and 2648 yd^3 for fill sections.

11. Shrinkage Factor. The total section volumes for fill section must be adjusted by the appropriate shrinkage factor. Section 64-2.03 discusses how to determine the appropriate shrinkage factor. For this example, the shrinkage factor was determined to be 15%. Note for earth fills, the factor is only shown in the fill column.

12. Adjusted Volume. This value is determined by multiplying the "TOTAL SECTION VOLUME" by the appropriate "SHRINKAGE FACTOR." For cut sections, the volume is 35,508 yd^3. For fill sections, the 2648 yd^3 is multiplied by 1.15 to obtain the "ADJUSTED VOLUME" (2648 x 1.15 = 3045 cubic yards).

64-2.03 Shrink and Swell Factors

Embankment fill quantities calculated manually or by the computer must be adjusted by the appropriate shrinkage factor to account for the compaction of material, loss from hauling, subsidence of the existing ground caused by the overburden, erosion, and clearing operation. The factors used in the calculations depend on the soil type, quantity to be moved, and engineering judgment. Sand and gravel have smaller shrinkage factors than clay and silt. For rock excavation, it may be necessary to apply an expansion or swell factor. Generally, the shrinkage factor will only be applied to the total fill area (see Section 64-2.02) unless highly variable materials are encountered along the alignment requiring different numerical values.

The use of more than one factor is often necessary to describe the characteristics of the material. The District Geotechnical Engineer will provide guidance in choosing the applicable factor(s) to be used in the calculations. The designer may need to adjust the shrinkage factor to account for the smaller quantities.

64-2.04 Earthwork Considerations

64-2.04(a) Excavation Quantities

The following procedures establish design guidelines for use of the earthwork pay items:

1. Earth and Rock Excavation. This work consists of excavation and transportation of suitable excavated material to embankment locations throughout the limits of the contract or the excavation, transportation, and disposal of excavated material. This work does not include excavation for structures or channel excavation.

   Calculate quantities in the normal manner according to Section 64-2.

   If the earth or rock excavation is to be used on the project in an embankment, the suitability and/or stability of the excavated material must be examined. Show the amount of suitable excavated material to be used in embankments in the Earthwork Schedule. The pay item is "Earth Excavation" or "Rock Excavation." If a portion or all of the excavated material is determined to be unsuitable or unstable, calculate the quantity and list it as "Removal and Disposal of Unsuitable Material."

   When possible, a shrinkage factor should be determined for the suitable excavation to be used as embankment. The shrinkage factor will determine the final volume of the excavated material once it is compacted within the embankment. This quantity is then used to determine the amount of material either to be wasted or to be hauled in from off-site. Contact the District Materials Engineer concerning the determination of a shrinkage factor. When a shrinkage factor is determined, show the factor in the plans. If no shrinkage factor is determined, assume a shrinkage factor of 25%.

   If topsoil is to be excavated and used on the project, include this quantity as "Topsoil Excavation and Placement," but do not include this quantity in the earth excavation quantity. Cross sections should show the different cut quantities.

2. Borrow and Furnished Excavation. Borrow and furnished excavation consists of excavating suitable materials obtained from borrow locations furnished by the contractor and transporting the materials to various locations throughout the limits of the contract.

   The only difference between borrow excavation and furnished excavation is the method of measurement as described below:

   a. Borrow Excavation. Borrow excavation is measured in its original position by taking cross sections of the borrow site before the work is started and again after it has been completed. The volume in cubic yards (cubic meters) of material will be computed by the method of average end areas. When possible, also determine the shrinkage factor of the borrow excavation. The shrinkage factor will determine the plan quantity of material to be excavated from the borrow site, which is the pay quantity, that will provide the required volume once it is compacted in the embankment. The District Materials Engineer should be contacted regarding the determination of a shrinkage factor. When a shrinkage factor is determined it should be shown on the plans. If no shrinkage factor is determined, assume a shrinkage factor of 25%.

b. Furnished Excavation. Furnished excavation will be determined either by an agreement to plan quantity or by measurement in its final place. For measurement in place, compute the volume of the compacted material in cubic yards (cubic meters) using the average end areas method and then subtract the final pay quantity of earth excavation, rock excavation and other excavation suitable to be used as embankment, adjusted by a shrinkage factor of 25% or as shown on the plans, as discussed above. Also, deduct the excavation quantities included in the cost of other items.

The use of borrow excavation or furnished excavation will be at the designer's discretion; however, the designer should consult with the District Materials Engineer and District Construction Engineer. In determining which pay item to use, consider the following:

- Do not use borrow excavation and furnished excavation on the same project; use one or the other.
- Furnished excavation should be used:
  + on projects where a small amount of borrow material is required (<50,000 yd^3 (40,000 m^3));
  + on bridge projects, minor realignments, and/or 3R type improvements;
  + on projects in urbanized areas where borrow may come from many sources;
  + where no suitable borrow locations are apparent; or
  + where use of commercial borrow sites or multiple borrow sites are anticipated.
- Borrow excavation should be used:
  + on projects where a significant amount of borrow material is required (>50,000 yd^3 (40,000 m^3)); or
  + where a borrow site may be readily available.

3. Embankment. This work consists of the construction of embankments by depositing, placing, and compacting earth, stone, gravel, or other materials of acceptable quality above the natural ground or other surface. The materials incorporated are from earth excavation, rock excavation, borrow excavation, furnished excavation, or other sources as mentioned in the contract documents.

Embankment will not be paid for directly, but is considered to be included in the various items of excavation, and their construction included in the unit prices of these items.

4. Topsoil and Compost. This work consists of furnishing, excavating, and placing topsoil, special types of topsoil or compost/topsoil blend.

The use of topsoil on projects is paid for either as "Topsoil Excavation and Placement" or as "Topsoil Furnish and Place." The designer will decide which pay item(s) to use and should consult with the District Landscape Architect, District Materials Engineer, and District Construction Engineer for assistance. Topsoil excavation and placement involves the use of topsoil obtained from within the project limits. Topsoil furnish and place requires the contractor to obtain topsoil from an off-site location. The use of topsoil within the project limits is encouraged and recommended. In determining contract quantities, on-site material should be used first and, if additional quantities are required, the amount of off-site material should be calculated. Consequently, on some projects both pay items may be used.

The quantity of topsoil excavation and placement is not included in the earth excavation quantity.

5. Earthwork Schedule. Earthwork schedules are shown on all plans involving earthwork pay items. The schedule should show:

- cuts and fills;
- earth and rock excavation quantities;
- removal and disposal of unsuitable material quantities;
- borrow or furnished excavation quality (Note that borrow excavation is calculated in the uncompacted state so a shrinkage factor must be assumed to arrive at this quantity from the known fill required. Furnished excavation is calculated in its final place (i.e., compacted state));
- shrinkage factors for earth excavation and borrow excavation; and
- topsoil excavation and placement, topsoil furnish and place, and/or compost furnish and place quantities.

6. Equations. Consider the following when calculating excavation quantities:

a. Shrinkage Factor (SF) = $\dfrac{\text{bank volume} - \text{compacted volume}}{\text{bank volume}}$

$$= 1 - \frac{\text{compacted volume}}{\text{bank volume}}$$

Where the bank volume is material as it lies in its natural state.

Unless otherwise determined, assume SF = 0.25.

b. Suitable Excavation is defined to be all earth excavation, rock excavation, and all other on-site excavation that is suitable to be used as embankment for the project.

c. Use the following to determine the quantity of embankment that will result from the suitable excavation:

Excavation to be used as Embankment = Suitable Excavation X (1 – SF)

d. If the quantity of excavation to be used as embankment is less than the embankment quantity required, then use one of the following equations:

Furnished Excavation = Embankment – (Suitable Excavation X (1 – SF)

Borrow Excavation = (Embankment – (Suitable Excavation X (1 – SF))) / (1 – SF)

It is the designer's option on use of the borrow excavation or furnished excavation when off-site material is needed.

7. Examples.

Example 64-2.04(1)

Earthwork Schedule

1 **Location**	**2** **Earth Excavation**	**3** **Earth Excavation Adjusted for Shrinkage**	**4** **Embankment**	**5** **Earthwork Balance Waste (+) or Shortage (-)**
	Cubic Yard	Cubic Yard	Cubic Yard	Cubic Yard
Sta. 100+00 to 105+00	500	375	100	+275
Sta. 105+00 to 110+00	400	300	100	+200
Sta. 110+00 to 115+00	500	375	200	+175
Side Road A	200	150	300	-150
Total	1600	1200	700	+500

Columns 1, 2, & 4 Location and quantities from cross sections:

Cut = Earth Excavation Fill = Embankment

Column 3 Quantity of earth excavation (cut) adjusted for a shrinkage factor of 25%.

Column 5 Earthwork required:

(-) = Quantity of Fill or Embankment needed (Furnished or Borrow Excavation).
(+) = Quantity to be wasted.

Because the earth excavation quantity is greater than embankment needed the only pay item is for "Earth Excavation," no pay item for "Borrow or Furnished Excavation" is needed.

Pay Item:

EARTH EXCAVATION 1600 cubic yards

Example 64-2.04(2)

Earthwork Schedule

1 Location	2 Earth Excavation	3 Earth Excavation Adjusted for Shrinkage	4 Embankment	5 Earthwork Balance Waste (+) or Shortage (-)
	Cubic Yard	Cubic Yard	Cubic Yard	Cubic Yard
Sta. 320+00 to 325+00	100	75	275	-200
Sta. 325+00 to 330+00	200	150	125	+25
Sta. 330+00 to 335+00	150	112.5	300	-187.5
Side Road X	50	37.5	250	-212.5
Total	500	375	950	-575

Columns 1, 2, & 4 Location and quantities from cross sections:

Cut = Earth Excavation Fill = Embankment

Column 3 Quantity of earth excavation (cut) adjusted for a shrinkage factor of 25%.

Column 5 Earthwork required:

(-) = Quantity of Fill or Embankment needed (Furnished or Borrow Excavation).
(+) = Quantity to be wasted.

Because the earth excavation quantity is not great enough to account for all embankment (fill) needed, additional earth is required from off-site either as borrow or furnished excavation.

Example 64-2.04(3)

Earthwork Schedule

1 Location	2 Earth Excavation	3 Rock Excavation	4 Unsuitable or Unstable Material	5 Excavation to be used in Embankment Adjusted for Shrinkage	6 Embankment	7 Earthwork Balance Waste (+) or Shortage (-)	8 Topsoil Excavation and Placement	9 Topsoil Furnish and Place
	Cubic Yard	Cubic Yard	Cubic Yard	Cubic Yard	Cubic Yard	Cubic Yard	Cubic Yard	Square Yard
Sta. 410+00 to 430+00	3,000		1,000	1,600	10,000	-8,400	600	
Sta. 430+00 to 450+00	2,000	500		2,100	8,000	-5,900	200	300
Sta. 450+00 to 470+00	5,000			4,000	2,000	+2,000	200	400
Frontage Road	1,000			800	5,000	-4,200	300	
Total	11,000	500	1,000	8,500	25,000	-16,500	1,300	700

Shrinkage Factors:
Earth Excavation: 20%
Rock Excavation: 0%
Borrow Excavation: 30%

Column 1 – Location from plans.

Column 2 – Cut quantities from cross sections, this does not include topsoil excavation.

Column 3 – Quantities from cross sections.

Column 4 – Cut material that is determined to be either unstable or unsuitable for use in embankment.

Column 5 – Earth and rock excavation quantities that are to be used as fill material in embankment. Includes deduction for unsuitable material. Earth excavation shrinkage factor was determined to be 20%. Rock excavation shrinkage factor was determined to be 0%.

Column 6 – Quantities from cross sections.

Column 7 – Off-site material needed or material to waste.

Column 8 – Quantities from cross sections, these quantities are not included in earth excavation or embankment.

Column 9 – Quantities required from off-site to complete project, quantities are not included in borrow or furnished excavation.

Furnished excavation is measured in its final (compacted) state. Borrow excavation is measured at the borrow site and, therefore, the borrow quantity must allow for shrinkage (assumed 25%). Borrow = 575 yd^3 / (1 – 0.25) = 766.67 yd^3.

Pay Items:

EARTH EXCAVATION	-	500 cubic yards
FURNISHED EXCAVATION	-	575 cubic yards

or

EARTH EXCAVATION	-	500 cubic yards
BORROW EXCAVATION	-	767 cubic yard

On projects in which cut material is paid for with multiple pay items (e.g., Earth Excavation and Rock Excavation), calculate the total quantity of cut material to determine the quantity of off-site material required for embankment. Each item may have a different shrinkage factor.

On projects in which topsoil is to be paid for, the topsoil quantities are not included in any other pay items (e.g., earth excavation, furnished excavation). First, calculate the total quantity of topsoil needed. Next, calculate the amount of topsoil available within the project limits. If not enough topsoil is available on the project, then the additional amount will be obtained from off-site and paid for as “Topsoil Furnish and Place.” A shrinkage factor may be used for topsoil, but is not usually required.

Borrow excavation quantity is 16,500/(1-0.30) = 23,571 cubic yards. If furnish excavation were used the quantity would be 16,500 cubic yards.

Pay Items:

EARTH EXCAVATION	-	10,000 cubic yards
ROCK EXCAVATION	-	500 cubic yards
REMOVAL AND DISPOSAL OF UNSUITABLE MATERIAL	-	1,000 cubic yards
BORROW EXCAVATION	-	23,571 cubic yards
TOPSOIL EXCAVATION AND PLACEMENT	-	1,300 cubic yards
TOPSOIL FURNISH AND PLACE	-	700 square yards

64-2.04(b) Earthwork Quantities for Separate Grading and Paving Contracts

On grading and paving contracts, the paving contractor may have the problem of either wasting substantial quantities of excess excavation or obtaining borrow to construct the subgrade. Often the plans do not provide the contractor with the proper quantities to adequately estimate the project. To ensure that sufficient quantities are provided, the designer should consider the following:

1. Grading Contracts. For grading contracts, show the grading cross sections parallel to the ultimate pavement and shoulder structure. Occasionally, special conditions may dictate a different grading cross section. For these situations, provide accurate earthwork quantities to construct the final paving cross section in the paving plans.

2. Graded Paving Contracts. For paving contracts on pregraded sections, do not include the earthwork in the cost of paving or use “token” quantities to establish unit prices. determine the earthwork quantities according to one of the following conditions:

    a. When a grading contract will be completed several months before the advertising of the paving contract, develop new cross sections to establish accurate earthwork quantities.

    b. When the paving contract will be advertised prior to the completion of the grading contract, accurate earthwork quantities cannot be determined for bidding purposes. For these situations, include the pay item “Shaping and Grading Roadway.”

64-2.04(c) Bridge Embankment Quantities

For determining bridge embankment quantities, the Bureau of Bridges and Structures will only show on the general plan and elevation sheet of the bridge plans the limits of the minimum embankment that must be constructed prior to the construction of the abutments. The road designer is responsible for determining the quantities for the embankment cones and including these quantities in the total earthwork for the project.

The bridge plans will present any pipe culverts under these embankment cones. However, the road designer determines the pipe culvert length and any quantities.

64-2.05 Landscaping

When determining landscaping quantities, the designer should consider the following:

1. Seeding and Sodding. Calculate the area for seeding and sodding by measuring the distance along the slope and not horizontally.

2. Fertilizer Nutrients. To determine the quantity of fertilizer nutrients, multiply the area to be fertilized by the application rate. The designer should check with the District Landscape Architect to determine the proper application rate. Show the selected application rate in the plans, typically in the general notes.

3. Mulch. To determine the quantity of mulch, multiply the area to be mulched by the application rate obtained from the District Landscape Architect. Show the application rate in the plans, typically in the general notes.

64-2.06 Subgrade

Calculate the area of subgrade using the out-to-out width of the paved shoulders. To ensure a proper pavement foundation, add 6 in (150 mm) to each side. If the paved shoulders are bituminous, include an allowance for the 1V:1H slope of the bituminous material before adding the 6 in (150 mm) to each side.

For urban sections with curb and gutter, calculate the subgrade width using the out-to-out distance from the back of curb plus the 6 in (150 mm) extension.

64-2.07 Subbase

To determine the area of subbase under rigid pavements, include an additional 18 in (450 mm) on each side to the pavement width. Where curb and gutter is used with rigid pavements, the extra width will be the curb and gutter width.

64-3 PAVEMENT COMPUTATIONS

64-3.01 Bituminous

64-3.01(a) Bituminous Binder and Surface Course

Where bituminous binder and surface course pay items are in square yards (square meters), calculate the quantities using the top surface area. For binder course construction without curb and gutter, allow for the 1V:1H side slope of the surface course material before determining the width of the binder course. For binder course construction with curb and gutter on an improved subgrade, allow for the additional thickness required below the curb and gutter.

Where the pay item is in tons, provide an allowance for the extra width required due to the slope of the bituminous material. This allowance is not required for curb and gutter sections.

64-3.01(b) Bituminous Materials Applied

The designer should consult with the District Materials Engineer to determine the proper application rate of material for the type of project being constructed. This rate should be shown on the plans.

64-3.02 Pavement Rehabilitation

When determining quantities for pavement patching, conduct a field inspection immediately prior to the plan submission. Add a growth factor of 10% to 20% if the bids on the project will be received in late summer or fall and there is a likelihood that patching would not be completed until the following spring.

64-3.03 Shoulders/Curb and Gutter

64-3.03(a) Shoulders

Where the pay item is in square yards (square meters), use the top width of the shoulder to determine the area of shoulders.

64-3.03(b) Curb and Gutters

To determine the length of curb and gutters, measure the length along the gutter flow line. This length is measured across entrances and not around an entrance radius. The curbs in entrances should be included in the area of the entrance. At street returns, measure the curb around the radius of the return.

64-4 MISCELLANEOUS COMPUTATIONS

64-4.01 Bridges Deck Slab Repair Quantities

There may be a lag time between the time of inspection of the deck and the recording of the plan quantities and the start of actual construction. To reduce possible overruns on deck slab repair quantities, inspection of the deck should not occur more than four months prior to taking of bids for work. On projects on which bids are taken in late summer or fall, add a growth factor of 5% to 10% to the measured quantities to allow for the additional winter period between the inspection and the start of construction.

When a project is delayed and the deck(s) are subject to additional winter wear, make an update inspection prior to taking bids for the work. Conduct this updated inspection in the same manner as the initial inspection. The designer is responsible for keeping the records of the dates for all inspections.

Also, to reduce possible overruns, conduct a thorough and complete deck inspection. A detailed visual inspection of the underside of the deck is extremely critical. Time may be saved by not determining the corrosion potential and chloride content of the concrete.

The Department may secure outside consultants to conduct these inspections.

64-4.02 Trench Backfill

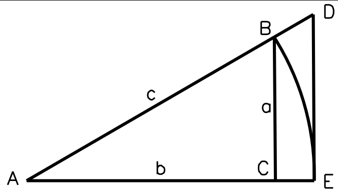
Calculate the trench backfill quantities using the trench backfill tables in the *IDOT Construction Manual*.

64-4.03 Aggregate

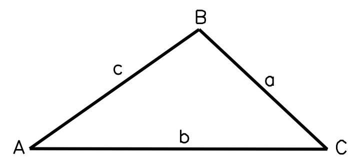
When calculating the quantity of aggregate required for temporary entrances, temporary lanes, etc., indicate the pay item in tons. Also, include additional quantities for maintenance during time the temporary facility is open to traffic.

64-5 MATHEMATICAL FORMULAS

This section presents mathematical formulas used by IDOT for various quantity determinations.



Right Triangle



Oblique Triangle

Right Triangles

$$\sin A = \frac{a}{c} = \cos B$$

$$\cos A = \frac{b}{c} = \sin B$$

$$\tan A = \frac{a}{b} = \cot B$$

$$\sec A = \frac{c}{b} = \operatorname{cosec} B$$

$$\operatorname{cosec} A = \frac{c}{a} = \sec B$$

$$\cot A = \frac{b}{a} = \tan B$$

$$a = c \sin A = c \cos B = b \tan A = b \cot B = \sqrt{c^2 - b^2}$$

$$b = c \cos A = c \sin B = a \cot A = a \tan B = \sqrt{c^2 - a^2}$$

$$c = \frac{a}{\sin A} = \frac{a}{\cos B} = \frac{b}{\sin B} = \frac{b}{\cos A}$$

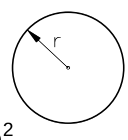
Given	Sought	Formula
A, B, a	b, c	$b = \frac{a}{\sin A} \bullet \sin B$ $\quad c = \frac{a}{\sin A} \bullet \sin(A+B)$
A, a, b	B, c	$\sin B = \frac{\sin A}{a} \bullet b$ $\quad c = \frac{a \sin (A + \text{arc} \sin (b \sin A / a))}{\sin A}$
C, a, b	$\frac{1}{2}(A+B)$ $\frac{1}{2}(A-B)$	$\frac{1}{2}(A+B) = 90° - \frac{1}{2}C$ $\text{Tan}\ \frac{1}{2}(A-B) = \frac{a-b}{a+b} \bullet \tan \frac{1}{2}(A+B)$
a, b, c	A	Givens $= \frac{1}{2}(a+b+c)$, then: $\sin \frac{1}{2} A = \sqrt{\frac{(s-b)(s-c)}{bc}}$ $\cos \frac{1}{2} A = \sqrt{\frac{s(s-a)}{bc}}$ $\tan \frac{1}{2} A = \sqrt{\frac{(s-b)(s-c)}{s(s-a)}}$ $\sin A = 2\frac{\sqrt{s(s-a)(s-b)(s-c)}}{bc}$

	Area	$\text{Area} = \sqrt{s(s-a)(s-b)(s-c)}$
c, a, b	Area	$\text{Area} = \frac{1}{2}\, ab \sin C$

Nomenclature

A = total surface area
d = distance
h = height
p = perimeter
r = radius
s = side (edge) length, arc length
V = volume
θ = vertex angle, in radians
ϕ = central angle, in radians

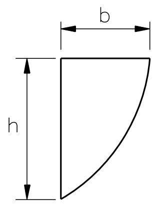
Circle



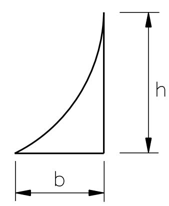
$p = 2\pi r$

$A = \pi r^2 = \frac{p^2}{4\pi}$

Parabola

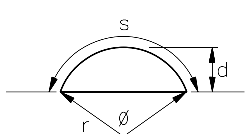


$A = \frac{2bh}{3}$



$A = \frac{1}{3}\, bh$

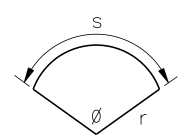
Circular Segment (1)



$A = \frac{1}{2} r^2(\phi - \sin\phi)$

$\phi = \frac{s}{r} = 2\left(\arccos \frac{r-d}{r}\right)$

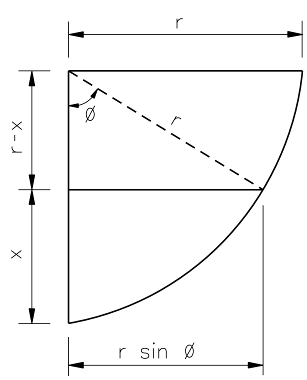
Circular Sector



$A = \frac{1}{2}\, \phi\, r^2 = \frac{1}{2}\, sr$

$\phi = \frac{s}{r}$

Circular Segment (2)



$\cos\ \phi = \frac{r - x}{r}$

<u>Area of Circle Segment</u>

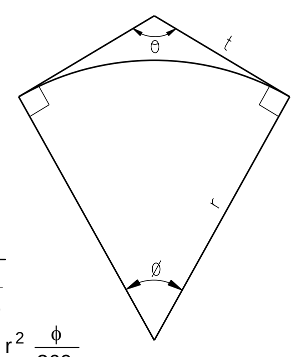
$\frac{\phi}{360^\circ} \pi r^2$

<u>Area of Triangle</u>

$\frac{1}{2}(r - x)(r \sin \phi)$

External Area

Total Area - Area of Circle Segment = External Area



$t = \frac{r}{\tan \frac{\theta}{2}}$

$\phi = 180^\circ - \theta$

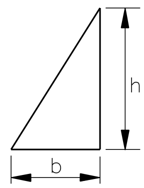
$\text{Total Area} = rt = \frac{r^2}{\tan \frac{\theta}{2}}$

$\text{Area of Circle Seg.} = \pi r^2 \frac{\phi}{360}$

$\text{Ext. Area} = r^2 \left[\frac{1}{\tan \frac{\theta}{2}} - \pi \frac{\phi}{360} \right]$

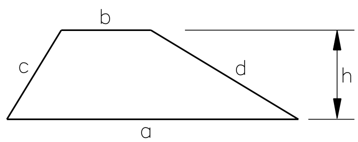
Number of Sides	Name of Polygon
3	triangle
4	rectangle
5	pentagon
6	hexagon
7	heptagon
8	octagon
9	nonagon
10	decagon

Triangle



$$A = \frac{1}{2} bh$$

Trapezoid

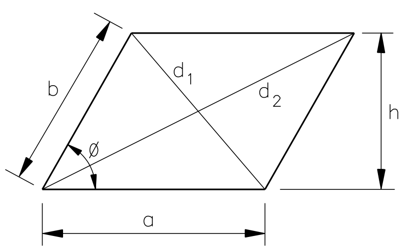


$$p = a + b + c + d$$

$$A = \frac{1}{2} h (a + b)$$

The trapezoid is isosceles if c = d.

Parallelogram



$$p = 2 (a + b)$$

$$d_1 = \sqrt{a^2 + b^2 - 2ab(\cos\phi)}$$

$$d_2 = \sqrt{a^2 + b^2 + 2ab(\cos\phi)}$$

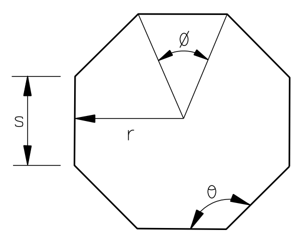
$$d_1^2 + d_2^2 = 2 (a^2 + b^2)$$

$$A = ah = ab(\sin\phi)$$

If a = b, the parallelogram is a rhombus.

Regular Polygon

(n equal sides)



$$\phi = \frac{2\pi}{n}$$

$$\theta = \frac{\pi (n - 2)}{n}$$

$$p = ns$$

$$s = 2r \left(\tan\left(\frac{\phi}{2}\right)\right)$$

$$A = \frac{1}{2} nsr$$

Chapter Sixty-five
COST ESTIMATING

To adequately define the project scope and to ensure sufficient construction funds are available, cost estimates are required during the various stages of project development. As the project progresses, the estimates are refined to ensure the project is still cost effective, sufficient funds are available for construction, and the contractor’s bid price is reasonable. Chapter 65 discusses the various project estimates that are required and the responsibilities of the district and Central Office estimators.

65-1 PROJECT ESTIMATES

65-1.01 Project Initiation Estimate

The districts and other units are responsible for nominating projects to be included on the Department’s Multi-Year Highway Improvement Program. Once a project is nominated, the Office of Planning and Programming is responsible for gathering the necessary information on the project before it can be included on the Program list. One part of this information gathering includes a preliminary cost estimate for construction. These cost estimates are prepared in cooperation with the District Programming Engineer and/or Estimating Engineer.

Once a project has been included on the Department’s Multi-Year Program, it may be several years before a Phase I study can be conducted. Consequently, the project initiation cost estimate must be updated annually until the Phase I study has been conducted.

At the time of project initiation, detailed project quantities have not yet been developed. The programmer determines the estimate based on information provided periodically by the estimator, by using broad units of cost (e.g., cost per mile (kilometer), cost per square yard (square meter)), and by reviewing similar, recent projects in the area. Project initiation cost estimates are generally determined according to the following:

1. Roadway Projects. For most highway projects, assume a cost per mile (kilometer) per roadway width. This estimate includes the cost for earthwork, pavement structures, drainage, and other miscellaneous items. Every effort should be made to include all anticipated work items.

2. Structure Projects. For most structural projects, assume a cost per square foot (square meter) based on similar structure types and lengths.

3. Traffic Signal Projects. Estimate traffic signal projects assuming a per intersection installation.

4. Unit Costs. If sufficient quantities are available, use the quantities with the average weighted unit prices to develop the estimate. Add a factor of 10% to 20% to account for minor items.

In addition, the programmer should add the cost for any major features that are beyond the basic assumptions used to develop the estimate. For example, the cost for a major box culvert should be added to the roadway cost per mile (kilometer) estimate.

Based on the proposed scope for the project, the programming engineer determines the unit cost basis considering the following factors:

- geographic location (e.g., urban/rural, State location, district);
- similarity of recent construction projects;
- inflation (adjustments of past prices to reflect the current year);
- reliability of recent construction cost data;
- recent trends in cost of materials, labor, and equipment;
- anticipated difficulty of construction;
- project size relative to size of previous projects;
- proposed project schedule;
- anticipated construction staging;
- right-of-way;
- railroads;
- utilities;
- expected environmental problems (e.g., hazardous wastes, wetlands); and
- engineering judgment.

65-1.02 Phase I Estimate

Once the Phase I study has been completed, the district programming engineer with input from the estimating engineer will work with the Office of Planning and Programming to prepare a more detailed cost estimate for the Phase I report. The programmer and/or estimating engineer preparing the estimate will use the quantities determined during the study. If quantities are not available, the designer should be requested to develop these quantities. If quantities are unavailable and cannot be estimated in a reasonable time frame, use the estimating procedures described in Section 65-1.01 (e.g., cost per mile (kilometer)). For consultant projects, the consultant develops the quantities and determines the unit prices. Department personnel will review and may adjust the consultant's proposed unit prices.

Figure 65-1.A lists the elements that should be estimated and included in the Phase I report for complex projects (e.g., reconstruction or new alignments). Typically, at this stage, not all of the quantities have yet been determined. The designer may include a 10% to 20% contingency factor depending upon engineering judgment for the minor items. Section 65-2 discusses the procedures for developing cost estimates based on quantities. Chapter 12 provides additional information on estimating procedures for Phase I reports. To adequately reflect construction and programming options, it may be necessary to use multiple columns on the estimate form or multiple estimate forms to show the costs for the various alternatives, segments, local participation, and construction breakdowns. In determining the breakdowns, the designer should consider the following:

1. Major Items. List the individual major elements separately (e.g., interchanges, bridges) and clearly identify their location on the estimate.

2. Rehabilitation Projects. On rehabilitation projects, breakdowns may be required for certain construction items because of the potential for specific items to become significant project costs.

3. Two or More Construction Seasons. On complex projects that require more than one construction season to complete, break the project into individual segments that can be completed in one season.

4. Project Funding. Identify construction, right-of-way, utility adjustments, local participation, and consultant PE costs separately to facilitate programming of these items.

Figure 65-1.B illustrates the cost estimate format that should be used for simple projects (e.g., 3R, widening, resurfacing).

COST ESTIMATE FORMAT
(Project Reports)

Figure 65-1.B

65-1.03 Phase II Estimates

One or more cost estimates may be prepared during the Phase II project stage. These estimates may include the following:

1. Preliminary Plan Review. At this project stage, a revised cost estimate is generally developed only to determine the appropriate preliminary Disadvantaged Business Enterprises (DBE) requirements. Recommended guidelines for DBE determinations are provided by the Office of Highways Project Implementation and approved by the Office of Business and Workforce Diversity. Under some circumstances, a preliminary plan cost estimate may be prepared to ensure that the program funding is still reasonable and appropriate. At this stage, the plans and major quantities are essentially complete. Therefore, the estimate can be prepared using the methodologies discussed in Section 65-2 (i.e., based on unit prices). The designer will work with the district estimating engineer to develop this estimate. Do not forward this estimate to the Project Management Unit in the Bureau of Design and Environment.

2. Project Scope Change. Whenever the scope of the project changes, the designer will be responsible for obtaining a new construction cost estimate. These estimates are forwarded to the Office of Planning and Programming to revise the Multi-Year Program. Estimates for scope of work changes are typically based on approximate quantities and are determined using the procedures discussed in Section 65-1.02.

3. Project Delay. If there has been a significant delay in the project since it was originally designed and estimated, it may be necessary to update the cost estimate to reflect inflation, new materials, new equipment, contractor workloads, etc.

4. Final Plan Submittal. Prior to submitting the plans to the Central Office for letting, the district estimating engineer prepares a cost estimate based on the final plans. This may be an update of an earlier cost estimate or, for many projects without a Phase I report, this estimate will be the first detailed estimate for the project. This estimate is forwarded to the Project Management Unit in the Bureau of Design and Environment, which will use it to develop the Engineer's Estimate.

5. Engineer's Estimate. The Engineer's Estimate is the official Department estimate for the project. This estimate is prepared by the Project Management Unit in the Bureau of Design and Environment based on the district estimating engineer's estimate. Section 65- 1.04 discusses the procedures for the Engineer's Estimate.

65-1.04 Engineer's Estimate

The Engineer's Estimate provides the Department with a basis for evaluating the bids for highway construction and allows the Department to determine if the low bid price is fair and reasonable for the work involved. This estimate, plus the data used to generate the estimate, is considered confidential and is not for general distribution. Section 65-2 discusses the procedures for developing the actual cost estimate. The following sections discuss the responsibilities of the various units for the Engineer's Estimate.

65-1.04(a) Originating Unit

Base cost estimates are prepared by the various units where the design originated (e.g., district, county, municipality, consultant). These estimates are submitted to the Engineer of Project Management in the Bureau of Design and Environment for final review and adjustment prior to contract letting. The originating estimator generally prepares the final plan submittal estimate as discussed in Section 65-2. The originating estimator's responsibilities include the following:

1. Quantities. The estimator is responsible for inputting all quantities into the Bureau of Design and Environment's Electronic Contract Management (ECM) System.

2. Unit Prices. The estimator adjusts the unit prices according to the procedures discussed in Section 65-2.

3. Worksheets. The estimator prepares all estimates submitted to the Central Office on hybrid and cost-based worksheets.

4. Data Input. The estimator must input all data into the ECM System prior to the PS&E date, or the project may not be scheduled for the anticipated letting.

5. Local Projects. For local road and bridge projects, the district estimator reviews the local agency estimate and prepares a district estimate. This may be, but is not required to be, an independent estimate. If the difference between the local agency's estimate and district estimate is 5% or less, enter both estimates into the ECM System. If the difference is greater than 5%, contact the local agency and negotiate an acceptable estimate to both parties. If an agreement cannot be reached, notify the Engineer of Project Management. Enter both the district's and local agency's final estimates into the ECM System.

6. Submittals. When submitting the estimate data to the Central Office Project Management Unit, the estimator should note the following:

    a. Data Transfer. Submit all estimates electronically to the Central Office through the ECM System. In addition, send an electronic file (.pdf) of the backup data and worksheets to the Central Office before the PS&E due date to DOT.DandEEstimates@illinois.gov.

    b. Approval. All cost estimates must be approved by a district estimator or an estimator-in-training before they can be forwarded to the Central Office Project Management Unit.

7. Revisions. If, after the estimate data has been submitted to the Central Office, the district estimator wishes to revise the estimate, the estimator must consider the following:

a. Review. Conduct all reviews of the data on-line through the ECM System. The estimate in the ECM System should always be the latest copy of the estimate.

b. Changes. If an estimate quantity, pay item, and/or unit price is changed on-line, notify the Engineer of Project Management, by email, that a change has been made. The Central Office may be unaware of the change, because on-line changes are nearly impossible to identify.

c. Due Date. Do not change any estimate on-line less than ten days prior to the letting. If a change is necessary, contact the Engineer of Project Management directly to discuss the change.

The Engineer of Project Management must be notified of any changes to ensure the latest data is transferred to the Department's Electronic Letting Management (ELM) System.

65-1.04(b) Central Office Project Management Unit

After the district submits a cost estimate to the Engineer of Project Management, the Unit responsibilities include the following:

1. Review. The estimator reviews the district's estimate and checks it for errors and/or omissions. If large discrepancies are noted, the Engineer of Project Management contacts the district estimator to discuss and resolve any differences. The Central Office estimator will not review every project cost estimate. For these situations, the district estimate is used as the Engineer's Estimate. However, the Engineer of Project Management will still have final authority for all estimates. Typically, the following estimates will not be reviewed by the Central Office:

   a. Projects < $250,000. For all projects less than $250,000, the estimates prepared by district estimators will be used without review.

   b. Lighting and Pumping Station Projects. All lighting and pumping station projects from the District 1 Bureau of Electrical Operations that are less than $250,000 are used without review. For lighting and pumping station projects from Districts 2 through 9, the Electrical and Mechanical Unit in the Bureau of Design and Environment is responsible for reviewing the estimate.

   c. Local Agency Projects. Local agency estimates may not be reviewed.

   d. Bridge Projects. For all bridges designed by the Bureau of Bridges and Structures and/or Department consultants, the Bridge Office reviews the estimate for bridge items.

   e. Bureau of Operations Projects. Estimates prepared by the Central Office Bureau of Operations may be used without review.

2. Opening and Processing the Bids. After the public reading of the bids, the Project Management Unit is responsible for checking the proposals for errors and obtaining computer printouts of itemized unit bid prices. The bid prices of each bidder are reviewed for omissions or extreme differences. If no extreme differences appear, the low bidder meets all criteria and the low bid is within a pre-established award range, the bids are forwarded to the Awards Committee for approval.

3. Rejection of Bids. When the low bid exceeds the pre-established award range, the estimate is reviewed for possible errors. If no errors are found, the rejection process begins, unless special circumstances such as public safety, etc., would be just cause for award.

65-1.04(c) Awards Committee

The Awards Committee is responsible for approving or rejecting the bid. This Committee consists of the following personnel:

- Director of the Office of Highways Project Implementation,
- Engineer of Design and Environment,
- Engineer of Construction,
- Engineer of Local Roads and Streets,
- Engineer of Project Management, and
- Office of Planning and Programming, Program Management

At the conclusion of the Awards meeting, the Engineer of Project Management prepares the official bid letting tabulation and the award memorandum for submittal to the Secretary.

65-2 DISTRICT ESTIMATING PROCEDURES

65-2.01 Responsibilities

65-2.01(a) Designer Responsibilities

Before a detailed cost estimate can be prepared, the designer typically provides the following information to the district estimating engineer:

1. Plans. Provide the estimator with a complete set of plans.

2. Quantities. In addition to providing quantities to the estimator, the designer must provide the following:

    a. Breakdowns. For those projects with separate breakdowns, separate the quantities for each breakdown category (e.g., construction and safety codes, funding appropriations). These breakdown categories are discussed in Section 63-4.04.

    b. Lump Sum Items. Provide the estimator with a summary of the individual items within the lump sum item. For example, the list of elements for the lump sum pay item "Traffic Control and Protection Standards" may include the number of barricades, barricade lights, construction signs, arrow boards, temporary guardrail, temporary signals, pavement marking tape, etc.

3. Specifications. Provide the estimator with a copy of the special provisions and a list of all recurring special provisions used in the project.

4. Other Cost Estimates. Several bureaus and sections may prepare their own cost estimates. The designer is responsible for collecting these estimates and forwarding them to the appropriate district or Central Office estimating engineer. The following bureaus or sections may develop their own cost estimate:

    a. Bureau of Bridges and Structures. The Bureau of Bridges and Structures may provide the cost estimates for bridges, retaining walls, major drainage structures, or any other work designed by the Bureau.

    b. Bureau of Operations. The Bureau of Operations may provide cost estimates for traffic signals, traffic surveillance, signing, pavement markings, and landscaping projects.

    c. District 1, Bureau of Electrical Operations. The Bureau of Electrical Operations in District 1 will provide the cost estimates for lighting and pumping stations.

    d. Other. Other units may provide cost estimates as appropriate.

5. Other. Provide the estimator with any other information that may impact the cost of the project (e.g., special commitments, experimental materials).

65-2.01(b) Estimator Responsibilities

The district estimating engineer reviews the information received from the designer and develops a cost estimate for the project. These estimates are generally formulated using the analyses discussed in Section 65-2.02. For estimates other than the Engineer's Estimate, the district estimating engineer returns the proposed estimate to the requesting party. For the Engineer's Estimate, the district estimating engineer follows the procedures in Section 65-1.04(a).

If for some reason there are project changes after letting, the contractor will request reimbursement for the item at a unit cost. The district Bureaus of Project Implementation and/or Program Development may request the district estimating engineer to review the contractor's proposal to ensure that the unit cost is reasonable. This review is typically conducted in the same manner as reviews for other estimates.

65-2.02 Unit Cost Determinations

The Department uses the Electronic Contract Management (ECM) System and the *Estimates Manual* for developing and managing Department cost estimates. Worksheets are used to determine the cost estimate. These worksheets may be prepared utilizing estimating software, and on Excel spreadsheets. Cost estimates are typically based on the quantities and applicable unit prices. The following sections discuss the basic procedures the Department uses to determine the applicable unit cost for each quantity. The estimator may adjust these procedures depending upon the project parameters. Both the *Estimates Manual* and the ECM System are for internal Department use and are not for general distribution.

65-2.02(a) Historical Data

The unit cost for minor work items are based upon an average price among projects of relative size and scope, utilizing recent unit cost bid tabulations. Adjustments to unit prices may be appropriate based on the factors listed in Section 65-1.01.

The following work types are typically considered minor; i.e., the estimator should use the historical data methodology to determine the unit prices:

- lighting;
- traffic signals;
- signing;
- weed spraying;
- crack routing;
- pavement marking (all types);
- guardrail;
- signing, guardrail maintenance;
- landscaping;
- pipe culverts;
- pipe underdrains and pipe drains;
- manholes, catch basins, inlets, etc.;
- marine construction;
- curb and gutter;
- sidewalk;
- driveway pavement;
- electrical maintenance;
- bridge deck overlay;
- reinforcing steel;
- bridge approach pavement;
- riprap;
- soil stabilization;
- anchors and tiebacks;
- fencing;
- railroad track construction; and
- miscellaneous bridge items (e.g., bearings, deck grooving).

65-2.02(b) Unit Cost Hybrid Worksheet

For intermediate work items, calculate the unit costs using a Unit Cost Hybrid Worksheet . An example for using this Worksheet would be to calculate the unit cost for Furnishing and Erecting Structural Steel (i.e., pounds (kilograms) of steel times dollars per pound (kilogram)). Section 65-1.01 lists several adjustment factors that should be considered when determining the final unit cost. The following are considered intermediate work types for which the estimator should use the Hybrid Worksheet:

- bridge painting,
- bridge cleaning,
- temporary support system, and
- structural steel.

65-2.02(c) Unit Cost Detailed Worksheet

For major work items and where these item quantities exceed the values in Figure 65-2.A, the estimator should calculate the unit cost using a Unit Cost Detailed Worksheet. For quantities less than those shown in Figure 65-2.A, use engineering judgment to determine whether or not to use the Worksheet. The following are considered major work types for which the estimator should use the Detailed Worksheet:

- earth excavation, borrow, and embankment;
- concrete paving, widening, shoulders, and CAM II;
- bituminous paving, widening, shoulders, and BAM;
- aggregate base, shoulders, subbase, and surface;
- patching;

- cold milling;
- hauling;
- traffic control;
- seal coat;
- storm sewers;
- cofferdams;
- concrete structures and concrete box culverts;
- piling;
- structure removal; and
- sweeping.

Work Item	Minimum Quantity	
	US Customary	Metric
Earthwork	5,000 yd^3	5,000 m^3
Aggregate	4,000 tons	3,500 m tons
Bituminous Mixes	2,000 tons	2,000 m tons
PCC Pavement & Bases	5,000 yd^2	4,000 m^2
Cold Milling	20,000 yd^2	17,000 m^2
Class A Patching	400 yd^2	350 m^2
Class B Patching	400 yd^2	350 m^2
Class C Patching	600 yd^2	500 m^2
Class D Patching	600 yd^2	500 m^2
Concrete Box Culverts	150 yd^3	150 m^3
Concrete Superstructures	150 yd^3	150 m^3
Concrete Structures	150 yd^3	150 m^3
Storm Sewers	1,800 ft	550 m
Structure Removal	Anytime in excess of $25,000 per structure	Anytime in excess of $25,000 per structure
Cofferdams	Anytime in excess of $25,000 per cofferdam	Anytime in excess of $25,000 per cofferdam
Drive and Furnish Piling	2,000 ft	600 m

MINIMUM QUANTITIES FOR UNIT COST DETAILED WORKSHEET

Figure 65-2.A

The Unit Cost Detailed Worksheet requires the estimator to determine the unit prices based on the following factors:

1. Production Rates. The estimator determines the appropriate production rates for the various items on the project. Section 66-2.03 provides typical production rates. Stage construction, congestion, urban work, size of quantity, traffic, seasonal work, expedited work schedule, local restrictions, etc., all affect the production rate. The estimator should consult with district construction personnel, review Means' *Heavy Construction Cost Data*, review the values within Section 66-2.03, and use engineering judgment when determining production rates.

2. Equipment. Equipment costs include ownership expenses to cover such items as depreciation, repairs, taxes, storage costs, fuel, oil, and grease. Equipment costs can be obtained from the *Rental Rate Blue Book.* To obtain any equipment costs not specified, other sources may include manufacturers of the equipment and the Means' *Heavy Construction Cost Data*.

3. Labor. Labor costs vary greatly throughout the State. The estimator must not only determine what types of crafts that will be required, but also the most efficient number of workers in each craft. In determining a unit cost for labor, the estimator considers the efficiency of the local labor, their working agreements, fringe benefits, social security, workers compensation, guarantees of minimum working hours per week, show-up time clauses, liability insurance, and non-working conditions due to mechanical breakdowns or bad weather.

   The labor rate used for Federal-aid projects must be at least equal to the Federal prevailing wage rate. The labor rate used for State projects must be at least equal to the Illinois prevailing wage rate. An exception is when the prevailing rates are not provided in a contract. Section 65-3.01 further discusses the wage rate determination.

4. Material. Contact the suppliers directly to obtain quotes for materials. The quoted prices are typically what suppliers hope to receive for their product. The final price the contractor will be required to pay will generally be lower due to competition and negotiations between the contractor and supplier. Such items as discounts for large quantities, early payment or extreme competition on a particular project may vary the final price. The estimator should adjust the quoted prices based on these factors, previous estimates, and engineering judgment.

5. Hauling. The hauling expense is based upon haul distance, truck capacity, load and unload time, driver wage and truck expense, and/or quoted hauling costs.

6. Incidental. Incidental costs cover any items that may or may not be addressed by a particular pay item in a contract. Incidental costs may include:

   - pay items included in other items by specification or special provision;

   - coordination with other contractors;

- “tight” completion dates which demand double shifts;
- payment of overtime;
- winter construction;
- congested work areas;
- high elevation work;
- hauling through heavy traffic, frequent railroad crossings, or traffic signals;
- work not adaptable to the normal equipment used which results in manual labor or renting of special equipment;
- location of plant sites, including costs of rental and renovation;
- the season during which the work will be performed;
- the cost of maintaining traffic including stage construction, flagmen, lights, and barricades; and
- other outside agencies rules and regulations (e.g., OSHA, EPA).

7. Mobilization. Mobilization costs consist of preparatory work and operations necessary for the movement of personnel, equipment, supplies, and incidentals to the project site; for the establishment of offices, buildings and other facilities necessary for work on the projects; and for all other work or operations that must be performed or costs incurred when beginning work on the project. Mobilization may include delivery and removal of all equipment utilized for a given type of work. This type of mobilization includes loading, unloading, set-up, delivery, and all necessary permits. When determining mobilization costs, the estimator needs to consider the following:

   - the same piece of equipment may be utilized for different work types and should only be mobilized once, if practical;
   - the type of operation;
   - how often and when the equipment is used;
   - the types of equipment; and
   - multiple types of mobilization.

8. Overhead. Overhead costs are divided into two classes — general overhead and job overhead. General overhead costs are main office expenses away from the job site, which include salaries and expenses for staff employees, office maintenance, office transportation, expenses of bidding on projects, local contributions to charities, dues to

contractor's associations, interest charges on borrowed capital, and any other expenses considered a part of the firm's general costs of doing business. Job overhead costs include general job supervision, general job supervision expenses, and security. Overhead costs are calculated differently depending upon whether it is equipment, material, labor, or subcontractor work. These differences are defined in the *Estimates Manual*.

9. Profit. Profit mark-up is the amount of money a contracting company retains after it has completed a project and paid all costs for materials, equipment, labor, overhead, taxes, insurance, etc. Profit costs are calculated differently depending upon whether it is for equipment, material, labor, or subcontractor work; see Section 109 of the Standard Specifications and the *Estimates Manual*.

10. Bond. Bond costs are a percentage mark-up of all costs associated with a project. This cost should include both bid bond and performance bond costs.

65-2.02(d) Lump-Sum Items

When lump-sum items appear in the contract, the designer should provide a list of the elements within the lump sum item. However, the estimator should also search the plans and special provisions to determine what materials, procedures, equipment, etc., are involved to construct the item. The unit cost for the lump sum item is then determined by combining the cost for each of the individual items.

65-2.03 Other Duties

The district estimating engineer is also responsible for the following:

1. Pavement Selection Cost Analysis. Providing the designer with the unit costs to be used in pavement selection cost analysis. If the pavement area exceeds 5000 yd^2 (4000 m^2), unit cost sheets must be prepared.

2. Cost Studies. Conducting cost studies for other bureaus within the district, upon request.

3. Agreed Unit Prices. Reviewing agreed unit prices submitted by the contractor to the district Bureau of Project Implementation and recommending acceptance or rejection.

4. Unit Price Tabulation of Bids. Obtaining a copy of the Unit Price Tabulations of Bids for all projects in their district. This information will be made available to the general public for review and should be maintained for the last three years.

65-3 CENTRAL OFFICE PROJECT MANAGEMENT UNIT

The following discusses the duties and responsibilities of the Bureau of Design and Environment Project Management Unit. Section 65-1.04 discusses the Unit's responsibilities for the Engineer's Estimate.

65-3.01 Wage Rate Tabulation

The Project Management Unit is responsible for preparing a tabulation of wage rates for laborers, operating engineers, carpenters, concrete finishers, ironworkers, etc. This tabulation includes the minimum hourly wage rates for these crafts for all Illinois counties, including the fringe benefits in the contract agreement. These rates are determined from contracts between the local unions. This tabulation is updated quarterly and distributed to all district estimators. The Project Coordination and Implementation Section is responsible for maintaining a file, by county, of the current wage rates. Contractors must pay the current prevailing wage rates and all subsequent changes.

Wage rate tabulation is required on all projects. When the advertisement for bids on any contract is for the construction of a project on the Federal-aid system, a wage rate determination is distributed to all bidders 10 days prior to the letting per agreement with the US Department of Labor. When the advertisement for bids on any contract is for State-funded contracts, the wage rates are included in the proposal. Any prevailing wage rate changes for State-funded contracts will be included in the Service Bulletin for the contractor's information.

65-3.02 Other Duties

The Project Management Unit is responsible for the following:

1. Day Labor Projects. Separate estimates are prepared based upon the day labor guidelines and the guidelines of the Project Management Unit. These two estimates are compared to determine the cost effectiveness of day labor versus competitive public bidding.

2. Pavement Selection Cost Analysis. The Project Management Unit reviews the cost of the pavement structural items included in the pavement design study submitted by the district to the Bureau of Design and Environment's Policy and Procedures Section. A detailed cost analysis is made of each structural pavement item submitted in the study. Corrections, if necessary, are made and the file returned to the Policy and Procedures Section.

3. Cost Studies. Cost studies within the realm of the Project Management Unit's expertise are conducted for all divisions and bureaus of the Department upon request.

4. Agreed Unit Prices. If the agreed unit prices initially negotiated between the district Bureaus of Project Implementation and Program Development are unacceptable to the

Central Office Bureau of Construction, the Project Management Unit will review the unit prices and provide a recommendation to the Central Office Bureau of Construction.

5. Incoming Estimates. The Project Management Unit maintains a list of all incoming estimates showing the total cost and data received for use by other internal offices.

6. Price Indices. The Project Management Unit develops and maintains material price indices for Department use in contract price adjustment clauses. Price adjustment clauses are available on steel, fuel and bituminous materials.

7. Federal Highway Administration. The Project Management Unit submits a complete estimate to the FWHA for all non-exempt Interstate projects as defined by the Oversight Committee. On exempt projects, only the total cost is submitted to the FHWA when Federal-aid is involved. However, the estimates should include fund type breakdowns and distances. As contracts are awarded, the Program Support Unit submits the Bid Price Data on FHWA Form PR-2 to FHWA.

8. Construction Breakdown. The Project Management Unit prepares unit price breakdowns by work categories for each contract and submits it to the Bureau of Construction to enable them to determine the bidding capabilities of contractors.

9. *Estimates Manual*. The Engineer of Project Management is responsible for maintaining, updating, and distributing the *Estimates Manual.*

10. Research. The Engineer of Project Management is responsible for developing new methods of computing unit costs, training, and instructing personnel involved in the art of cost estimating. This may involve seminars with district estimators to instruct and inform the estimators of revised or new methods of estimating and to discuss new equipment, materials, and unit cost items.

CONTRACT PROCESSING

66-1 SPECIFICATIONS, SPECIAL PROVISIONS, AND HIGHWAY STANDARDS

66-1.01 General

The *Standard Specifications for Road and Bridge Construction* (Standard Specifications), Supplemental Specifications, Recurring Special Provisions, Contract Special Provisions, and plans all are essential parts of the contract. They should complement each other and provide complete instructions for the work to be accomplished. If a discrepancy does exist among these documents, the relationships as described in Article 105.05 of the *Standard Specifications* will apply.

The *Standard Specifications* and Supplemental Specifications are included in the contract documents by the designer by referencing the applicable editions in the first paragraph of the special provision portion of the contract. Recurring Special Provisions are included through the use of a check sheet. Contract Special Provisions are included with the contract documents provided to the contractor.

The *Standard Specifications* and Supplemental Specifications are reviewed by the Specifications Committee which acts in an advisory capacity to the Director of Highways. The Specifications Committee includes permanent representatives from the Bureaus of Bridges and Structures, Design and Environment, Construction, Materials and Physical Research, Operations, and Local Roads, District One, FHWA, and Illinois State Toll Highway Authority. Three seats are also held by the other eight downstate districts on a three-year rotating basis. The chairperson is chosen by the Director of Highways for a four-year term. The Standards and Specifications Engineer in the Bureau of Design and Environment is the recording secretary.

66-1.02 Specifications

66-1.02(a) Standard Specifications

The *Standard Specifications for Road and Bridge Construction* (*Standard Specifications*) are the requirements adopted by the Department for work methods, materials, and basis of payment used in construction. The *Standard Specifications* are intended for general and repetitive use. They provide Department criteria for:

- the scope of work,
- control of work,
- control of materials,
- legal regulations and responsibilities to the public,
- contract prosecution and progress, and

- measurement and payment of contract items.

The *Standard Specifications* are published in book form and are updated every three to four years. Copies of the *Standard Specifications* can be obtained from the Department's website.

66-1.02(b) Supplemental Specifications

Supplemental Specifications are additions, deletions, and/or revisions to the *Standard Specifications*, which have been adopted by the Department since the last printing of the *Standard Specifications*. They are automatically considered part of the *Standard Specifications*.

Supplemental Specifications are printed in book form and are revised each year. Copies of the latest editions can be obtained from the Department's website.

66-1.03 Special Provisions

66-1.03(a) General

Special provisions are additions or revisions to the *Standard Specifications* and the Supplemental Specifications documenting conditions and requirements for special situations. Special provisions are either included in the contract documents or referenced through a check sheet.

66-1.03(b) Recurring Special Provisions

Recurring Special Provisions are special provisions that are commonly used on many projects. Unlike *Standard Specifications* and Supplemental Specifications, Recurring Special Provisions do not require the approval of the Specifications Committee. Recurring Special Provisions are printed with the Supplemental Specifications and inserted into a project by reference (i.e., check sheet). Each district is provided a copy of the check sheet, which contains a list of all the latest Recurring Special Provisions, by the BDE. The designer can obtain the check sheet from the district Program Development Engineer. The designer is responsible for checking the appropriate Recurring Special Provisions for the project and including the check sheet with the contract documents.

66-1.03(c) Contract Special Provisions

Contract Special Provisions are the special provisions the designer includes with the proposal submitted with the plans to BDE. They may include one or more of the following:

1. <u>BDE Special Provisions</u>. BDE Special Provisions are Contract Special Provisions issued for Statewide use. These special provisions are fill-in-the-blank specifications or specifications that are issued between publications of the Recurring Special Provisions. They are issued through BDE effective beginning with a specific letting. All special

provisions effective for a letting are transferred to the districts through the LAN and via email. The designer is responsible for marking the appropriate BDE Special Provisions on the BDE Check Sheet and BDE will insert the paper copy into the proposal for each project.

2. Bridge Special Provisions. Bridge Special Provisions are Contract Special Provisions issued by the Bureau of Bridges and Structures that may have changes from letting to letting. These special provisions may become BDE Special Provisions when no revisions have been made for at least a year. The Bureau of Bridges and Structures is responsible for including the appropriate Bridge Special Provisions into the contract documents for each project.

3. District Special Provisions. District Special Provisions are Contract Special Provisions addressing concerns unique to a district (e.g., material shortages, labor agreements). These special provisions are approved by BDE prior to their repetitive use. The district may also recommend these special provisions for consideration as BDE Special Provisions. The designer is responsible for including the appropriate District Special Provisions into the proposal for each project.

4. Project Specific Special Provisions. Project Specific Special Provisions are Contract Special Provisions written by the designer to address a unique situation on a project. These special provisions should not be used in more than one project. Project Specific Special Provisions are required wherever a project contains work, material, unique sequence of operations, or any other requirements that are necessary for the completion of the project but are not included in the *Standard Specifications,* Supplemental Specifications, Recurring Special Provisions, BDE Special Provisions, or Bridge Special Provisions. These special provisions should not be prepared to personalize the work to the ideas of the designer or to place emphasis on certain aspects of a project. The practice of emphasizing particular procedures and requirements already stated in the *Standard Specifications* is more properly accomplished at the preconstruction conference. The district may recommend these special provisions for consideration as District Special Provisions or BDE Special Provisions. The designer is responsible for writing and including the appropriate Project Specific Special Provisions into the proposal for each project.

66-1.04 Special Provisions Preparation

66-1.04(a) Preparation Steps

The designer should use the following steps when preparing a special provision:

1. Define Need. The designer should review the existing specifications, standards, details, special provisions, and plans to ensure that there is a need for the special provision. If the topic is not adequately covered in one of the other documents, only then should a special provision be prepared.

2. Research. The designer should research the topic so that complete and detailed information is available before writing the special provision. If the designer determines this special provision will be applicable in more than one project, the special provision should be submitted to BDE for consideration as a District Special Provision or BDE Special Provision.

3. Format. Prepare special provisions in the same manner as the *Standard Specifications*. Section 66-1.04(b) presents the format that should be used.

4. Writing the Special Provision. Once all research has been completed, the first draft can then be prepared. The designer may want to review existing special provisions for guidance. The following are several grammatical recommendations for preparing special provisions:

   a. Wording. Write in the passive voice.

   b. Sentences. Prepare the special provision using simple language and words. Keep words and sentences short (20 words or less), unless complexity is unavoidable.

   c. Paragraphs. Limit paragraphs to three or four sentences.

   d. Terminology. Words should be used consistent with their exact meaning. Use the same word throughout; do not use synonyms. Avoid any words that have a dual meaning. Section 66-1.04(d) presents the recommended terminology that should be used. Omit extraneous words and phrases.

   e. Pronouns. Avoid the use of pronouns, even if this results in frequent repetition of nouns.

   f. Punctuation. Carefully consider the punctuation using the minimum number of punctuation marks consistent with the precise meaning of the language. Ensure that the meaning of any sentence is not in doubt.

   g. Parentheses. Avoid the use of parentheses ( ). Instead, use commas or rewrite the sentence.

   h. Numbers. Write all numbers numerically. It is unnecessary to write numbers both in words and figures. Show times and dates numerically. Write fractions as decimals. Decimals less than one should be preceded by the zero.

5. Reviewing. Review the previously completed paragraphs as succeeding ones develop. Where necessary, redraft preceding paragraphs to reflect later thoughts.

6. Submissions. The designer should prepare and distribute the preliminary draft of the special provisions within the district for review and comment as soon as practical. The designer will be responsible for incorporating the reviewers' comments into the final draft.

66-1.04(b) Format

Prepare special provisions in the same format as the *Standard Specifications*. The sections of the special provision that should be addressed, when needed, include:

1. Description. Provide a brief narration of the work to be performed with references to specifications, plans, or other special provisions that further define the work. The description usually begins with "This work shall consist of...". Only mention the major aspects of the work.

2. Materials. Designate the materials to be used in the work and establish their requirements. Delineate complete specifications of the properties of each material and the test method. References may be made to AASHTO, ASTM, or other recognized specifications. Where a material is already specified in the *Standard Specifications*, reference the appropriate article or section with any necessary changes stated. Do not reproduce a standard specification in its entirety to revise one or two elements.

   The use of proprietary specifications is generally prohibited by the Illinois General Statutes. However, the Statutes do allow, under certain conditions, proprietary items to be used. Where the designer has a need for a proprietary specification, contact the Policy & Project Development Section in the Bureau of Design and Environment for guidance.

3. Equipment. Designate the equipment to be used in the work and establish its requirements. Where a piece of equipment is already specified in the *Standard Specifications,* reference the appropriate article or section with any necessary changes stated. Do not reproduce a standard specification in its entirety to revise one or two requirements.

4. Construction Requirements. Describe the sequence of construction operations or the desired end product. Only use the presentation for the sequence of construction operations if it is critical to achieve the desired result.

5. Method of Measurement. Describe the units of measurement for each pay item and where the item will be measured (e.g., in place, in truck, at plant). Designate any modifying factors and other requirements needed to establish a definite measured unit.

6. Basis of Payment. Describe the units and the pay item name for which payment will be made. Note the entire pay item name in upper-case letters. Do not include a listing of all elements of the work.

66-1.04(c) Guidelines

In addition to the above sections, the following presents several guidelines the designer should consider when developing special provisions:

1. Completeness. The designer should ensure that the essentials have been included, each requirement is definitive and complete, and the *Standard Specifications* have not been duplicated. The special provision should not be vague.

2. Clarity. To ensure clarity, the designer should:

   - Clearly delineate the method of measurement and basis of payment.
   - Make a clear, concise analysis of the job requirements for general conditions, types of construction, and quality of workmanship. Do not leave the contractor in doubt on what they will be required to do.
   - Give directions, never suggestions.
   - Never assume the contractor knows what is meant.
   - Avoid conflicting or ambiguous requirements. Every specification should have only one meaning.
   - Never conceal difficulties or hazards from the contractor.

3. Conciseness. Each special provision should be as concise as practical. When reviewing the special provision, the designer should consider the following suggestions:

   - Where practical, refer to an existing specification and delineate only the portion changed.
   - Avoid duplications between different special provisions and any related contract documents.
   - Do not give reasons for a specification requirement.
   - Do not provide additional information that is unnecessary for the preparation of bids and the accomplishment of the work.
   - Once stated, do not repeat any instruction, requirement, direction, or information.
   - Use cross references, wherever practical.
   - Write the specification in the positive form (e.g., use “will” instead of “will not”).
   - Do not include instructions to the Department in the specification.

4. Correctness. To ensure that the special provision is written correctly, the designer should review the following:

   - Do not include items that cannot be required or enforced.
   - Ensure that the specification does not punish the contractor or supplier.

- Ensure that the specification does not unintentionally exclude an acceptable product, construction method, or any equipment.

- Ensure that the provision does not change the basic design of the item.

- Do not specify impossibilities. The practical limits of workers and materials must be known and recognized.

- Specify standard sizes and patterns wherever practical.

- Avoid personal whims and pet requirements.

- Ensure that the contractor will not be held responsible for the possible inaccuracy of information furnished by the Department.

- Ensure sufficient attention has been provided to assessing the durability or reliability of the material or procedure discussed. The use of recognized standards should be referenced to ensure that the specified performance or characteristics are achieved. If not, define the testing criteria completely and accurately.

- Make a careful, critical examination of manufacturers' or trade associations' recommendations, and require supporting evidence.

- Requirements should be stringent. A strong requirement can be relaxed more economically, when the need arises. Weak specifications cannot be strengthened without increasing cost and generating claims.

- Ensure that the provision gives directions that are consistent with the standard practice currently used by the Department.

66-1.04(d) Terminology

Phraseology and terminology used in the *Standard Specifications* also should be used in the special provisions. In addition, the designer should consider the following:

1. <u>Abbreviations</u>. Generally, avoid abbreviations. However, they may be used if they are defined and the definitions are consistent with the accepted meanings. Always use the abbreviations for the terms listed in Article 101.01 of the *Standard Specifications*.

2. <u>Amount, quantity</u>. Use "amount" when writing about money only. When writing about measures of volume, use "quantity."

3. <u>Any, all</u>. The word "any" implies a choice and may cause confusion. In place of "any," the term "all" should be used.

4. <u>Article</u>. Capitalize "Article" when referring to an article of the *Standard Specifications*.

5. As per. Do not use “as per”; instead, use “according to.”

6. As shown on the plans. Use “as shown on the plans” instead of “as shown in the plans,” “as detailed on the plans,” “as shown on the detail sheets,” “as shown on the highway standards,” or “as shown on sheet ____________ of the plans.”

7. Contractor. Use the word “Contractor” in place of the word “bidder” when writing special provisions for construction. “Bidder” should only be used for proposals. Contractor should always be capitalized.

8. Course. Use “course” for layers, not for “lifts.”

9. Day. Define the type of day to be used (e.g., calendar day, work day).

10. Department. Use “Department” in place of “Illinois Department of Transportation.” Department should always be capitalized. IDOT should not be used in the contract documents.

11. Included In. Use “included in the cost” instead of “incidental to.” The price of all work will be factored somewhere into the contract. Bid prices are generally lower when the contractor knows where to include costs.

12. Pay item. Use “pay item” instead of “bid item.”

13. Proposal. Do not use the word “proposal” when the word “contract” is intended. The term “proposal” only should be used to describe requirements during the bidding process.

14. Said. Do not use “said pipe,” “said aggregates” but, instead, use “the pipe,” “the specified aggregates.”

15. Same. Do not use “same” to replace a pronoun like “it” or “them” standing alone, such as “connected to same,” “specified for same,” or “same will be given consideration.” Rewrite the sentence to clearly describe what is meant.

16. Section. Capitalize “Section” when referring to a section in the *Standard Specifications*.

17. Shall, will. Use the word “shall” when specifying the responsibilities of the contractor. Use the word “will” when specifying the responsibilities of the Department (“we will,” “they shall”).

18. State. The term “State” is preferred over the “State of Illinois” or “Illinois.”

19. Such. Do not end a sentence with the word “such.” “Such” usually means “of this or that kind,” or similar to something stated. Instead, state that which is actually meant, or name the work to be completed or rephrase the sentence.

20. The. Do not eliminate “the” for brevity.

21. Unless Otherwise Specified. Do not use the term "unless otherwise specified." In special provisions, the designer should know if something will be "otherwise specified." In the *Standard Specifications* everything can be "otherwise specified" in the plans or through Contract Special Provisions.

22. Unit Price. Use "contract unit price" instead of "contract unit price bid."

66-1.04(e) Unit Abbreviations

Figure 66-1.A provides a list of unit abbreviations adopted for the Standard and Supplemental Specifications and the Recurring and BDE Special Provisions.

66-1.04(f) Rules

The following is a list of rules adopted for the Standard and Supplemental Specifications and the Recurring and BDE Special Provisions:

1. Do not use hyphens to combine units (e.g., foot pounds would be ft lb not ft-lb). Do not use hyphens between the number and the unit (i.e., use 10 ft versus 10-ft).

2. Use the "/" symbol instead of the word "per" to combine units (e.g., inch per foot would be in./ft).

3. Always write out and do not abbreviate units used within Method of Measurement and Basis of Payment Articles.

4. Write out the words "percent" and "degrees" (i.e., angles) within text, but they may be abbreviated within charts and tables.

5. Write out the words "hour(s)" and "minute(s)" within the text, but they may be abbreviated within charts and tables (except: they will be abbreviated when used in combination with other unit abbreviations (e.g., m/min or ft/min))

6. Numbers within charts and tables are always written as numbers. Numbers associated with an abbreviated unit will also be written as numbers (e.g., 2 m, 8 mph, 32 kPa).

Unit Metric (US Customary)	Abbreviations
Length	
nanometer (thousands of an inch)	nm (mils)
micrometer (thousands of an inch)	µm (mils) or µm (in.)
millimeter (inch)	mm (in.)
meter (foot)	m (ft)
kilometer (mile)	km (mile)
Area	
square meter (square foot)	sq m (sq ft)
square meter (square yard)	sq m (sq yd)
hectare (acre)	ha (acre)
Volume	
liter (gallon)	L (gal)
cubic meter (cubic yard)	cu m (cu yd)
Weight	
gram (ounce)	g (oz)
kilogram (pound)	kg (lb)
metric ton (ton)	metric ton (ton)
Force	
Newton (pound)	N (lb)
kiloNewton (pound)	kN (lb)
Pressure, Stress	
kilopascal (pounds per square inch)	kPa (psi)
Energy, Work	
Joule (foot pound)	J (ft lb)
Torque	
Newton meter (foot pound)	N m (ft lb)
kiloNewton meter (foot pound)	kN m (ft lb)
Speed	
meter per minute (feet per minute)	m/min (ft/min)
kilometer per hour (miles per hour)	km/hr (mph)

UNIT ABBREVIATIONS

Figure 66-1.A
(1 of 2)

Unit Metric (US Customary)	Abbreviations
Temperature	
degrees Celsius (Fahrenheit)	°C (°F)
Electrical	
millivolt	mV
volt	V
kilovolt	kV
kilovoltampere	kVA
millampere	mA
ampere	A
hertz	Hz
watt	W
kilowatt	kW
ohm	ohm

UNIT ABBREVIATIONS

Figure 66-1.A
(2 of 2)

7. For numbers not associated with an abbreviated unit, use the following:

   - numbers from zero to ten will be spelled out (e.g., ten hours, two-way radio, seven tires);
   - numbers greater than ten will always be written as numbers (e.g., 12 hours, 50 cycles, 11 percent); and
   - numbers less than one will be written as decimal numbers except inches will be written as fractions (e.g., 0.2 acre, 3/4 in.).

66-1.05 IDOT Highway Standards

The *IDOT Highway Standards* provide details on various design elements that are consistent from project to project. They provide information on how to lay out or construct the various design elements. Design data and/or specifications are not included on the *IDOT Highway Standards.* The designer is responsible for providing the standard number, including revision number, in the Standard Index included in the plans; see Chapter 63.

IDOT Highway Standards are developed by the Bureau of Design and Environment and are approved for general use by the Engineer of Design and Environment. *IDOT Highway*

Standards are developed in collaboration with other bureaus. Districts may submit ideas and details for the *IDOT Highway Standards* to BDE.

Copies of the *IDOT Highway Standards* are available on the Department's website.

66-2 SUBMISSION OF PLANS, SPECIFICATIONS & ESTIMATES

66-2.01 District Pre-Letting List

To consider all improvements that are available for letting, the district will submit to the Engineer of Design and Environment a list of recommended improvements for each scheduled letting. This list will be submitted at least 12 weeks in advance of the scheduled letting date. Identify the improvements by route, section, and county. It is desirable that improvements that are included in the published program be available for letting as early in the calendar year as practical, especially those that will require less than 100 working days and include bituminous work. Letting improvements early also gives the prospective bidders better opportunities to schedule their work and may result in more competitive bidding.

66-2.02 PS&E Submittal

The district must electronically submit the plans, specifications and estimates (PS&E) to the Program Support Unit within the Bureau of Design and Environment by the applicable PS&E deadline for the letting (typically 10-12 weeks before the letting date). Each district has its own folder on the Cosep1\Letting directory with sub-folders for each letting date. Within each letting date sub-folder, there will be a folder for each project on that letting named with the contract number where electronic copies of the following PS&E documents must be submitted:

1. Certification Acceptance/Project Status (Form BDE 488). Complete and include this form to ensure that all applicable Federal/State requirements have been addressed (e.g., right-of-way, utilities, railroads). This form must be signed by both the designer and the Regional Engineer. See Figure 66-2.A for instructions on completing the form.

2. Plans. Include 11”x17” PDF files of the plans after they are signed by the Regional Engineer (note: paper copies of the signed sheet(s) are no longer required as the signature may be hand-written, stamped, scanned or computer-generated). There must be one PDF file for each individual plan sheet as well as one multiple-page PDF file containing all sheets, up to 100 sheets. If there are more than 100 sheets, then additional multiple-page PDF files will be required. Do not include copies of the *IDOT Highway Standards* with the plan submittal as they will be incorporated into the plans by the Bureau of Design and Environment. Print styles, .pltcfgs and pen tables are available in the IDOT CADD Standards folder on every district CADD server to assist the districts in creating PDFs directly in MicroStation that meet these requirements.

3. Contract Special Provisions. Include a Microsoft Word file of the contract special provisions written for the project. Section 66-1.04 discusses the procedures for developing special provisions. Also include a copy of the Recurring Special Provisions check sheet and the BDE Special Provisions check with the applicable special provisions marked.

4. Quantities Estimate. Include the project quantities on Form BDE-213 or Bureau of Design and Environment approved equal. The unit prices are provided to the Central

Office by the district estimating engineer under a separate submittal. Copies of form may be obtained from the Department's website. Chapter 64 provides the procedures for determining plan quantities.

5. Estimate of Time. Determine the expected construction time for the project. Section 66-2.03 provides the Department's guidelines for determining the expected construction time.

6. Permits and Agreements. Include electronic copies of permits, agreements, and other such documents required for the project.

Once all required PS&E documents have been placed in the project folder, send a notification email to: DOT.CO.D&E-Plan&SpecSubmittal.

The above process only applies to the original PS&E submittal. If any revisions or addenda need to be submitted at a later time, those documents and notification of the change(s) must be coordinated directly with the appropriate Regional Field Engineer in BDE except for revisions to structure plans which must be submitted through the Bridge Office. All new and/or revised plan sheet PDFs must follow the same naming conventions as the original submittal.

The following documents are considered part of PS&E with documents retained by the district as project files when the recommendations are incorporated into the plans, contract special provisions and/or documented on the Certification Acceptance/Project Status form (Form BDE 488):

1. Design Exceptions

2. Experimental Features

3. Value Engineering Approved Recommendations

4. Environmental Commitments

5. Results or Recommendations from the Transportation Management Plan

6. Erosion and Sediment Control

7. Final Plan Submittal Estimate

Length, Type & Location of Work:

District - Which district the project is taking place in. If central office is submitting plans for work to be done in a different district, please indicate in which district the project is located

Contract No. - Construction contract number

Functional Classification - Classification by which highways and streets are grouped into classes or systems based on the character of service they are intended to provide (See Chapter 43: Highway Systems for more information). Identifiers to use:

- Interstate
- Freeway or Expressway
- Other Principle Arterial
- Minor Arterial
- Major/Minor Collector

Route -

- FAI: Interstate
- FAP: Primary
- FAS: Secondary
- FAU: Urban

Marked Route - State Bond Issued (SBI) Marked Route. The interstate, state or US route marking or street/road/avenue that is noted for the public on state maps

Project - If Federally funded: fund type prefix + 7 digit federal project number generated from the State Job Number database (SJN).
Examples: NHPP-0JBU(103) or STP-000V(123) or HSIP-BQUJ(586)
Else if State funded: “State” or “Illinois” funded

BDE 488 Certificate Acceptances/Project Status Instructions
Figure 66-2.A
(1 of 8)

Section - Section number assigned to the project

County - The County or Counties project is taking place in, if it’s greater than 3 counties list “Various” (for Electronic Letting Management (ELM) mainframe allows only 3 counties to be entered)

State Job No. - State Job Number assigned and developed through the State Job Number database (SJN) which should always be the “C” number

- P = Phase 1 – Studies & Environmental work
- D = Phase 2 – Design & Plans
- C = Phase 3 – Construction

Submittal Date - Date submitted to Springfield Central Office

Recommended Letting Date - The letting date project is anticipated to be let on

Annual Program No. – A 9 digit program number generated through Windows Program Planning System (WPPS) database. Identifies how the money is programmed whether it be across multiple fiscal years, single fiscal year, multiple fund types, straight state or federally funded.
Example: 1-76489-0100
If there are multiple program numbers list them all or add to the “Remarks” field at the bottom of the form.

Program Cost - Estimated cost of the project, amount that is programmed in WPPS using the 9 digit program number

Congressional District - List the congressional district/legislative district

Maintenance Responsibility - List who will maintain finished product of the project, typically “State” responsibility (Chicago may have maintenance responsibility for State routes within Chicago)

Population of Urbanized Area - List the population of the area and if it’s considered rural or urban use the following:

- Urban = places identified by the US Bureau of Census having a population ≥ 5,000
  - Urbanized > 50,000
  - Small urban areas > 5,000 but < 50,000
- Rural = places identified by the US Bureau of Census having a population < 5,000

More information is provided in Chapter 43: Highway Systems

BDE 488 Certificate Acceptances/Project Status Instructions
Figure 66-2.A
(2 of 8)

Length, Type & Location of Work - • Location must be described in sufficient detail to be identified on a state map.

- Include mileage, municipality, location identified by road to road or street to street
- On bridge jobs state what the structure/culvert is over (route, body of water, RR etc.)
- Include brief description of the type of work
- This information will be used for the service bulletin

Middle of Form

The following will go in numerical order in line with the form.

For reference for the rest of the form, please mark the appropriate statement for each category/descriptor of the project:

- A = Approved, Clear, or Yes;
- R = Required but Not Clear;
- E = Exempt or Not Applicable

If something is not required, then mark (E) or else provide the necessary information requested below. Per each statement one of the three checkboxes should be marked.

1. Plans and Special Provisions - Mark if the statement is true and comply with current policies, and if there are exceptions list them out in the "Remarks" at the bottom of the form

2. Completion Date and Working Days - Use a minimum of 15 working days and use of multiples of 5 days. The completion date should match the completion date as stated in the Special Provisions (SP) and if there are additional working days to the completion date be sure to note them.

3. Design Approval - On projects where design approval is not required, put the date Plans, Specifications, and Estimates (PSE) is signed by the Regional Engineer.

BDE 488 Certificate Acceptances/Project Status Instructions
Figure 66-2.A
(3 of 8)

4. NEPA Category - Check which one applies (i.e., EIS/ROD, EA/FONSI, State CE (using BDE 2301), Federal CE, or State CE (exempt from Phase I report). For the Date of ROD/FONSI/CE box enter the date as described below:

- the date the Regional Engineer or Authorized Designee approved the State CE from BDE 2301 in the Phase I report;
- For projects that meet the criteria in Section 12-3.10 and are exempt from a Phase I report, the CE determination can be made directly on BDE 488. The date will be the date that the Regional Engineer signs BDE 488. However, for these types of projects to ensure NEPA compliance when Federally funded, the Appendix (Appendix A or B) and the item # must be filled out on this form (see the CE Agreement in Appendix A of the BDE Manual for this information);
- the date the Federal CE was approved by the FHWA Transportation Engineer (TE);
- the date of the Finding of No Significant Impact (FONSI) for an EA; or
- the date of the Record of Decision (ROD) for an EIS.

If a reevaluation was completed, then enter the date of the re-evaluation.

3 classes of environmental signoff:

- EIS/ROD
  - Environmental Impact Statement: know there is a significant impact
  - For More information see Chapter 25 Environmental Impact Statements
- EA/FONSI
  - Environmental Assessment: don’t know if there will be a significant impact
  - For more information see Chapter 24 Environmental Assessments
- Categorical Exclusions
  - State Approved CE: No potential for unusual circumstances
  - Federal Approved CE: Potential for unusual circumstances
  - For more information see Chapter 23 Categorical Exclusions

5. ESR/PMA Sequence Number - Project Monitoring Application (PMA) sequence number is required if an Environmental Survey Request (ESR) was submitted to BDE.

6. Natural Resource Review - If an ESR was submitted to BDE for biological and/or wetland resources and a Natural Resource Review was received in response, then mark the ‘A” and enter the date of the Natural Resource Review. Please note that the date of the Natural Resource Review must be within two years of the letting date. If it will be more than two years, then district should either ensure there is a valid IDNR review response or request the Natural Resource Unit to update the review.

   Note: Submittal of the biological review validation takes a minimum of 3 months to complete, provided no additional coordination or surveys are required.

BDE 488 Certificate Acceptances/Project Status Instructions
Figure 66-2.A
(4 of 8)

If an ESR was submitted to BDE for biological and/or wetland resources and a Natural Resource Review was not received, then mark “R”. The Natural Resource Review must be received, and all coordination complete prior to letting.

If an ESR was not required to be submitted to BDE for biological, then mark “E.”

7. Regulated Substances Evaluation - Choose from one of the following scenarios when an ESR was submitted to BDE for regulated substances evaluation and make the appropriate notation on line 7 of the CA sheet:

   a. If a Level I, II, or III screening was successfully completed, list “BDE 2737” on the line, enter BDE’s approval date from the BDE 2737 Regulated Substances Screening form, and mark “A” for approved.

   b. If a Level I, II or III screening was unsuccessful, a Preliminary Environmental Site Assessment (PESA) is required. If results of the PESA identified no recognized environmental conditions (RECs), or if RECs were identified in the PESA but they can be avoided, list “No RECs/Avoided” on the line, enter the date of the PESA report, and mark “A” for approved. Please note that the date of the PESA must be within three years of the PS&E date associated with the project’s letting. If it will be more than three years old at the time of the PS&E date, then request the Geologic & Waste Assessment Unit to validate the PESA.

   c. If the Level I, II or III screening was unsuccessful and a PESA was not completed, mark “R” on line 7 for required but not cleared.

   d. If the PESA identified RECs and they could not be avoided, a special provision is required. In this case, list “Special Provision” on the line, enter the date of the BDE special provision final memorandum and mark “A” for approved. Please note that, if a PSI was completed, the date of the PSI must be within five years of the PS&E date associated with the project’s letting date. If it will be more than five years old at the time of the PS&E date, then request the Geologic & Waste Assessment Unit to complete a new PSI.

   e. If a PESA was completed, and a special provision was required but was not received, mark “R” for required but not cleared.

   If an ESR was not required to be submitted to BDE for regulated substances, then mark “E” for exempt or not applicable.

8. Cultural Resource Review
   If an ESR was submitted to BDE for cultural resources, then mark ‘A’ and enter the date of the Cultural Resource Review

BDE 488 Certificate Acceptances/Project Status Instructions
Figure 66-2.A
(5 of 8)

If an ESR was submitted to BDE for cultural resources and a Cultural Resource Review memorandum was not received, then mark "R". The Cultural Resource Review must be received and all coordination complete prior to letting.

If an ESR was not required to be submitted to Central Office for cultural, then mark "E."

9. Cultural Resource Review - If an ESR was submitted to BDE for cultural resources, then mark 'A' and enter the date of the Cultural Resource Review

   If an ESR was submitted to BDE for cultural resources and a Cultural Resource Review memorandum was not received, then mark "R". The Cultural Resource Review must be received and all coordination complete prior to letting.

   If an ESR was not required to be submitted to Central Office for cultural, then mark "E."

10. Incidental Take Authorization from IDNR - If the Illinois Department of Natural Resources requested IDOT to obtain an Incidental Take Authorization, it would be noted in the Natural Resource Review memo. If IDNR did not request an Incidental Take Authorization mark "E." If IDNR did request an Incidental Take Authorization and the signed copy has been received, then mark "A." IF IDNR requested an Incidental Take Authorization and the signed copy has not been received then mark "R."

11. TIP (Urbanized Areas)
    - Supply the TIP number
    - Areas that apply: Beloit, Chicago, Bloomington/Normal, Champaign/Urbana, Decatur, DuBuque, Kankakee, Peoria, Rock Island/Moline, Rockford, St. Louis, and Springfield
    - Project must be approved with the funding source and dollar amount before it can go to letting
    - If there is a change in the scope of work that would increase the dollar amount substantially the TIP must be amended to reflect this fluctuation in cost

12. Right-of-Way (ROW) Status - Right-of-Way (ROW) is the property that the state owns or needs to acquire to construct a project.
    - Check "Exempt" if NO ROW is required.
    - Check "Approved" if additional ROW or temporary easements have already been acquired.
    - Check "Required" if ROW or temporary easements are necessary but have not been acquired. If ROW is not clear, show the total number of parcels, total number parcels cleared, and total number of parcels NOT cleared.

13. Relocation Status - If required but not approved indicate the type of relocation: Business, residential, farm etc. and status.

BDE 488 Certificate Acceptances/Project Status Instructions
Figure 66-2.A
(6 of 8)

14. Joint Agreement (Local Agency) -
- Joint Agreement
  - Indicate who the agreement is with on the line provided
  - Approved means signed by the Local Agency and the Regional Engineer or Central Office
  - Send a copy of Agreement along with plan submittal
  - If not approved, send a copy of the current draft copy
- Letter of Understanding
  - Indicate who the letter is with on the line provided
  - Approved means signed by the Local Agency
- Letter of Intent/Information
  - Indicate who the letter is with on the line provided
  - Approved means sent to the Locals

15. Railroad Agreement (Railroad) -
- Indicate name of Railroad company on the line provided
- Approved means signed by the Railroad and the Central Office
- Must have a plan approval signed by the Railroad

16. Utility Adjustment - Indicate name of Utility on the line provided.
- Add a special provision for status of utilities to be adjusted showing the name and address of utility, location and when the adjustment is to be done
  •Utility Agreements (Company)
- For reimbursable work ONLY
- Indicate name of Utility on the line provided

17. Permits -
- If there are more than one permit required show number on the line provided
- Submit a copy of each permit listed below that is applicable to the project with the plan submittal to Springfield Central Office

Fill in the date the permit was received for each permit that is applicable to the project:

U.S. Corps. Of Engineers 404, and select the appropriate type of permit and date
U.S. Coast Guard permit and date
IDNR Office of Water Resources (OWR) and date
FAA and date

For more information on these permits see Chapter 28: Environmental Permits/Certifications

BDE 488 Certificate Acceptances/Project Status Instructions
Figure 66-2.A
(7 of 8)

18. Existing Structure. - Provide existing structure number on the line provided

19. Experimental Features Work Plan -
    - Required on all federally funded projects which has any type of Experimental procedures
    - If a work plan is required the district must submit it to Bureau of Materials and they will submit it to FHWA for approval
    - Must be approved before project will go on the letting

20. Construction Engineering -
    - Indicate either: state; local agency; consultant
    - IF done by local agency or consultants supply the name on line provided.

21. Pavement Design Approval - Pavement Design Approval is required if certain quantities of new pavement are needed, refer to Chapter 11: Phase I Studies for more information.

22. Value Engineering Report - Projects estimated at a certain dollar threshold will require a value engineering report, refer to Chapter 11: Phase 1 Studies for more information.

23. Work Zone Transportation Management Plan Approval - Plan approval is required if certain safety and mobility thresholds are exceeded, refer to BDE Chapter 13: Work Zone Traffic Management Studies for more information.

Bottom of Form

Remarks:

Code: **A** = Approved, Clear, or Yes; **R** = Required but Not Clear; **E** = Exempt or Not Applicable
The above information is certified to be true and correct.

Prepared By: Name Telephone No. Regional Engineer Date

- Remarks: any additional comments or provide extra information as noted above.

- Prepared by: District contact that Central office can contact if there are questions in regard to the information provided on this form.

- Regional Engineer: signature of Regional Engineer or authorized designee.

(8 of 8)

66-2.03 Construction Time Estimates

The contract duration is a very important part of the design data that accompanies plan submittals. It is essential that care be exercised in the determination of the working days or completion date. It must be remembered that a severe time requirement imposed upon a contractor will very probably be reflected in the bid prices, and the Department will pay a premium for that particular job when it may not be absolutely necessary. Also, with a provision for liquidated damages, it is extremely important that the designer arrive at a reasonable time limit to alleviate differences between the contractor and the Department.

To determine a feasible time limit, the designer must devote special attention to the sequence of construction operations to determine the order in which the work will progress. Also, sound engineering judgment is necessary to determine which construction operations will overlap to ascertain the days not affecting the total working days. The magnitude of the job is significant; i.e., the contractor for a small resurfacing job will use a much smaller work force than a contractor engaged in a large freeway project. Therefore, it is not probable that the contractor for the small job will be engaged in numerous operations at one time. Another consideration for the designer is the delivery of materials to the job site; e.g., in the case of a grade separation structure, it may be necessary to allow slack time between the completion of the substructure and initiating work on the superstructure due to the time required for fabrication and delivery of the structural steel. Although such determinations cannot always be made with absolute certainty, an estimate must be made to determine a reasonable time limit. If the contract will be placed on a completion date basis, the designer must devote special attention to construction operations that are limited by the *Standard Specifications.*

To determine the contract duration, the number of working days must be estimated. The “Estimate of Time Required,” Form BDE 220A, is used to determine working days and should accompany the plan submittal. Copies of the form may be obtained from the Department’s website. The number of days required for each item is obtained by dividing each quantity by its respective production rate. Figure 66-2.B provides the production rates for major items. The production rates shown in Figure 66-2.B apply to an average eight-hour work day. Construction production rates in Figure 66-2.B should be reviewed periodically and revisions made for any advancement in equipment output or construction techniques. Use the low rates on small projects and the higher rates on larger projects. For expedited contracts, it will be necessary to adjust the rates for longer working days. For items not contained in Figure 66-2.B, the district may supplement rates from their own design or construction files. The production rates of a single improvement are not conclusive in establishing these rates. Extremely high rates are often reached on a particular project or on any given day in the normal highway improvement but using these rates for the entire project would materially affect the accuracy of the time estimate.

The designer determines the “total days required” and “days not affecting time limit” on Form BDE 220A. These can be ascertained more readily by using a bar diagram, particularly when it is anticipated that many operations will be performed simultaneously or intermittently therefore making them difficult to schedule. In assigning work days, the minimum number used is 15 days and the total number of days assigned is in multiples of five. The number of working days required must also be calculated for contracts that will be completion date contracts. This will ensure that the completion date is realistic and allow the estimator to make allowances in the unit costs for anticipated overtime and extra crews the contractor may need to meet the completion date. Completion date contracts must be approved by BDE.

Where the major contract items require a tight completion date and it is not necessary for the minor items (e.g., seeding, clean-up) to be included in that date, the designer may use a completion date plus working days. The number of working days allowed after the completion date should be kept to a minimum and only allow minor work to be completed. The designer must clearly state in the Project Specific Special Provisions which items must be completed by the completion date and which items are involved in the working days. Completion date contracts with working days must be approved by BDE.

Major Worktype	Sub Worktype	Description	Unit	Low	High
Bridge	Bridge	Bearing Assembly	each	5	10
Bridge	Bridge	Bridge Deck Concrete Overlay	square yard	200	500

66-2.04 Selecting Contract Time and Project Letting Dates

66-2.04(a) Guidance for Selecting Project Letting Dates

A major Department goal is the delivery of the Highway Improvement Program. Proposed projects should go to letting as soon as practicable within the fiscal year as specified in the annual program. To determine what is practical, the designer must consider the type of work involved, the estimated time of completion, the availability of critical materials, other work in the area, and commitments. Typically, letting dates are chosen to prevent projects from being active through the winter months (December, January, February, and March). Winter construction is usually less productive, more expensive, and more disruptive to the traveling public.

The designer should become familiar with public activities and traffic patterns in the project area early in the Phase I engineering and recommend the best letting date for the project to the district programming engineer that will minimize delays and impacts to the traveling public and adjacent property owners. The designer should have a good idea how long the construction will take from the general scope and size of the project. The majority of projects are estimated to take less than 112 working days or approximately seven months to complete.

If a project (e.g., an eight mile, two-lane, resurfacing job) is estimated to take less than 45 working days to complete, it will be practical to schedule the project for a June letting with a construction start date around the first of August, allowing 45 days for the award of the contract and a completion around the first of November. This assumes no public event clauses are included in the contract (e.g., no lane closures allowed during the Illinois State Fair). Indicate how many working days are anticipated to complete the project in the Estimate of Time Required. The designer should determine the anticipated contract duration knowing when work items can or cannot be completed by the critical schedule of work anticipated, factoring in the contract work time restrictions. If work cannot be completed by the first part of November, the designer should recommend that the project go to a September letting or later and restrict the start of work until the following spring.

Districts prefer to have very small resurfacing projects completed before winter weather and will try for a June or August letting. If the project is scheduled for an August letting, estimate the time to take less than 20 working days, assuming construction starts around the middle of September (allowing 45 days for the Award of the contract) and is completed around the first of November.

The designer should recommend that the project go to a September letting or later and restrict the start of work until the following spring for larger projects (e.g., bridge replacements, bridge rehabilitations) that are estimated to take more than 45 working days. This avoids winter lane closures and the fall letting allows the contractor more time to order and fabricate critical materials ahead before the start of construction. The Department ends up with lower bid prices and more work completed within budget by allowing the contractor more time to order materials and schedule work.

If the designer estimates a project will take between 75 and 112 working days, recommend a November or January letting (possibly with a specific start date) to allow for a full construction season. If the designer estimates a project will take between 45 and 75 working days, target a January, March, or April letting.

On very large projects (e.g., new construction, reconstruction, major bridges) with more than 112 estimated working days (over one year) to complete, the designer must understand the major phases of construction and determine the critical path in order to recommend the appropriate letting date.

For a new bridge on a new alignment, the designer may want to place the project on a June letting to allow the bridge cones to be built in late summer or early fall and bridge work to proceed throughout the winter. For a large urban project, target a November letting to allow for off pavement utility relocations and storm sewers to be completed during the winter without disrupting traffic.

66-2.04(b) Selecting the Type of Contract Time

After estimating the anticipated number of working days to complete a project, the next step is to determine the type of Contract Time for the Completion of Work.

The Department’s goal is to use Contract Time for the Completion of Work in all contracts that will minimize inconveniences to the traveling public, but also foster reasonable contract unit bid prices for the proposed work from the contractors.

Figure 66-2.C shows working days per month based on a Working Days Contract versus that for Completion Date (Via Calendar Days) Contract.

WORKING DAYS PER MONTH												
	JAN	FEB	MAR	APR	MAY	JUN	JUL	AUG	SEPT	OCT	NOV	DEC
WORKING DAYS	0	0	0	0	15	17	17	17	16	16	14	0
CALENDAR DAYS	31	28	31	30	31	30	31	31	30	31	30	31

WORKING DAYS PER MONTH

FIGURE 66-2.C

The following explains general uses of each type of Contract Time for the Completion of Work:

1. Working Day Contract. A Working Day Contract is the preferred type of contract. The completion of the contract is set by the specified number of working days allowed in the contract. If the contractor exceeds the specified number of working days, liquidated damages, as specified in the *Standard Specifications*, will be charged until all contract work is completed.

   This type of contract is used when work does not need to be completed by a certain date. It allows more flexibility in getting materials ordered and fabricated. The contractor is not dependent on work by others being completed within a reasonable time (e.g., utilities being relocated during construction). The contractor is not charged a working day unless work is performed on a controlling item of work.

2. Completion Date Contract. Use Completion Date Contracts selectively. The latest possible completion of the contract is set by the completion date specified in the contract. If the contractor exceeds the specified completion date, liquidated damages, as specified in the *Standard Specifications*, will be charged until all contract work is completed.

   This type of contract does not guarantee the contractor a certain number of workable days; therefore, the contractor is more at risk. Use this type of contract when all project work must be completed by a specific date (e.g., State Fair, special events, farming operations, school start or end dates) or when coordination with other contracts requires work to be completed prior to start of next contract.

3. Completion Date Plus Working Day Contract. Use Completion Date Plus Working Day Contracts when a facility must be open to traffic by a specific date, but all work does not have to be completed by the completion date. The latest possible completion of specified work items in the contract is set by the completion date specified in the contract and it allows a number of working days in the contract to complete the remaining work. If the contractor exceeds the specified completion date or the number of working days allowed, liquidated damages will be assessed.

   When this type of contract is specified, the designer must identify the work to be completed by the completion date. The work to be completed during the allowed working days that are weather sensitive and/or require performance or establishment periods (e.g., landscaping, pavement markings) must also be identified.

4. Completion Date (Via Calendar Day) Contract. Use Completion Date (Via Calendar Day) Contracts when the work must be completed in a specific timeframe, not by a specific date. A Completion Date (Via Calendar Day) Contract is a completion date contract with a floating start date. The specified number of calendar days sets a date of project completion at the time the contract is started; therefore, the contractor is not affected by a late award.

Use this type of contract when a specific completion date is not required, but a completion date is necessary to expedite the work once the contract is started.

5. Completion Date (Via Calendar Day) Plus Working Day Contract. Use Completion Date (Via Calendar Day) Plus Working Day Contracts when a facility must be open in a specific timeframe, not by a specific date, but all work does not have to be completed by the completion date. A date of completion is established by the specified number of calendar days in the contract at the time the contract is started and allows a number of working days to complete the remaining work. If the contractor exceeds the specified date of completion or the number of working days allowed, liquidated damages will be assessed.

   When this type of contract is specified, the designer must identify the work to be completed by the completion date. The work to be completed during the allowed working days that are weather sensitive and/or require performance or establishment periods (e.g., landscaping, pavement markings) must also be specified.

   Use this type of contract when a specific completion date is not required, but a completion date is necessary to expedite the work once the contract is started.

Figure 66-2.D is a matrix summarizing definitions, benefits, weaknesses, and applicability for each type of contract.

66-2.04(c) Increased Use of Completion Date Contracts

As traffic volumes increase, so do the impacts to the motoring public and businesses during construction. To lessen these impacts, the use of Completion Date Contracts is encouraged as well as the use of Incentive/Disincentive specifications.

The provisions for Completion Date Contracts and Completion Date Contracts with Incentive/Disincentive provisions are as follows:

- Use on all multi-lane roadway projects with more than 25, 000 ADT.
- Use on all routes in urban areas where construction has the potential to severely impact the adjacent businesses.
- Consider using on projects where there is a need to control the completion of the project. Projects where completion is anticipated in the fall of the year may require a completion date to help ensure the work is completed and does not extend over the winter period. Large projects that will be let in multiple contracts should contain provisions to keep the overall project on schedule. Use completion dates to avoid conflicts with special events.

	Working Day	Completion Date	Completion Date plus Working Days	Completion Date (Via Calendar Days)	Completion Date (Via Calendar Days) plus Working Days
Definition	Defined in Article 108.04. Contracts specify the number of working days, by Special Provision, it should take for the contractor to complete the work.	Defined in Article 108.05(a). Contracts specify a date, by Special Provision, when the work is to be completed.	Defined in Article 108.05(b). Contracts specify a date, by Special Provision, that major items of work must be completed and allows working days to complete miscellaneous work.	Defined in Article 101.06. Contracts specify the number of calendar days, by Special Provision, to establish the completion date based on when the contract is started.	Defined in Article 101.06. Contracts specify the number of calendar days, by Special Provision, to establish completion date based on when the contract is started and allows working days to complete misc. work.
Benefits	● Allows the contract to be awarded late (> 45 days) without penalty to the contractor. ● Bids are generally better because of guaranteed working days. ● District can delay start without penalty to the contractor. ● Easier to administer.	● Specifies a date when all work must be completed (before special events or before winter). ● Can prevent contractor from prolonging the work over more than one season.	● Specifies a date when the major items of work must be completed (before special events). ● Working days allow time for miscellaneous work to be completed after the completion date.	● Allows the contract to be awarded late (> 45 days) without penalty to the contractor. ● Can prevent contractor from prolonging the work over more than one season. ● Completion date is established based on start date. ● Establishes a date when all work will be completed.	● Allows the contract to be awarded late (> 45 days) without penalty to the contractor. ● Can prevent contractor from prolonging work over more than one season. ● Completion date is established based on start date. ● Specifies a date when the major items of work must be completed (before special events)
Weakness	● No specified date for completion. ●Charging working days can be subjective.	● Possible conflicts due to potential time extension requests. ● Could result in higher bid prices if expedited schedule is required. ● Potential for project delays if contract is awarded > 45 days after letting or if contractor rejects.	● Possible conflicts due to potential time extension requests but easier to administer than completion date contracts. ● Could result in higher bid prices if expedited schedule is required. ● Potential for project delays if contract is awarded > 45 days after letting or if contractor rejects.	● Possible conflicts due to potential time extension requests. ● Could result in higher bid prices if expedited schedule is required.	● Possible conflicts due to potential time extension requests. ● Could result in higher bid prices if expedited schedule is required.
Applicability	● Preferred type of contract method. ● Use on contracts that do not have strict dates that the work needs to be completed.	● Use on contracts when all project work must be completed by a specific date (e.g., State Fair, special events, farming operations, school start or end dates) or when coordination with other contracts requires all work to be completed prior to start of next contract.	● Use when facility needs to be open by a specific date, but all work does not have to be completed. ● Use when miscellaneous items in the contract are weather sensitive and/or require performance or establishment periods (landscaping, pavement markings, etc.).	● Use when you want the work to be completed in a specific timeframe, not by a specific date.	● Use when the work is to be completed in a specific timeframe, not by a specific date and when the facility could be open sooner and all work does not have to be completed. ● Use when misc. items in the contract are weather sensitive and/or require performance or establishment periods (e.g., landscaping, pavement markings).

BENEFITS, WEAKNESSES, AND APPLICABILITY OF EACH CONTRACT TYPE

Figure 66-2.D

66-2.04(d) Expanded Use of Lane Rental Contracts

Lane rental is a contracting technique where the contractor bids the number of days of work requiring lane closures as part of the contract, or the Department sets the number of days that lane closures are allowed. If the contractor finishes early, an incentive is paid. If the contractor exceeds the number of days allowed, a disincentive payment is deducted from the contract for each day the limit is exceeded. This type of contract forces the contractor to schedule resources and perform work in a more timely manner.

Contracts using a lane rental specification should be considered on all high-volume, multi-lane projects (e.g., Interstates, expressways). Complete a traffic capacity analysis for these projects to determine the level-of-service to be anticipated during construction. In addition, complete a queuing analysis to determine the anticipated traffic backups at different times during the day and week. Once a traffic capacity analysis and queuing analysis are complete, a decision may be made on whether or not to use a lane rental specification. If a lane rental specification is used, this information will aid in determining the average road user benefit cost.

Include lane rental specifications for all Interstate and expressway projects. The lane rental specification must apply to the patching operation and may be applied to the whole project. Prepare a traffic capacity analysis and queuing analysis to determine the anticipated back-ups at different times during the day and week. This information is used in determining the average road user benefit cost for purposes of developing the Lane Rental Specification.

66-2.05 <u>Incentive/Disincentive Policy</u>

The term Incentive/Disincentive describes a contract provision, which compensates the contractor a prescribed amount of money for each day identified that critical work is completed ahead of schedule, and assesses a deduction for each day the contractor overruns the schedule. The Incentive/Disincentive clause is used to motivate contractors to complete critical projects by an expedited work schedule on or before a specified date. The use of Incentive/Disincentive provisions should be restricted to those critical projects where it is highly desirable for traffic inconvenience and delays to be minimized. Before an Incentive/ Disincentive clause is included in a contract, prior approval must be obtained from BDE. Unique cases not covered in Section 66-2.05(a) may be submitted for review and approval to the BDE.

66-2.05(a) Guidelines for Project Selection

Incentive/Disincentive clauses are intended for those projects where early completion would greatly benefit both the road user and the Department and where ramifications of not meeting the completion date are extreme. Use of Incentive/Disincentive clauses should be limited to projects that involve one or more of the following characteristics:

1. <u>Adverse Effects</u>. High-volume roads/high-volume truck traffic/structures that involve: high road-user cost increases, extended inconveniences, hazards to the motoring public, or severe disruption on adjacent business communities. Lower volume roads and river

structures that involve long adverse travel and area economic impact also may be considered.

2. Timing. Projects that have a direct bearing on the start and/or interruption of progress on major freeways, arterials, or structures may be considered for Incentive/Disincentive (e.g., utility relocations). However, where late completion, not early completion, is the primary concern, the designer should instead consider adding a clause providing for higher liquidated damages based on other Department costs per the *Code of Federal Regulations — Title 23*. A beam fabrication project is an example where late completion may be the primary concern.

3. Urban River Crossings. River structures in or adjacent to central business districts.

4. Night Time Construction. Nighttime construction (rehabilitation and/or resurfacing) on major urban freeways.

66-2.05(b) Application

Incentive/Disincentive clauses can be applied to a single project or to a combination of two or more projects. The following will apply:

1. Single Projects. The Incentive/Disincentive can apply to all or part of the project. The designer should consider the following:

   a. Entire Project. For projects where the Incentive/Disincentive applies to the entire project, all work must be completed before the Incentive/Disincentive is applied. River structure (rehabilitation or replacement) and urban freeway resurfacing projects are examples of single projects with the Incentive/Disincentive applied to the entire project.

   b. Project Portion(s). For projects where the Incentive/Disincentive applies to a portion of the work, a completion date is set on the specific portion of the project in which the Incentive/Disincentive is applied, and the remaining work is covered by liquidated damages. For example, an interchange reconstruction project where the primary concern is to restore traffic flow, the Incentive/Disincentive could be applied to only the work necessary to reopen the ramps and the interchange structure to traffic. Miscellaneous items, such as seeding and lighting, are not critical to reopening the roadway and could be completed after the Incentive/Disincentive completion date. These miscellaneous items would be covered by liquidated damages.

2. Multiple Projects. Cooperative Incentive/Disincentives are used to expedite a combination of two or more projects. The cooperative Incentive/Disincentive clause will require that work be completed on all projects before the total Incentive/Disincentive is applied. This type is used where a greater benefit is received by completion of a combination of projects. Adjacent sections of roadway that would provide usable

segments of a freeway would be an example where a cooperative Incentive/Disincentive could be used.

66-2.05(c) Amount Determination

The Incentive/Disincentive amount is the daily rate to compensate the contractor for early completion or assess the contractor for overrunning the completion date. This Incentive/Disincentive amount is based on the sum of the road-user delay cost and liquidated damages and should, in general, be adjusted downward for fiscal responsibility.

The Incentive/Disincentive amount should not exceed a total of road-user delay costs and liquidated damages. On projects where the Incentive/Disincentive amount applies to a portion of a single project, this amount is based only on the road-user delay cost. On projects where the Incentive/Disincentive amount applies to the completion of all work, the amount is based on the sum of road-user delay costs and liquidated damages.

The final costs are determined as follows:

1. Road-User Delay Cost. This cost is based on the change in travel time, number of passengers per vehicle, and an hourly cost per person determined as follows:

   a. Travel Time. The change in travel time is determined by comparing the travel time through the project under normal conditions versus the estimated travel time through the project or along the designated detour during construction.

   b. Passengers. The number of passengers per vehicle is assumed to be 1.25, based on research by the Chicago Area Transportation Study.

   c. Hourly Cost. The hourly cost per passenger is assumed to be \$10.00/hour, based on average earnings issued by the Department of Employment Security.

2. Liquidated Damages. Liquidated damages rates are based on construction engineering costs. Liquidated damages rates are found in Section 108 of the *Standard Specifications* and the Supplemental Specifications.

3. Rate Adjustment. The final daily rate for the Incentive/Disincentive amount should be adjusted downward from the sum of the calculated road-user delay costs and the liquidated damages. When setting the rate, the designer should note the following:

   a. The Incentive/Disincentive amount must provide a favorable benefit-cost ratio (B/C) of at least 1.0.

   $$\frac{B}{C} = \frac{\text{calculated road user delay cost and liquidated damages}}{\text{adjusted road user delay cost and liquidated damages}}$$

   b. The final daily Incentive/Disincentive amount must be large enough to motivate the contractor to work an accelerated schedule.

66-2.05(d) Determination of Scheduled Completion Date

The setting of the completion date is a very important step in the use of Incentive/Disincentive clauses. The completion date must be based on a realistic and expedited work schedule. The work schedule will involve accelerated construction procedures because projects with Incentive/Disincentive clauses are critical projects. Expedited work schedules may involve one or more of the following:

- six-day work week, double shift with night illumination;
- extended work hours with 12 to 14 hours per day;
- expedited work schedule with 228 working days per calendar year; and/or
- multiple work crews in multiple areas.

66-2.05(e) Limits of Incentive/Disincentive

The incentive amount should not exceed five percent of the total construction cost. All Incentive/Disincentive clauses should include an upper limit to the number of days that an incentive will be paid. The incentive payment limit is a maximum of 30 calendar days. These limits are used to protect the Department. Disincentives are not time limited so that the contractor is effectively encouraged to meet the scheduled completion date.

66-2.05(f) Extension of Contract Time

Contract extensions may be granted by the Department as noted in Section 108 of the *Standard Specifications*. Extension of time applies to only the Disincentives. Incentive payments will be based on the completion date in the special provisions regardless of any extension of time. The extension of the completion date for Incentive payments will only be considered where significant extra work is added to the contract due to unforeseen circumstances.

66-2.05(g) Project Development

During the development of Incentive/Disincentive projects, greater attention to plans, specifications, and schedules is required. Omissions or errors in the plans or specifications may result in a claim from the contractor. The plans and specifications should indicate any unusual conditions or restrictions on the contractor. Specifications should clearly delineate the work that must be completed to meet the Incentive requirements.

The preconstruction phase of Incentive/Disincentive projects should include contacts with local officials, police, and/or other agencies to ensure a coordinated effort during the construction phase. A prebid meeting may be necessary to address the special features of an Incentive/Disincentive project.

66-2.05(h) Example Calculations

The following are two examples of how to calculate road-user delay costs and the Incentive/Disincentive rates.

* * * * * * * *

<u>Example 66-2.04(1)</u>

Given: Urban Freeway Rehabilitation
$5.0 million construction cost
60,000 ADT
Project Length — 1.8 miles
Average Normal Speed — 55 mph
Average Construction Speed — 35 mph

Problem: Determine the appropriate Incentive/Disincentive rate for the project.

Solution: $$\text{Motorist Time (normal conditions)} = \frac{\text{(Project Length) (ADT)}}{\text{Average Normal Speed}}$$

$$\text{Motorist Time (NC)} = \frac{(1.8)(60{,}000)}{55} = 1{,}964 \text{ hrs}$$

$$\text{Motorist Time (under construction)} = \frac{(1.8)(60{,}000)}{35} = 3{,}086 \text{ hrs}$$

Motorist Time Lost = (3,086 hrs - 1,964 hrs) = 1,122 hrs

Total Road-User Delay Cost = (1,122 hrs) (1.25 Passengers/Vehicles) ($10/hr)

Total Road-User Delay Cost = $14,025.00

Liquidated Damages Per Specifications = $1,800.00

Calculated Road-User Delay Cost + Liquidated Damages = $14,025.00 + 1,800.00 = $15,825.00

Based on the 5% incentive cap and the 30-day time limit, the maximum incentive is determined as follows:

$$\frac{(\$5{,}000{,}000)(0.05)}{30} = \$8{,}333.33\,/\,\text{day}$$

Therefore, the adjusted road-user delay cost and liquidated damages must be less than $8,333.33/day. See Section 66-2.04(e).

For this example, the Incentive/Disincentive rate was set at $8,000/day.

The B/C ratio is: $\frac{15{,}825.00}{8{,}000.00} = 1.98$

Example 66-2.04(2)

Given: Rural River Bridge Replacement
$3.25 million construction cost
2,000 ADT
Project Length — 1 mile
Detour Length — 20 miles
Average Normal Speed — 55 mph
Average Construction Speed — 55 mph

Problem: Determine the appropriate Incentive/Disincentive rate for the project.

Solution: Motorist Time (normal conditions) $= \frac{(1.0)(2{,}000)}{55} = 36.4$ hrs

Motorist Time (under construction) $= \frac{(20.0)(2{,}000)}{55} = 727.3$ hrs

Motorist Time Lost = (727.3 hrs - 36.4 hrs) = 691 hrs

Total Road-User Delay Cost = (691 hrs) (1.25 Passengers/Vehicles) ($10/hr) = $8,638.00

Liquidated Damages Per Specifications = $1,800.00

Calculated Road-User Delay Cost + Liquidated Damages = $8,638.00 + 1,800.00 = $10,438.00

Based on the 5% incentive cap and the 30-day time limit, the maximum Incentive is as follows:

$$\frac{(\$3{,}250{,}000)(0.05)}{30} = \$5{,}416.67$$

The Incentive/Disincentive rate was set at $5,400/day.

The B/C ratio is: $\frac{10{,}438.00}{5{,}400.00} = 1.93$

* * * * * * * * * *

66-2.05(i) Sample Special Provisions

The following are two sample special provisions that may be used where Incentive/Disincentive clauses are used in the project. The first is a sample for an Incentive/Disincentive contract where the Incentive/Disincentive applies to the completion of all work. The second is a sample where the Incentive/Disincentive applies to a portion of the contract.

(Sample Special Provision for Entire Project)

Incentive/Disincentive: Effective ________ *(DATE)* ______

Date of Completion: The Contractor shall schedule his/her operations so as to complete all work and open all the roadway to traffic on or before _____ *(DATE)* ______. The Contractor shall note that this completion date is based on an expedited work schedule.

Failure to Complete the Work on Time: Should the Contractor fail to complete the work on or before the specified date of completion, or within such extended time allowed by the Department, the Contractor shall be liable to the Department in the amount of ____ *($)* ____, not as a penalty but as liquidated and ascertained damages for each calendar day beyond the date of completion or extended time as may be allowed. Such damages may be deducted by the Department from any monies due the Contractor.

In fixing the damages as set out herein, the desire is to establish a certain mode of calculation for the work because the Department's actual loss, in the event of delay, cannot be predetermined, would be difficult of ascertainment, and a matter of argument and unprofitable litigation. This mode is an equitable rule for measurement of the Department's actual loss and fairly takes into account the loss of use of the roadway if the project is delayed in completion. The Department shall not be required to provide any actual losses to recover these liquidated damages provided herein, as these damages are very difficult to ascertain. Furthermore, no provision of this clause shall be construed as a penalty, as such is not the intention of the parties.

A calendar day is every day on the calendar and starts at 12:00 midnight and ends at the following 12:00 midnight, twenty-four hours later. No payment will be paid for any day less than twenty-four hours.

Incentive Payment Plan: The nature of this project is such that the use of this roadway cannot be safely and efficiently used until all roadway work is essentially complete. On this basis, the Contractor shall be entitled to an Incentive Payment for the completion of all work including clean up as set forth by the date of completion.

The Incentive Payment shall be paid at the rate of ________ *($)* _________ per calendar day for each day of completion prior to ___________ *(DATE)* ___________. The maximum payment under this incentive plan will be limited to ___ *(#)* ____ calendar days.

A calendar day is every day on the calendar and starts at 12:00 midnight and ends at the following 12:00 midnight, twenty-four hours later. No payment will be paid for any day less than twenty-four hours.

(Sample Special Provision for Entire Project)

(Continued)

Should the Contractor be delayed in the commencement, prosecution, or completion of the work for any reason, there shall be no extension of the incentive payment calculation date even though there may be granted an extension of time for completion of the work unless significant extra work is added to the contract by the Department. No Incentive Payment will be made if the Contractor fails to complete the work before the specified date of completion or within such extended time allowed by the Department. Failure of the Contractor to complete all work as required by the contract before ______(*DATE*)______ shall release and discharge the State, the Department and all of its officers, agents, and employees from any and all claims and demands for the payment of any incentive amount or damages arising from the refusal to pay any incentive amount.

If the contract is part of a combination award, no Incentive Payment shall commence on this contract, which is part of the combination until all work on contracts that are part of the combination award has been completed.

(Sample Special Provision for a Portion of the Project)

Incentive/Disincentive Plus Working Days: Effective ______(*DATE)*_____

Date of Completion: The Contractor shall schedule his/her operations so as to complete all work, except as specified below, and open all the roadway to traffic on or before ___(*DATE*)___.

The Contractor shall note that this completion date is based on an expedited work schedule. The Contractor will be allowed ___(#)___ working days, after the ___(*DATE*)___ completion date, to complete any remaining planting, seeding, and sodding work.

Failure to Complete the Work on Time: Should the Contractor fail to complete the work on or before the specified date of completion or within such extended time allowed by the Department, the Contractor shall be liable to the Department in the amount of ____(*$*)____ not as a penalty but as liquidated and ascertained damages for each calendar day beyond the date of completion or extended time as may be allowed. Failure to complete the remaining planting, seeding, and sodding work within ___(#)___ working days shall be governed by the provision of Article 108.09 of the Standard Specifications. Such damages may be deducted by the Department from any monies due the Contractor.

In fixing the damages as set out herein, the desire is to establish a certain mode of calculation for the work because the Department’s actual loss, in the event of delay, cannot be predetermined, would be difficult of ascertainment, and a matter of argument and unprofitable litigation. This mode is an equitable rule for measurement of the Department’s actual loss and fairly takes into account the loss of use of the roadway if the project is delayed in completion. The Department shall not be required to provide any actual losses to recover these liquidated damages provided herein, as these damages are very difficult to ascertain. Furthermore, no provision of this clause shall be construed as a penalty, as such is not the intention of the parties.

A calendar day is every day on the calendar and starts at 12:00 midnight and ends at the following 12:00 midnight, twenty-four hours later. No payment will be paid for any day less than twenty-four hours.

Incentive Payment Plan: The nature of this project is such that the use of this roadway cannot be safely and efficiently used until all specified work is complete. On this basis, the Contractor shall be entitled to an Incentive Payment for the completion of all work as set forth by the date of completion.

The Incentive Payment shall be paid at the rate of ____(*$*)____ per calendar day for each day of completion prior to ___(*DATE*)___. The maximum payment under this incentive plan will be limited to ___(#)___ calendar days.

A calendar day is every day on the calendar and starts at 12:00 midnight and ends at the following 12:00 midnight, twenty-four hours later. No payment will be paid for any day less than twenty-four hours.

(Sample Special Provision for a Portion of the Project)

(Continued)

Should the Contractor be delayed in the commencement, prosecution, or completion of the work for any reason, there shall be no extension of the incentive payment calculation date even though there may be granted an extension of time for completion of the work unless significant extra work is added to the contract by the Department. No Incentive Payment will be made if the Contractor fails to complete the work before the specified date of completion or within such extended time allowed by the Department. Failure of the Contractor to complete all work as required by the contract before ______(*DATE*)______ shall release and discharge the State, the Department and all of its officers, agents, and employees from any and all claims and demands for the payment of any incentive amount or damages arising from the refusal to pay any incentive amount.

If the contract is part of a combination award, no Incentive Payment shall commence on this contract which is part of the combination until all work on contracts which are part of the combination award has been completed.

66-3 PROJECT COORDINATION AND IMPLEMENTATION SECTION

The following sections discuss the responsibilities of the Project Coordination and Implementation Section within the Bureau of Design and Environment to advance the plans and special provisions to letting after they have been submitted by the district.

66-3.01 Plan Check-In and Review

66-3.01(a) Program Support Unit

The Program Support Unit duties include the following:

- Checking in all plans submitted to the BDE for letting.
- Verifying that the plans are on the list of recommended projects previously submitted to the Section.
- Checking the CA/Project Status Form. All items listed as "Required" on the CA Form are noted.
- Verifying that the project is programmed and that the scope of work is correct.
- Checking eligibility for projects using bridge funds.
- Determining final funding of the project based on availability of the funds as initially programmed.
- For a project with joint agreements requiring local, private, or other sources of funding, checking the agreements and summary of quantity sheets to ensure that they are consistent and correct.

66-3.01(b) Project Development Unit

The Program Support Unit forwards the plans to the Project Development Unit where the project file folder is set up and the project is sent to the Regional Field Engineer and technicians for review. Plans and special provisions are also sent to appropriate central bureaus for review of bridge, traffic signals, landscaping, and other special items for concurrent reviews.

The technician will prepare the Transportation Bulletin worksheets to advertise the project. The Bulletin worksheet should address the following information:

1. Basic Information. The Transportation Bulletin worksheet must include the following:

    - the contract number, county, section, project number, route, and district;
    - the location and a brief description of the improvement;
    - a summation of the major items of work including the unit of measure and quantity of each; and
    - the working days or completion date and the job number.

2. Improvement Description. In preparing the material for the Bulletin worksheet, describe the basic or main part of the improvement and any other work of major importance. For example, if the improvement is primarily roadway construction but includes major quantities for storm sewers, frontage roads, ramps, pumping stations, box culverts, and bridges, also reference these element descriptions. The description of the location of the improvement should be such that the beginning and ending can be identified on a current Illinois Official Highway Map.

3. Location Description. When describing an improvement in relation to other routes, show the approximate distance to the nearest large city (e.g., on Illinois Route 4 between Illinois Route 104 and FAI Route 72 approximately 2 mi (3 km) southwest of Springfield). Place the corresponding marked route, as shown on a current Illinois Official Highway Map, in parentheses after the designated FA or SBI routes (e.g., FA Route 68 (Illinois Route 4)) and, if the improvement is in an urban area, show the corresponding street name.

4. Bridge Improvements. When describing the replacement of a bridge superstructure, note the face-to-face curb width of the existing and proposed roadway. If the improvement involves two or more independent types of work or if both urban and rural type construction is involved, describe and give the length of each type. Show distances to the nearest hundredth of a mile (thousandth of a kilometer). The Bulletin worksheet description for bridge and structure improvements should give a brief description and location of the improvement similar to that shown on the title sheet of the plans. If approaches are included with the structure contract, list the length, type, and width of the approach. Also list the number of spans, span sizes, and material type.

5. Patching and Resurfacing Improvements. Where patching and resurfacing are included in the same improvement and portions of the patching quantities are outside the limits of resurfacing, list the length of patching outside the resurfacing limits separately. In describing intermittent bituminous resurfacing, show the total length of the improvement and also the net length of resurfacing. When resurfacing is on less than four routes or in less than four counties, show the length, width, type, and location for each route; otherwise, this work may be summarized as “various routes and counties” in the given district.

6. Traffic Signals. If the improvement is for the installation of traffic signals and the number of locations is ten or less, describe each location separately. Where more than ten locations are involved, the description may be summarized (e.g., at 14 intersections on various routes in the north portion of Cook County).

Prior to reviewing a set of plans, the Regional Field Engineer should review the project file folder and determine if the plans are in accordance with the approved scope of work. The engineer will review the plans to determine if they comply with the criteria presented in this *Manual* unless the design file indicates prior approval for deviations.

Due to the complexity and varied nature of highway plans, it is impractical to establish a set of rules which will completely govern a comprehensive review of plans; however, certain features should always be checked. Figure 66-3.A provides a checklist of items to consider during the review of plans prior to advertisement for letting.

All changes to special provisions and plans (including quantity changes), performed at the Central Office, must be supported with documentation from either the district or their consultant. This documentation will either be in writing or via email and will clearly describe the changes to be made. If the district or their consultant comes to the Central Office to make changes personally, they must document the changes with marked-up sheets or an itemized list. The documentation will then be kept in the contract file until the project is complete.

66-3.02 Final Plan and Proposal Review

66-3.02(a) Special Provision Review

The special provisions are reviewed by the Project Development Unit for compliance with the requirements in Section 66-1.04. For plan reviews, inflexible rules cannot be established for reviewing special provisions. The engineer should be certain that all pay items are covered by the *Standard Specifications,* Supplemental Specifications, Recurring Special Provisions, or Contract Special Provisions, and that on applicable Federal-aid projects FHWA requirements are met. An especially important aspect of special provisions is that they must adequately cover the intended work and that details must be given which will distinguish the equipment or method required to perform the work. Generalities in special provisions are undesirable because they can often lead to misinterpretation and disputes with resultant claims for extra work. The performance of work on a force account basis should be minimized.

66-3.02(b) Procedures

After the special provisions have been reviewed and found satisfactory, return the prints of the plans and special provisions to the district for a final review prior to advertising bids. The memorandum transmitting the plans and special provisions to the district for final review should note significant changes in the plans or special provisions made by the Bureau of Design and Environment.

The Regional Field Engineer prepares the check sheet of appropriate Recurring Special Provisions and attaches the check sheet to the contract. Plans ready for letting are then forwarded for duplicating. Contract Special Provisions are sent to the Project Management Unit where the appropriate State or Federal boilerplate sheets are added which completes the proposal. The proposal is then sent for duplication.

Figure 66-3.B presents the minimum advance time that the Project Development Unit should plan for when preparing a contract for letting.

Date Completed ______________________ Route ______________________

Project No. ______________________ Section ______________________

Checker ______________________ County/City ______________________

☐ 1. Ensure that the CA/Project Status Form has been completed. If not, return it to the district for completion.

☐ 2. Ensure that the plans are complete by checking them against:

- ☐ the approved Phase I report;
- ☐ the design criteria presented in the *Bureau of Design and Environment Manual*, except where revised by a design exception;
- ☐ the criteria presented in the Procedural Memoranda;
- ☐ any reports prepared for the project (e.g., soils, pavement, intersection design study); and
- ☐ the plan preparation guidelines presented in Chapter 63 (see Section 63-6 for a plan preparation checklist).

☐ 3. Ensure the plans and/or special provisions have addressed the maintenance and protection of traffic through construction zones.

☐ 4. Ensure that the designer has addressed all the issues in the Commitment File somewhere in the plans, special provisions, or agreements.

☐ 5. Ensure that all applicable units have reviewed the plans and Contract Special Provisions by checking the transmittal memoranda between the designer and the bureaus. For example, the Bureau of Operations should have reviewed the signal plans and the Bureau of Bridges and Structures should have reviewed the structural plans.

☐ 6. Ensure that the Recurring Special Provision Checklist is included and properly completed.

☐ 7. Ensure that all applicable Contract Special Provisions have been provided including:

- ☐ Project Specific Special Provisions,
- ☐ District Special Provisions,
- ☐ Bridge Special Provisions, and
- ☐ Inserted Special Provisions.

PLAN REVIEW CHECKLIST

Figure 66-3.A
(1 of 2)

☐ 8. Check the Contract Special Provisions prepared by the designer to ensure they meet the criteria presented in Section 66-1.04.

☐ 9. Ensure that all pay items are covered by the *Standard Specifications*, Supplemental Specifications, Recurring Special Provisions, or Contract Special Provisions.

☐ 10. Copy and distribute the special provisions for review as discussed in Section 66-3.02(b).

☐ 11. Ensure the designer has completed the quantity estimate sheet and has segregated the quantities according to the criteria presented in Section 63-4.04.

☐ 12. Ensure that the quantities, coded numbers, and pay items on the plans, summary of quantities, and proposals agree.

☐ 13. Ensure that the district estimating engineer has forwarded the unit prices to the Project Management Unit.

☐ 14. Ensure that the Project Management Unit has prepared the Engineer's Estimate.

☐ 15. Check the designer's construction time estimate to ensure that it is reasonable and complete.

☐ 16. Prepare the Bulletin worksheet and forward it to the Project Management Unit for copying and distribution.

☐ 17. Verify with the Program Support Unit that all agreements with utility companies, railroads, local municipalities, etc., are signed prior to letting.

☐ 18. Verify through the Program Support Unit that all applicable permits have been approved before letting (e.g., Corps of Engineers, Coast Guard, USEPA).

☐ 19. Verify through the Program Support Unit that any right-of-way acquisitions, easements, agreements, etc., are completed prior to letting.

☐ 20. Forward all construction documents to the Project Management Unit.

PLAN REVIEW CHECKLIST

Figure 66-3.A
(2 of 2)

Submittal	Minimum Time In Advance Of Letting
PS&E to Federal Highway Administration	6 Weeks
Transportation Bulletin	5 Weeks
Addendums to FHWA (See Chapter 31)	17 Days
Addendums to Contractors	10 Days

PLANNING SCHEDULE
(Project Development Unit)

Figure 66-3.B

66-4 PROPOSALS AND CONTRACTS

66-4.01 <u>Transportation Bulletin and Advertising</u>

66-4.01(a) Transportation Bulletin

The Project Development and Implementation Engineer selects the projects that will be on the letting. Bulletin worksheets of projects to be advertised are prepared by the Project Development Unit in the Bureau of Design and Environment or the Central Bureau of Local Roads and Streets. The worksheets are sent to the Contracts Office where they are logged in. Once selected, the Bulletin worksheets are numbered and the Contracts Office prepares a draft of the Transportation Bulletin.

The draft bulletin is emailed to the Office of Planning & Programming and the Office of Finance & Administration for review. Once their concerns, if any, are addressed a revised draft bulletin is emailed to the Chief Contracts Official for final review. A marked-up copy is returned for final processing and posting on the IDOT Internet site.

66-4.01(b) Electronic Advertising

Once the Transportation Bulletin has been prepared, it is published on the IDOT Internet site and emailed a notice to subscribers of the IDOT electronic subscription service at least 21 days before the letting.

66-4.02 <u>Proposals and Plans</u>

66-4.02(a) Assembly of Proposal

As specifications are received from the districts, the Project Development Unit or the Bureau of Local Roads and Streets will review the specifications for accuracy, prepare a copy of the Illinois wage rates (if applicable), and develop the schedule of prices to form the draft proposal. The Contracts Office will prepare a typing package which consists of the cover sheet, certifications, financial disclosure sheets, bidder's employee utilization form, bidder's affidavits (if required), signature sheet, assurances, and the notice-to-bidders sheet. The draft proposal is combined with the typing package to form an original proposal. The proposal is reviewed for accuracy and posted on the IDOT Internet site. Hard copies are processed by the Reproduction Service Unit for internal use.

66-4.02(b) Plans

Plans are received from the districts and reviewed for accuracy by the Project Development Unit. Once reviewed, the plans are posted on the IDOT Internet site. Hard copies are processed by the Reproduction Service Unit for internal use.

66-4.02(c) Authorization to Bid

Authorization to bid is issued to prequalified contractors who have sufficient financial and work ratings that indicate their ability to complete work on which they wish to bid. Requests for authorization to bid (BDE 124) are to be submitted to the Contracts Office. The Bureau of Construction's Prequalification Section reviews the submitted BDE 124. The Prequalification Section analyzes each request for authorization to determine if the contractor has sufficient prequalification. Upon determination of sufficient prequalification, notification is given to the Contracts Office to authorize or deny the contractor to bid.

66-4.02(d) Subcontractors and Material Suppliers

Subcontractors and material suppliers can download proposals and plans from the IDOT Internet site.

66-4.02(e) Bidder's List

As proposals and plans are posted to the IDOT Internet site, a list of contractors receiving authorization to bid is maintained by the Contracts Office. A similar list is maintained for other interested parties (e.g., subcontractors and material suppliers). The bidder's list is updated four times with the final list being available the day before the letting. The lists are available for review on the IDOT Internet site.

66-4.02(f) Addendums to Proposals and Plans

The Program Development Unit will be responsible for making corrections to the original proposal and the original plans. Addenda on local roads projects are handled similarly between the Bureau of Local Roads and Streets and the Contracts Office.

When an addendum will be issued on a project, the Project Development Unit notifies the Contracts Office of the item number and if the correction is on the proposal, plans, or both. The Contracts Office updates the Addendum/Revision Checklist on the IDOT Internet site.

66-4.03 <u>Letting Process</u>

66-4.03(a) Receipt of Bids

Bids sealed in proposal envelopes are deposited in locked bid boxes, or electronically submitted through the department's EBids system, at the place and time designated in the Transportation Bulletin. Bidders may also submit their bids by mail to the Contracts Office where they are stamped, logged and locked until the time of the letting. After the specified time, no additional bids will be accepted. The bid boxes are unlocked and the bids are sorted by item number. The total amount of each bid, including alternatives and combinations, if any, are marked and then read publicly. A bidder's proposal package is not read at the letting if a bidder has not been authorized to bid. When bids have been publicly read, they are reviewed for bid bonds or guaranty checks. If proposal guaranty checks are received, they are detached from the bids and submitted to the Contracts Office for further processing. Once this is completed, the bids are then transferred to the Project Development and Implementation Section for further processing.

66-4.03(b) Bid Tabulations

The afternoon of the letting the Contracts Office posts on the IDOT Internet site the “As-Read” Tabulation of bids. These are the bid amounts identified in the bid proposal packages and publically read aloud. After the bids have been reviewed for any calculation errors the Corrected Tabulation of Bids is posted to the IDOT Internet site identifying low bidders and any revised bid totals.

66-4.03(c) Proposal Guaranty Checks and Bid Bonds

A proposal guaranty check or bid bond must accompany each bid, if applicable. If the proposal guaranty check or bid bond is missing or incomplete, the Contracts Office will notify the bidder by letter of the problem and what is required for correction. A copy of the letter is kept in the Chief Contracts Official’s letting folder and a note is included in the Letting Status database. Once received, guaranty checks are placed into individual envelopes and locked in a safe. The envelope indicates the contractor’s name, item number, check amount, and check number. The guaranty checks of the low and second low bidder are retained in the safe until the contract documents are executed by the Department. The guaranty checks of the low and second low bidders are returned by United Parcel Service (UPS) after the contract is executed. The guaranty checks of the other bidders are returned by the UPS Ground. Bid bonds of the low bidders are retained in the safe until all contracts are executed. After all contracts are executed, the bid bonds are destroyed. A bid bond may be submitted by the low and second low bidder no sooner than 3 working days after the letting as a substitute for the guaranty check.

66-4.03(d) Processing of Bids Received

The Project Development and Implementation Section is responsible for the processing of bids received. All bids are entered into the computer system to be checked for accuracy. Once a low bid has been determined, the system is locked and the low bid is transferred to the Contracts Office for further processing pending the decision of the Awards Committee.

66-4.03(e) Awards Committee

The Awards Committee is responsible for approving or rejecting the bids. This Committee consists of the following personnel:

- Deputy Director of Program Development,
- Engineer of Design and Environment,

- Engineer of Construction,
- Engineer of Project Development and Implementation,
- Engineer of Project Management,
- Chief Contracts Official,
- representative from Bureau of Local Roads and Streets,
- representative from Office of Planning and Programming, and
- representative from FHWA.

At the conclusion of the Awards Committee meeting, the Engineer of Project Management prepares the official bid letting tabulation and the award memorandum for submittal to the Secretary.

66-4.03(f) Preparation of Contract Prior to Award

Once low bids are received in the Contracts Office, they are placed in numerical order by item number. Bids are checked for Form A (Financial Information & Potential Conflicts of Interest Disclosure), Form B (Other Contracts & Procurement Related Information Disclosure), Apprenticeship and Training certification, Doing business in Iran certification and Workforce projection (Form BC-1256), to see if the contractor included the Steel, Bituminous or Fuel Cost Adjustment forms, and check the Signature page. DBE plans (SBE 2025 & 2026) are pulled off and taken to the Bureau of Small Business Enterprises, if applicable. Bidders are checked for delinquent debt. Bids are reviewed by the Chief Procurement Office for registration with the Secretary of State and with the state Board of Elections. Contracts that included a Project Labor Agreement are checked for the Letter of Assent. If any deficiencies are found while the sub-unit is reviewing the bidder's proposal package the bidder is notified by telephone or e-mail of the issue and what is required for correction. A note is included in the Letting Status database of the notification. Subsequently, a contract schedule of prices showing the low bidders unit prices is requested through the Bureau of Design and Environment's Letting Management (ELM) System. The bid, contract schedule of prices, and the original proposal are combined to form a draft contract. The Contracts Office will type two original contracts and two original contract bonds. All original copies of the contract and contract bond, plus the bidder's Federal taxpayer identification sheet, and a copy of insurance requirements, are taken to the Reproduction Service Unit for preparation prior to award.

66-4.03(g) Award and Rejection

Prior to the award or rejection of bids, concurrences may be required. Local agency concurrence for local projects is obtained by the Bureau of Local Roads and Streets. Concurrence may also be required from other State and Federal agencies or other States. This information is obtained by the Program Support Unit and logged by the Contracts Office, when notified. Agreements between the State of Illinois and local agencies, private benefits, and utilities must also be cleared prior to award. DBE utilization plans, if required, must also be approved prior to award. Email notification of approval is received from the Bureau of Small Business Enterprises. Prior to award, the Bureau of Land Acquisition advises the Contracts

Office of the status of the right-of-way concerning projects advertised in the Transportation Bulletin. Also prior to award, any potential conflicts of interest that were noted on Form A (Financial Information & Potential Conflicts of Interest Disclosure) must be cleared by the Procurement Policy Board. After the Chief Contracts Official has determined that all required concurrences, agreements, and right-of- way have been received, the award or rejection letter is prepared by the Contracts Office, approved by the Engineer of Project Development and Implementation, and transmitted to the Deputy Director of Program Development for review. The letter is then forwarded to the Director of Highways for signature. When the award or rejection letter has been signed for the Secretary, it is returned with all correspondence to the Contracts Office for dating, mailing, and distribution. The Contracts Office also notifies the Reproduction Service Unit to mail out the package that was previously prepared that includes an office copy and a bonding company copy of the draft contract package. Additional copies of the draft contract package are sent to the responsible district handling the project and the Bureau of Materials and Physical Research. (Note that when a project is rejected the low bid is filed with the unsuccessful bids.) The award date is entered into the Letting Management (ELM) System; this triggers the contract to pull into the Highway Procurement Policy Review (HPPR) system. The Form A (Financial Information & Potential Conflicts of Interest Disclosure) is attached to the contract information and the Disadvantaged Business Enterprise (DBE) goal is entered for each bidder, the contract is then submitted to the Procurement Policy Board (PPB) for their review and approval. The PPB waiver date is added to the Letting Status database and all emails from the PPB are electronically stored in the Letting folder.

66-4.04 Execution of Contracts

The bidder's Federal taxpayer identification form, contracts, contract bonds, power of attorney, trust agreement forms, and required insurance are reviewed for accuracy and compliance with Department policy. If it is determined the contract documents or the insurance requirements have not been properly executed, the paperwork is returned by mail to the contractor for correction. A copy of the letter is kept in the Chief Contracts Official's letting folder and a note is included in the Letting Status database. When it is determined the paperwork has been properly executed, the contract documents are dated and signed by the Chief Contracts Official (for the Secretary) or the Bureau Chief of Design and Environment (for the Secretary) and the Chief Procurement Officer or designee. If the department is unable to execute the contract the contractor is notified by letter of the problem and allowed to withdraw their bid. A copy of the letter is kept in the Chief Contracts Official's letting folder and a note is included in the Letting Status database. Once fully executed, one copy of the contract is returned to the contractor via the United Parcel Service (UPS) utilizing the UPS tracking system. The original copy is transmitted to the Bureau of Construction for further processing. The State Comptroller's Office receives a copy of the bidder's schedule of prices, certifications, affidavits, signature sheet, and executed contract documents. A certified copy of the contract is sent to the Federal Highway Administration on non-exempt Federal and Interstate projects only.

66-4.05 Railroad Insurance

Railroad insurance is required for projects on or adjacent to railroad right-of-way. Information concerning this requirement can be found in the special provisions of the proposal. The contractor must furnish the Contracts Office with one original policy, one copy of the policy, and a copy of the general, workman's compensation and automobile liability insurance certificate. The original, plus the copy of the general, workman's compensation and automobile liability certificate, are forwarded to the railroad for approval. Approval must be received before the contractor can undertake any work on the railroad or railroad right-of-way. Once approval is received, the contractor and the applicable district are notified by letter that the policy has been approved.

66-4.06 Contractor Services

Prior to each letting, the proposal and plans for each project being advertised in the Transportation Bulletin are available for inspection on the IDOT Internet site. The authorized For Bid and Not For Bid list is also available on the IDOT Internet site. Other services provided to the public are the Pay Item Report and the Pay Item Report with Awarded Prices available on the IDOT Internet site.

As contracts are executed, the Contracts Office prepares a unit price tabulation for the IDOT Internet site. Each individual tabulation will contain the following information — contractors bidding on the project, low bidder, unit prices, and totals. These tabulations are published on the IDOT Internet site approximately once per week.

DISPOSITION OF BDE PROCEDURE MEMORANDA (2002 Manual -2010 Manual)

The following disposition discusses where previously issued Procedure Memoranda have been incorporated into the 2010 BDE Manual or retired.

Memo No.	PM Title	Disposition
1-00	New Series of BDE Procedure Memorandums	See BDE PM 10-01.
2-00	Project Files Documentation	See BDE PM 10-02.
5-07	Value Engineering Program	Incorporated in Section 11-7.03 of the BDE Manual 2010 edition.
6-00	Local Participation in Spot Safety Improvement Projects	See BDE PM 10-03.
8-00	Federal Participation in Stockpiling of Salvage Materials	Incorporated in Section 64-1.06 of the BDE Manual 2010 Edition.
9-00	Surplus Excavation Disposal	Incorporated in Section 63-4.07(d) of the BDE Manual 2010 Edition.
10-01	New Series of BDE Procedure Memorandums	Retired as BDE no longer issues stand-alone Procedure Memoranda.
10-02	Project Files Documentation	Retired as it has been superseded by an update to Record Retention Schedule 12-75.
10-03	Local Participation in Spot Safety Improvement Projects	Retired as its content has been replaced by the Bureau of Safety Engineering Policy Memorandum1-06, “Highway Safety Improvement Program (HSIP)”.
10-04	Architectural and Engineering Report and Negotiation Guidelines for Engineering Agreements and Supplements	Retired as updates to Chapter 8 of the BDE Manual, BDE Form 17-09, and implementation of the Engineering Prequalification and Agreement System (EPAS) have made its content obsolete.
10-05	Compliance with Asbestos Requirements for Highway Bridges	Incorporated in Section 27-4 of the BDE Manual in October 2015.
10-06	Borrow, Use, and Waste Site, and Excess Material Disposition Documentation, Review, and Approval	Incorporated in Section 27-1.03(e) of the BDE Manual 2010 Edition in February 2011.
10-07	Special Waste Procedures	Incorporated in Section 27-2 of the BDE Manual 2010 Edition in February 2011.
15-02	Procedures to Minimize Motorists’ Costs and Inconvenience	Incorporated in Chapters 13 and 34 of the BDE Manual 2010 Edition.
16-00	Quality Assurance/Quality Control Guidelines for Work By Consulting Engineers	Incorporated in Section 8-6 of the BDE Manual 2010 Edition.
17-09	Architectural and Engineering Report and Negotiation Guidelines for Engineering Agreements and Supplements	See BDE PM 10-04.

19-08	Procedures for Concurrent NEPA/404 Processes	Incorporated in Section 22-4 and updated NEPA/404 Agreement included in Part III, Appendix A of the BDE Manual 2010 Edition.
23-01	Pavement Patching for Multilane Jointed Plain Concrete Pavement (JPCP), Jointed Reinforced Concrete Pavement (JRCP), Asphaltic Concrete (AC) Overlaid JPCP and AC Overlaid JRCP	Incorporated in Chapter 53 of the BDE Manual 2010 Edition.
26-02A	Compliance with Asbestos Requirements For Highway Bridges	Still active and re-issued as BDE PM 10-05
27-02	Temporary Concrete Barrier	Incorporated in Section 55-4.02 of the BDE Manual 2010 Edition.
28-02	Validity of Special Waste Assessment Results	Incorporated in PM 66-09A, which was incorporated in Section 27-2 of the BDE Manual 2010 edition.
31-03	Incidental Taking Authorization Procedures	Incorporated in Section 26-9.06(h) of the BDE Manual 2010 Edition.
32-03	Changes in 4(f) Applicability for Actions Involving U.S Coast Guard Permits	Incorporated in Section 26-2.04(b) of the BDE Manual 2010 Edition.
33-03	Wetlands Compliance Procedures	Incorporated in Section 26-8 of the BDE Manual 2010 Edition.
34-08	Impact Attenuators (Crash Cushions)	Incorporated in Section 38-8 of the BDE Manual 2010 Edition.
35-05	Detectable Warnings for Curb Ramps, and Other Locations	Incorporated in Section 58-1.09 of the BDE Manual 2010 Edition.
36-08	Roadside Barriers	Incorporated in Sections 38-5 and 38-6 of the BDE Manual 2010 Edition.
37-03	Documenting Microscale Analysis Information	Incorporated in Section 26-14 of the BDE Manual 2010 Edition.
38-04	Errata for the BDE Manual 2002 Edition	Incorporated in the BDE Manual 2010 Edition.
39-08	Median Barriers and Glare Screens	Incorporated in Section 38-7 of the BDE Manual 2010 Edition.
40-04	Addressing Impaired Waters/TMDLs in Project Environmental Documentation	Incorporated in Sections 24-3.02(e), 253.08(j), and 26-21 of the BDE Manual 2010 Edition.
41-08	Delegation of Approval Authorities to Districts	Incorporated in applicable Sections of the BDE Manual 2010 edition.
42-04	Changes in the BDE Manual Guidance on Air Quality and Related Subjects	Incorporated in Sections 24-3.02(e), 253.08(f), and 26-11 of the BDE Manual 2010 Edition.
43-09	Coordination with IDNR on Natural Resource Issues	Incorporated in Sections 22-5.02(b) and 27-1 and updated Coordination Agreement included in Part III, Appendix A of the BDE Manual 2010 Edition.

44-05	Timeframes for Environmental Impact Statements and Environmental Assessments	Incorporated in Sections 24-2 and 25-2 and Timeframes Agreement included in Part III, Appendix A of the BDE Manual 2010 Edition.
46-05	FHWA Section 4(f) Policy Paper and Final Programmatic Section 4(f) Evaluation and Determination for Federal-Aid Transportation Projects That Have a Net Benefit to a Section 4(f) Property	Incorporated in Part III, Appendix A of the BDE Manual 2010 Edition.
47-05	Guidelines for Pavement Preservation	Incorporated in Chapter 52 of the BDE Manual 2010 Edition.
48-06	Design Flexibility and the Stakeholder Involvement Process for Context Sensitive Solutions (CSS)	Incorporated in applicable Sections of the BDE Manual 2010 edition.
49-06	Guidance for Determining De Minimis Impacts to Section 4(f) Resources	Incorporated in Section 26-2.04(d) of the BDE Manual 2010 Edition.
50-06	Final Rule for 23 CFR 772 “Procedures for Abatement of Highway Traffic Noise and Construction Noise”	Incorporated in Section 26-6 of the BDE Manual 2010 Edition.
51-06	Plan, Specification and Quantity Changes	Incorporated in Section 66-3.01(b) of the BDE Manual 2010 Edition.
52-06	Mobile Source Air Toxics	Incorporated in Section 26-13 of the BDE Manual 2010 Edition.
53-06	Design Guidance for Median and Curb Treatments at Railroad Grade Crossings	Incorporated in Sections 7-3.02(f) and 34-2.04 of the BDE Manual 2010 Edition.
54-07	Categorical Exclusion Group II Approval Documentation	Incorporated in Section 24-1.03(c) of the BDE Manual 2010 Edition.
55-07	Wetland Impact Accumulation	Incorporated in Section 26-8.05(c) of the BDE Manual 2010 Edition.
56-08A	Borrow, Use, and Waste Site, and Excess Material Disposition Documentation, Review, and Approval	See BDE PM 10-06
57-08	Use of Commercial and Department Wetland Mitigation Bank Site Credits	Incorporated in Section 26-8.05(c) of the BDE Manual 2010 Edition.
58-08	Exisiting Public Educational Facility Entrances	Incorporated in Chapter 12 of the BDE Manual 2010 edition.
59-08	Selecting Contract Time and Project Letting Date	Incorporated in Section 66-2.04 of the BDE Manual 2010 Edition.
60-08	Transportation Conformity Project-Level Qualitative Hot-Spot Analysis in PM2.5 and PM10 Nonattainment and Maintenance Areas	Incorporated in Section 26-12 of the BDE Manual 2010 Edition.
61-08	Meeting SAFETEA-LU Section 6002, Context Sensitive Solutions, and NEPA/404 Merger Process Requirements for Environmental Impact Statements	Incorporated in Chapter 3 and Section 25-2 of the BDE Manual 2010 Edition.

62-08	Control of Emerald Ash Borer on Department Owned Lands	Incorporated in Section 59-7.01(a) of the BDE Manual 2010 Edition.
63-08	Local Agency Agreements – Municipality Reimbursements	Incorporated in Section 55-5.03(a) of the BDE Manual 2010 Edition.
64-08	Portland Cement Concrete Inlay or Overlay	Incorporated in Chapter 53 of the BDE Manual 2010 Edition.
65-08	Pipe Culverts and Storm Sewers	Incorporated in Section 40-3.07 of the BDE Manual 2010 Edition.
66-09A	Special Waste Procedures	Incorporated in Section 27-2 of the BDE Manual 2010 Edition prior to the issuance of BDE PM 66-10 which superseded it.
66-10	Special Waste Procedures	See BDE PM 10-07
67-09	Surface Finish for Concrete Pavements	Incorporated in Section 41-4.01(o) of the BDE Manual 2010 Edition.
68-10	Bicycle and Pedestrian Accommodation (Complete Streets)	Incorporated in Chapters 5 and 17 of the BDE Manual 2010 edition.
